This paper analyzes the effects of foreign direct investment on technical progress in Spanish manufacturing. Particularly, we study how foreign direct investment (FDI)'s contributions vary depending on the economic structure of the industry. The results show that most FDI goes to capital-intensive sectors, especially when those sectors are also research and development (R&D)-intensive. Our estimates of the Solow residual show that the positive effect of contemporaneous and lagged FDI on manufacturing productivity is only attributable to capital- and R&D-intensive industries in what seems to be related to a dynamic capabilities explanation or to complementarities with R&D expenditures.

I. Introduction

It is well known that foreign direct investment (FDI) is a powerful driver of growth in developing countries. The mechanism through which FDI causes growth works differently across countries and reverse causality from growth to FDI exists for some countries (Duttaray *et al.*, 2008). So, FDI inflows and exports are elements to explain the economic growth in different regions (Liu *et al.*, 2009; Yao, 2006).

In Spain some years ago, low wages attracted investments that brought knowledge and technical progress to their economies. In fact, multinational automotive corporations and other industries brought striking development to Spanish manufacturing. Today, Spain is considered a developed country and is no longer competitive in wages when attracting FDI compared to most developing countries. Also, Spain is no longer a net receiver of foreign investment.

In this context, some questions arise: What role did FDI play in Spanish manufacturing's low rates of technical progress in recent years? How do FDI and research and development (R&D) expenditures relate to industry performance? How do FDI and R&D contribute to technical progress?

Previous studies evaluate FDI spillovers in the Spanish economy (Varela and Rodríguez de Pablo, 1974; Donges, 1976; Bajo, 1991; Egea and López, 1991; Felipe and Fernández, 1991; Bajo and Sosvilla, 1991, 1992; Muñoz, 1999; Díaz, 2001; Hernández, 2008; Rodríguez and Pallas, 2008). Among other things, many

1
2
3
4 studies find that firms and industries with FDI are more productive than locally
5 funded ones (Caves, 1974; Globerman, 1979; Blomström, 1986; Blomström and
6
7 Wolff, 1989; Haddad and Harrison, 1993; Doms and Jensen, 1998; Aitken and
8
9 Harrison, 1999) and others find that FDI and trade are the most important paths to
10
11 domestic advances in technology (Grossman and Helpman, 1991; Coe and
12
13 Helpman, 1995; Blomström and Kokko, 1998; Xu, 2000; Buckley *et al.*, 2002;
14
15 Keller and Yeaple, 2003; Liu and Wang, 2003; Sinani and Meyer, 2004).

20
21 Many studies also find that FDI influences host countries through
22
23 technology transfers and increases in the intensity of competition (Caves, 1974;
24
25 Wang and Blomström, 1992; Glass and Saggi, 2002). The research generally finds
26
27 that nonmarket transactions generate spillovers, which refers to the spread of
28
29 resources (in particular, knowledge) without contractual relationships (Meyer,
30
31 2004). Spillovers result in improved productivity, or other benefits, in the local
32
33 industry (Perez, 1998; Griffith *et al.*, 2002; Aghion *et al.*, 2004; Haskel *et al.*,
34
35 2007). However, such improvements are different in particular sectors, depending
36
37 on the intensity of labour and R&D (Buckley *et al.*, 2007).

41
42 This relationship between R&D and productivity is a key factor in
43
44 economic growth (Griliches, 1979, 1988; Grossman and Helpman, 1991; Coe and
45
46 Helpman, 1995). So, FDI is a mover of production efficiency in the host country
47
48 (Chuang and Hsu, 2004; Yao *et al.*, 2008). In fact, innovation is crucial to
49
50 developing an economic structure (Schumpeter, 1934, 1939) and increasing
51
52 investment and production (Arrow, 1962), adding human capital (Uzawa, 1965),
53
54 or acquiring better inputs (Goto and Suzuki, 1989) can facilitate this growth.
55
56
57
58 Considering the relationship between R&D and FDI, FDI is a noteworthy
59
60

1
2
3
4 technology-transfer mechanism (Hubert and Pain, 2000; van Pottelsberghe de la
5
6
7 Potterie and Lichtenberg, 2001; Cecchini and Lai-Tong, 2008; Managi and
8
9
10 Bwalya, 2010).

11
12 The aim of this paper is to estimate the role of FDI in technical progress in
13
14 Spanish manufacturing, accounting for other determinants of technical progress
15
16 such as R&D expenditures. Including R&D expenditures in the measure of
17
18 technical progress is consistent with Nadiri (1993) and Sinani and Mayer (2004).
19

20
21 Many studies at the manufacturing level explain the influence of physical
22
23 inputs on outputs (Todd, 1984; Hazledine, 1985; Baldwin and Rafiquzzaman,
24
25 1994; Oulton and O'Mahony, 1994). Inward FDI in the manufacturing sector
26
27 plays a very important role in enhancing the economic growth, but FDI in non
28
29 manufacturing sectors does not (Wang, 2009). The industry level, however, is
30
31 where we study the interaction among the economic structure of the industries,
32
33 innovation intensity, and the attraction of foreign investment. Accordingly, we
34
35 search for differences in the manner in which industries profit from foreign
36
37 investments. The analysis identifying FDI's technical-progress effect and it is a
38
39 precursor to analyzing spillovers.
40
41
42
43

44
45 This paper is structured as follows: Section 2 provides a brief overview of
46
47 the theoretical background as well as a descriptive approach to FDI in Spanish
48
49 manufacturing. Section 3 presents the model, the data, and the methodology to
50
51 estimate the technical progress associated to FDI. Section 4 contains a discussion
52
53 of the estimations. The paper ends with some concluding remarks.

II. Foreign Direct Investment and the Economic Structure of Industries

A significant avenue of research exists regarding FDI and the productivity of local firms. The common view is that foreign-owned firms have distinct labour demands compared with domestic firms, even within the same industry (Conyon *et al.*, 2002). Also, foreign-owned enterprises usually have better technologies and organizational skills than locally owned enterprises, which enhances their knowledge (Smarzynska, 2003).

Foreign-owned firms tend to put more effort toward training employees who may later take their acquired skills to domestic firms (Görg and Strobl, 2001; Görg and Greenaway, 2004; Tian, 2007). At the same time, foreign firms tend to steal the most productive employees away from local firms and make the process of assimilating foreign technology harder (Wang and Yu, 2007). Foreign firms also use more skill-intensive technology than domestic companies, and they are more likely to attract and retain highly qualified personnel by raising wages (Aitken *et al.*, 1997; Feenstra and Hanson, 1997; Fosfuri *et al.*, 2001; Glass and Saggi, 2002; Mody, 2004). Nonetheless, FDI in the host country produces a labour-displacing effect because it creates a technology transfer, a corresponding excess supply of labour, and subsequent downward pressure on labour costs (Chakraborty and Basu, 2002).

Domestic firms may learn from the foreign firms with which they have close relationships, and they may even benefit from the technical support, as well as the supply and demand from those firms (Aitken and Harrison, 1999; Buckley *et al.*, 2002). In this way, foreign firms must leverage special advantages, often

1
2
3
4 information-based intangibles, in order to compete in these markets (Morck and
5
6
7 Yeung, 1991, 1992).

8
9 At the industry level, these results suggest that every sector may present a
10
11 different sensibility toward profiting from FDI, depending on the skills in that
12
13 sector or even its economic structure. As a first approximation of the problem, in
14
15 Figure 1 we present the FDI evolution in Spanish manufacturing between 1993
16
17 and 2006. In general, the interannual variability is remarkable, so two trends
18
19 appear: an upward trend during 1993–2001 and a downward trend after 2001. The
20
21 2001 value includes some unusual deals, including the Mexican cement firm
22
23 Cemex's significant FDI in Valenciana de Cementos and in La Auxiliar de la
24
25 Construcción Sanson. The manufacture of cement, lime, and plaster industrial
26
27 sector is 12.24% of FDI weight.

40 We analyze 100 Spanish manufacturing industries for the 14 years from
41
42 1993 to 2006. The data source is the Industrial Companies Survey by the National
43
44 Statistics Institute (INE). We analyze the industries receiving FDI for two main
45
46 characteristics: capital intensity and R&D intensity. We do this because capital is
47
48 traditionally the main driver of technological progress and productivity gains,
49
50 supporting the relationship between capital investment and the incorporation of
51
52 technology progress. However, many studies also find that the interaction between
53
54 capital investment and R&D investment drives productivity (Arrow, 1962;

Bresnahan, 1986; Jaffe, 1986; Bernstein and Nadiri, 1989; Coe and Helpman, 1995) because it facilitates the incorporation of new knowledge and skills.

Thus, the sample is divided into four subsamples (see tables 1, 2, 3, and 4) according to how companies rate in two areas. On one hand is capital intensity, which equals the accumulation of capital stock per worked hour during all years versus the median value in all the industrial sectors. On the other hand is R&D intensity, which measures R&D expenditures during all years versus the median value in all industrial sectors. After categorizing all the industrial sectors, we rank them according to their FDI. Our taxonomy gains inspiration from Basant and Fikkert (1996), Peneder (2001), Hu *et al.* (2005), Bin (2008), and O'Mahony (2009), which study the technological dimension of sectors.

As tables 1, 2, 3 and 4 show, FDI is higher in capital-intensive sectors. In fact, 83.5% of FDI went to capital-intensive sectors during the sample period. At the same time, sectors that are both capital-intensive and low-R&D (Table 2) receive more FDI than sectors that are capital-intensive and R&D-intensive (Table 1). It verifies for FDI weight (48,94% is higher than 34,56%) as well as for FDI over value added (26,58% versus 23,49%). However, labour-intensive, low-R&D sectors (Table 4) receive less FDI than labour-intensive, R&D-intensive sectors (Table 3). It verifies for FDI weight (6,88% is lower than 9,62%) as well as for FDI over value added (8,81% versus 11,52%). FDI is concentrated in a few sectors. In the end, only 21 capital-intensive sectors and only four labour-intensive sectors have FDI weights greater than 1%.

Some sectors are notable for their high FDI. Within the capital-intensive and R&D-intensive sectors (Table 1), FDI over value added for manufacture of

1
2
3
4 aircraft, pharmaceutical products, and of motorcycles reaches 80.8%, 39.7%, and
5
6 36.6%, respectively, whereas FDI weight for manufacture of chemical products,
7
8 motor vehicles, and pharmaceutical products and publishing reaches 5.62%,
9
10 5.44%, 5.19%, and 4.26%, respectively.
11
12

13
14 On the other hand, in the capital-intensive, low-R&D sectors (Table 2), the
15
16 aforementioned manufacture of cement, lime, and plaster have the highest FDI. In
17
18 addition, manufacture of manmade fibers, cleaning, and paper receive 130.9%,
19
20 55.5%, and 54.4%, respectively, of FDI over value added, whereas production of
21
22 electricity, cleaning, and alcoholic beverages reach 9.89%, 4.06%, and 3.36%,
23
24 respectively, of FDI weight. However, in labour-intensive and R&D-intensive
25
26 sectors (Table 3), the FDI over value added for television and radio, as well as
27
28 manufacture of machine tools, other textile industries, accumulators, and railway
29
30 reaches 96.5%, 32%, 28.4%, 26.5%, and 25.9%) respectively, whereas the FDI
31
32 weight for television and radio and accumulators reach 2,47% and 1,66%
33
34 respectively.
35
36
37
38

39
40 Alternatively, in labour-intensive, low-R&D sectors (Table 4), FDI over
41
42 value added for companies in the textile fibres industries, bread, and cork sectors
43
44 reaches 48.5%, 30.9%, and 20.4%, respectively, whereas FDI weight for bread
45
46 and textile fibres reach 2,68% and 1,06%.

59 **III. Model and Methodology**

60

1
2
3
4
5
6
7 Solow (1957) proposes the most common way to estimate technical progress. We
8
9 suppose the production function to be a Cobb-Douglas that, using natural
10
11 logarithms, is expressed as:
12
13

$$14 \quad \ln X_t = \ln A + a \ln K_t + b \ln L_t \quad (1)$$

15
16
17
18
19
20
21 where X is the output, K is the capital input, and L is the labour input. The Solow
22
23 residual is the constant term in the equation and represents the growth of output
24
25 unexplained by the growth of inputs, when variables are expressed in relative
26
27 increases. In this formulation, the constant represents the technical level. The
28
29 coefficients of inputs, a and b , are the output elasticity to the corresponding input.
30
31 If constant returns to scale exist, the sum of these coefficients is one. If increasing
32
33 (decreasing) returns to scale exist, the sum of a and b is bigger (smaller) than one.
34
35
36

37
38 The expression (1) is true under certain conditions, particularly constant
39
40 input prices. In an environment of decreasing prices, the demand for factors could
41
42 generate smaller marginal values of input productivity. For that reason, the
43
44 equation calls for a term that reflects the cost of inputs.
45
46

47
48 Another implicit condition in the expression is that only one type of capital
49
50 input exists; that is, no heterogeneity exists in marginal productivity. In this paper,
51
52 we aim to identify the role of FDI and its interaction with R&D as it relates to
53
54 productivity and technical progress. The estimates of capital inputs make no
55
56 distinction about the origin of the capital; thus, the equation introduces them in a
57
58 redundant manner.
59
60

1
2
3
4 We use the Industrial Companies Survey from the Instituto Nacional de
5 Estadística (INE), which includes comprehensive data for the manufacturing
6 sector in Spain. The data contains homogeneous information from 1994 to 2006
7 for 100 subsectors within manufacturing. FDI data are from the Spanish Ministry
8 of Industry's DataInvex Foreign Investment Statistics database, and price data
9 comes from INE's Industrial Price Index.
10
11
12
13
14
15
16
17

18
19 Output is measured by value added (revenues minus external purchases) in
20 constant prices (by every industry production deflator). Capital use equals the
21 estimated depreciation of fixed assets (calculated using the average depreciation
22 rate from the Central Balance Sheet Data Office from the Bank of Spain and
23 expressed in constant terms via the gross fixed capital formation deflator). Labour
24 inputs equal the number of worked hours. Cost of inputs is a proxy of the average
25 wage in constant terms. FDI is gross foreign direct investment expressed in
26 constant prices using the gross fixed capital formation deflator. R&D equals
27 capitalized R&D expenditures, expressed in constant terms using a gross fixed
28 capital formation deflator.
29
30
31
32
33
34
35
36
37
38
39
40
41

42 The estimation model is usually expressed as a log-linear regression (Bajo and
43 Sosvilla, 1992; Muñoz, 1999; Rodríguez and Pallas, 2008). We propose a model
44 that relates the natural logarithm of the value added for the manufacturing
45 industry i in year t , $x_{i,t}$ to a number of variables in the following way:
46
47
48
49
50
51
52
53

$$x_{i,t} = \alpha + \beta_0 x_{i,t-1} + \beta_1 w_{i,t} + \beta_2 k_{i,t} + \beta_3 l_{i,t} + \beta_4 g_{i,t} + \beta_5 f_{i,t} + \beta_6 f_{i,t-1} + \tau_t + \varepsilon_{i,t} \quad (2)$$

54
55
56
57
58
59
60

1
2
3
4 where α is the natural logarithm of technical level, w is the natural logarithm of
5 labour cost, k is the natural logarithm of capital stock, l is the natural logarithm of
6 worked hours, g is the natural logarithm of R&D expenditures, f is the natural
7 logarithm of gross FDI, τ_t is time effect evaluated through a series of time
8 dummies, and $\varepsilon_{i,t}$ is an independent and identically distributed (i.i.d.) error term.
9

10
11
12
13
14
15
16 We also allow for persistence in value added by specifying a dynamic
17 production function including the lagged value of x as the regressor. In addition,
18 we introduce a lagged value of f as a regressor to address the question of causality
19 with respect to value added. We have been considered a panel data analysis
20 (Meliciani, 2000). Estimation is carried out by the Generalized Method of
21 Moments (GMM) for dynamic panel data, proposed by Arellano and Bond
22 (1991), which gives a consistent estimation in the presence of heteroskedasticity
23 of unknown form. This model is consistent with theoretical considerations as well
24 as existing empirical evidence in Crepon, *et al.* (1998), Blundell *et al.* (1999),
25 Aghion *et al.* (2005), Jefferson, *et al.* (2006) and Girma *et al.* (2009).
26
27
28
29
30
31
32
33
34
35
36
37
38
39

40 Tables 5 and 6 provide a correlation matrix and descriptive statistics
41 (mean, standard deviation, minimum, and maximum) for the independent and
42 dependent variables to facilitate the interpretation of the regression results. Value
43 added has a very high correlation with capital and labour inputs, but a modest
44 correlation exists among the inputs themselves, suggesting a kind of input
45 substitution during this period of time. As expected, the correlation with the
46 labour input is negative but is positive with capital, which also suggests input
47 substitution in these years. In general, significant correlations point to some
48 common covariance.

58
59
60

[Insert Tables 5 and 6 about here]

IV. Estimation and Discussion

All the estimations were obtained from Stata 9.0 and are shown in Table 7. The first column contains the estimations for the complete model (2), with time dummies and for the whole manufacturing sector. The second column is the same estimation excluding time dummy variables. The remaining columns are the estimations for the partial datasets: capital-intensive and R&D-intensive industries; capital-intensive and low-R&D industries; labour-intensive and R&D-intensive industries; and labour-intensive and low-R&D industries.

In general, Wald tests indicate that the global significance of the model is high. Differentiated residuals behave in most estimations as white noise, and the null of correct specification of the restrictions (Sargan test) is not rejected.

In all the estimations, the intercept is positive and highly significant, demonstrating the positive influence of productivity over value added. The lagged endogenous exhibits a quite low coefficient; that is, there is a low persistence in the endogenous variable. The highest value of this coefficient is 0.126; it is significant in the first estimation (with time dummies) and statistically equal to zero in the first, third, and fourth subsets.

The production-function parameters, output elasticity to labour and capital, are consistent with a hypothesis of constant returns to scale. The estimation for

1
2
3
4 total sectors with time dummies gives a coefficient for capital of 0.216 and a
5
6 coefficient for labour of 0.735 (worked hours)—a sum of about 0.95. This is
7
8 rejected as statistically equal to one (the standard errors are very small, being a
9
10 particularly efficient estimation), suggesting slightly decreasing returns to scale.
11
12

13
14 The second estimation, without time dummies, gives a sum of estimated
15
16 coefficients of 0.97, very close to constant returns to scale. The estimations for the
17
18 subsets of industries give a sum of about 0.95 (constant returns to scale would not
19
20 be rejected now, with higher standard deviations of the coefficients), except for
21
22 the subset of labour-intensive and R&D-intensive industries (the third subset), for
23
24 which the sum of the coefficients of capital and labour is 0.82. However, this
25
26 estimation warrants caution because tests for serial correlation indicate that the
27
28 residuals are not white noise.
29
30
31

32
33 The coefficient of the labour control variable is positive and highly
34
35 significant in all cases, representing a positive association between inputs costs
36
37 and output. Its value ranges between 0.49 and 0.77 across estimations.
38
39

40 Time is important when measuring FDI spillover (Buckley *et al.* 2007;
41
42 Altamonte and Pennings, 2009). The time variables tend to be positive and
43
44 significant during the first years of the period, and they are generally negative and
45
46 significant during last years. In this model, the time coefficients suggest decreases
47
48 in productivity that reach a minimum in 2003. The evolution of input prices as
49
50 control variables does not explain the change, consistent with some other
51
52 estimations of total factor productivity for the Spanish economy in prior years.¹
53
54
55
56
57
58
59

60
¹ See, for instance, estimations of the Bank of Spain.

1
2
3
4
5 In our proposed model, FDI is an explanatory variable for value added in a
6
7 production function (Kokko, 1996; Narula and Marin, 2003; Ben Hamida and
8
9 Gugler, 2009). R&D and FDI are redundantly included in the estimation of
10
11 output. Both investments are included in capital input and estimated as a stock
12
13 (proxy of capital services). If the coefficient of one of these variables is zero, this
14
15 type of capital thus has the same elasticity as the rest of the assets. A positive
16
17 coefficient indicates that the investment has a higher elasticity.
18
19

20
21 R&D expenditures offer a negative and significant coefficient in the two
22
23 first estimations. That is, R&D expenditures have a negative contemporaneous
24
25 effect on output. This result contradicts many studies that identify a positive effect
26
27 of innovation on productivity, such as Coe and Helpman (1995), Eaton and
28
29 Kortum (1996), Coe *et al.* (1997). In fact, R&D improves production technology,
30
31 increases productivity, and increases return on investment at both the firm and
32
33 industry levels, according to Griliches (1986, 1990), Mansfield (1988), Goto and
34
35 Suzuki (1989), Meliciani (2000), Timmer (2003), Gonzalez and Gascon (2004).
36
37 Besides, R&D is the largest contributor to the creation of knowledge and the
38
39 increase of productivity (Griliches, 1958, 1973; Hulton, 1975; Scherer, 1982;
40
41 Fagerber, 1988; Solow, 1988).
42
43
44
45
46

47 Thus, the measurement of R&D in the Industrial Companies Survey
48
49 explains our particular result: R&D expenditures are only recognized when they
50
51 are accounted for as fixed assets. That happens when innovation has been real,
52
53 effective, and valuable. Implicitly, any amount of R&D in the data required a
54
55 larger consumption of factors to become a valuable innovation. This negative
56
57 coefficient reflects higher adjustment costs than in other assets. When estimating
58
59
60

1
2
3
4 the model for the four subsets of data, we obtain a positive, significant sign for the
5
6 coefficient of the group of capital-intensive and R&D-intensive industries in
7
8 which the positive effects on productivity overcome the adjustment costs. For the
9
10 rest of the subsets, we obtain a negative, contemporaneous, net effect. This
11
12 finding is consistent with Ten Raa and Wolff (2000), which shows the relevance
13
14 of technological spillovers for the growth of total factor productivity in high-tech
15
16 sectors. We conclude that capital-intensive and R&D-intensive sectors offer the
17
18 most convenient conditions for innovation to generate technical progress. In this
19
20 regard, as illustrated in some research (Koo, 2005), knowledge-intensive
21
22 industries are more likely to create spatially mediated technology spillovers. In
23
24 fact, according to Castellani and Zanfei (2007), even R&D-intensive foreign
25
26 subsidiaries generate positive spillovers in domestic firms.
27
28
29
30
31
32

33 Foreign direct investment has a positive, significant (at 90%) effect on
34
35 contemporaneous output, according to the first column of results in Table 7. In the
36
37 estimation with dummy time variables, however, maximum significance and a
38
39 bigger positive value for the coefficient is obtained for the one-year lagged FDI.
40
41 This result is equivalent to those obtained by Blomström (1989), Haskel *et al.*
42
43 (2002), Alvarez and Molero (2005).
44
45
46

47 The second estimation offers some contradictory results. When time
48
49 variables are not included in the model, the sign of the contemporaneous FDI is
50
51 negative and significant at 95%, whereas the lagged variable has a positive and
52
53 significant (at a 99% level) coefficient. The estimations for the four industry
54
55 subsets give in all cases a contemporaneous coefficient that is not significant. The
56
57 same happens with the lagged variable: it is statistically insignificant except for
58
59
60

1
2
3
4 the subset of capital-intensive and R&D-intensive industries. In this particular
5
6 case, FDI has a positive and significant effect on productivity with one year of
7
8 delay.
9

10
11 As stated, in section 2 and now in empirical estimations, this subset of
12
13 sectors exhibits different behaviour. This group of industries offers the
14
15 opportunity to create or benefit from innovations and capital entries, and it offers
16
17 the opportunity to transform them into value that exceeds the value obtained from
18
19 existing investments.
20
21

22
23 Some new research questions arise from these results. First, what industry
24
25 and firm conditions help organizations learn how to take the most advantage of
26
27 innovations and foreign investments? Second, what are the spillovers of FDI and
28
29 innovation, and how are they transmitted?

42 **V. Concluding Remarks**

43
44
45
46

47 The aim of this paper is to explain the relationship between foreign direct
48
49 investment and technical progress in Spanish manufacturing. This study's sample
50
51 data come from the Industrial Companies Survey and DataInVex: Foreign
52
53 Investment Statistics in Spain.
54

55
56 First, we describe the behaviour of FDI in the Spanish manufacturing
57
58 sector. We find that Spanish capital-intensive industries receive of most of the
59
60

1
2
3
4 FDI and have the highest FDI intensity, measured as FDI over value added by the
5 sector. Our hypothesis is that this kind of FDI generates technological progress
6 and productivity gains.
7
8
9

10
11 We estimate a model based on a production function that accounts for the
12 effects of FDI and R&D on value added (output). We perform a GMM estimation
13 on a balanced sample of 100 industries over 14 years. We also estimate the model
14 for four subsamples (capital-intensive and R&D-intensive sectors; capital-
15 intensive and low-R&D sectors; labour-intensive and R&D-intensive sectors; and
16 labour-intensive and low-R&D sectors).
17
18
19
20
21
22
23
24

25
26 The results show that positive effects of contemporaneous and lagged FDI
27 exist for manufacturing productivity, especially in capital- and R&D-intensive
28 industries. In fact, in that subset, R&D expenditures are more elastic in terms of
29 productivity than the other assets. At the same time, this subset is most able to
30 generate or benefit from innovations and capital entries and to convert those
31 things into higher value added than domestic investments can.
32
33
34
35
36
37
38
39

40 This suggests some avenues for future research. First, researchers might
41 use this information to determine which industry and firm conditions improve
42 organizational learning from innovation and foreign investments. Second,
43 researchers might try to identify reasons for spillovers of FDI and innovation, as
44 well as the way they are transmitted.
45
46
47
48
49
50

51
52 In addition, the difference in the coefficients of FDI among the subsamples
53 suggests not only that heterogeneity resides in the industries' ability to absorb the
54 positive effects of foreign capital, but also that heterogeneity exists in the foreign
55 investments, depending on the type of target industry. Thus, FDI in labour-
56
57
58
59
60

1
2
3
4 intensive and less innovative industries may be searching for different competitive
5
6 advantages than FDI in capital-intensive, innovative sectors.

Figures and Tables

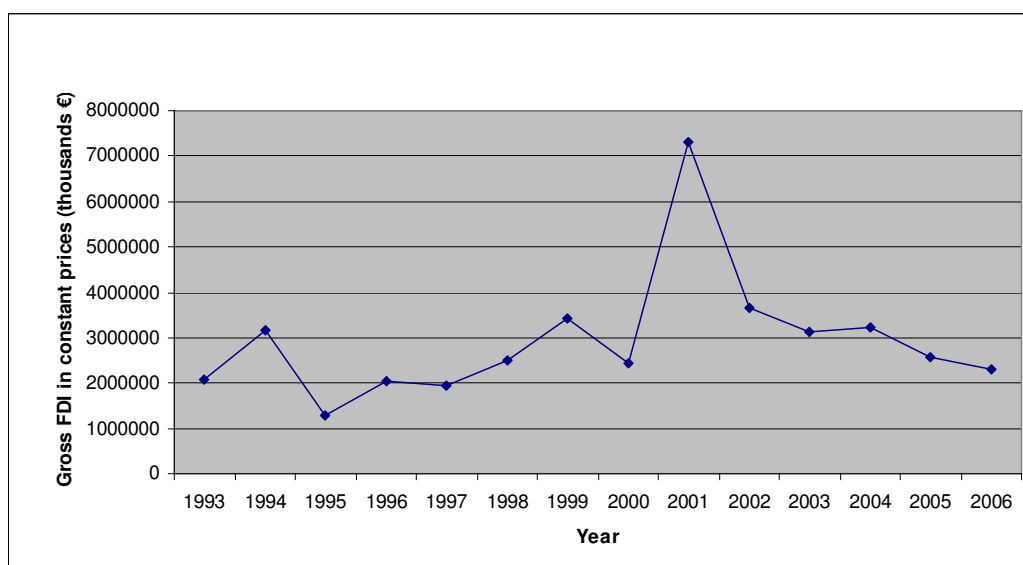

Fig. 1. FDI in Spanish manufacturing

Source: DataInvox: Foreign Investment Statistics in Spain and own elaboration

Industrial sector number (1)	Industrial sector name (1)	Capital stock per worked hour (thousands €/hour) (2)	R&D expenditures over capital (%) (3)	FDI weight (%) (4)	FDI over value added (%) (5)
39	Manufacture of basic chemical products	67.5	5.4	5.62	33.5
86	Manufacture of motor vehicles	33.6	20.1	5.44	24.0
42	Manufacture of pharmaceutical products	22.1	17.1	5.19	39.7
37	Publishing	16.4	9.4	4.26	32.3
88	Parts and accessories for motor vehicles and their engines	15.1	16.1	2.89	23.0
91	Manufacture of aircraft and spacecraft	22.1	140.4	2.14	80.8
47	Manufacture of plastic products	13.7	4.9	1.72	12.2
3	Extraction of nonenergy producing minerals	25.6	7.0	1.67	30.1
48	Manufacture of glass and glass products	19.4	6.0	1.08	25.3
44	Manufacture of other chemical products	24.3	15.5	1.02	26.5
57	Other first processing of iron and steel	28.2	6.4	0.60	37.6
59	Casting of metals	20.3	3.9	0.49	14.1
41	Paints, varnishes, printing ink and mastics	18.3	10.0	0.44	12.1
74	Manufacture of household appliances	13.1	8.6	0.43	12.3
78	Manufacture of insulated wire and cable	13.6	3.8	0.38	26.2
75	Manufacture of office machines and computers	14.7	35.6	0.32	12.4
2	Petroleum, natural gas and nuclear fuels	142.1	10.9	0.25	1.8
97	Recycling	17.6	4.1	0.20	36.6
92	Manufacture of motorcycles, bicycles and other transport equipment	17.3	24.8	0.14	15.9
95	Manufacture of sports goods, games and toys	14.3	18.2	0.11	7.1
1	Extraction and agglomeration of anthracite, coal, lignite and peat	23.7	10.6	0.10	3.1
54	Various nonmetallic ore products	22.6	14.5	0.04	2.5
40	Manufacture of pesticides and other agro-chemical products	24.0	4.4	0.03	3.6
Total FDI weight per sector (%) / FDI intensive sectors over value added (%)				34.56	23.49

73	Miscellaneous special purpose machinery. Weapons and ammunition	8.3	19.6	0.47	7.3
90	Manufacture of railway and tramway locomotives and rolling stock	10.3	38.8	0.42	25.9
60	Manufacture of metal structures and parts of structures	6.7	9.4	0.41	8.1
49	Ceramic goods other than for construction purposes	10.2	9.8	0.27	11.5
67	Manufacture of cutlery, tools and general hardware	9.9	4.2	0.26	7.2
81	Manufacture of electronic valves, tubes and other electronic components	12.4	15.1	0.23	13.0
77	Manufacture of electricity distribution and control apparatus	8.7	12.5	0.23	8.5
85	Measuring, control, optical and photographic appliances	8.0	58.9	0.22	7.4
83	Television and radio receivers, sound or video recording or reproducing	11.4	15.4	0.17	11.7
79	Manufacture of electric lamps and lighting equipment	7.2	5.9	0.15	9.2
76	Manufacture of electric motors, generators and transformers	9.9	36.2	0.13	4.4
93	Manufacture of furniture	4.8	4.5	0.12	1.0
89	Building and repairing of ships and boats	7.6	24.2	0.07	2.4
62	Tanks, large deposits, metal containers, central heating radiators, boilers	5.4	8.7	0.07	4.0
84	Medical surgical equipment and instruments and orthopaedic appliances	4.4	10.9	0.05	3.2
87	Bodies coachwork for motor vehicles; trailers and semi-trailers	5.8	51.8	0.04	2.3
22	Manufacture of knitted and crocheted fabrics	10.0	5.7	0.02	3.1
19	Textile finishings	10.3	4.7	0.01	0.5
63	Manufacture of steam generators	7.4	15.4	0.01	2.5
71	Manufacture of agricultural and forestry machinery	5.2	6.2	0.01	0.8
23	Manufacture of knitted and crocheted articles	5.8	4.1	0.00	0.1
Total FDI weight per sector (%) / FDI intensive sectors over value added (%)				9.62	11.52

Table 4: Labour-intensive and low-R&D sectors

Industrial sector number (1)	Industrial sector name (1)	Capital stock per worked hour (thousands €/hour) (2)	R&D expenditures over capital (%) (3)	FDI weight (%) (4)	FDI over value added (%) (5)
11	Bread, biscuits, pastry goods and cakes	7.6	1.6	2.68	30.9
17	Preparation and spinning of textile fibres	13.0	2.5	1.06	48.5
68	Manufacture of other fabricated metal products, except furniture	11.4	3.1	0.98	13.8
38	Graphic arts and reproduction of recorded media	12.1	0.6	0.82	6.6
24	Manufacture of wearing apparel	3.6	1.8	0.24	3.0
96	Various other manufacturing industries	6.6	1.6	0.20	15.1
61	Manufacture of builders' carpentry and joinery of metal	3.0	1.2	0.17	2.8
18	Textile weaving	11.6	2.8	0.14	6.7
5	Production and preserving of fish and fish products	10.1	1.4	0.11	4.4
34	Manufacture of cork, straw and plaiting materials	8.4	2.1	0.09	20.4
27	Leather goods, luggage, saddlery and harness	2.7	0.9	0.09	13.1
20	Other made-up textile articles, except apparel	5.3	2.2	0.08	4.1
25	Fur industry	5.5	0.2	0.05	17.3
29	Sawmilling, planing and industrial preparation of wood	8.5	0.2	0.04	3.6
65	Treatment and coating of metals	9.1	1.3	0.04	1.4
33	Manufacture of other products of wood	5.0	0.1	0.04	3.8
94	Manufacture of jewellery and related articles	4.4	0.8	0.02	2.0
66	General mechanical engineering	8.2	1.8	0.02	0.3
28	Manufacture of footwear	4.0	1.5	0.01	0.3
26	Tanning and dressing of leather	9.5	3.2	0.01	0.9
53	Cutting, shaping and finishing of stone	10.1	1.8	0.01	0.1
32	Manufacture of wooden containers	6.4	0.7	0.00	0.1
31	Manufacture of builders' carpentry and joinery	4.7	1.1	0.00	0.0
Total FDI weight per sector (%) / FDI intensive sectors over value added (%)				6.88	8.81

(1) Industrial sector number is arranged in CNAE-93 Rev.1 code order, used by Industrial Companies Survey from INE.

(2) Capital stock per worked hour (thousands €/hour) is the mean of the quotient between capital stock in constant prices and the gross fixed capital formation deflator recorded by the Spanish National Accounts from INE. Capital stock in constant prices equals the annual asset amortization extracted from the Industrial Companies Survey divided by the mean of the asset amortization rate in the period 1993-2004, recorded by the Central Balance Sheet Data Office at the Bank of Spain. Asset amortization rate is the quotient of the annual asset amortization and the mean of the previous and the current year recorded by the Central Balance Sheet Data Office.

(3) R&D expenditures over capital (%) is R&D expenditures in constant prices divided by capital stock in constant prices. R&D expenditures in constant prices equals the quotient between the R&D expenditures in current prices from the Industrial Companies Survey and the gross fixed capital formation deflator recorded by the Spanish National Accounts.

(4) FDI weight (%) equals gross FDI in constant prices in the industrial sector divided by the gross FDI in constant prices of all industrial sectors. Gross FDI in constant prices equals gross FDI in current prices (from DataInx: Foreign Investment Statistics in Spain, from the Ministry of Industry) divided by the gross fixed capital formation deflator recorded by the Spanish National Accounts.

(5) FDI over value added (%) equals the addition of the gross FDI in constant prices divided by the mean of the value added in constant prices. Value added in constant prices is the quotient of the value added in current prices and the Industrial Price Index (IPRI) from INE. Value added in current prices equals total operating income minus consumption and work done by other companies. This data is from the Industrial Companies Survey.

Table 5: Correlation matrix

Variables	Value added	Labour costs	Capital stock	Worked hours	R&D expenditures	Gross FDI
Value added	1	0.3626	0.9214	0.8069	0.5155	0.4320
Labour costs		1	0.4103	-0.1765	0.3605	0.2625
Capital stock			1	0.6503	0.4781	0.4165
Worked hours				1	0.3855	0.2845
R&D expenditures					1	0.2454
Gross FDI						1

Table 6: Descriptive statistics

Variables (in logs)	Mean	Standard deviation	Minimum	Maximum
Value added (thousands €)	13.82	0.97	11.00	16.33
Labour costs per worked hour (thousands €/hour)	2.63	0.36	1.76	3.61
Capital stock (thousands €)	12.98	1.21	9.53	17.32
Worked hours (hours)	10.32	0.88	7.69	12.39
R&D expenditures (thousands €)	6.43	2.80	-2.99	11.85
Gross FDI (thousands €)	6.07	5.15	-6.21	14.58
