# Does foreign aid increase private investment? Evidence from panel cointegration

Dierk Herzer<sup>a,\*</sup> and Michael Grimm<sup>b</sup>

<sup>a</sup> *Johann Wolfgang Goethe-University, Grüneburgplatz 1, 60323 Frankfurt am Main, Germany*

<sup>b</sup> *International Institute of Social Studies, Erasmus University Rotterdam, Kortenaerkade 12, 2518 AX The Hague, The Netherlands*

This paper uses panel cointegration and causality techniques to examine the long-run relationship between foreign aid and private investment. Our main result is that aid has a statistically significant negative effect on private investment. This result is robust to outliers, different measures and forms of aid, sample selection, and the sample period. In addition, we find that long-run causality runs in both directions, suggesting that an increase in aid reduces private investment and that, in turn, higher private investment leads to lower aid inflows.

## I. Introduction

The financing of aid is a key component of international development strategies. Developing countries, particularly the poorest, have insufficient domestic resources to finance their investment and development needs, while rich countries have, for various reasons (humanitarian, economic, and political), a desire to help countries that are less well off. Aid serves these purposes as rich donors provide concessional financing to poor recipients. The fundamental assumption underlying the allocation of aid is that it effectively contributes to economic growth and development in the recipient country. The

1  
2  
3 2002 Financing for Development Conference in Monterrey, Mexico and the 2005 G-8  
4  
5 Summit in Gleneagles, Scotland endorsed commitments by rich countries to increase the  
6  
7 amount of foreign aid significantly, especially to Africa. Likewise, the Report of the  
8  
9 Commission for Africa (2005) advocated a doubling of aid to Africa. These commitments  
10  
11 are often reiterated, such as at the L'Aquila Summit in 2009. Thus, there is a political  
12  
13 belief in the effectiveness of aid, although sceptics could counter that the plans are merely  
14  
15 rhetorical, as the commitments have not yet been fully met.  
16  
17  
18

19  
20 The economics profession, on the other hand, is far more cautious than politicians  
21  
22 in its conclusions about aid effectiveness. A considerable amount of empirical research  
23  
24 since the 1970s has tested whether or not aid has a positive impact on economic growth in  
25  
26 recipient countries, but without any consensus being reached. Studies such as Burnside and  
27  
28 Dollar (2000, 2004) and Collier and Dollar (2004) find that aid per se has no effect on  
29  
30 growth, although when interacted with policy, there is a conditional effect; aid has a  
31  
32 positive impact on growth in countries with 'good' economic policies. Other studies such  
33  
34 as those by Easterly et al. (2004) and Rajan and Subramanian (2008) suggest however that  
35  
36 this result is not robust and, hence, make the argument that aid is insignificant, irrespective  
37  
38 of economic policy. Still others, Dalgaard and Hansen (2001) and Daalgard et al. (2004),  
39  
40 for example, find that aid has a positive effect on growth and that this effect is not  
41  
42 conditional on economic policy.  
43  
44  
45  
46  
47

48 Most of these studies in the tradition of Burnside and Dollar (2000) do not include  
49  
50 investment in the estimated aid-growth relationship. If investment were to be included, the  
51  
52 estimate of the growth-effect of aid would not account for those effects of aid operating  
53  
54 through investment. Thus, an implicit assumption of all these studies is that the main effect  
55  
56 of aid on economic growth is through investment (Gomanee et al., 2005). This assumption  
57  
58 is also the basis of the Harrod-Domar-type models still used by international financial  
59  
60

1  
2  
3 institutions to calculate aid requirements for target growth rates (Dalgaard and Erickson,  
4 2009). Obviously, aid can affect overall investment by financing public investment (since  
5 aid is typically given to governments). However, not all aid is intended for investment, and  
6 not all investment is financed by aid (Herzer and Morrissey, 2009). Hence, an important  
7 question is, to what extent does aid affect private investment, particularly in the long run?  
8 This is the subject of the present paper.

The focus on private investment is interesting, since many studies suggest that private investment is associated with larger growth effects than is public investment (Khan and Reinhard, 1990; Greene and Villanueva, 1991; Dollar and Easterly, 1999; Devarajan et al., 2003). Consistently, Dollar and Easterly (1999) find that total investment is not a good predictor of growth in Africa. Moreover, Pritchett (1996) finds that high levels of public investment do not necessarily translate into higher levels of physical capital.

Despite the importance of this subject, there have been very few empirical studies investigating the effect of aid on private investment in the recipient country. The results of the few studies which have been done are mixed. Mosley et al. (1987), in a time-series study of eight countries, find that the private investment effect of aid is negative in one recipient country, statistically significant in three, and positive in four. Mahdavi (1990) uses cross-country data and finds a positive but insignificant association between aid and private investment. The pooled time-series cross-sectional regressions by Snyder (1996) suggest that aid has a statistically significant negative effect on private investment. Hadjimichael et al. (1995) investigate the impact of aid on private investment in a sample of Sub-Saharan African countries and find that the impact is positive for countries under structural adjustment and negative for countries with negative per-capita growth. Finally, Dollar and Easterly (1999) use a sample of 49 countries with up to six four-year periods. Employing pooled ordinary least squares (OLS) regressions, they find a positive effect of

1  
2  
3 aid on private investment in a good economic policy environment, but this effect is subject  
4  
5 to diminishing returns; the marginal impact of aid declines and becomes negative at high  
6  
7 volumes of aid. If policies are poor, aid reduces private investment.  
8  
9

10 A limitation of all these studies, with the exception of Dollar and Easterly (1999), is  
11 that they do not adequately account for the potential endogeneity of aid, and this failure  
12 may bias the results. If, for example, donors are more willing to give aid to countries with  
13 high private investment rates, possibly because they believe that such countries use foreign  
14 aid more effectively, the results are biased towards a positive relationship between aid and  
15 private investment. If, in turn, donors prefer to provide aid to those countries in which  
16 private investment has declined—possibly due to factors such as natural disasters,  
17 economic shocks, or debt overhang—the results are biased towards a negative correlation  
18 between aid and private investment. Dollar and Easterly attempt to circumvent this  
19 problem by instrumenting aid through population and ‘donors’-interest’ variables.  
20 However, the quadratic aid-policy interaction term loses significance when instrumented.  
21 Moreover, the results seem to be sensitive to outliers, period length, and the exact  
22 definition of good economic policies.

33  
34  
35  
36  
37  
38  
39  
40

41 A second problem is that, with the exception of Mosley et al. (1987), all studies use  
42 standard cross-sectional regression techniques. These techniques, however, are known to  
43 be unable to control for country-specific factors, and this inability gives rise to omitted-  
44 variable bias.  
45  
46  
47  
48  
49

50 This paper examines the relationship between aid and private investment using  
51 panel cointegration and causality techniques to control for endogeneity and omitted-  
52 variable bias. Given that private investment is considered one of the main drivers of  
53 economic growth in developing countries, the paper contributes to the understanding of the  
54 mechanisms underlying the impact of aid on economic growth. Our results suggest that aid  
55  
56  
57  
58  
59  
60

1  
2  
3 has a statistically significant negative effect on private investment, and that long-run  
4  
5 causality runs in both directions, i.e., larger amounts of aid lead to lower private  
6  
7 investment and higher levels of private investment lead to lower inflows of aid.  
8  
9

10 The remainder of this paper is organised into four sections. In Section II, we discuss  
11  
12 the potential ways in which aid can affect private investment. Section III sets out the basic  
13  
14 empirical model and describes the data. The econometric implementation and the  
15  
16 estimation results are presented in Section IV, while Section V concludes.

## 22 **II. Theoretical Framework**

23  
24  
25  
26

### 27 *The basic set up*

28  
29

30 In what follows we present a theoretical framework that will guide our empirical analysis.  
31  
32 It is well known that modelling investment behaviour of private firms is a serious  
33  
34 challenge. Investment is the most volatile component of aggregate demand. Investment  
35  
36 behaviour is a forward-looking activity with irreversible aspects and is driven by  
37  
38 expectations, which are difficult to observe. As we will show below, the developing-  
39  
40 country context adds many other particularities that make it difficult to come up with a  
41  
42 straightforward model of investment behaviour. For industrial countries much of the  
43  
44 literature relies upon the ‘flexible-accelerator approach’ (Agénor and Montiel, 2008). The  
45  
46 flexible-accelerator approach models investment as being mainly dependent upon expected  
47  
48 aggregate demand, the cost of capital and labour, and the initial capital stock. Assuming  
49  
50 the profit function  
51  
52  
53  
54  
55  
56  
57

$$58 \pi(k) = py[k, n(w/p, k)] - wn(w/p, k) \quad (1)$$

59  
60

where  $\pi$  are profits,  $p$  is the price of output,  $y$  is output,  $k$  is capital stock,  $w$  is the wage rate, and  $n(\cdot)$  is the level of employment, derived from profit maximisation conditioned upon the existing capital stock, we find that the optimal capital stock  $k^*$  must satisfy:

$$\pi'(k^*) = (\rho + \delta)p_k \quad (2)$$

where  $\rho$  is the discount rate,  $\delta$  the rate of depreciation and  $p_k$  the price of capital. The right-hand side of Equation 2 reflects the user cost of capital.

Given an initial capital stock  $k_0$ , net investment in this model represents a gradual adjustment of the actual to the desired capital stock. Gross investment is derived by adding to this an amount of replacement investment that is proportional to the initial capital stock. Hence, relying on this type of model, a structural investment function needs to include expected future values of aggregate demand, the user cost of capital, the wage rate, and the initial stock of capital, which will all interact in a non-linear way. Since the above representation is static in the sense that it ignores short-run frictions (through short-run adjustment costs, for example), we adopt an empirical specification that captures the long-run relationship between aid and private investment. In doing so, we do not need to be concerned about the lags through which aid affects private investment. However, before we translate this model into a parsimonious empirical specification, we must discuss the aspects of the model that need to be adapted to fit the circumstances of a typical developing country (Rama, 1993; Servén and Solimano, 1993; Agénor and Montiel, 2008), and to form assumptions about how foreign aid may intervene in this context.

1  
2  
3 *Developing country context and foreign aid*  
4

5 First, in many developing countries, financial systems are only poorly developed and credit  
6 rationing may seriously affect the behaviour of private investment. Mlambo and Oshikoya  
7 (2001), for example, show that credit availability has a large effect on private investment in  
8 Africa.  
9

10  
11  
12  
13  
14  
15 Second, in developing countries a large share of capital goods is imported; thus,  
16 entrepreneurs will not only take into account the user cost of capital and the wage rate, but  
17 also the exchange rate and the availability of such goods. Obviously, in this case, a  
18 depreciation of the real exchange rate will have ambiguous effects on investment in export-  
19 oriented industries, since the depreciation would increase their competitiveness on the  
20 world market; but, at the same time, the industry would have to bear higher costs for  
21 imported capital goods. Which effect dominates will depend upon the structure of the  
22 particular firm. Foreign aid can in principle relax such foreign exchange constraints and  
23 may boost private investment by this mechanism. In other words, given that investment in  
24 developing countries generally depends strongly upon the foreign exchange available to  
25 import the capital goods necessary to expand production or to keep installed capacity  
26 functioning, aid may encourage private investment by relaxing foreign-exchange  
27 constraints.  
28  
29  
30  
31  
32  
33  
34  
35  
36  
37  
38  
39  
40  
41  
42  
43  
44

45  
46 Third, many developing countries suffered in the past from a serious debt overhang,  
47 which is seen by many as a factor, if not the main factor, inhibiting private investment,  
48 since it may imply confiscatory future taxation. Given that aid in recent years is often paid  
49 in the form of debt relief, aid may also boost private investment via this channel.  
50  
51  
52

53  
54  
55 Fourth, macroeconomic instability, which is often induced by political instability,  
56 has been shown to be an important determinant of private investment (Rodrik, 1991;  
57 Aizenmann and Marion, 1993; Larrain and Vergara, 1993). Alesina and Tabellini (1989),  
58  
59  
60

1  
2  
3 in particular, illustrate analytically how political uncertainty may lead to a reduction in  
4  
5 productive domestic investment in favour of capital flight and consumption. This implies  
6  
7 that, in a context where aid helps to stabilise an economy, aid may again have positive  
8  
9 effects on private investment. Guillaumont and Chauvet (2001) and Collier and Dehn  
10  
11 (2001), for example, find that increased aid mitigates the adverse effects of external  
12  
13 shocks, such as climatic shocks and trade shocks, on economic growth.  
14  
15

16  
17 Fifth, given that developing countries typically have relatively high public  
18  
19 investment rates, public investment is very likely to affect private investment through  
20  
21 complementarity/substitutability relationships. Whether on balance public investment  
22  
23 raises or lowers private investment is difficult to say. On the one hand, public sector  
24  
25 investment can crowd out private investment expenditure if it uses scarce physical, human  
26  
27 and financial resources that would otherwise be available to the private sector. On the other  
28  
29 hand, public investment to maintain or expand infrastructure and the provision of public  
30  
31 goods and services is likely to be complementary to private investment and may actually  
32  
33 increase the productivity of capital invested by the private sector. Therefore, it is a priori  
34  
35 unclear which effect will dominate. Bleaney and Greenaway (1993) and Ramirez (2000),  
36  
37 for example, find a positive effect of public investment on private investment and attribute  
38  
39 this effect to complementarities. Agénor et al. (2007) examine specifically the effect of  
40  
41 public infrastructure investment on private investment in three countries—Egypt, Jordan,  
42  
43 and Tunisia—using time-series analysis. They find that the effects are positive, but very  
44  
45 small and short-lived. They explain these effects by the rather unfavourable environment  
46  
47 for private investment in these three countries. Other studies, such as Nazmi and Ramirez  
48  
49 (1997) and Mitra (2006), find clear evidence of crowding out.  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

How does foreign aid intervene in the relationship between public and private investment? To answer this question, we assume for the moment that public investment,  $I^{Pub}$ , is financed by international aid,  $A$ , and domestic savings,  $S$ :

$$I^{Pub} = \alpha A + \beta S \quad (3)$$

where  $\alpha$  and  $\beta$  are the shares of foreign aid and domestic savings, respectively, that are used for public investment. Thus, not all aid finances public investment and not all public investment is financed by aid. Hence, Equation 3 shows that public investment is financed by foreign aid and domestic savings if  $\alpha > 0$  and  $\beta > 0$ . From this, it follows that the share of domestic savings available for private investment is  $(1 - \beta)$  and that government consumption,  $G$ , can be written as the sum of the remaining part of aid and income,  $R$ :

$$G = (1 - \alpha)A + R \quad (4)$$

According to Equation 3, a major channel through which aid can affect private investment is aid-financed public investment (if  $\alpha > 0$ ). Crowding-out effects occur when aid encourages the public sector to undertake investment projects that would otherwise be undertaken by the private sector, or when competition from aid-financed government projects for scarce resources, such as skilled labour, increases the costs facing private investors. If, on the other hand, foreign aid is used to finance public investment projects that would otherwise have been financed using scarce domestic financial resources, aid can eliminate a potential source of crowding out;  $\beta$  would decline such that  $\Delta A = -(\Delta \beta)S$ . In addition, aid may generate positive externalities to private firms, thus stimulating private

1  
2  
3 investment, if it is used to finance public investment in human and physical capital and in  
4  
5 the economic infrastructure.  
6  
7

8 The inflow of aid may also create incentives for governments to relax their tax  
9 effort, a phenomenon that is widely recognized in the theoretical and empirical literature  
10 on the fiscal consequences of foreign aid (McGillivray and Morrissey, 2004). As a result,  
11 tax-financed public investment may be reduced. A weaker tax effort, in turn, reduces  
12 domestic distortions and transfers resources to the private sector (lower taxation means  
13 more income available for the private sector, implying that  $(1 - \beta)$  increases). This may  
14 then increase private sector investment.  
15  
16  
17  
18  
19  
20  
21  
22  
23

24 However, it may also happen that aid is just used to increase government  
25 consumption, implying that  $a = 0$  so that  $\Delta A = \Delta G$ , according to Equation 4. In this case  
26 aid just replaces domestic savings. This was an important argument against international  
27 aid put forward by the dependency school (Griffin, 1970; Weisskopf, 1972). Positive  
28 externalities of the type described above are generated only if aid does not substitute  
29 domestic savings, but instead finances additional public investment projects that would not  
30 have been undertaken without aid. Given that the literature on aid effectiveness largely  
31 concludes that aid is effective only under certain conditions, such as in the presence of  
32 good institutions and policies, and that aid has hardly made development miracles possible  
33 (although in most cases, economic growth would have been lower without aid  
34 [McGillivray et al., 2006]), one may expect that a substantial portion of aid is indeed  
35 consumed (Boone, 1996).  
36  
37  
38  
39  
40  
41  
42  
43  
44  
45  
46  
47  
48  
49  
50  
51  
52

53 A sixth characteristic of developing countries is that institutions are often weak or  
54 non-existent. Institutions lower transaction costs by reducing uncertainty and establishing a  
55 stable economic structure to facilitate interactions, thus helping to allocate resources to  
56 their most efficient uses. Without institutions, individuals do not have incentives to invest  
57  
58  
59  
60

1  
2  
3 in physical or human capital or adopt more efficient technologies, implying that resources  
4 are misallocated and private investment opportunities go unexploited. Thus, private  
5 investment is likely to depend strongly upon the quality of institutions, and aid may  
6 therefore affect private investment through its effects on institutions. The conventional  
7 argument is that by expanding a government's resource envelope, aid may reduce the  
8 government's need to explain its actions to citizens, which may in turn alleviate pressure  
9 on it to govern well. Poor governance is generally associated with a weakening of  
10 institutions necessary for a good investment climate, given that the government falters in  
11 its responsibilities to protect property rights, ensure a predictable judiciary, and limit  
12 corruption. The hypothesis of an aid-induced weakening of institutions is supported by  
13 several studies. Knack (2001) finds that higher aid levels erode the quality of governance;  
14 Bräutigam and Knack (2004) and Rajan and Subramanian (2007) suggest that aid is  
15 associated with weak governance, while Djankov et al. (2008) find that aid reduces the  
16 level of democratisation.

Similarly, it can be argued that aid can affect private investment if it encourages a  
diversion of resources from productive activities into unproductive rent seeking. More  
specifically, aid may induce self-interested individuals to engage in rent-seeking activities  
aimed at appropriating part of the resource windfall, and, as a result, scarce resources are  
withdrawn from other productive activities, as several theoretical models predict (Hodler,  
2007; Economides et al., 2008). Rent-seeking may, in extreme cases, directly harm the  
economy by provoking civil conflicts. Such conflicts, of which war is the extreme  
example, affect the investment climate of a country in a number of ways, such as by  
generating uncertainty in the economic environment and/or by destroying the economic  
and political institutions and infrastructure that facilitate an efficient allocation of  
resources. Maren (1997), for example, argues that Somalia's civil war was caused by the

1  
2  
3 desire of different factions to control the large amount of food aid the country was  
4 receiving.  
5  
6

7  
8 In summary, aid may stimulate private investment by relaxing foreign exchange  
9 constraints (thus reducing  $p_k$ ), reducing the debt overhang, and increasing macro-economic  
10 stability (this should raise positive expectations among entrepreneurs). In addition, and  
11 perhaps most importantly, if aid is used by the recipient government to finance public  
12 investment in education, research and development, and physical infrastructure, such  
13 investment may generate positive externalities for the private sector and thus increase the  
14 productivity of private investment (by raising  $\pi'$ ). Aid may also eliminate a possible  
15 source of crowding out if it is used to finance public investment projects that would  
16 otherwise have been financed using scarce domestic financial resources ( $p_k$  declines). In  
17 addition, foreign aid can be used to reduce taxes, thereby reducing distortions in the  
18 economy and increasing the income of the private sector, which may then have a similar  
19 positive effect on private investment (by reducing  $p_k$ ). However, the other side of the coin  
20 is that foreign aid may reduce private investment when the recipient government uses the  
21 aid to finance investment projects that would otherwise be undertaken by the private  
22 sector. Crowding-out effects may also occur when aid-financed public investment  
23 competes with private investment for scarce resources, such as skilled labour. Finally, high  
24 levels of aid over long periods of time can have substantial negative effects on private  
25 investment by weakening institutions and encouraging rent-seeking activities.

46  
47  
48  
49

50 Thus, aid can affect private investment in several ways, perhaps the most important  
51 of which is aid-financed public investment. From this, it follows that the net effect of aid is  
52 theoretically ambiguous and becomes an empirical question. Although our objective is to  
53 examine the long-run relationship between aid and private investment in detail, we have to  
54 admit that the available data do not adequately allow identification of the exact channels  
55  
56  
57  
58  
59  
60

1  
2  
3 through which aid affects private investment. Our focus is thus primarily on the net long-  
4  
5 run effect, which we will investigate using estimation techniques that are robust (under co-  
6  
7 integration) to a variety of estimation problems, such as omitted variables and endogeneity;  
8  
9 to our knowledge these techniques have not been used thus far in the existing literature.  
10  
11 Moreover, we analyse whether aid-financed public investment crowds in or crowds out  
12  
13 private investment.

### 20 III. Model and Data

21  
22 The analysis will examine the long-run relationship between aid and private investment. In  
23  
24 this section, we present the basic empirical model, discuss some econometric issues, and  
25  
26 describe the data.  
27  
28  
29  
30  
31

32 Following common practice in panel cointegration studies (Drine and Rault, 2003;  
33  
34 Herzer, 2008a; Crowder and de Jong, 2010), we consider a bivariate long-run relationship  
35  
36 of the form  
37  
38  
39  
40  
41

$$42 \quad I_{it} = a_i + \delta_i t + \beta A_{it} + \varepsilon_{it} \quad (5)$$

43  
44  
45  
46

53  
54  
55  
56  
57  
58  
59  
60

where  $I_{it}$  is the private-investment-to-GDP ratio over time periods  $t=1, 2, \dots, T$  and  
countries  $i=1, 2, \dots, N$ , and  $A_{it}$  is represented by the standard measure of aid—the  
percentage share of net Official Development Assistance (ODA) in GDP. The coefficient  
 $\beta$  can be interpreted as the long-run elasticity of private investment with respect to aid,  
measuring the net long-run effect of aid on private investment. As the principal interest is  
on the long-run effect, it is not essential to be concerned about the variable lags through  
which aid will impact private investment (as discussed in Section II). Finally, any country-

1  
2  
3 specific omitted factors which are relatively stable in the long run or which evolve  
4 smoothly over time are captured by country-specific fixed effects,  $a_i$ , and country-specific  
5  
6 time trends,  $\delta_i t$ .  
7  
8  
9

10  
11 Equation 5 assumes a long-run bivariate relationship between permanent  
12 movements in the aid-to-GDP ratio and permanent movements in the private-investment-  
13 to-GDP ratio. Necessary conditions for this assumption to hold, and thus for our model to  
14 be a correct description of the data, are that both the individual time series for aid (relative  
15 to GDP) and the individual time-series private investment (relative to GDP) are non-  
16 stationary or, more specifically, integrated of the same order, and that  $I_{it}$  and  $A_{it}$  form a  
17 cointegrated pair. A regression consisting of two cointegrated variables has a stationary  
18 error term,  $\varepsilon_{it}$ , in turn implying that no relevant integrated variables are omitted; any  
19 omitted nonstationary variable that is part of the cointegrating relationship would enter the  
20 error term, thereby producing nonstationary residuals and thus leading to a failure to detect  
21 cointegration. If, on the other hand, cointegration between a set of variables is detected,  
22 this same stationary relationship will also be found in an enlarged variable set (Johansen,  
23 2000).  
24

33  
34  
35  
36  
37  
38  
39  
40  
41

42 Another assumption underlying Equation 5 is that private investment is endogenous  
43 in the sense that, in the long run, changes in aid cause changes in private investment.  
44 However, although the existence of cointegration implies long-run Granger causality in at  
45 least one direction, long-run causality may also run from private investment to aid, as  
46 discussed in the beginning of this paper. The empirical implication is that it is not only  
47 crucial to examine the integration and cointegration properties of the variables, but it is  
48 also important to deal with this endogeneity problem and to investigate the direction of  
49 causality.

The data on private investment as a percentage of GDP are from the International Finance Corporation (IFC)'s *Trends in Private Investment in Developing Countries: Statistics for 1970-2000*, authored by Everhart and Sumlinski (2001). The data on aid come from the World Development Indicators of the World Bank. Since the World Development Indicators do not report data on net ODA as a percentage of GDP, we calculate the aid-to-GDP ratio by multiplying ODA per capita (in current US dollars) by population, divided by GDP (in current US dollars). ODA consists of net disbursements of loans and grants made on concessional terms by official agencies of the members of the Development Assistance Committee (DAC) and certain Arab countries to promote economic development and welfare in recipient countries listed as developing by the DAC. However, although the DAC collects and reports only non-military grant and low-interest loan assistance to developing countries, this standard measure has limitations. For example, it also includes non-financial aid in the form of technical assistance, which may contribute to capacity building and aggregate productivity (although much of this aid is actually spent in the donor, rather than the recipient, country) and food aid (which could be considered as investment in human capital in the broadest sense). Since these two types of aid might not directly affect private investment, we use a second measure of aid to check the robustness of our results: net ODA, excluding technical cooperation and food aid,  $A_{it}^{Financial}$ . The data on  $A_{it}^{Financial}$  are from the International Development Statistics 2010 CD-ROM, published by the OECD.

51  
52  
53  
54  
55  
56  
57  
58  
59  
60

The fundamental problem, however, is that ODA does not identify the aid used for public investment; the coefficient on  $A_{it}$  captures the (net) effect of total aid and thus not necessarily the effect of aid-financed public investment on private investment. To explicitly test whether public investment financed by aid crowds in or crowds out private investment, we construct a third measure of aid: We regress public investment (from the

1  
2  
3 IFC's *Trends in Private Investment in Developing Countries*) on aid for each individual  
4 country,  $I_{it}^{Pub} = b_i A_{it} + \xi_{it}$ . The estimated residuals,  $\hat{\xi}_{it}$ , from this regressions represent the  
5 part of public investment that is not attributed to aid. Then, we subtract  $\hat{\xi}_{it}$  from  $I_{it}^{Pub}$  to  
6 obtain that part of public investment that is financed by aid,  $A_{it}^{Invested}$ . The difference  
7 between  $A_{it}$  and  $A_{it}^{Invested}$  is, in turn, a measure of consumed aid,  $A_{it}^{Consumed}$ , which will also  
8 be considered in the next section. As shown by Pagan (1984), the use of such generated  
9 regressors produces asymptotically efficient estimates and the correct values for the  
10 standard errors.  
11  
12  
13  
14  
15  
16  
17  
18  
19  
20  
21  
22  
23

24 The identification and estimation of cointegrating relationships requires the use of  
25 data over a sufficiently long period of time. Since a period of 30 years should be long  
26 enough for this purpose, we select a sample of countries for which continuous data are  
27 available over a 30-year period from 1970 to 1999. This sample selection results in a  
28 balanced panel of 540 observations on 18 countries: Argentina, Brazil, Chile, Colombia,  
29 the Dominican Republic, Ecuador, El Salvador, Guatemala, India, Kenya, Malaysia,  
30 Mexico, Pakistan, Paraguay, Thailand, Tunisia, Turkey, and Uruguay. Obviously, this is  
31 not a random sample of aid recipients. For example, it does not include any countries from  
32 Sub-Saharan Africa, except Kenya. Moreover, most of the countries in the sample are  
33 currently relatively stable politically, and almost all have well-developed institutions and a  
34 well-performing private sector. They also receive less aid, as measured by its share of  
35 GDP, than the average aid recipient, among other things, because many of these countries  
36 have good access to international capital markets.  
37  
38  
39  
40  
41  
42  
43  
44  
45  
46  
47  
48  
49  
50  
51  
52  
53

54 Therefore, we provide an additional robustness check by using a second sample  
55 with 585 observations on 39 countries over the period from 1985 to 1999. Admittedly, this  
56 period is possibly too short to capture the long-run relationship between aid and private  
57 investment. Given, however, that panel cointegration methods can be implemented with  
58  
59  
60

1  
2  
3 shorter data spans than their time-series counterparts (due to exploitation of both the time-  
4 series and cross-sectional dimensions of the data), the use of this short sample period  
5 should not seriously affect the results. Of the countries in this sample, Malawi is the most  
6 aid-dependent economy, with aid amounting to more than 24 percent of GDP on average in  
7 the period from 1985 to 1999, followed by Madagascar, Dominica, Haiti, Kenya, Grenada,  
8 Belize, El Salvador, Egypt, and St. Lucia. All these countries have an average ratio of aid  
9 to GDP of more than five percent. In Argentina, Barbados, Brazil, Chile, China, Colombia,  
10 India, Malaysia, Mexico, Panama, South Korea, Thailand, Trinidad and Tobago, Turkey,  
11 Uruguay, and Venezuela, aid accounts for less than one percent of GDP, while in  
12 Bangladesh, the Dominican Republic, Ecuador, Guatemala, Indonesia, Mauritius,  
13 Morocco, Namibia, Pakistan, Paraguay, Peru, the Philippines, and Tunisia, the aid-to-GDP  
14 ratio is between one and five percent. To also test whether there are significant differences  
15 in the effects of aid on private investment between highly aid-dependent countries,  
16 moderately aid-dependent countries, and minimally aid-dependent countries, we will  
17 divide the sample into three sub-samples: countries with aid inflows above five percent of  
18 GDP, countries with aid-to-GDP ratios between one and five percent, and countries with  
19 aid inflows below 0.1 percent.

#### 46 **IV. Empirical Analysis**

47  
48  
49  
50

51 This section examines the long-run impact of aid on private investment. Specifically, we  
52 use panel data techniques that allow us to control for omitted-variable and endogeneity  
53 bias. We begin this section by first examining the basic time-series properties of the data.  
54  
55 Then, we test for the existence of a long-run or cointegrating relationship between  $A_{it}$  and  
56  
57  
58  
59  
60

$I_{it}$ . Thereafter, we estimate this relationship and examine the robustness of the results.

Finally, we test the direction of causality between the two variables.

### *Time series properties*

To examine the time-series properties of the data, we use the panel unit root test of Im, Pesaran, and Shin (2003) (IPS), which is based on the augmented Dickey-Fuller (ADF) regression for the  $i$ th cross-section unit:

$$\Delta x_{it} = z_{it}'\gamma + \rho_i x_{it-1} + \sum_{j=1}^{p_i} \varphi_{ij} \Delta x_{it-j} + \varepsilon_{it} \quad (6)$$

where  $p_i$  is the lag order and  $z_{it}$  represents deterministic terms, such as fixed effects or fixed effects combined with individual time trends. The IPS test tests the null hypothesis of a unit root for all  $i$ ,  $H_0 : \rho_i = 0$ , against the alternative of (trend) stationary,  $H_1 : \rho_i < 0$ ,  $i = 1, 2, \dots, N_1$ ;  $\rho_i = 0$ ,  $i = N_1 + 1, N_1 + 2, \dots, N$ , using the standardised  $t$ -bar or IPS statistic

$$\Gamma_i = \frac{\sqrt{N}[\bar{t}_{NT} - \mu]}{\sqrt{v}} \quad (7)$$

where  $\bar{t}_{NT}$  is the average of the  $N = 18$  cross-sectional ADF  $t$ -statistics, and  $\mu$  and  $v$  are, respectively, the mean and variance of the average of the individual  $t$ -statistics, tabulated by Im et al. (2003).

However, the standard IPS test can lead to spurious inferences if the errors,  $\varepsilon_{it}$ , are not independent across  $i$ , for example, due to common shocks or spillovers between countries. Therefore, we also employ the cross-sectionally augmented IPS test proposed by

Pesaran (2007), which is designed to filter out the cross-section dependency by augmenting the ADF regression with the cross-section averages of lagged levels and first-differences of the individual series. Accordingly, the cross-sectionally augmented ADF (CADF) regression is given by

$$\Delta x_{it} = z_{it}'\gamma + \rho_i x_{it-1} + \sum_{j=1}^{p_i} \varphi_{ij} \Delta x_{it-j} + \alpha_i \bar{x}_{t-1} + \sum_{j=0}^{p_i} \eta_{ij} \Delta \bar{x}_{t-j} + v_{it} \quad (8)$$

where  $\bar{x}_t$  is the cross-section mean of  $x_{it}$ ,  $\bar{x}_t = N^{-1} \sum_{i=1}^N x_{it}$ . The cross-sectionally augmented IPS statistic is the simple average of the individual CADF statistics and is defined as

$$CIPS = t\text{-bar} = N^{-1} \sum_{i=1}^N t_i \quad (9)$$

where  $t_i$  is the OLS  $t$ -ratio of  $\rho_i$  in Equation 8. Critical values are tabulated by Pesaran (2007).

The test results for the variables in levels and in first differences are presented in Table 1. Both the IPS and the CIPS test statistics are unable to reject the hypothesis that all countries have a unit root in levels. Since the unit root hypothesis can be clearly rejected for the first differences, we conclude that  $I_{it}$  and  $A_{it}$  are integrated of order 1, I(1)—the necessary condition for cointegration in a bivariate context. Thus, the next step in our analysis is an investigation of the cointegration properties of the variables.

**[Table 1 about here]**

### Cointegration tests

We first test for cointegration using the Larsson et al. (2001) approach, which is based on Johansen's (1988) maximum likelihood estimation procedure. Like the Johansen time series cointegration test, the Larsson et al. panel test treats all variables as potentially endogenous, thus avoiding the normalization problems inherent to residual-based cointegration tests. It involves estimating the Johansen vector error correction model for each country separately and then computing the individual trace statistics  $LR_{iT}\{H(r)|H(p)\}$ . The null hypothesis is that all countries have the same number of cointegrating vectors  $r_i$  among the  $p$  variables  $H_0 : rank(\Pi_i) = r_i \leq r$ , and the alternative hypothesis is  $H_1 : rank(\Pi_i) = p$ , for all  $i = 1, \dots, N$ , where  $\Pi_i$  is the long-run matrix of order  $p \times p$ . To test  $H_0$  against  $H_1$ , a panel cointegration rank trace test is constructed by calculating the average of the  $N$  individual trace statistics by

$$\overline{LR}_{NT}\{H(r)|H(p)\} = \frac{1}{N} \sum_{i=1}^N LR_{iT}\{H(r)|H(p)\} \quad (10)$$

and then standardising it as follows:

$$\Psi_{\overline{LR}}\{H(r)|H(p)\} = \frac{\sqrt{N}(\overline{LR}_{NT}\{H(r)|H(p)\} - E(Z_k))}{\sqrt{Var(Z_k)}} \Rightarrow N(0, 1) \quad (11)$$

where the mean,  $E(Z_k)$ , and variance,  $Var(Z_k)$ , of the asymptotic trace statistic are tabulated by Breitung (2005) for the model we use (the model with a constant and a trend in the cointegrating relationship). As shown by Larsson et al. (2001), the standardized panel trace statistic has an asymptotic standard normal distribution as  $N$  and  $T \rightarrow \infty$ .

In addition, we compute the Fisher statistic proposed by Madalla and Wu (1999), which is defined as

$$\lambda = -2 \sum_i^N \log(p_i) \quad (12)$$

where  $p_i$  is the  $p$ -value of the trace statistic for country  $i$ , calculated from the response surface estimates in MacKinnon et al. (1999). The Fisher statistic is distributed as  $\chi^2$  with  $2 \times N$  degrees of freedom.

However, these test procedures do not take into account potential error cross-sectional dependence, which could bias the results. To test for cointegration in the presence of possible cross-sectional dependence we follow Holly et al. (2010) and adopt a residual-based two-step approach in the style of Pedroni (1999). But unlike Pedroni, we use the common correlated effects (CCE) estimation procedure developed by Pesaran (2006) in the first-step regression. This procedure allows for cross-sectional dependencies that potentially arise from multiple unobserved common factors by augmenting the cointegrating regression with the cross-sectional averages of the dependent variable and the observed regressors as proxies for the unobserved factors. Accordingly, the cross-sectionally augmented cointegrating regression we estimate for each country is given by

$$I_{it} = a_i + \delta_i t + \beta_i A_{it} + g_{i0} \bar{A}_t + g_{i1} \bar{I}_t + e_{it} \quad (13)$$

where  $\bar{I}_t$  and  $\bar{A}_t$  are the cross-sectional averages of  $I_{it}$  and  $A_{it}$  in year  $t$ . In the second step, we compute the cross-sectionally augmented IPS statistic for the residuals from the individual CCE long-run relations,  $\hat{\mu}_{it} = I_{it} - \hat{\delta}_i t - \hat{\beta}_{it} A_{it}$ , including an intercept. Thus, we

account for unobserved common factors that could be correlated with the observed regressors in both steps.

The results of these tests are presented in Table 2. For completeness, we also report the standard panel and group ADF test statistics suggested by Pedroni (1999). As can be seen, all tests strongly suggest that  $I_{it}$  and  $A_{it}$  are cointegrated. The standardized trace statistics and the Fisher  $\chi^2$  statistics clearly support the presence of one cointegrating vector. Also, the CIPS, the panel ADF, and the group ADF statistics reject the null hypothesis of no cointegration at least at the five percent level, implying that there exists a long-run relationship between aid and private investment.

**[Table 2 about here]**

*The long-run relationship between aid and private investment*

Having tested for cointegration, the next step of the analysis is to estimate the long-run effect of aid on private investment—the parameter  $\beta$  in Equation 5. To this end, we use the within-dimension panel DOLS estimator suggested by Kao and Chiang (2000). The DOLS regression in our case is given by

$$I_{it} = a_i + \delta_i t + \beta A_{it} + \sum_{j=-p}^p \Phi_{ij} \Delta A_{it-j} + \varepsilon_{it} \quad (14)$$

where  $\Phi_{ij}$  are coefficients of current, lead, and lag differences, which account for possible serial correlation and endogeneity of the regressor(s), thereby yielding unbiased estimates. Thus, an important feature of the DOLS procedure is that it generates unbiased estimates for variables that cointegrate even with endogenous regressors. Consequently, in contrast to cross-sectional and conventional panel approaches, this approach does not require

exogeneity assumptions nor does it require the use of instruments. In addition, the (panel) DOLS estimator is superconsistent under cointegration, and is robust to the omission of variables that do not form part of the cointegrating relationship.

In Table 3 we present panel DOLS point estimates of the long-run effect of aid on private investment for the raw data as well as for data that have been demeaned over the cross-sectional dimension (i.e., in place of  $I_{it}$  and  $A_{it}$ , we use  $I'_{it} = I_{it} - \bar{I}_t$ ,  $A'_{it} = A_{it} - \bar{A}_t$ , where  $\bar{I}_t = N^{-1} \sum_{i=1}^N I_{it}$  and  $\bar{A}_t = N^{-1} \sum_{i=1}^N A_{it}$ ). The latter allows us to account for potential cross-sectional dependence through common time effects. As can be seen, the results for both the unadjusted and the demeaned data show a significant negative relationship between aid and private investment. More precisely, the point estimates imply that, in the long run, a one-percentage-point increase in the aid-to-GDP ratio decreases the private-investment-to-GDP ratio by about 0.27 to 0.34 percentage points. As noted earlier, possible channels are that, in the long run, aid crowds out private investment and/or undermines institutional quality by weakening accountability, encouraging rent seeking and corruption, and alleviating pressure to reform inefficient policies.

**[Table 3 about here]**

Given the small number of countries in this sample, we need, however, to ensure that the negative effect on private investment is not due to outliers. To this end, we re-estimate the DOLS regression (with cross-sectionally demeaned data), excluding one country at a time from the sample. The estimated coefficients and their  $t$ -statistics are presented in Figure 1. Since the coefficients are fairly stable around -0.33 and always statistically significant at least at the five percent level, we conclude that the negative effect of aid on private investment is not the result of possible outliers.

Next, we examine whether the negative relationship between aid and private investment is robust to different forms or measures of aid. To this end, we re-estimate the DOLS regression (with demeaned data) using net ODA, excluding technical cooperation and food aid ( $A_{it}^{Financial}$ ), invested aid by the government (aid-financed public investment) ( $A_{it}^{Invested}$ ), and consumed aid ( $A_{it}^{Consumed}$ ) in place of  $A_{it}$ . The results are presented in Table 4. Regardless of which aid measure is used, the long-run relationship between aid and private investment remains negative and statistically significant. Particularly worth noting is that the coefficient on  $A_{it}^{Invested}$  is highly significant and of a similar magnitude as its counterpart in Table 3 (column 2). From this it can be concluded that the negative net effect of aid on private investment is primarily due to the presence of crowding out by aid-financed public investment. The fact that the coefficient on  $A_{it}^{Consumed}$  is also significant and negative could suggest that aid also reduces private investment by weakening institutions and encouraging rent-seeking activities; these two mechanisms, however, seem of minor importance since the effect of consumed aid is smaller in magnitude than the effect of invested aid.

59  
60

Finally, we examine whether the negative long-run relationship between aid and private investment is due to sample-selection bias. Sample-selection bias occurs when the selected sample is not random and thus not representative. A potential problem with our sample could be that it does not include any countries from Sub-Saharan Africa, except Kenya, and that it consists mainly of countries with low aid-to-GDP ratios, as discussed in Section III. We therefore re-estimate the DOLS regression (with demeaned data) for a second sample of 39 countries over the period from 1985 to 1999. In addition, we split this sample into three sub-samples: countries with aid inflows above five percent of GDP, countries with aid-to-GDP ratios between one and five percent, and countries with aid

1  
2  
3 inflows below 0.1 percent. The resulting coefficients are listed in Table 5. They are all  
4  
5 significant at least at the five percent level (although somewhat smaller than the estimates  
6  
7 for the original sample), suggesting that the negative effect on private investment is not  
8  
9 due to sample-selection bias. Moreover, given that all aid-coefficients in Table 5 have the  
10  
11 same magnitude, it can be concluded that there are no significant differences in the effects  
12  
13 of aid on private investment between highly aid-dependent countries, moderately aid-  
14  
15 dependent countries, and minimally aid-dependent countries. And lastly, the fact that the  
16  
17 results for the period 1985 to 1999 (in Table 5) are qualitatively similar to those for the  
18  
19 period 1970 to 1999 (in Table 3) suggests that the estimated negative coefficient on  $A_{it}$  is  
20  
21 not sensitive to the sample period.  
22  
23  
24  
25

26  
27 **[Table 5 about here]**  
28  
29

### 30 31 *Long-run causality*

32  
33 Even though estimation by DOLS does not require the regressor(s) to be exogenous (and  
34  
35 even though cointegration implies long-run Granger causality in at least one direction), we  
36  
37 are interested in detecting the direction of long-run causality. Specifically, given that a  
38  
39 negative correlation between  $A_{it}$  and  $I_{it}$  could also imply that countries in which private  
40  
41 investment declined (for example, due to natural disasters or economic shocks) get more  
42  
43 aid, it could well be that causality runs in both directions, that is, not only from aid to  
44  
45 private investment but also from private investment to aid. Thus, the final step in our  
46  
47 analysis is to examine the direction of causality.  
48  
49  
50  
51

52  
53 Our causality test involves estimating a panel vector error correction model  
54  
55 (VECM) given by  
56  
57  
58  
59  
60

$$\begin{bmatrix} \Delta I_{it} \\ \Delta A_{it} \end{bmatrix} = \begin{bmatrix} c_{1i} \\ c_{2i} \end{bmatrix} + \sum_{j=1}^p \Gamma_j \begin{bmatrix} \Delta I_{it-j} \\ \Delta A_{it-j} \end{bmatrix} + \begin{bmatrix} a_1 \\ a_2 \end{bmatrix} ec_{it-1} + \begin{bmatrix} \varepsilon_{1it} \\ \varepsilon_{2it} \end{bmatrix} \quad (15)$$

where  $ec_{it} = I_{it} - [\hat{a}_i + \hat{\delta}_i t + \hat{\beta}_i A_{it}]$  are the residuals from the DOLS long-run relations of the individual countries. A statistically significant coefficient on  $ec_{it-1}$  ( $a_{1,2}$ ) implies long-run Granger causality from the independent to the dependent variable(s), where long-run Granger non-causality and weak exogeneity can be regarded as equivalent. Following Herzer (2008a, 2008b), we test for weak exogeneity by first imposing zero restrictions on the statistically insignificant short-run parameters ( $\Gamma_j$ ) and then using a conventional Wald test of the null hypothesis  $a_{1,2} = 0$ . As in the previous section, we use both the raw and the cross-sectionally demeaned data for this purpose.

The Wald statistics and the corresponding  $p$ -values are presented in Table 6. As can be seen from the table, the unadjusted and demeaned data produce similar results. In both cases, the null hypothesis of weak exogeneity is rejected for both  $I_{it}$  and  $A_{it}$  at the one percent significance level. Thus, private investment is endogenous in the long run, implying that the estimates in the previous section reflect a causal long-run effect of aid on private investment, as expected. However, this long-run causality is bidirectional, suggesting that increased private investment also reduces (quite plausibly) the amount of aid given to a country.

**[Table 6 about here]**

## V. Conclusion

This paper has examined the relationship between development aid and private investment in developing countries using panel cointegration and causality techniques that are

1  
2  
3 specifically designed to deal with key problems (endogeneity and omitted variables)  
4  
5  
6 plaguing previous studies of the aid-private investment nexus. Our main result is that aid  
7  
8 has a statistically significant negative effect on private investment. This result is robust to  
9  
10 outliers, different measures or forms of aid, sample selection, and the sample period.  
11  
12 Specifically, an important conclusion of our robustness analysis is that the effect of aid on  
13  
14 private investment is qualitatively the same for highly aid-dependent countries, moderately  
15  
16 aid-dependent countries, and less aid-dependent countries. Moreover, we find evidence  
17  
18 that the negative effect of aid on private investment is primarily due to the crowding out of  
19  
20 private investment by aid-financed public investment. Given that private investment must  
21  
22 be considered as a key determinant of economic growth, our findings suggest that  
23  
24 development aid does not exploit its full growth potential. Furthermore, our results show  
25  
26 that the long-run causality between aid and private investment runs in both directions,  
27  
28 specifically, larger amounts of aid lead to lower levels of private investment, and  
29  
30 correspondingly, higher levels of private investment lead to lower inflows of aid.  
31  
32  
33  
34  
35

36 If we find that aid has rather negative effects on private investment and that this is  
37  
38 at least partly due to crowding out through public investment, then the implication can or  
39  
40 should of course not be that aid is bad for private investment per se. It suggests rather that  
41  
42 aid is clearly not used in a way that would generate optimal complementarities between  
43  
44 public and private investment. This implies in turn that if aid were more systematically  
45  
46 used for investment in infrastructure, research and development, improvements in the  
47  
48 quality of institutions, and for a better skilled work force, private investment would likely  
49  
50 respond positively to aid. This is consistent with the broader view that aid is effective if  
51  
52 economic policies are good (Burnside and Dollar, 2000, 2004; Collier and Dollar, 2004).  
53  
54 Another implication of our findings is that the link between aid and private investment can  
55  
56 be strengthened if policy enhances the development of capital markets and it is accordingly  
57  
58  
59  
60

1  
2  
3 less likely that public and private investors would compete for the same financial  
4  
5 resources. Obviously, these conclusions are suggestive and need further investigation, but  
6  
7 this is beyond the scope of this article.  
8

**Table 1. Panel unit root tests**

Variable	Deterministic terms	IPS statistics	CIPS statistics
Levels			
$I_{it}$	$c, t$	-1.52	-1.80
$A_{it}$	$c, t$	-0.10	-1.98
First differences			
$\Delta I_{it}$	$C$	-6.39**	-2.51**
$\Delta A_{it}$	$C$	-6.07**	-2.37**

Notes:  $c(t)$  indicates that we allow for different intercepts (and time trends) for each country. Three lags were selected to adjust for autocorrelation. The IPS statistic is distributed as  $N(0, 1)$ . The relevant 5% (1%) critical value for the CIPS statistics is -2.67 (-2.83) with an intercept and a linear trend, and -2.15 (-2.32) with an intercept. \*\* denote significance at the 1% level.

**Table 2. Panel cointegration tests**

	Cointegration rank	
	$r = 0$	$r = 1$
Standardized panel trace statistics	4.34**	-0.61
Fisher statistics	75.71**	29.69
CIPS statistic		-2.18*
Panel ADF statistic		-4.87**
Group ADF statistic		-5.40**

Notes: The panel trace statistic, the panel ADF statistic, and the group ADF statistic are distributed as  $N(0, 1)$ . The Fisher statistic is distributed as  $\chi^2$  with  $2 \times N$  degrees of freedom. It has a critical value of 58.62 (51) at the 1% (5%) level. The relevant 5% (1%) critical value for the CIPS statistic is -2.15 (-2.32). The number of lags was determined by the Schwarz criterion with a maximum of three lags. \*\* (\*) indicate a rejection of the null hypothesis of no cointegration at the 1% (5%) level.

**Table 3. DOLS estimates of the long-run effect of aid on private investment for the period from 1970 to 1999 (coefficients on  $A_{it}$ )**

Raw data	Demeaned data
-0.265*	-0.338**
(-2.11)	(-2.69)

Notes: The dependent variable is  $I_{it}$ ,  $t$ -statistics in parenthesis. \*\* (\*) indicate significance at the 1% (5%) level. The DOLS regression was estimated with one lead and lag.

**Table 4. Parameter estimates using alternative measures of aid**

$A_{it}^{Financial}$	$A_{it}^{Invested}$	$A_{it}^{Consumed}$
-0.260**	-0.344**	-0.033*
(-3.12)	(-4.54)	(-2.54)

Notes: The dependent variable is  $I_{it}$ .  $t$ -statistics in parenthesis. \*\* (\*) indicate significance at the 1% (5%) level. The DOLS regression was estimated with one lead and lag.

**Table 5. Estimates of the long-run impact of aid on private investment using different samples over the period from 1985 to 1999**

	Coefficients on $A_{it}$	$t$ -statistics	Number of countries in the sample
Total sample	-0.170**	-3.00	39
Countries with aid inflows above 5 percent of GDP	-0.165*	-2.32	10
Countries with aid-to-GDP ratios between 1 and 5 percent	-0.182**	-2.83	13
Countries with aid inflows below 0.1 percent	-0.168**	-3.22	16

Notes: \*\* (\*) indicate significance at the 1% (5%) level. The DOLS regression was estimated with one lead and lag.

**Table 6. Weak exogeneity tests / long-run causality tests**

Variable (Coefficient)	$I_{it}$ ( $\alpha_1$ )	$A_{it}$ ( $\alpha_2$ )
Raw data		
$\chi^2(1)$	101.97	8.08
( $p$ -values)	(0.000)	(0.005)
Demeaned data		
$\chi^2(1)$	120.23	8.39
( $p$ -values)	(0.000)	(0.004)

Notes: The number of degrees of freedom  $\nu$  in the standard  $\chi^2(\nu)$  tests corresponds to the number of zero restrictions. The models were estimated with up to three lags.

**Fig. 1. DOLS estimation with single country excluded from the sample**
