8 Although the importance of proximity has been highlighted, it remains an open
9 question which types and levels of proximity are critical for knowledge networks.
10 This paper addresses this issue by examining the role of spatial, social and cognitive
11 proximity of personal knowledge relationships in the Cambridge IT Cluster. It is
12 shown that distinguishing between sub-dimensions of cognitive proximity can clarify
13 the 'proximity paradox'. Moreover, the results highlight that local relationships enable
14 access to cognitively more diverse knowledge than non-local ones. Finally, the paper
15 provides empirical evidence of a compensation mechanism: distance in one dimension
16 is compensated by proximity in at least one other dimension. However, similarity in
17 terms of technical language cannot be easily substituted.

1. INTRODUCTION

The role of spatial proximity for knowledge networks and innovation has been widely emphasised in economic geography and regional studies. However, increasingly the literature has been critical of the focus on spatial proximity in two respects: first, non-local knowledge networks have been claimed and shown to be important. And second, recent literature has argued for a wider perspective to explore the significance of alternative types of proximity such as social or cognitive proximity (e.g. BOSCHMA, 2005; LAGENDIJK and LORENTZEN, 2007; LAGENDIJK and OINAS, 2005; TORRE and RALLET, 2005).

However, there is a lack of empirical investigations on these issues. First, it remains an unresolved question which types and levels of proximity are critical for knowledge networks. Whilst proximity of some sort is generally regarded as being essential, it has been asserted that too much proximity can be detrimental for innovation (BOSCHMA and FRENKEN (2010) called this the 'proximity paradox'). However, there is a dearth of empirical investigations to examine these arguments in detail. Second, there is a lack of understanding on how the different types of proximity are related to one another. In particular, whether distance in one dimension (for instance, cognitive distance) can be compensated by proximity in another dimension (for instance, spatial proximity) remains an open question.

This paper aims to address these gaps by examining spatial, social and cognitive proximity of personal knowledge relationships in the Cambridge Information Technology (IT) Cluster. The analysis is based on a survey and interviews with 105 R&D workers in 46 companies and focuses on personal relationships which were regarded as most important for gaining work-related knowledge in the past year. The

1
2
3 objectives of the paper are to show (i) which types and levels of proximity are critical
4
5 for personal knowledge relationships, (ii) how the R&D workers deal with the
6
7 'proximity paradox', and (iii) how spatial, social and cognitive proximity are
8
9 interrelated.
10
11

12
13 The results suggest that social proximity in terms of feelings of personal
14
15 obligations and emotional closeness is very high, whereas knowing each other in
16
17 terms of private life is significantly less important. Furthermore, this paper argues that
18
19 distinguishing between sub-dimensions of cognitive proximity is fruitful: whereas
20
21 high levels of similarity in terms of technical language is essential, a certain degree of
22
23 dissimilarity in terms of know-how, know-what and the way of thinking can be
24
25 beneficial for the R&D workers. This seems to be a viable strategy of the individuals
26
27 to deal with the 'proximity paradox'. Moreover, this paper highlights the effects of
28
29 spatial proximity: contrary to widespread views, local contacts are not socially more
30
31 proximate than non-local ones, and, interestingly, local contacts are cognitively more
32
33 diverse than non-local ones. The latter suggests that an important benefit of spatial
34
35 proximity is that it enables knowledge flows with cognitively different actors. Finally,
36
37 this paper provides empirical evidence of a compensation mechanism: for knowledge
38
39 relationships that are regarded as important, distance in one dimension (spatial, social
40
41 or cognitive) is compensated by proximity in at least one other dimension. However,
42
43 there is one dimension of proximity that can hardly be substituted: similarity in terms
44
45 of technical language is very high for nearly all relationships and can be regarded as
46
47 essential.
48
49
50
51
52
53

54
55 This paper is organised as follows. Section 2 critically discusses the literature on
56
57 different types of proximity and knowledge networks, highlights open questions and
58
59 links it to the research questions of this paper. Section 3 presents the research design
60

1
2
3 and the methods used in this study. Afterwards, section 4 analyses the data to examine
4
5 which types of proximity are important for personal knowledge relationships. By
6
7 differentiating various dimensions of cognitive proximity, the 'proximity paradox' is
8
9 critically reflected upon. Finally, section 5 explores the interrelationships between
10
11 spatial, social and cognitive proximity and investigates several hypotheses. In
12
13 particular, the question of whether distances in one type can be compensated by
14
15 proximity in other types will be examined. Section 6 concludes.

22 2. TYPES OF PROXIMITY AND KNOWLEDGE NETWORKS 23 24 25 26

27 The question of how spatial proximity impacts on learning and knowledge
28
29 networks has been one of the most prominent topics in economic geography and
30
31 regional studies. It has been widely assumed that co-located actors benefit from local
32
33 knowledge flows enabled by regular face-to-face contacts and tacit knowledge
34
35 transfers (GERTLER, 2003). In particular, an extensive body of *territorial innovation*
36
37 *models* (MOULAERT and SEKIA, 2003) has been developed, which has highlighted
38
39 the geographical dimension of the knowledge-economy. This literature has focused on
40
41 the significance of spatial proximity and territorially defined cultural, social and
42
43 institutional assets that lead to regional knowledge interactions, which shape regional
44
45 competitiveness (see e.g. BRESCHI and LISSONI, 2001; CAMAGNI, 1991;
46
47 CAPELLO and FAGGIAN, 2005; COOKE et al., 2005; HAUSER et al., 2007;
48
49 HUBER, 2009; LAWSON and LORENZ, 1999; MALMBERG and MASKELL,
50
51 2002; STORPER, 1997).
52
53
54
55
56

57 Despite the voluminous literature on the role of space/spatial proximity for
58
59 knowledge networks, the role of geographical distance in knowledge transmissions is
60

1
2
3 still unclear (DÖRING and SCHNELLENBACH, 2006, 388-9). Recent literature has
4
5
6 rightly questioned the academic focus on the local level and called for a wider spatial
7
8 focus integrating extra-local networks and structures (e.g. AMIN and COHENDET,
9
10 2004; BATHELT et al., 2004; BUNNELL and COE, 2001; GIULIANI et al., 2005;
11
12 MACKINNON et al., 2002; YEUNG, 2005). However, the debate about the spatial
13
14 dimension of knowledge relations “[...] has been handicapped by a high degree of
15
16 abstraction coupled with a scarcity of fine-grained empirical analysis on which to
17
18 support sound conceptual advancement” (GERTLER, 2004, 4). The generally
19
20 accepted view is that first, local *and* global relations are important for learning and
21
22 knowledge networks, and second ‘proximity matters’. However, there is a lack of
23
24 empirical work to substantiate these claims. Rather than stating over and over again
25
26 that we have to consider local *and* global links, more empirical studies are needed to
27
28 investigate which specific types of knowledge activity actually operate in which
29
30 spatiality (MALECKI and OINAS, 1999, 2).
31
32
33
34
35

36 Furthermore, rather than simply stating ‘proximity matters’, there is a great need
37
38 to substantiate how and why which type of proximity matters. As Gertler points out, a
39
40 careful analysis
41
42

43 “[...] would examine the strength and type of local relationships, but set this within a
44
45 comparative analysis of the strength and type of non-local relationships as well. It
46
47 would also inquire into the reasons why proximity matters, what particular aspects of
48
49 distance are responsible for attenuating economic interaction [...]” (GERTLER,
50
51 2004, 15).
52
53

54 Importantly, recent literature suggests that the discussion about proximity needs to
55
56 be extended beyond *spatial proximity* to investigate the role of other forms of
57
58 proximity such as organisational, social, cultural or cognitive proximity (BOSCHMA,
59
60 2005; GERTLER, 2004; KNOBEN and OERLEMANS, 2006; LAGENDIJK and

1
2
3 LORENTZEN, 2007; LAGENDIJK and OINAS, 2005; TORRE and RALLET, 2005;
4
5 ZELLER, 2004). The starting point of such an endeavour is the idea that successful
6
7 knowledge flows and interactions require a certain form of proximity as a pre-
8
9 condition to be successful (BOSCHMA, 2005). Generally, proximity is a relational
10
11 concept referring to the degree of closeness of actors. But it remains an empirical
12
13 question which type and which degree of proximity is vital for knowledge networks.
14
15 In addition to spatial proximity, this paper focuses on the critical concepts of social
16
17 and cognitive proximity.ⁱ

18
19
20
21
22 *Social proximity* refers to the issue of the strength of interpersonal links, in
23
24 particular to what extent people know each other and interact in private or
25
26 professional contexts. The traditional argument is that strong, trust-based ties facilitate
27
28 knowledge interaction (GERTLER, 2004, 156). However, the existing literature on
29
30 social proximity (sometimes also referred to as relational proximity or personal
31
32 proximity)ⁱⁱ is dominated by a rather loose usage of this idea (see e.g. AMIN and
33
34 COHENDET, 2004). To clarify and operationalise the notion of social proximity,
35
36 more specific concepts and measures of strengths of relationships are needed.
37
38
39

40
41 *Cognitive proximity*, broadly understood, denominates similarity in the way
42
43 people perceive, interpret, understand and evaluate the world (WUYTS et al., 2005).
44
45 Here the argument is that cognitive proximity is required to understand each other and
46
47 to communicate with each other effectively. Also here empirical research that clarifies
48
49 which quality of cognitive proximity is important for valuable knowledge flows is
50
51 needed. Empirical studies which use crude proxies such as technological profiles
52
53 derived from patent data (e.g. NOOTEBOOM et al., 2007) seem limited in this
54
55 respect. In particular, the existing empirical studies do not differentiate between sub-
56
57
58
59
60

1
2
3 dimensions of cognitive proximity, which seems important to grasp the complexity of
4
5 the broad concept of cognitive proximity.

58
59
60

However, the emphasis on the importance of proximity involves an intricate problem: whilst on the one hand there is the argument that proximity is vital, on the other hand there is an increasing awareness that resource heterogeneity and access to diverse knowledge is beneficial for innovation (NOOTEBOOM, 2000). This leads to a '*proximity paradox*'ⁱⁱⁱ (BOSCHMA and FRENKEN, 2010): too much proximity can be in fact problematic because there is the risk of not learning any new knowledge, but too much distance is also problematic because the actors might not understand each other any more when they are too different (NOOTEBOOM et al., 2007). More empirical research is needed to clarify this dilemma. The empirical results by BROEKEL and BOSCHMA (2011) show that cognitive proximity reduces firms' innovative performance but geographical and social proximity does not reduce it. This suggests that the proximity paradox is particularly relevant for cognitive proximity. Also analytically one can argue that cognitive proximity is the type of proximity that is most closely linked to knowledge and innovation as also discussed by NOOTEBOOM (2000). Therefore, the discussion of the proximity paradox in this paper will focus on cognitive proximity.

Furthermore, there is the important question of *how the various types of proximity are related to one another*. Whilst this issue has been discussed as being critical, there is a dearth of empirical exploration of it as indicated by BOSCHMA (2005, 72). Traditionally it tends to be explicitly or implicitly assumed in the literature that spatial proximity also leads to other forms of proximity. However, new theoretical views have emerged. In particular, it has been argued that other forms of proximity may be a substitute for spatial proximity (BOSCHMA, 2005). MENZEL (2008) made a more

1
2
3 general claim that distance in one type can be bridged by proximity in other types.
4
5 However, these are all conjectures which need to be empirically tested.
6
7

8 To conclude, there is an empirical void of studies that explore which types and
9
10 aspects of proximity actually matter for knowledge interactions and how these types
11
12 of proximity are interrelated.
13
14

15 This paper aims to address these open questions by examining the following
16
17 research questions:
18

- 19
20 (a) Which type and which level of proximity is critical for personal
21
22 knowledge relationships that are regarded as important?
23
24 (b) How do the R&D workers deal with the proximity paradox?
25
26
27 (c) What is the relationship between spatial, social and cognitive proximity?
28
29
30
31
32
33

34 3. RESEARCH DESIGN AND METHODS 35 36 37 38

39 Since the question of proximity and knowledge networks has been mainly
40
41 discussed in the context of knowledge-intensive industries, this study focuses on R&D
42
43 workers in one of the most prominent high-tech clusters in Europe, the Cambridge
44
45 Information Technology (IT) Cluster. IT is the largest sector in terms of the number
46
47 of innovation-based businesses in the Cambridge region (LIBRARYHOUSE, 2004)
48
49 and therefore constitutes the dominant sector of the 'Cambridge phenomenon'. Within
50
51 the Cambridge IT Cluster, innovation-based firms (excluding purely service-based
52
53 firms) of the dominant sub-sectors hardware and software were randomly selected. In
54
55 each firm individual R&D workers were chosen as the embedded unit of analysis.
56
57
58
59
60

1
2
3 The list of the firms in the target population was constructed by using the data of
4 the 'Library House', a research and (now dissolved) data service company, merged
5 with the data available from the research and consultancy company 'Cambridge
6 Investment Research Ltd.'. The target population (sampling frame) at firm-level
7 consists of 220 firms in the Greater Cambridge Region, 156 in software and 68 in
8 hardware. The sample is constituted by first taking a random sample of 100 firms (70
9 in software, 30 in hardware).^{iv} Within those the firms were asked to select R&D
10 workers in various job positions from junior engineers, technology managers to
11 Managing Directors (if s/he is actively involved in research or development).
12
13
14
15
16
17
18
19
20
21
22
23
24

25 It has to be emphasized that getting access to the firm was incredibly difficult.
26 After 11 months (January-November 2008), data from 105 individuals in 46 firms
27 were collected, which represents a response rate of 46% of the firms in the sample. In
28 terms of the *sub-sector* 58 individuals in 25 firms are in software, and 47 individuals
29 in 21 firms in hardware. The average *firm size* in terms of the number of employees
30 (full-time head count) is 35 for the Cambridge sites (median 20) and 81 for all
31 locations world-wide (median 30). On average there are 17 R&D workers in each firm
32 site in Cambridge (median 9). In terms of the *job position* in the sample there are 14
33 Managing Directors, 33 Directors of Research/Development or Chief Technology
34 Officers, 34 senior engineers/developers, 16 mid-level engineers/developers, 6 junior
35 engineers/developers and 2 in other positions.
36
37
38
39
40
41
42
43
44
45
46
47
48
49

50 Taking a *multi-method approach*, face-to-face meetings with the R&D workers
51 were arranged to go through structured questionnaires and conducted semi-structured
52 interviews. Overall, the meetings lasted from 20 to 120 minutes (mean 45 minutes).
53
54
55
56

57 The paper is based on an ego-network analysis of the following kind: the
58 interviewees were asked to nominate the most important personal contact outside of
59
60

1
2
3 their firm for gaining work-related knowledge in the past year.^v Subsequently, data
4
5 about this contact and the relationship were collected and analysed. The data
6
7 discussed in this paper were collected using a self-administered questionnaire.
8
9 Interestingly, 18 interviewees could not think of any contact;^{vi} thus, the analysis is
10
11 based on 87 nominated relationships. It needs to be highlighted that the ‘importance’
12
13 of personal contacts is assessed subjectively by the respondents, but no ‘objective’
14
15 performance indicator is used.^{vii}
16
17
18
19
20
21
22
23

24 25 4. WHICH TYPE OF PROXIMITY IS CRITICAL FOR PERSONAL 26 27 KNOWLEDGE RELATIONSHIPS? 28 29 30

31
32 Let us first examine the role of social proximity (section 4.1) and cognitive
33
34 proximity as well as the proximity paradox (4.2).
35
36
37

38 39 4.1. Social proximity 40 41 42

43
44 Social proximity “is defined here in terms of socially embedded relations between
45
46 agents at the micro-level” (BOSCHMA, 2005, 66). This idea seems equivalent to the
47
48 popular concept of the strength of ties (GRANOVETTER, 1973). However, although
49
50 tie strength seems to be a clear, intuitive concept, its conceptualisation and
51
52 operationalisation usually remains fuzzy and unspecific. The widespread dichotomy
53
54 between strong and weak ties often seems too simplistic. A more careful reflection on
55
56 the pre-theoretic idea of tie strength reveals that it is more complicated and cannot be
57
58
59
60

1
2
3 easily captured by one indicator (see e.g. MARSDEN and CAMPBELL, 1984). For
4
5 the purposes in this study, the following dimensions of social proximity are examined:
6
7

8 (a) *Knowing each other*: the degree to which one knows each other in terms of the
9
10 private life on the basis of previous interaction.
11

12 (b) *Emotional closeness*: how emotionally close one feels to the contact in terms
13
14 of caring about his/her personal well-being.
15

16 (c) Feeling of *personal obligation*: how much one feels personally obliged to help
17
18 the contact if he/she asks for help but it would require a significant amount of time.
19
20

21 These three dimensions of social proximity were measured by asking the
22
23 respondents to rate on a Likert scale from 1 (= very proximate) to 7 (= very distant).
24
25 As an overall indicator, the social proximity index represents the mean of the three
26
27 dimensions.
28
29
30

31
32
33 Overall, 53.1% of the nominated personal knowledge contacts are purely private
34
35 (in the sense of not involving any official professional relationship)^{viii}, whereas 33.6%
36
37 are professional relationships (clients, collaborators or suppliers) and 13.3% a mixture
38
39 of private and professional relationships. This confirms the results by TRIPPL et al.
40
41 (2009) that informal channels of knowledge transfer are very important in software.
42
43 On which levels of social proximity are these relationships based?
44
45
46
47

48 The empirical results show that the social proximity in terms of the level of
49
50 *emotional closeness* (caring about personal well-being) is very high with 77.9%
51
52 stating closeness (rating 1-3), the mean being 2.55 and the median 2 (see Table 1 for
53
54 all details)^{ix}.
55
56

57
58 *Insert Table 1 about here.*
59
60

1
2
3 The highest level of social proximity is in terms of a feeling of *personal*
4 *obligation* to help: 89.5% rated the question with 1-3, which explicitly means obliged
5
6 to help, the mean is 1.94 and the median 2. This underscores the importance of
7
8 reciprocity.^x Yet, a few interviewees highlighted that they would even help people
9
10 whom they do not know so well, if it concerns a technical issue they are interested in.
11
12

13
14
15 *Knowing each other* in terms of their *private life* is also rated rather highly, but the
16
17 proximity is statistically significantly lower (paired samples t-tests, $p = 0.000$) than
18
19 the other indicators: the mean is 3.58, the median 3, and only 55.8% rated 1-3. This
20
21 suggests that, many personal knowledge relationships that are regarded as important
22
23 are of a more work-centred, strategic nature.
24
25

26
27 Overall, we can conclude that the social proximity of the nominated most
28
29 important knowledge relationships is high in various dimensions. In particular, the
30
31 feeling of personal obligation and emotional closeness is very high, whereas knowing
32
33 each other in terms of private life is lower.
34
35

36 37 38 4.2. Cognitive proximity 39 40 41

42
43 The notion of *cognitive proximity* can be broadly understood as similarity in the
44
45 way actors perceive, interpret, understand and evaluate the world (WUYTS et al.,
46
47 2005). The 'proximity paradox' (BOSCHMA and FRENKEN, 2010) seems most
48
49 relevant in the context of cognitive proximity as also the study of BROEKEL and
50
51 BOSCHMA (2011) suggests. However, this paper aims to show that to clarify this
52
53 paradox, rather than speaking about cognitive proximity in general terms, it is fruitful
54
55 to analyse the importance of various sub-dimensions. In particular, the analysis
56
57 differentiates between (i) proximity regarding a common technical language, (ii)
58
59
60

1
2
3 similarity of the way of thinking about the technology or product, (iii) similarity in
4 terms of work-related technical details/facts (know-what), and (iv) similarity in terms
5 of work-related know-how (how to do things or to solve a problem). Again, a 7-point
6 Likert scale was used.^{xi}
7
8
9

10
11
12 The results illustrate that similarity in terms of technical language is the most
13 critical form of cognitive proximity (mean: 2.28, median: 2; 92% rated 1-3). The
14 cognitive proximity in other dimensions is not as high (means: 3.31, 3.90 and 3.52;
15 medians: 3, 4 and 3 – see Table 2); their levels of proximity are statistically
16 significantly lower (paired samples t-tests, $p = 0.000$).
17
18
19
20
21
22
23

24
25 *Insert Table 2 about here.*
26

27 Only four respondents rated very high levels (answers 6 or 7) of dissimilarity in
28 terms of technical language and two rated undecided (4). Why is this lack of cognitive
29 proximity not problematic for those six relationships? The interview material suggests
30 that, first, for several respondents very strong personal bonds (very high levels of
31 social proximity) can overcome language differences (see section 5.2.1 for a further
32 examination of this issue). For example, in one case a Managing Director receives
33 confidential advice on how to manage people from his wife who does not know
34 anything about the technology. Related to this, second, for a few people a certain
35 degree of dissimilarity does not matter because they are discussing business
36 knowledge and not technological knowledge.^{xii} Third, one respondent developed a
37 technical 'half-jargon' to be able to communicate with his friend.
38
39
40
41
42
43
44
45
46
47
48
49
50
51
52

53 However, let us reiterate that these are exceptions. 92% of the nominated most
54 important knowledge contacts are similar (rating 1-3) in terms of the technical
55 language.
56
57
58
59
60

1
2
3
4 Whilst most of the respondents highlighted that a common language is critical,
5
6 many emphasised that a certain degree of dissimilarity in *other* dimensions of
7
8 cognitive proximity is useful. The plausible reason for this put forward by many
9
10 interviewees is that otherwise they would not be able to learn anything new from
11
12 them:

13
14
15 “If we were completely similar in terms of work-related details, there wouldn’t be much point
16
17 talking to him, I suppose, haha” (Senior developer, large software company).

18
19 That is, although very rarely the contacts are very dissimilar and the means of the
20
21 ratings are still pointing towards similarity rather than dissimilarity (see Table 2), a
22
23 certain degree of dissimilarity is considered to be useful for acquiring new
24
25 knowledge. One could argue that the optimal situation to deal with the proximity
26
27 paradox would be to have a highly similar technical language but to be different in
28
29 other dimensions of proximity. A similar language would ensure smooth
30
31 communication, and yet one would be able to learn a lot of new things. Why is this
32
33 not the case? As we can see later in Table 4, the way of thinking, know-what and
34
35 know-why are moderately correlated with similarity regarding technical language
36
37 (0.30-0.38). That is, it seems that, in order to ensure similarity in terms of technical
38
39 language and therefore smooth communication, the other dimensions also have to
40
41 show a certain level of proximity and cannot be fully different. A plausible reason for
42
43 this seems to be that the processes of learning a technical language usually go hand in
44
45 hand with learning theories about the world, know-how or know-what (in particular,
46
47 in contexts of professional socialisation at universities or official work-contexts).
48
49 Indeed, the vast majority of the respondents have initially formed their relationships
50
51 with the knowledge contacts in either work-related contexts or in taking the same
52
53 course at university.
54
55
56
57
58
59
60

1
2
3
4 To sum it up, the results suggest that a differentiation of sub-dimensions of
5
6 cognitive proximity can clarify an important aspect of the innovation paradox: high
7
8 levels of similarity in terms of technical language seems vital for effective
9
10 communication, but in order to learn new things other forms of cognitive proximity
11
12 (the way of thinking, know how and know what) benefit from not being too high.
13
14 However, given that these dimensions are correlated with similarity concerning
15
16 technical language, it seems that these dimensions cannot show high levels of
17
18 difference because this would undermine similarity in terms of language (which tends
19
20 to be an essential requirement for knowledge contacts that are regarded as important).
21
22
23
24
25
26
27
28

29 5. INTERRELATIONSHIPS BETWEEN TYPES OF PROXIMITY: BRIDGING 30 31 DISTANCE THROUGH PROXIMITY? 32 33 34 35

36 Let us now turn to the question of how the types of proximity (including spatial
37
38 proximity) are related to each other. Let us discuss the theoretical expectations which
39
40 can be derived from the literature.
41
42

43 It has been argued, for instance by BOSCHMA (2005), that spatial proximity is
44
45 likely to be effective through influencing other types of proximity. First, the
46
47 traditional view of territorial innovation models is that spatial proximity is highly
48
49 interrelated with social proximity in the sense that the former facilitates the latter. The
50
51 territorial interpretations of the 'embeddedness' of economic activity reinforced this
52
53 view (for a critical review see HESS, 2004). That is, explicitly or implicitly, it tends
54
55 to be assumed that spatial proximity quasi-automatically leads to social proximity, at
56
57 least in the sense that co-located individuals benefit from strong, trust-based ties
58
59
60

1
2
3 (GRABHER, 2006, 165). According to this view, the possibility of frequent face-to-
4
5 face interaction in contexts of co-location increases the chances that stronger social
6
7 bonds develop as highlighted by several territorial innovation models (CAMAGNI,
8
9 1991; CAPELLO and FAGGIAN, 2005; e.g. LAWSON and LORENZ, 1999;
10
11 STORPER, 1997).

12
13
14
15 *Hypothesis 1: Important local knowledge contacts tend to be more socially*
16
17 *proximate than non-local ones.*

18
19
20
21
22 Furthermore, it is usually assumed that, based on a shared regional culture,
23
24 frequent face-to-face interaction and collective learning, it is likely that co-located
25
26 actors also share a common knowledge base (LAWSON and LORENZ, 1999). Based
27
28 on common interpretative schemes, local actors can understand and benefit from local
29
30 'buzz' or 'noise' (BATHELT et al., 2004, 39; GRABHER, 2002, 254). And, as
31
32 argued by Boschma (2004, 2005), due to local practices of imitation and selection,
33
34 competences and routines converge within regions rather than between regions.
35
36

37
38
39 *Hypothesis 2: Important local knowledge contacts tend to be more cognitively*
40
41 *proximate than non-local ones.*

42
43
44 However, although hypothesis 2 above seems to be the prevalent view in the
45
46 literature, also an alternative argument of an inverse relationship between spatial
47
48 proximity and cognitive proximity could be put forward: as hypothesised by FREEL
49
50 (2003), the more cognitively distant the knowledge, the more important is spatial
51
52 proximity (see also MENZEL, 2008). This is, one could maintain, because the
53
54 possibility of regular face-to-face contacts among co-located actors facilitates the
55
56 more complex communication processes in the case of cognitive distance. In other
57
58 words, co-location represents an advantage to access diverse knowledge.
59
60

1
2
3
4 *Hypothesis 2A: Important local knowledge contacts tend to be more cognitively*
5
6 *diverse than non-local ones.*
7
8
9

10
11 Also in terms of the interrelationship between social and cognitive proximity one
12 can develop theoretical expectations. As we have seen above in section 4.2, a few
13 interviews suggest that large cognitive distances go hand in hand with strong social
14 relationships (such as being a spouse or a close friend). One could generalise this and
15 argue that cognitively distant relations require a higher level of social proximity in
16 order to function.
17
18
19
20
21
22
23

24
25 *Hypothesis 3: Cognitively distant knowledge contacts tend to be more socially*
26 *proximate than cognitively close ones.*
27
28

29
30 Similarly, conversely, one could argue that the governance of socially distant
31 contacts is based on being cognitively close.^{xiii} If people are socially distant, one
32 could maintain, what makes the relationship work is a higher level of cognitive
33 proximity.
34
35
36
37

38
39 *Hypothesis 4: Socially distant knowledge contacts tend to be more cognitively*
40 *proximate than socially close ones.*
41
42
43
44
45

46 Furthermore, one can explore a more general theory of the interrelationship
47 between the various types of proximity: one could argue that distance in one type of
48 proximity can be compensated by proximity in at least one other type. In other words,
49 at least one type of proximity needs to be present for important knowledge
50 relationships but the other types can be distant. That is, social or cognitive proximity
51 can offset spatial distance, spatial or cognitive proximity can compensate social
52 distance, and spatial or social proximity can compensate cognitive distance.
53
54
55
56
57
58
59
60

1
2
3 The few discussions on the issue of compensation that exist in the literature have
4 focused on spatial proximity. As, in particular, BOSCHMA (2005) has argued, other
5 forms of proximity may be a substitute for spatial proximity. The most general
6 thoughts on the topic of compensation have been recently put forward by MENZEL
7 (2008) who hypothesised that bridging distance in one dimension requires proximity
8 in other dimensions. But no empirical studies exist which explore this thesis and
9 which specific dimensions matter for bridging distance.

10
11
12 *Compensation hypothesis: for important knowledge relationships, distance in one*
13 *dimension is compensated by proximity in at least one other dimension.*

14
15
16 In this context, the following question emerges: *is there a type of proximity which*
17 *is a requirement for knowledge relationships and cannot easily be substituted by*
18 *another form of proximity?*

19
20
21 Let us investigate these issues in the following subsections.

22 23 24 25 26 27 28 29 30 31 32 33 34 35 36 37 38 39 40 41 42 43 44 45 46 47 48 49 50 51 52 53 54 55 56 57 58 59 60

5.1. The relationship between spatial proximity and social/cognitive proximity

Let us first contrast local versus non-local^{xiv} knowledge contacts in terms of social and cognitive proximity to investigate hypotheses 1 and 2.

Insert Table 3 about here.

We can see that, whilst local contacts show a slightly higher level of social proximity, these differences are not statistically significant (at the 5% level, independent samples t-test). Hence, we cannot confirm hypothesis 1; important local knowledge contacts are not more socially proximate than non-local ones.

However, there is a statistically significant difference in terms of cognitive proximity: non-local contacts show a higher level of proximity in terms of a common

1
2
3 technical language (nearly one point on the Likert-scale), in terms of work-related
4
5 technical details and in terms of the overall cognitive proximity index. In the light of
6
7 this, hypothesis 2 is rejected but hypothesis 2A is confirmed: important local
8
9 knowledge contacts tend to be more cognitively diverse than non-local ones.
10
11
12
13
14

15 5.2. How is social and cognitive distance compensated? 16 17 18 19

20 Let us now turn to the interrelationship between social and cognitive proximity.
21
22 As a first starting point, let us first look at the correlation between social and cognitive
23
24 indicators. As Table 4 shows, the sub-indicators of social proximity are significantly
25
26 positively correlated with one another; the same applies to the sub-indicators of
27
28 cognitive proximity. However, there is no significant correlation between indicators
29
30 of social proximity and cognitive proximity. The only exception is a significant
31
32 weakly positive correlation (5%-level) of knowing each other in terms of private life
33
34 and cognitive proximity (0.214) as well as similarity in terms of know-how (0.222).
35
36
37
38

39 Overall, this suggests that there is no negative correlation between social
40
41 proximity and cognitive proximity. That is, there is no strong version of a
42
43 compensation mechanism going in the sense of the higher social distance the higher
44
45 cognitive proximity, and conversely.
46
47
48
49

Insert Table 4 about here.

50 Let us now explore the cases of social distance and cognitive distance in more
51
52 detail to investigate our hypotheses.
53
54
55
56
57

58 5.2.1. Does social or spatial proximity compensate cognitive distance? 59 60

1
2
3 Let us first contrast the instances of cognitively distant and cognitively close
4 contacts in terms of technical language.^{xv} The results show that there is no statistically
5 significant difference in terms of indicators of social proximity (see Table 5). That is,
6 hypothesis 3 is rejected, since cognitively distant knowledge contacts tend not to be
7 more socially proximate than cognitively close ones.
8
9

10

45
46
47
48
49
50
51
52
53
54
55
56
57
58
59
60
Insert Table 5 about here.

For the other indicators of cognitive distance, there is also no statistically significant difference, the only exception being distance regarding work-related know-how: cognitively distant contacts in terms of know-how are more distant in terms of knowing each other privately than cognitively close ones. This also impacts on the overall social proximity index (see Table 6).

Insert Table 6 about here.

That is, contrary to hypothesis 3, also here one can observe that cognitively distant contacts are not socially closer than cognitively close ones.

In terms of the spatial dimension, one can see a tendency that cognitively distant contacts tend to be more localised. Whilst there is no statistically significant difference regarding proximity in terms of know-how^{xvi}, relationships with a different technical language tend to be co-localised: 80% of those five who have a different language are located within the Greater Cambridge region. That is, this suggests that cognitive distance (in particular regarding technical language) is compensated by spatial proximity.

5.2.2. Does cognitive or spatial proximity compensate social distance?

1
2
3 Let us now contrast the cases of social distance with social proximity using the
4 indicator of knowing each other in terms of private life.^{xvii} As shown in Table 7,
5
6
7
8 cognitive proximity tends to be lower for socially distant relationships. In particular,
9
10
11 similarity in terms of work-related technical details, similarity in terms of work-
12
13 related know-how and the overall cognitive proximity index exhibit statistically
14
15 significant differences: socially close ('not distant') contacts are also cognitively
16
17
18 closer.

19
20
21 *Insert Table 7 about here.*

22 Hence, hypothesis 4 is rejected: socially distant knowledge contacts tend not to be
23
24 more cognitively proximate than socially close ones.

25
26
27 What about the spatial dimension? There is no statistically significant difference
28
29 between socially distant versus not distant ties; thus, in this sense, social distance is
30
31 not compensated by spatial proximity.
32
33

34
35
36 5.3. Are there critical types of proximity that cannot easily be substituted?
37
38

39
40
41 Are there any indicators which are consistently rated very highly regardless of the
42
43 level of spatial, social or cognitive proximity?
44

45
46 First, the contacts tend to feel very obliged to help and care very much about the
47
48 personal well-being regardless of the level of spatial and cognitive proximity (see
49
50 Table 3, Table 5 and Table 6). That is, in this weaker sense, one could say that spatial
51
52 and cognitive distance is 'compensated' by these forms of social proximity. However,
53
54 as noted earlier, caring about the personal well-being seems not very relationship-
55
56 specific (but, as gleaned from the interviews, often reflects the tendency to wish every
57
58 human being on earth all the best); and feeling obliged to help can also be seen as an
59
60

1
2
3 effect of receiving important knowledge rather than a necessary prerequisite.
4
5
6 Therefore, these two variables rather should not be interpreted as causally active
7
8 'ingredients' of a compensation mechanism. In other words, it seems that they cannot
9
10 be regarded as a necessary requirement for bridging distances in other dimensions.
11
12 Second, it is important to note that the absolute level of similarity in terms of a
13
14 common technical language is very high regardless of the levels of spatial and social
15
16 proximity (see Table 3 and Table 7). This underscores the importance of being close
17
18 concerning technical language *regardless* of whether you are spatially or socially
19
20 close or not. Since the interviewees consistently mentioned that a similar language is
21
22 critical, and since similarity of language is usually not an effect of receiving
23
24 knowledge, similarity of language can be seen as a prerequisite for important personal
25
26 knowledge relationships in nearly all cases.
27
28
29
30
31
32
33

34 5.4. Conclusion: is there an overall compensation mechanism? 35 36 37 38

39 Let us reflect on these results and discuss their theoretical implications in the light
40
41 of the hypotheses put forward at the beginning of this section.
42

43 As we have seen in section 5.1, local versus non-local relationships do not differ
44
45 in terms of social proximity but differ in terms of cognitive proximity: local contacts
46
47 tend to be more cognitively distant than non-local ones. These results question
48
49 widespread views that co-located actors in innovative clusters benefit from a shared
50
51 regional cognitive culture and social contexts: contrary to hypothesis 1, important
52
53 local knowledge contacts are not more socially proximate than non-local ones. This
54
55 underscores that social proximity can be maintained over long distances and does not
56
57 require permanent spatial proximity. And contrary to hypothesis 2, important local
58
59
60

1
2
3 knowledge contacts do not tend to be more cognitively proximate than non-local ones.
4
5
6 Instead, the results support the alternative view (hypothesised by only very few
7
8 authors, in particular by FREEL, 2003; MENZEL, 2008) that co-location makes it
9
10 possible to benefit from cognitively diverse contacts (hypothesis 2A).^{xviii} Indeed, the
11
12 reason for this might be the possibility of regular face-to-face contacts which makes it
13
14 easier to communicate about knowledge which is cognitively more distant and
15
16 therefore harder to grasp.^{xix}

17
18
19
20 Afterwards, in section 5.2 we have explored the compensation of social and
21
22 cognitive distance. Contrary to hypothesis 3, we have seen that cognitively distant
23
24 contacts are not socially closer than non-distant ones (but rather the contrary); and the
25
26 results show that, contrary to hypothesis 4, socially distant contacts are not
27
28 cognitively closer than non-distant ones (rather the contrary). That is, social and
29
30 cognitive proximity are not forming a general compensation mechanism.
31
32

33
34 Can we confirm our overall compensation hypothesis? Let us look at the overview
35
36 picture of the interrelationships between spatial, social and cognitive
37
38 proximity/distance (see Table 8). As we can see, not a single case exists for the
39
40 combination of spatial, social and cognitive distance. This suggests that a general
41
42 compensation mechanism operates: for important knowledge relationships, distance in
43
44 one dimension is compensated by proximity in at least one other dimension. More
45
46 specifically, more than 50% of the cases are in contexts of spatial distance but social
47
48 and cognitive proximity. The second most frequent combination is where all three
49
50 types (spatial, social and cognitive) are proximate (25.9%). Moreover, 11.8% of the
51
52 relationships are in a context of spatial and social distance but cognitive proximity.
53
54 And 4.7% are cognitively distant but spatially and socially proximate.
55
56
57
58
59
60

Insert Table 8 about here.

1
2
3 Since the overall indices in the table above are leaning towards social and
4
5 cognitive proximity (rather than distance), let us also look at the sub-indicators which
6
7 are most diversely distributed: know-what and knowing each other in terms of private
8
9 life (Table 9).
10
11

12 *Insert Table 9 about here.*
13
14

15 We can observe a similar pattern as in Table 8 but with one exception: distance
16
17 regarding know-what is more frequent, and it is more often combined with other types
18
19 of distances. Interestingly, 11.6% of the relationships exhibit spatial, private and
20
21 know-what distance, which one could interpret as undermining the compensation
22
23 hypothesis. However, let us recall that similarity in terms of language tends to be very
24
25 high in all cases, also in the cases of distance regarding know-what.^{xx} This, again,
26
27 highlights the importance of differentiating the sub-dimensions of cognitive
28
29 proximity; difference in know-what, know-how or the way of thinking can be
30
31 compensated through a similar technical language. Overall, we can confirm the
32
33 general compensation hypothesis but only with one critical qualification: similarity in
34
35 terms of technical language is a prerequisite for nearly all knowledge relationships;
36
37 only very few are able to compensate a different language by other proximities.
38
39
40
41
42
43
44
45
46
47

48 6. CONCLUDING REMARKS 49 50 51

52 This paper aimed to address the dearth of empirical research on the role of
53
54 proximities for knowledge networks. I investigated which *kinds of proximity* are
55
56 critical for the most important personal knowledge contacts in the past year.
57
58
59
60

1
2
3 In terms of *social proximity* we have seen that the most important knowledge
4 relations are based on high levels of feelings of personal obligations and emotional
5 closeness, whereas knowing each other in terms of private life is significantly less
6 proximate.
7
8
9
10
11

12 Furthermore, we have seen that a distinction between *sub-dimensions of cognitive*
13 *proximity* clarifies the significance of cognitive proximity. This shows that high levels
14 of similarity in terms of sharing a technical language are very important, but a certain
15 degree of dissimilarity in terms of know-how, know-what and the way of thinking can
16 be fruitful for the R&D workers. Importantly, this contributes to understanding the
17 ‘proximity paradox’ (BOSCHMA and FRENKEN, 2010): the results suggest that
18 knowledge workers deal with this problem by ensuring that they share a common
19 technical language and allowing a certain degree of difference in the other dimensions
20 of cognitive proximity. However, as we have argued, the difference in terms of the
21 way of thinking, know-how and know-what cannot be very high because this would
22 undermine similarity in terms of technical language.
23
24
25
26
27
28
29
30
31
32
33
34
35
36
37

38 Finally, we investigated the *interrelationships between spatial, social and*
39 *cognitive proximity*. We have seen that, contrary to widespread views, local contacts
40 are not socially and cognitively closer than non-local contacts. This highlights that
41 social proximity can be maintained over spatial distances, and it does not indicate that
42 there is a homogeneous regional cognitive milieu (see also HUBER, 2011). It is
43 usually argued that non-local connections are critical for sourcing new knowledge
44 because local relationships tend to be cognitively homogeneous, which represents a
45 danger for spatial lock-in processes (BOSCHMA, 2005, 70). However, the empirical
46 results suggest that, in particular if there is a variety of organisations in the local
47 region such as in Cambridge, local contacts are even more likely to act as cognitive
48
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3 'bridges' to diverse knowledge than non-local ones. This is compatible with the
4
5 results of the study by BROEKEL and BOSCHMA (2011) which show that
6
7 relationships to geographically close actors with different knowledge bases is likely to
8
9 positively influence firms' innovative performance. The results support the minority
10
11 view (in particular, expressed by FREEL, 2003; MENZEL, 2008) that the advantage
12
13 of co-location is to gain access to cognitively different knowledge. A plausible
14
15 explanation for this is that the possibility of regular face-to-face contacts makes it
16
17 more likely to understand and benefit from cognitive distance.
18
19
20
21

22 Furthermore, we have seen that cognitively distant contacts are not socially closer
23
24 than non-distant ones, and that socially distant contacts are not cognitively closer than
25
26 socially close ones. Hence, social proximity/distance and cognitive proximity/distance
27
28 do not form a mutual compensation mechanism.
29
30
31

32 However, overall, including spatial proximity, the results confirm a general
33
34 compensation mechanism for spatial, social and cognitive proximity: for important
35
36 knowledge relationships, distance in one dimension is compensated by proximity in at
37
38 least one other dimension. There is no case where the most important knowledge
39
40 relationships were based on spatial, social and cognitive distance (at least cognitive
41
42 distance regarding technical language). However, there is a critical qualification to the
43
44 compensation mechanism: similarity in terms of technical language is consistently
45
46 very high, and distance in this respect seems very hard to be compensated by other
47
48 dimensions.
49
50
51
52
53
54

55 In terms of the generalisability of the findings, one can make the following
56
57 arguments. One can argue that there are general implications for theorising the role of
58
59 proximity for personal knowledge relationships in innovative industries. The existing
60

1
2
3 literature on proximity to which this study contributes—cf. section 2 and the
4
5 hypotheses discussed in section 5—tends to apply to innovative practices in general,
6
7 regardless of the industry. However, more empirical research in different places and
8
9 industries is needed to clarify whether the results (e.g. the compensation mechanism
10
11 or the critical role of sharing a technical language) really hold in other industries. That
12
13 is, it remains to be seen whether certain results might be specific to regions or
14
15 industries with certain characteristics. In particular, it needs to be investigated
16
17 whether, for instance, the effect that local contacts tend to be cognitively more diverse
18
19 than non-local ones requires a significant regional agglomeration of (perhaps diverse)
20
21 high-technology companies.
22
23
24
25
26
27
28

29
30 There are several aspects that have not been investigated by this study. First, this
31
32 study did not aim to link various forms of proximity to a dependent variable of
33
34 innovative success; thus, this analysis is not able to calculate ‘objective’ optimal
35
36 forms and levels of proximity for successful knowledge sourcing and innovation.
37
38 Instead, this research looks at the phenomenon from the R&D workers’ perspective to
39
40 understand the characteristics and functioning of important knowledge relationships
41
42 as perceived by the individuals.
43
44

45
46 Second, this study is based on data at a specific point in time, and potential
47
48 evolutionary changes of proximities over time (BOSCHMA, 2005; BOSCHMA and
49
50 FRENKEN, 2010; TORRE and RALLET, 2005) were not investigated.
51
52

53
54 Third, this study did not examine other forms of proximity, notably organisational
55
56 and institutional proximity.
57

58
59 Fourth, this paper focused on inter-organisational relations (through the lens of
60
people) and did not investigate knowledge relationships within companies, which can

1
2
3 involve globally distributed firm sites. This would add additional dimensions to the
4
5 question of proximity.
6
7

8 Regardless of this, this study suggests that *knowledge management and R&D*
9
10 *policies* need to be more sensitive towards the importance of a shared language as a
11
12 precondition for personal knowledge relationships that are regarded as important by
13
14 R&D workers. Furthermore, the results suggest that that scope of local networking
15
16 initiatives might be greatest when aiming to link cognitively diverse actors, perhaps
17
18 ideally in contexts of related variety (BOSCHMA and IAMMARINO, 2009;
19
20 FRENKEN et al., 2007).

Table 4. Correlation between all indicators of social and cognitive proximity (Spearman’s rho correlation coefficients, N = 86)

| | How much do you care about personal well-being | How well do you know each other personally in terms of your private life | How much obliged to help if three hours of work | Tie strength: average of 3 variables | To what extent share common technical language | How similar in terms of way of thinking about technology or product | How similar in terms of work-related technical details | How similar in terms of work-related know-how |
|--|--|--|---|--------------------------------------|--|---|--|---|
| How much do you care about personal well-being | | | | | | | | |
| How well do you know each other personally in terms of your private life | .719** | | | | | | | |
| How much obliged to help if three hours of work | .407** | .441** | | | | | | |
| Tie strength: average of 3 variables | .855** | .942** | .619** | | | | | |
| To what extent share common technical language | .022 | .046 | .179 | .071 | | | | |
| How similar in terms of way of thinking about technology or product | -.005 | .085 | -.060 | .030 | .306** | | | |
| How similar in terms of work-related technical details | .043 | .141 | -.032 | .091 | .296** | .332** | | |
| How similar in terms of work-related know-how | .058 | .222* | .011 | .155 | .384** | .280** | .487** | |
| CognitiveProximity: average of 4 variables | .080 | .214* | .056 | .161 | .636** | .645** | .779** | .742** |

** = Correlation is significant at the 1% level (2-tailed)
* = Correlation is significant at the 5% level (2-tailed)

Table 5. Distance versus proximity in terms of technical language (distant (rating > 4): N = 5, not distant (rating < 5): N = 81).

| | Distant in terms of language? | Mean |
|--|-------------------------------|------|
| How much do you care about personal well-being? | Distant | 2.4 |
| | Not distant | 2.6 |
| Ho well do you know each other personally in terms of your private life? | Distant | 3.4 |
| | Not distant | 3.6 |
| How much obliged to help if three hours of work? | Distant | 2.4 |
| | Not distant | 1.9 |
| Social proximity index | Distant | 2.7 |
| | Not distant | 2.7 |
| Percentage of contacts located within the Greater Cambridge region | Distant | 80% |
| | Not distant | 32%* |

* Statistically significant difference at the 5% level (independent samples t-test)

Table 6. Distance versus proximity in terms of know-how (distant (rating > 4): N = 19, not distant (rating < 5): N = 67).

| | Distant in terms of know-how? | Mean |
|--|-------------------------------|------|
| How much do you care about personal well-being? | Distant | 3.1 |
| | Not distant | 2.4 |
| Ho well do you know each other personally in terms of your private life? | Distant | 4.7 |
| | Not distant | 3.3* |
| How much obliged to help if three hours of work? | Distant | 2.1 |
| | Not distant | 1.9 |
| Social proximity index | Distant | 3.3 |
| | Not distant | 2.5* |
| Percentage of contacts located within the Greater Cambridge region | Distant | 47% |
| | Not distant | 31% |

* Statistically significant difference at the 5% level (independent samples t-test)

Table 9. Interrelationships between spatial proximity, private proximity and proximity in terms of know-what (N = 86).

| | | Know-what proximity | Know-what distance |
|-------------------|-------------------|---------------------|--------------------|
| Spatial proximity | Private proximity | 15.1% | 9.3% |
| | Private distance | 2.3% | 8.1% |
| Spatial distance | Private proximity | 33.7% | 7.0% |
| | Private distance | 12.8% | 11.6% |

ⁱ There is some conceptual confusion in the literature on different forms of proximity (KNOBEN and OERLEMANS, 2006). This paper focuses on concepts and definitions which seem to grasp some of the main ideas in the literature. But it does not discuss the notions of organisational, institutional or cultural proximity based on national characteristics. A principal reason for this was that the respondents had only very limited time; therefore the study pragmatically needed to concentrate on some of the major dimensions. Furthermore, a detailed analysis of proximity regarding regional/national characteristics would require an alternative focus of the study in different places (such as in GERTLER, 2004).

ⁱⁱ Schamp et al. (2004) used the term ‘personal proximity’ and Coenen et al. (2004) ‘relational proximity’.

ⁱⁱⁱ Strictly speaking, it does not seem to be a ‘paradox’ but rather a ‘dilemma’.

^{iv} That is, the distribution of hardware versus software firms in the sample is (roughly) the same as in the population. Because of a lack of data on the firms and individuals in the population, the sample cannot be compared with the population in greater detail.

^v Whilst the sample focuses on firms, the ego-network analysis is open towards nominated non-firm actors and potentially includes, for instance, universities.

^{vi} Those individuals use alternative sources of knowledge—in particular local colleagues within the firm and the Internet—which is regarded as sufficient to do their job successfully. That is, those R&D workers are not insular nerds but tend to use personal knowledge networks *within* the company extensively. All of them are working in firms with more than four R&D workers.

vii That is, the term ‘important personal knowledge relationships’ throughout this paper is based on the subjective assessments of the respondents but not on an ‘objective’ indicator of importance/performance.

viii However, the majority initially got to know each other in official work-contexts or at university.

ix However, the interview material suggests that there is a potential bias towards closeness, since several interviewees seem to have a tendency to wish every human being in the world well-being.

x Obligation can also be seen as a result of receiving valuable knowledge.

xi The questionnaire included statements which aimed to clarify the meaning of these sub-dimensions for the interviewees. However, standardisation of such complex concepts always involve a certain amount of uncertainty in terms of validity.

xii However, overall in terms of the cognitive proximity ratings there is no statistically significant difference between senior managers and non-managerial technical workers.

xiii Since no correlation between the two variables is hypothesised, hypothesis 4 does not automatically follow from hypothesis 3.

xiv Local means that the personal contact is located within the Greater Cambridge region (but outside of ones own company). Non-local refers to personal contacts located anywhere outside the Greater Cambridge region.

xv Note that there are only five cases of distance in terms of technical language.

xvi However, also here 47% of those with different know-how are located within the Greater Cambridge region; a reason why there is no statistically significant difference is the low number of distant cases (N = 19).

xvii The overall index of social proximity involves several quite different sub-dimensions. ‘Knowing each other in terms of private life’ seems to be the sub-

1 indicator which reflects the theoretical arguments cognitive distance goes hand in
2
3
4 hand with strong *private* bonds best.

5
6 ^{xviii} However, recall that although non-local contacts are *relatively* more diverse, the
7
8 *absolute* ratings still indicate proximity (e.g. cognitive proximity index: 3.6).

9
10
11 ^{xix} Since this study measures the frequency of communication but not of face-to-face
12
13 communication, this plausible explanation could not be investigated.

14
15
16 ^{xx} This is the reason why in Table 8 there is no case of cognitive distance in
17
18 combination with spatial and social distance.
