Introduction

The increase in female labour force participation, the availability of new technologies for housework and changed attitudes towards the time parents spend with their children for their future behavioural and cognitive development have had a strong impact on the patterns of time allocation of both working and non-working parents in all developed countries (Sayer *et al.*, 2004; Bianchi, 2000; Craig, 2006).

Changes in the time allocation of Italian couples are a particularly interesting case, for although still ranking among the lowest in Europe, Italy's female employment rate has grown steadily over the last 30 years. Over the same period, fertility has sharply declined, while traditional family values persistently steer household decisions.¹

We compare the two existing waves of the Italian Time Use dataset (1988 and 2002) to analyze how family time allocation changed over time in a period that saw the female employment rate increase from 34.9% to 42%² and the total fertility rate drop from 1.36 to 1.26. We investigate how parents' time with their children depends on household structure and employment status, focusing especially on the mothers' working time.

The question of mothers' working time is an important one. Data from the US indicate that an increase in mothers' labour force participation reduces not only the number of hours dedicated to childcare, but also the number of children per household. Thus, even if mothers devote less time to childcare overall, no negative effects emerge on individual children's outcomes, since there are

¹ According to research by the *Fondazione Rodolfo Debenedetti*, 35% of Italian households think that very young children are better staying at home with relatives than going to a crèche (Boeri, Del Boca, Pissarides, 2005).

² See OECD (2008).

1
2
3 fewer children per household who require care (Sandberg and Hoffert, 2001).
4
5 Moreover, children's academic achievements depend less on the total time
6
7 parents devote to them than on the type of activities parents engage in with
8
9 their children (Zick *et al.*, 2001). In addition, changes in social norms regarding
10
11 parenting imply that parents place a higher value on the time they allocate to
12
13 childcare and, as a result, women's entry into the labour market has not
14
15 resulted in a one-to-one decrease in the time they devote to children (Craig,
16
17 2006). The effect of women's work on the time fathers devote to their children is
18
19 in contrast more controversial. Nock (1988) and Sundberg and Hoffert (2001), in
20
21 fact, found that fathers do not compensate for the reduced amount of time
22
23 mothers spend with their children, while Zick *et al.* (2001) and Sayer *et al.*
24
25 (2004) found that they do.
26
27
28
29
30
31

32 Most of the literature on the time allocation of couples focuses on how
33
34 spouses divide their time between work, domestic tasks and childcare, without
35
36 distinguishing between time spent on basic care and quality time (Kalenkoski *et al.*
37
38 2005, 2006 and 2008; Connelly and Kimmel, 2007; Craig and Bittman, 2008;
39
40 Mencarini *et al.*, 2004; Anxo *et al.*, 2007; Burda *et al.*, 2006; Bloemen and
41
42 Stancanelli, 2008; Bloemen *et al.*, 2010). While all of these papers show that
43
44 working women devote less time to children than non-working mothers, none of
45
46 them breaks down how that time is actually spent. Yet this is an important
47
48 distinction to make if we hold that the development of children's future abilities
49
50 depends on the "quality" of time their parents spend with them. Likewise, it is
51
52 important to establish not only the extent to which fathers compensate for the
53
54 reduction in maternal childcare time, but also the sorts of activities they engage
55
56 in with their children.
57
58
59
60

1
2
3 Therefore, in addition to investigating how parents' employment status
4 affects the total time they spend with their children, we also need to investigate
5 whether it is basic care time or quality time that is affected more. It seems
6 plausible to hypothesize that parents are willing to find substitutes for basic care
7 time (in the form of help from grandparents, babysitters or childcare centres),
8 while preferring to allocate as much of their own time as possible to engaging in
9 "quality" activities with their children.

10
11 While most of the empirical literature on time allocation uses separate
12 Tobit or OLS equations for different time uses, here we use a simultaneous
13 approach to analyse how parents allocate their time between work, domestic
14 tasks, basic childcare and "quality" time with children. We use a Multivariate
15 Tobit model (as in Yen *et al.*, 2005, and Barslund, 2007), which was developed
16 to estimate large censored demand systems. This approach allows us to take
17 into consideration links among the different time uses of individuals and
18 correlations between their spouses' decisions. In addition, we also estimate a
19 sequential model in which the working time of wives and husbands affects -
20 both directly and indirectly (through the correlation in the error terms) - other
21 time uses.

22
23 To the best of our knowledge, only a few studies³ have analysed the time
24 allocation of Italian couples, and only Ichino and Sanz de Galdeano (2004)
25 differentiates between the time parents devote to their children on quality versus
26 basic care.

27
28 In our empirical investigation we find that in 1988 the presence of children
29 in the household did not affect fathers' working decisions and only marginally
30 affected their other time uses, whereas in 2002 fathers were more involved in

³ Anxo *et al.* (2007), Mencarini *et al.* (2004), Ichino and Sanz de Galdeano (2004), Tanturri and Mencarini and Bloemen *et al.* (2010).

1
2
3 the caring and rearing of their children. As in Zick *et al.* (2001) and Sayer *et al.*
4
5 (2004), this increase in the time fathers devote to their children seems to be a
6
7 response to mothers' greater participation in the labour market. In 2002,
8
9 mothers' work was less responsive to family characteristics. Our findings also
10
11 indicate that although women allocated more time on average in 2002 to their
12
13 children than previously, they also relied more on other adults (mainly their
14
15 partners) for help. Moreover, by distinguishing between quality and basic care
16
17 activities, we are able to show that mothers tend mainly to delegate basic care
18
19 activities rather than "quality" time. Our results also indicate that spouses'
20
21 decisions are correlated, and that this correlation seems to have been greater in
22
23 2002.

38

39 1. Literature

40
41
42 Pioneering models of time allocation (Becker, 1965; Gronau, 1976) and
43
44 human capital theories explained that better educated women allocate more
45
46 time to work and less time to housework. These theories have been developed,
47
48 extended and tested to include fertility decisions and the effects of children on
49
50 parents' time allocation and to take into account the role of each spouse's
51
52 bargaining power in the decision process.
53
54
55

56 Most of the empirical literature on couples' time allocation focuses on the
57
58 effects of children on the time mothers and fathers devote to labour market work
59
60 and housework. The presence of children in the household reduces the hours

1
2
3 mothers participate in the labour market (Kalenkoski *et al.*, 2005), especially in
4
5 association with the birth of the first child (Craig and Bittman, 2008), while it
6
7 increases their average hours of domestic work (Craig and Bittman, 2008).
8
9 Women therefore do most of the extra, unpaid domestic work stemming from
10
11 the presence of children. Women's education tends to increase their hours of
12
13 market work, but, *ceteris paribus*, better-educated women also devote more
14
15 time to childcare activities (Kalenkoski *et al.*, 2006). At the same time, a father's
16
17 time with his children increases as his wife's working hours and wages
18
19 increase (Connelly and Kimmel, 2007; Bianchi, 2000). As a consequence,
20
21 women's work does not seem to have a strong negative effect on the total time
22
23 parents devote to their children. However, the amount of time parents spend on
24
25 childcare drops as the children grow up (Drago and Lee, 2008), and fathers'
26
27 spend the most time with children when the youngest child is below 3 years of
28
29 age (Yeung *et al.*, 2001).
30
31
32
33
34
35

36 By constructing an index of specialization within the couple using time use
37
38 data Bonke *et al.* (2007) find that a more egalitarian division of housework
39
40 emerges when men are more highly educated and where social values are
41
42 more egalitarian. However, the presence of children always increases
43
44 specialisation within the household.
45
46
47

48 There are very few studies on the time allocation of Italian couples.
49
50 Mencarini *et al.* (2004) studied data from five Italian cities, finding that men in
51
52 dual-earner households did not significantly increase their participation in
53
54 housework after children were born, but increased their time at work instead.
55
56 More than 10% of fathers never help with childcare. However, women's
57
58 education increases the egalitarian division of housework. Tanturri and
59
60

1
2
3 Mencarini (2009), using a different dataset, confirm that childcare in Italy is
4
5 mainly a woman's task.
6
7

8 Burda *et al.* (2006) consider time allocation in four countries, including
9
10 Italy. For Italy they use, as we do, the Multiscopo dataset for the years 1988
11
12 and 2002. In all countries with the exception of Italy, the total work (defined as
13
14 the sum of market work and domestic work) is roughly equal between men and
15
16 women. In Italy, in contrast, the total work of women exceeds that of men by 72
17
18 minutes on a representative day in 1988 and by 75 minutes in 2002. Moreover,
19
20 men enjoy more leisure than women in both waves. Bloemen *et al.* (2010) also
21
22 use the Multiscopo dataset for the year 2002, imputing wage data from a
23
24 different survey (SHIW). Their results show that time spent by husbands on
25
26 housework increases with wives' wages, while the time spent by wives
27
28 decreases. Regarding childcare, the time devoted by fathers increases with
29
30 their own wage and with the presence of small children in the household,
31
32 although strong regional differences emerge.
33
34
35
36
37

38 Anxo *et al.* (2007) compare time allocation over the life cycle in Italy,
39
40 France, Sweden and the U.S. and find that the gender gap in worked hours in
41
42 Italy and France increases after union formation. Moreover, after childbirth,
43
44 Italian women spend 22 additional hours per week on domestic tasks, with men
45
46 spending only an additional six hours.
47
48
49

50 The only study examining time allocation of Italian couples that
51
52 distinguishes between quality and basic care spent by parents with their
53
54 children is a descriptive paper by Ichino and Sanz de Galdeano (2004), in which
55
56 the authors compare three countries: Italy, Germany and Sweden. Their results
57
58 show that when the mother works, basic care time is reduced more than quality
59
60 care time. Basic care time is reduced by 49% in Italy, by 40% in Germany and

1
2
3 3% in Sweden; quality care time is reduced by 37% in Italy, 24% in Germany
4
5 and by an insignificant amount in Sweden. Interestingly, Italy is the only country
6
7 where the time devoted to children by other adults increases when the mother
8
9 works. Among working women, the more educated devote more time to
10
11 childcare than their less educated peers.
12
13

14
15 Other studies distinguishing between basic care and quality time refer to
16
17 other countries, mainly Anglo-Saxon ones. Nock and Kingston (1988) show that
18
19 dual-earner households spend less time with children than single-earner
20
21 households, with the main difference being that working mothers devote less
22
23 time to their children. Fathers seem not to compensate for this reduction in
24
25 mothers' time, unless she works at night. Nonetheless, the quality time devoted
26
27 to children when the mother is working only declines slightly, if at all. In fact,
28
29 Zick *et al.* (2001) find that when the mother is employed, the quality time spent
30
31 by both parents on their children actually increases: employed mothers spend
32
33 more time than non-working mothers on reading and helping children with
34
35 homework while the fathers' overall time with children also grows.
36
37
38
39
40

41
42 A general trend of increasing quality time and paternal involvement with
43
44 children emerges when we compare data for the U.S. in the 1960s with that in
45
46 the 1990s (Bianchi, 2000; Sayer *et al.* 2004). This is undoubtedly attributable to
47
48 the higher average level of parents' education, which has been shown to have
49
50 an impact. For example, Craig (2006), using Australian data for the year 1997,
51
52 finds that parents' education increases time spent with children, mainly in
53
54 physical care, but that only university education increases quality time.
55
56 Moreover, the effect of education is stronger for mothers: women with higher
57
58 educations increase time for paid work and for time with their children, by
59
60 decreasing the amount of time spent on housework and personal care.

1
2
3 In another paper distinguishing between basic and quality time, Gutierrez-
4 Domenech (2008) uses the 2002-2003 Spanish time use survey to analyse how
5 parents spend their time with their children in basic and quality activities
6 according to their working status. She finds that Spanish women perform almost
7 all primary basic childcare activities, but that primary quality childcare is shared
8 by the parents. Moreover, working and non-working fathers spend the same
9 amount of time on childcare. The education level of both parents increases the
10 time spent with children. Spanish data also seem to indicate that working
11 mothers tend to prioritise quality childcare time over basic care time in their time
12 allocation decisions. These findings are particular relevant to our study, given
13 the similarities between Spanish and Italian culture.
14
15
16
17
18
19
20
21
22
23
24
25
26
27
28

29 From the methodological point of view, many of the studies cited above
30 rely mainly on descriptive statistics or on the estimation of separate equations –
31 linear or Tobit – for each time use (for example Ichino and Sanz De Galdeano,
32 2004, Zick *et al.*, 2001, Burda *et al.*, 2006, and Mencarini and Tanturri, 2004).
33 Some studies, like Gutierrez-Domenech (2008), use a two-step instrumental
34 variable approach⁴ to eliminate the simultaneous equation bias. Bloemen *et al.*
35 (2010) and Kalenkoski *et al.* (2006) use, as in the present paper, a multivariate
36 Tobit model where the time uses of each spouse are correlated to those of the
37 other spouse through the unobservables. However, Bloemen *et al.* (2010) do
38 not consider the distinction between the time devoted to basic and quality
39 childcare, while Kalenkoski *et al.* (2006) do not take into account housework
40 time. Moreover, neither considers both the direct and indirect impact of each
41 spouse's working time on his/her own other time uses or on the time uses of the
42 spouse, as we do in our sequential model.

⁴ They instrument childcare time using the previously predicted working time.

2. Strategy for empirical estimation

We are interested in estimating the effect of different individual and family characteristics on husband and wife time allocation decisions and the possible correlations among decisions.

We imagine a typical model of household decisions in which husband and wife maximize the household utility function that can be thought as the averaged sum of the utilities of the two spouses that depend on the consumption of market goods, on home produced goods, on leisure time and on the quality of children. Market goods and leisure are pure private goods, while both home produced goods and child quality are “public goods” for the couple that can be produced with spouses’ time and/or with goods bought on the market. The household utility is maximised subject to a household budget constraint, to each spouse’s time constraint and to a household production function (for home produced goods). The solution of the model gives the time allocation chosen by each parent, *i.e.*, how each spouse divides his/her total time between work, domestic activities, basic childcare and quality care time⁵. The decisions are taken simultaneously and they are all affected by individual and family characteristics and by social background. Given the nature of public goods for the couple of both domestically produced goods and child quality and given the unique household’s budget constraint, spouses’ decisions are interdependent. Depending on the functional form of the utility functions, the model can produce corner solutions, meaning that each individual may allocate zero time to one or more uses.

⁵ Leisure is the residual time category

We do not set out to estimate a full structural model, since we want to specify neither a functional form for the utility function nor the form of spouses' interactions. We will nevertheless use a model that takes into account that the time allocated by each spouse to different activities is jointly decided and, therefore, that there are interdependence in spouses' time decisions. We will handle the existence of corner solutions by using limited dependent variable models. For these reasons, we estimate the following interdependent simultaneous equations:

$$\begin{cases} h_k^* = \alpha_{0k} + \alpha_{1k} X_m + \alpha_{2k} X_f + \alpha_{3k} F + \alpha_{4k} Y + \varepsilon_{hk} \\ d_k^* = \beta_{0k} + \beta_{1k} X_m + \beta_{2k} X_f + \beta_{3k} F + \varepsilon_{dk} \\ bc_k^* = \gamma_{0k} + \gamma_{1k} X_m + \gamma_{2k} X_f + \gamma_{3k} F + \varepsilon_{bck} \\ qc_k^* = \varphi_{0k} + \varphi_{1k} X_m + \varphi_{2k} X_f + \varphi_{3k} F + \varepsilon_{qck} \end{cases} \quad k = (m, f)$$

$$\begin{cases} h_k = \max(0, h_k^*) \\ d_k = \max(0, d_k^*) \\ bc_k = \max(0, bc_k^*) \\ qc_k = \max(0, qc_k^*) \end{cases}$$

where h_k is work time for individual k , d_k is domestic time, bc_k is time for basic care and qc_k is time for quality care; X_m are husband characteristics, X_f are wife characteristics, F are family characteristics and Y are wealth controls that affect only labour supply⁶.

⁶ Given the types of wealth controls available in our dataset, we believe that Y directly affects only the amount of time dedicated to paid work. It is, in fact, unlikely that families rely on wealth to pay for housework or child care substitutes. Generally, the decision to use housework or childcare services depends more on income, i.e., mainly paid work. Nevertheless, we run a sensitivity analysis including the wealth controls in all our equations. Results are robust and the wealth variables included in Y were never significant in the non-work time use equations.

1
2
3 As pointed out in Hallberg and Klevmarken (2003), our equations are not
4 Marshallian demand functions⁷ because they do not depend on wages. They
5 are behavioural equations derived from the first-order conditions of the
6 optimization problem of the household.
7
8
9
10
11

12 A different model of household time allocation can be imagined in which
13 time uses are not all simultaneously decided. Work time is, in fact, the most
14 difficult time use to be adjusted at the intensive margin: flexibility in the number
15 of working hours depends upon the type of contract, the type of job and the
16 employer and, therefore, the decision is mainly whether or not to work.
17 Therefore, it is likely that working hours depend not directly on the other
18 possible time uses, but only indirectly, through error correlation. Moreover,
19 woman's labour supply is often considered more flexible and adaptable to
20 household domestic and childcare needs (Craig and Sawrikar, 2009). It is
21 therefore likely the time devoted by the spouses to domestic and childcare
22 activities depends directly on how much time they, and particularly the woman,
23 commit to work. Additionally, children need a minimum amount of basic care
24 time, while "quality" time is not strictly necessary. At the same time, it is easier
25 to find substitute providers for basic care than for quality care activities.
26 Therefore, parents first decide how much time they want to devote to basic
27 childcare and only then to how much time they want to devote to quality care.
28
29
30
31
32
33
34
35
36
37
38
39
40
41
42
43
44
45
46
47
48
49

50 We thus assume a sequence of time allocation decisions in which spouses
51 first decide how much time they want to devote to market work and only then to
52 how to divide the residual time between domestic work, basic care, quality care
53 and other activities (leisure). Moreover, we model each spouse's quality care
54
55
56
57
58
59
60

⁷ In the empirical analysis, we disregard the price of market substitutes for home production, since they are not known.

time use as dependent directly on his/her own basic care time. Therefore, in our empirical model, domestic time, basic care and the quality care of both spouses depend on both spouses' work time, while the husband's and wife's quality time depends on each of their own basic care time. The simultaneous equations system becomes:

$$\begin{cases} h_k^* = \alpha_{0k} + \alpha_{1k} X_m + \alpha_{2k} X_f + \alpha_{3k} F + \alpha_{4k} Y + \varepsilon_{hk} \\ d_k^* = \beta_{0k} + \beta_{1k} X_m + \beta_{2k} X_f + \beta_{3k} F + \beta_{4k} h_f + \beta_{5k} h_m + \varepsilon_{dk} \\ bc_k^* = \gamma_{0k} + \gamma_{1k} X_m + \gamma_{2k} X_f + \gamma_{3k} F + \gamma_{4k} h_f + \gamma_{5k} h_m + \varepsilon_{bck} \\ qc_k^* = \varphi_{0k} + \varphi_{1k} X_m + \varphi_{2k} X_f + \varphi_{3k} F + \varphi_{4k} h_f + \varphi_{5k} h_m + \varphi_{6k} bc_k + \varepsilon_{qck} \end{cases} \quad k = (m, f)$$

$$\begin{cases} h_k = \max(0, h_k^*) \\ d_k = \max(0, d_k^*) \\ bc_k = \max(0, bc_k^*) \\ qc_k = \max(0, qc_k^*) \end{cases}$$

We expect the mother's work coefficients to be more significant than the husband's, because men's work is rather stable across families (Italian men almost always work full time) while women's work is more flexible and thus heterogeneous. A negative sign of a spouse's work coefficient on his/her own time uses (β_{4f} , γ_{4f} and φ_{4f} for mothers and β_{5m} , γ_{5m} and φ_{5m} for fathers) points toward a substitution effect between individual time uses. A positive sign of a spouse's work coefficient on the other spouse's time uses (β_{4m} , γ_{4m} and φ_{4m} and β_{5f} , γ_{5f} and φ_{5f} respectively), instead, suggests a compensation mechanism between spouses' time allocations. Finally, we expect the basic care coefficient φ_{6k} to be negative and significant for both spouses, because it should capture

the joint effect of the time constraint and the minimum amount of basic care need by children.

All the errors are assumed to be identically and independently jointly normally distributed with an unrestricted covariance matrix.

$$\begin{pmatrix} \varepsilon_{hm} \\ \varepsilon_{hf} \\ \dots \\ \varepsilon_{qcm} \\ \varepsilon_{qcf} \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \\ \dots \\ 0 \\ 0 \end{pmatrix}, \begin{pmatrix} \sigma_{hm}^2 & \sigma_{hm,hf} & \dots & \dots & \sigma_{hm,qcf} \\ \sigma_{hm,hf} & \sigma_{hf}^2 & \dots & \dots & \dots \\ \dots & \dots & \dots & \dots & \dots \\ \dots & \dots & \dots & \dots & \dots \\ \sigma_{hm,qcf} & \dots & \dots & \dots & \sigma_{qcf}^2 \end{pmatrix}$$

where σ_i^2 is the variance of the ε_i and σ_{ij} is the covariance between ε_i and ε_j . Correlation in unobservables among the errors of the eight time-use equations may arise from unobserved household-specific correlations in preferences or productivity. Rather than using a 3SLS as in Hallberg and Klevmarken (2003), we estimate our models (both the simultaneous and the sequential) as Seemingly Unrelated Regressions system. In particular, we draw from the literature on large censored demand systems and we estimate two multivariate Tobit models (for details, see Yen *et al.*, 2005, and Barslund, 2007). Observations that are censored in three or more equations involve calculation of a cumulative jointly normal distribution up to eight dimensions, depending on the number of non-negative binding constraints. To solve this problem, we use the GHK algorithm developed by Børsh-Saupan and Hajivassiliou (1993), Hajivassiliou and McFadden (1990) and Keane (1994). This algorithm evaluates the probability each individual contributes to the likelihood exploiting the fact that a multivariate normal distribution function can be expressed as the product

1
2
3 of sequentially conditioned univariate normal distribution functions. Finally, as
4
5 pointed out by Greene (2003), in limited dependent variables models with
6
7 simultaneous equations the endogeneity of one or more variables can be
8
9 ignored in formulating the likelihood if the system is sequential (with a triangular
10
11 coefficient matrix) and if the endogenous variables enter the subsequent stages
12
13 as observed (h and not h^*). Therefore, in our sequential model we introduce
14
15 working time and caring time as observed in our sample in the following time
16
17 use equations without modifying the likelihood.
18
19
20
21
22
23
24

25 **3. Data and sample selection**

26
27 We investigate the time allocation of Italian families using data from the
28
29 national time use surveys 1988-89 and 2002-03, "Indagine Multiscopo sulle
30
31 Famiglie – Uso del Tempo", carried out by the Italian National Statistical Office
32
33 (ISTAT). The 1998 dataset covers 13,729 households corresponding to 38,110
34
35 individuals while the 2002 wave covers 21,075 households corresponding to
36
37 55,773 individuals, including children and other adults living in the household.
38
39
40

41
42 An individual questionnaire containing socio-demographic information and
43
44 a time diary were collected. All members older than three years⁸ completed the
45
46 time diary on a selected day. In each municipality covered by the survey,
47
48 households were divided into three groups and each group was asked to fill in
49
50 the daily diary at a different time: a weekday, Saturday or Sunday⁹. Our analysis
51
52 is based on diaries completed on weekdays.
53
54
55
56
57
58
59
60

⁸ The time diary of very young children was completed by parents.

⁹ The oversampling of weekend diaries was a deliberate choice of the data collector (ISTAT).

1
2
3 This dataset has the advantage of being representative of the Italian
4 population and of requiring all household members to fill in a time diary. Its main
5 disadvantage is that no information was collected on earnings or income.
6
7

8
9
10 The diary reports information on the time spent on a large number of
11 tasks. Activities were coded by the respondent as main or secondary
12 activities¹⁰. In addition, the respondent specified if the activity was carried out
13 with another family member and if this member was a child younger than ten.
14
15
16
17
18

19
20 The data allow us to construct three different definitions of childcare:
21 *primary childcare*, when the main activity is reported as childcare, *secondary*
22 *childcare*, when childcare is defined as a secondary activity, and *passive*
23 *childcare*, when parents report any activities with a family member younger than
24 ten years old. Primary and secondary childcare could be divided in two
25 subgroups according to the type of activities parents do with their children.
26 *Basic childcare* includes all activities related to the child's essential needs, e.g.,
27 feeding, dressing, bathing, while *quality childcare* refers to activities related to
28 children's educational, cultural and emotional development. Quality childcare is
29 generally understood to be more effective in fostering children's development.
30
31
32
33
34
35
36
37
38
39
40
41
42

43 Distinguishing between primary, secondary and passive childcare and
44 between basic and quality childcare is very important in order to understand if
45 the time spent with children is reduced in families where both parents work and,
46 if so, what kind of time is reduced. *Primary childcare* is the definition that best
47 reflects parents' decision to commit time to their child, because it requires the
48 highest degree of parental involvement among the above described definitions.
49 Moreover, *secondary childcare* and *passive childcare* are more dependent on
50
51
52
53
54
55
56
57
58
59
60

¹⁰ For example, someone may be cooking and watching television or cooking and looking after the children. It is the respondent that chooses which of the activities is the main one and which is the secondary one.

1
2
3 how the parents fill in the diary¹¹. Therefore we focused our analysis only on
4
5 *primary childcare* and distinguished between time spent with children on basic
6
7 care and on quality care.
8
9

10 11 12 13 **3.1. Sample selection and time categories** 14

15
16 For our empirical analysis we construct one sample for 1988 and one for
17
18 2002. In both years we selected only married or cohabiting couples in which
19
20 both partners were older than 18 and younger than 56 years at the time of the
21
22 interview and with at least one child younger than 14. We excluded couples for
23
24 which the weekly diary was filled in during the weekend or on a “special” day
25
26 (on a vacation day or a sick day, for example)¹². We also excluded couples in
27
28 which one (or both) spouse(s) was enrolled in full-time education, retired,
29
30 disable, chronically ill or doing military service¹³. We were also forced to exclude
31
32 single parents because the sub-sample size was too small, especially in 1988¹⁴.
33
34 Finally, we excluded all households in which one or more variables used in the
35
36 analysis were missing. Table 1 shows the construction of our two samples. In
37
38 both years, the most significant reduction in the size of the sample is due to the
39
40 selection of spouses of working age with at least one child younger than 14 and
41
42 who filled in the diary on a normal weekday¹⁵.
43
44
45
46
47
48

49 Our final samples consist of 665 households in 1988 and 1,259
50
51 households in 2002.
52
53
54
55

56
57 ¹¹ For example, in the 1988 survey, almost no one reported childcare as a secondary activity,
58 whereas in 2002 parents often did.

59 ¹² In 2002 we were also able to exclude couples in which the mother is on compulsory maternity
60 leave

¹³ It is likely that in these type of household, in fact, time allocation process works differently.

¹⁴ 69 observations in 1988 and 288 in 2002.

¹⁵ The effect of the sample selection on the variables most relevant in the analysis is not presented. Available to the authors upon request.

1
2
3 As already mentioned, our main interest was to understand how husbands
4 and wives allocate their time into four different activities: market work, domestic
5 work, basic childcare and quality childcare. The empirical definitions of our four
6 time categories are reported below.
7
8
9
10
11

12 Market work: time in paid job (main or secondary); coffee breaks and other
13 breaks during the job; other activities related to employment, excluding job
14 searching activities.
15
16
17
18

19 Domestic work: food management and preparation; housekeeping;
20 laundry; ironing; shopping, commercial and administrative services.
21
22
23

24 Basic care: physical care; supervision; taking to school or to other child's
25 activities.
26
27
28

29 Quality care: doing homework with the child; playing with the child; reading
30 to the child; reading with the child; talking to the child; watching children's
31 movies and shows.
32
33
34
35
36
37
38

39 Tables 2 and 3 show some summary statistics on time allocation in 1988
40 and 2002 according to the mother's working status¹⁶. We divide couples into
41 two main types: dual earner households (44.5% in 1988 and 50% in 2002) and
42 male breadwinner households (51.3% in 1988 and 46.6% in 2002). Residual
43 categories were female breadwinner and no breadwinner (where both spouses
44 are unemployed). Because the latter two categories were too small (4.2% in
45 1988 and 3.3%) to give reliable descriptive statistics, they are not reported.
46 Table 2 reports the unconditional mean of work time, domestic time, basic care
47 and quality care while Table 3 shows the ratio of individuals with non-zero
48
49
50
51
52
53
54
55
56
57
58
59
60

¹⁶ An individual is classified as "working" when he/she declares to be employed.

1
2
3 values in each time category and the means conditioned on declaring a positive
4
5 value¹⁷.
6
7

8 Work time was significantly higher in 2002 than in 1988 for both men and
9
10 women. In both periods, housework accounted for the largest part of a female's
11
12 tasks, even if wives' domestic time had dropped significantly in 2002.
13
14 Husband's domestic time, instead, underwent fewer variations between 1988
15
16 and 2002, but the amount of time fathers spent with their children increased
17
18 significantly. At the same time, the amount of time mothers devoted to children
19
20 also increased. When mothers do not work, fathers seem to be less involved in
21
22 basic childcare tasks, and the time they spend with the children is more oriented
23
24 towards quality time. When mothers work, the amount of time fathers spend
25
26 with their children increases, mainly due to an increase in basic childcare time
27
28 rather than quality care time.
29
30
31
32
33

34 Looking at Table 3, we notice that parents who allocate time to childcare
35
36 activities (*i.e.*, those with positive values) always allocate a significant amount of
37
38 time: at least half an hour in basic care and almost one hour in quality care per
39
40 day. Moreover, not only did both mothers and fathers increase the time spent
41
42 with children from 1988 to 2002 (higher conditional means), but also the number
43
44 of parents spending time with their children grew. In 1988, among dual earners
45
46 couples, 24.7% of fathers and 72.3% of mothers declared a positive amount of
47
48 basic care, while in 2002 the percentages raise to 47.7% and 83.2%
49
50 respectively. In 1988, among male breadwinner families, 16.7% of fathers and
51
52 31.4% of mothers spend quality time with their children, while in 2002 the
53
54 percentages grow to 41.4% and 61.8% respectively.
55
56
57
58
59
60

¹⁷ A well-known problem in time use studies is that the time diary reflects a one day time allocation and it is possible that individuals do not engage that day in some activities they normally do. For example, the ratio of employed individuals who declare a positive amount of working hours is less than 100% for both men and women.

1
2
3 In Table 4 we report the unconditional average time spent on each activity
4 by the two spouses as a function of each spouse's education level. The total
5 impact of parental schooling on different time uses is not clear *a priori*. It is
6 proven that education increases market work, but the effect of education on
7 other activities is uncertain and depends crucially on how parents value
8 childcare time relative to other possible time uses. It seems reasonable to
9 expect a positive correlation between education and childcare time (in particular
10 quality care time) and a negative correlation between education and domestic
11 work time. Domestic work time, in fact, is a low-human-capital activity easily
12 substitutable with goods and services bought in the market, while the opposite
13 is true for childcare, especially for quality care.
14
15
16
17
18
19
20
21
22
23
24
25
26
27
28

29 In both 1988 and 2002, female university graduates spent more time on
30 paid work and less time on domestic work than women with compulsory
31 education or less. In 1988, the husband's education had a U-shaped effect on
32 own time in domestic work, with the exception of middle educated husbands of
33 middle educated wives, and the higher the wife's education the lower the
34 husband's domestic work. Twelve years later, things changed: the husband's
35 education had a reverse U-shaped effect on husband's domestic work
36 (secondary school husbands do more domestic work than compulsory and
37 college-educated husbands) and the wife's education increased the husband's
38 domestic work.
39
40
41
42
43
44
45
46
47
48
49
50
51
52

53 In 2002, fathers with a secondary school degree allocated the highest time
54 to childcare tasks, both care and quality care, while in 1988, they increase with
55 husband's educational level. Childcare time increases with mothers' educational
56 level, too, but highly educated women married to highly educated men decrease
57
58
59
60

1
2
3 their childcare time supply. The higher the education level of the wife, the more
4
5 time their husbands allocate to childcare.
6
7
8
9

10 11 **3.2. Variables**

12
13 Our dependent variables are the four time categories: market work,
14
15 domestic work, basic care and quality care.
16
17

18 We consider both individual's characteristics, household characteristics as
19
20 independent variables, and we control for the geographical area of residence.
21
22

23 To capture the effect of parental education, we use compulsory education
24
25 (8 years of schooling) as the reference group. The other educational levels that
26
27 can be distinguished are lower 'secondary education' (2 years of secondary
28
29 school); upper secondary education (5 years of secondary school); a short
30
31 university degree (2 years); and a standard university degree (4 or more years).
32
33 These last two categories are aggregated together in the estimation of the
34
35 model, as there are few individuals in the dataset with a short university degree.
36
37 For the same reason, we also aggregate lower and upper secondary schooling,
38
39
40
41

42 We use dummy variables for the age of the youngest child in the
43
44 household. We distinguish two categories: the youngest child is (i) younger than
45
46 3 years and (ii) from 3 to 5 years old. We distinguish between these two
47
48 categories because the availability of childcare facilities for children below the
49
50 age of 3 is very limited in Italy, especially in the Southern regions of the country,
51
52 while public childcare covers on average 95% of the population of children from
53
54 3 to 5 (Del Boca *et al.*, 2007 and 2009).
55
56
57

58 We also include the total number of children living in the household, since
59
60 the higher the number of children, the more the time parents need to devote to

1
2
3 them. However, the amount of time required should increase less than
4
5 proportionally with respect to the number of children, due to economies of scale.
6
7

8 We control for the presence of healthy adults other than the parents in the
9
10 household (grandparents, adult children, other parents)¹⁸. Their role could be
11
12 two-fold: they might either help the family by providing free childcare services,
13
14 and they might also be an income source.
15
16

17 We include three regional dummies to capture systematic differences
18
19 across different parts of Italy. Living in the North is our reference group,
20
21 compared to living in the Centre and living in the South. Households that reside
22
23 in different parts of Italy face different unemployment rates and labour market
24
25 conditions, different childcare availability and different living costs, all elements
26
27 that could strongly affect time allocation decisions.
28
29
30

31 Unfortunately, the dataset contains no information about the wealth or
32
33 income of the family and we have almost no variables allowing us to proxy the
34
35 economic situation of the household. Richer families can more easily purchase
36
37 substitutes for their time uses (for example, wealthier families can afford a
38
39 housekeeper), and from this and other information, we try to recover some
40
41 economic controls from the two waves. In both years, we construct a dummy
42
43 equal to 1 if the family owns the apartment or the house they live in. Home
44
45 ownership is the first and main investment an Italian family makes whenever
46
47 possible. Families that do not own the apartment/house are often families that
48
49 cannot afford to do so. In the 1988 sample, we also construct a dummy variable
50
51
52
53
54

55 ¹⁸ We tried to control also for the presence of sick adults within the household. In general, sick
56 adults play a competing role with children for the wife (but also for the husband) time, since they
57 need care for themselves, and their care might also require additional expenses. However, in
58 1988 the sickness status is based on a question that asks if the individual is chronically ill, while
59 in 2002 is based on a self-reported variable on the individual health status, with possible
60 answers that varies from very good to very bad. Therefore, even if our results were robust to the
inclusion of the dummy "sick adults", we were not convinced by the comparability of the two
definitions and therefore we preferred not to include the variable in the estimates here
presented.

1
2
3 equal to 1 if the family lives in subsidized housing, as an indicator for families
4 that are in the lowest part of the income distribution. Unfortunately, the 2002
5 dataset does not include the same information, so we control for the family
6 owning a holiday house as an indicator of belonging to the upper part of the
7 income distribution. We also define another dummy for 2002 to control for those
8 families that declare that they are poor or very poor on the basis of the survey
9 question¹⁹ “How do you define the economic situation of your family?”

10
11
12 Table 5 reports sample summary statistics for the years 1988 and 2002.

13
14
15 The 2002 sample is older than the 1988 one. Education increased
16 drastically in 2002 with respect to 1988 for both men and women. In particular,
17 the number of men and women with at least a secondary school education grew
18 significantly, as did the percentage of women with a university degree. More
19 women worked in 2002 than in 1988, but strong regional differences in female
20 employment rates persists over time. In fact, in both years, women are much
21 more likely to be housewives if they live in Southern regions than in Northern
22 regions. The number of children per household decreased slightly, from 1.95 to
23 1.84. Looking at our wealth controls, the ratio of homeowners rose from 65.6%
24 to 67.7%. In 2002, 11.5% of households have a holiday house and 6.4% feel
25 that they are poor or very poor. In 1988 27.4% of households lived in subsidized
26 housing.

4. Results

We estimate the two models described in Section 3 separately for the two years. The first model, called the simultaneous model, is a SUR system of eight

¹⁹ Since it is a self-reported variable, it depends crucially on individual beliefs and it is likely to be downward bias and centered around the mean (as it is). Nevertheless, we think that those individuals who report to be poor or really poor are likely to be families that suffer for some kind of real economic constraints.

1
2
3 left-censored Tobit equations without endogenous variables. In the second
4
5 model, called the sequential model, we estimate a SUR system of eight left-
6
7 censored Tobit equations in which we allow domestic time, basic care and
8
9 quality care depend directly on the husband's and wife's observed working
10
11 hours; the husband's and wife's quality care time depends directly on their own
12
13 basic childcare.
14
15

16
17 Table 6 shows the estimation results of the simultaneous model for wives
18
19 and Table 7 for husbands. In general, the wife's time allocation is more
20
21 responsive to family and individual characteristics than the husband's in both
22
23 years.
24
25

26
27 The wife's education has a positive impact on her working hours which is
28
29 stronger in 2002 than in 1988, but it has a negative impact on the husband's
30
31 time at work, although this is statistically significant only in 1988 and when the
32
33 wife has a secondary degree. More highly educated women spend significantly
34
35 less time doing domestic work in both years. In 1988, the wives of college-
36
37 educated husbands also spend less time doing domestic work, while husbands
38
39 with a secondary school degree increase their domestic time significantly in
40
41 2002. In 1988, the wife's education has a positive effect on the time both
42
43 parents spend on basic care, while in 2002 this positive effect holds only for the
44
45 wife's secondary school degree on the husband's basic care. The educational
46
47 level of the parents plays no significant role in spouses' quality time in either
48
49 year.
50
51
52
53

54
55 In both years, living in a Southern region significantly decreases the time
56
57 devoted to market work by both parents, but increases the amount of quality
58
59 time mothers devote to their children. However, it also increases the time spent
60
by wives on domestic work and reduces husbands' domestic time (although to a

1
2
3 lesser extent in 2002 than in 1988). Thus, it is not true (at least in the South)
4
5 that mothers who work less spend more quality time with their children: they
6
7 spend more time cleaning the house. Living in central regions, in 2002 is
8
9 associated with husbands spending less time both on housework and on basic
10
11 care for children.
12
13

14
15 In both in the dataset, having at least one child younger than 6 has no
16
17 effect on either spouses' work time or on the father's domestic time; however, it
18
19 has a decreasing negative effect on mother's domestic time in 2002. Parents
20
21 allocate more time to both basic and quality care in both years if they have
22
23 children younger than 6, but this positive effect decreases with the child's age.
24
25 In particular, having a child younger than 3 increases parents' basic care in both
26
27 1988 and 2002, and having at least one child between 3 and 5 increases both
28
29 parents' basic care in 2002 and the mother's basic care in 1988. Having at least
30
31 one child under 6 positively influences the mother's quality time, too, but only in
32
33 2002, whereas it has a positive effect on father's quality care in both years.
34
35

36
37
38 The number of children in the household has a significant negative effect
39
40 on the time devoted by mothers to market work, although to a lesser extent in
41
42 2002 than in 1988. The number of children has a positive effect on the father's
43
44 time at work, but the difference is significant only in 2002. In the same year, the
45
46 number of children has a positive effect on the time women spend on basic
47
48 child care as well as on the time they spend doing housework (both 1988 and
49
50 2002), while it has a negative effect on the husband's quality time in 2002.
51
52

53
54
55 In 2002, living with other adults significantly decreases the basic care time
56
57 of both parents, as expected, but also the quality care time of both.

These results seem to support the fact that the male breadwinner family, where the man provides the income and the woman provides domestic work and care, is still a strong reference model for Italian couples.

Finally, home ownership had a positive effect on both spouses' work time, but only in 2002. This effect is probably related to mortgage payment needs. Perceived poverty had the reverse effect, decreasing both parents' work time. This variable could capture negative psychological (discouraged worker) and social effects associated with poverty.

In the simultaneous model we can examine the effect of wives' work on the time parents devote to their children only if we look at the correlations in the error terms (Table 8). The variances of the unobservables of the eight time use equations are always statistically significant, and we find a significant negative correlation across unobservables between the wife's work and the wife's basic and quality care, and a positive correlation between the wife's work and the husband's basic and quality care both in 1988 and in 2002 (although not significant in 2002). Moreover, in our basic model, the husband's work time is negatively related to the husband's type of care both in 1988 and in 2002. This indicates that the same unobservable characteristics that increase labour supply also decrease the time devoted children. However, fathers with working wives are more willing to take care of their children.

The sequential model allows us to go one step further to also measure the direct impact of wife's work on childcare time.

Table 9 and Table 10 report the results of the sequential model for wives and husbands. Most of the results of the simultaneous model are confirmed. This means that education and work time coefficients are actually capturing two distinct effects: the first is related to personal characteristics and to the social

1
2
3 background, while the second is related to the pure time constraint. For both
4
5 parents, the time spent on domestic tasks is less responsive to spouses'
6
7 education. In 1988, the wife's education had a positive effect on the husband's
8
9 basic care but not on her own care, while the reverse is true in 2002. In contrast
10
11 to what was revealed by the simultaneous model, the wife's education proves to
12
13 have a positive effect on both the wife's and husband's quality care in 2002.
14
15

16
17 Living in the South decreases the mother's basic and quality care (the
18
19 coefficients of the variable "South " becomes weakly significant and negative in
20
21 2002).
22
23

24
25 Looking at work time coefficients, the wife's work time decreases her
26
27 domestic time as well as both her care and quality time with children in 2002.
28
29 The effect on the wife's basic care changed over time: it was positive and
30
31 significant in 1988 and it became negative and significant in 2002. It seems that
32
33 women were more time constrained in 2002 than in 1988, so more time at work
34
35 was reflected in less time dedicated to all other activities. The effect of the wife's
36
37 working hours on the father is almost null in 1988 but becomes positive in 2002:
38
39 the more she works, the more time he allocates to domestic work and to basic
40
41 care. The effect on quality care is positive in 2002, but not statistically
42
43 significant. Thus, in 2002, fathers compensate for the loss in maternal time by
44
45 dedicating more time to the basic care of their children.
46
47

48
49 The husband's work time had a negative effect on basic care and quality
50
51 care of both spouses in 2002, but no statistically significant effect in 1988. It
52
53 also had a negative effect on spouses' domestic time. An income effect seems
54
55 to prevail when we look at the husband's working decisions: couples with higher
56
57 incomes buy substitutes for time in domestic activities.
58
59
60

1
2
3 Finally, as expected, basic care time had a negative effect on quality time
4 with children. This negative effect was weaker in 2002 than in 1988 for women,
5
6 while the opposite was true for men.
7
8
9

10 By comparing the results for the sequential model in the two years, we get
11 some interesting results. Fathers were, in fact, more involved child rearing and
12 childcare activities in 2002 than in 1988. Moreover, living with other adults
13 helped parents manage both basic and quality care; this was particularly true in
14 2002, when time constraints seemed to be more stringent. Mothers worked
15 more in 2002 and allocated less time to their children, relying more on other
16 adults for help (mainly fathers, but also other family adults).
17
18
19
20
21
22
23
24
25
26

27 Table 11 reports the correlation matrix for the sequential model. When we
28 control for the direct effect of the wife's work time on other time uses, we find a
29 negative correlation in 1988 between the wife's work and her basic care time
30 that becomes positive in 2002, while the negative correlation with husband's
31 basic care found in 1988 is no longer significant in 2002. The correlation
32 between the wife's work and the husband's quality care in the sequential
33 scenario is positive and significant both in 1988 and in 2002. Again, the father's
34 time allocation in 2002 seems to compensate for the reduction in maternal time.
35 Moreover, in 2002, the husband's work time becomes positively correlated to
36 both types of care time (whereas the sign was positive only for basic care in
37 1988) and also to maternal care time.
38
39

41
42
43
44
45
46
47
48
49
50
51
52

53 It seems that in 2002 spouses tended to coordinate their time allocation by
54 substituting one spouse's time with the other spouse's time.
55
56

57 In 2002, the wife's basic care was positively correlated with the husband's
58 basic care and with both parents' quality care, and the husband's basic care
59 was positively correlated with the wife's basic care and both parents' quality
60

1
2
3 care. These results imply that parents who spend more time with their children
4
5
6 tend to divide it between basic and quality care.

7
8 Finally, we test the specification of our sequential model of time allocation
9
10 against the non-sequential, more traditional simultaneous one using a Wald test
11
12 on the null of work coefficients and basic care coefficients jointly equal to zero.
13
14 Our test strongly rejects, on both years, the null. We conclude that our
15
16 sequential specification is better than our basic specification.
17
18

21 22 **5. Conclusions**

23
24 This paper uses the two existing waves of the Italian Time Use dataset
25
26 (1988 and 2002) to analyze family time allocation decisions and their changes
27
28 over time in a period that showed an increase in female employment rate and a
29
30 decline in total fertility rate.
31
32

33
34 We use two models, one simultaneous and one sequential, to take into
35
36 consideration both the direct and the indirect links among different time uses for
37
38 the individual and the correlation between spouses' decisions.
39
40

41
42 Our results show that women's time allocation is generally more
43
44 responsive to family and individual characteristics than men's time allocation.
45
46 This seems to indicate that women are still considered as secondary earners in
47
48 the household. Women's time allocation, in fact, depends strongly on the
49
50 presence, the age and the number of children. Craig and Sawrikar (2009) found
51
52 a similar result for Australia: women are more likely to adjust their hours of work
53
54 as family commitments change. The presence of children in the household,
55
56 instead, did not affect fathers' working decisions in 1988, becoming important
57
58 only in 2002, when fathers were more involved in children caring and education
59
60 as a response to women's increased participation in the labour market.

1
2
3 Substitution by fathers for working mother's time thus seems to be a relatively
4 recent phenomenon. Similar results have been obtained in other studies
5 comparing time allocation in the U.S. in different years (Bianchi, 2000, and
6
7
8
9
10
11 Sayer *et al.*, 2004).

12
13 Another aspect that appears is that mothers' work is less responsive to
14 family characteristics in 2002 than in 1988. Although they allocate more time on
15 average to their children, childcare time diminishes with their work time, even
16

However, in 2002 the indirect (through error terms) effect of mother's working
time becomes positive and significant on both quality and basic childcare,
meaning that the same unobservables that increase labour supply of mothers
also tend to increase the time devoted to children (both by the mother and by
the father).

Women's education increases both the time mothers spend with their
children and the time fathers spend with their children (although only for basic
care in 1988), while men's higher education has an effect on woman's quality
care (only in 2002). Surprisingly, men's education has no effect on either the
care or quality time they spend with their children.

Despite the traditional household model of Italian couples, these results
seem to be consistent with those found for other countries, confirming that
parents are placing higher value on the time they spend with their children,; this
can be seen in the increase in time they devote to "quality" activities. The
implications of this for children's development processes and outcomes are
therefore very important in terms of policy implications. The number of hours
mothers spend at work inevitably decreases both the basic and quality care
time they spend with their children, but this is compensated by an increase in

1
2
3 the amount of time fathers are devoting to their children. Unfortunately, no
4
5 datasets are currently available on child outcomes for Italy, making it difficult to
6
7 analyze the consequences on children of these relevant changes.

Table 5

Descriptive statistics 1988 and 2002

	1988	2002
Wife's age	34.01	36.45
Husband's age	37.84	39.78
Wife's education		
<i>Compulsory and lower</i>	63.01%	47.02%
<i>Secondary school</i>	31.43%	45.04%
<i>University or higher</i>	5.56%	7.94%
Husband's education		
<i>Compulsory</i>	60.15%	50.68%
<i>Secondary school</i>	30.98%	40.43%
<i>University or higher</i>	8.87%	8.90%
Number of children	1.95	1.84
Highest number of children in the household	8	7
Working wife		
<i>Italy</i>	45.26%	51.15%
<i>North</i>	57.02%	61.66%
<i>Centre</i>	54.81%	59.82%
<i>South</i>	33.98%	37.64%
Other (not sick) adults within the household	14.29%	17.71%
Home owners	65.56%	67.75%
Living in subsidized housing?	27.37%	-
Poor households	-	6.43%
Holiday house owners	-	11.52%
Observations	665	1,259
