**Abstract**

The gas phase Fourier transform infrared spectra of bromodifluoromethane,  $\text{CHBrF}_2$ , have been recorded up to  $10100\text{ cm}^{-1}$  with a resolution of  $0.5\text{ cm}^{-1}$ . All the most relevant absorptions in the overtone region have been ascribed to the CH chromophore. 26 bands involving either the CH-stretching ( $\nu_1$ ) and bending ( $\nu_2, \nu_7$ ) modes have been assigned and their relative band strengths have been determined. The vibrational analysis of the corresponding polyads (up to  $N = 7/2$ ) has been performed by means of an effective Hamiltonian which takes into account anharmonic resonances, thus leading to the determination of Fermi and Darling-Dennison coupling terms. The obtained effective spectroscopic parameters have been able to quantitatively describe both the position and intensity of all the absorption bands, and also to rationalize the effects and the magnitudes of the various resonances in each polyad. The results obtained by this approach have been compared with those computed by using high quality *ab initio* electronic structure calculations employing the second order vibrational perturbation theory (VPT2). An overall satisfactory agreement between the observed and the *ab*

## 1. Introduction

The analysis of vibrational overtone spectra provides the spectroscopic ground work towards a detailed understanding of intramolecular vibrational energy redistribution (IVR) [1, 2], vibrationally mediated photodissociation (VMP) [3] and infrared resonance multiple photon (IRMP) excitation in the fields of the infrared laser chemistry [4, 5]. The anharmonic couplings among vibrational states, being considered efficient pathways for allowing the vibrational quantum energy in one vibrational mode to be transferred to other modes, strongly influence the overall intramolecular flow of energy among the vibrational degrees of freedom. In a VMP investigation, different experimental techniques are employed to first obtain a vibrationally excited molecule and then to promote it to excited electronic states. The vibrational excitation may strongly influence the course of the following photolysis and so the analysis of the vibrational overtone spectra is useful as a first step for better determining the role of the anharmonic resonances among different molecular vibrations involved in the VMP mechanism. In an IRMP experiment, the timescale of the IVR is one of the key factor ruling the overall process of the excitation by the intense laser field employed. Within this context, one of the most advanced application involves the selective isotope separation. Revealing and determining the anharmonic couplings influencing the energy exchange among vibrational states is therefore of central importance for exploring the intramolecular dynamics and gaining insights in all the processes above mentioned.

Bromodifluoromethane ( $\text{CHBrF}_2$ , halon 1201) belongs to the class of anthropogenic halons, halogenated compounds which are classified among the major sources of reactive bromine in the atmosphere. In accordance to the Montreal protocol,

1  
2  
3  
4 the production and use of fully halogenated halons, characterized by long atmospheric  
5 lifetimes, is now definitely stopped. Bromodifluoromethane, having one CH bond, can  
6  
7 react in the troposphere with hydroxyl radicals thus leading to a shorter atmospheric  
8  
9 lifetime [6 – 8]. On this basis bromodifluoromethane has been suggested as an interim  
10  
11 replacement of fully halogenated halons. In the field of infrared laser chemistry,  
12  
13 CHBrF<sub>2</sub> has been proposed [9, 10] as working molecule for practical <sup>13</sup>C enrichment by  
14  
15 IRMP decomposition. In view of these features, we have recently started a detailed  
16  
17 investigation on the infrared spectra of bromodifluoromethane. In a first work [11] we  
18  
19 have reported on the vibrational analysis of its infrared gas phase spectra in the 200 –  
20  
21 9500 cm<sup>-1</sup> region coupled to *ab initio* calculations and to the accurate determination of  
22  
23 absorption cross sections. Subsequently, a combined microwave and high-resolution  
24  
25 infrared study [12] supported by high-level quantum chemical computations has been  
26  
27 carried out leading to accurate values of spectroscopic parameters for both the ground  
28  
29 and the  $\nu_4 = 1$  vibrational states.

30  
31  
32  
33  
34  
35  
36  
37  
38 In the present work, we focus on the absorptions due to the CH chromophore  
39  
40 [13] in the overtone spectral region up to 10100 cm<sup>-1</sup>. The results of the vibrational  
41  
42 analysis involving the CH-stretching and bending modes, which appear to dominate the  
43  
44 near infrared (NIR) spectrum, have led to the determination of Fermi and Darling-  
45  
46 Dennison anharmonic coupling terms (together with spectroscopic parameters such as  
47  
48 vibrational frequencies and anharmonicity constants), by means of an effective  
49  
50 vibrational Hamiltonian approach. Besides, the CH vibrational states have been also  
51  
52 analyzed by using *ab initio* electronic structure calculations. In this work, the harmonic  
53  
54 part of the *ab initio* force field previously calculated [11] at the CCSD(T) (the acronym  
55  
56 stands for coupled cluster with all single and double substitutions augmented with a  
57  
58  
59  
60

1  
2  
3  
4 quasi-perturbative account for connected triple excitations) level has been scaled in  
5  
6 order to achieve a better agreement with the observed fundamental wavenumbers. From  
7  
8 this adjusted force field anharmonicity constants, Fermi and Darling-Dennison coupling  
9  
10 terms, which are needed to study the absorption of the CH chromophore in the overtone  
11  
12 region, have been calculated by means of second order vibrational perturbation theory  
13  
14 (VPT2) [14].

## 20 21 **2. Experimental details**

22  
23  
24  
25  
26 The synthesis of  $\text{CHBrF}_2$  has been carried out as previously described [11]. The  
27  
28 gas phase infrared spectra have been measured on a Bruker Vertex 70 FTIR  
29  
30 spectrometer employing resolutions of 0.2 and 0.5  $\text{cm}^{-1}$ . In the spectral region up to  
31  
32 4000  $\text{cm}^{-1}$  a 13.4 cm fixed path-length cell fitted with KBr windows has been used,  
33  
34 while at higher wavenumbers a White-type multipass cell, with the effective optical  
35  
36 path ranging from 10.5 to 77.5 meters, has been employed. All the spectra have been  
37  
38 measured at room temperature, and the pressure measurements have been carried out  
39  
40 employing capacitance vacuum gauges. For this molecule we have found [11] no  
41  
42 significant differences between the determined band intensities from spectra recorded at  
43  
44 a resolution of 0.5  $\text{cm}^{-1}$  and those obtained from the spectra taken at a resolution of 0.2  
45  
46  $\text{cm}^{-1}$  (thus confirming the observation of Orkin et al. [15]). Therefore in this work the  
47  
48 band intensities have been derived by employing the spectra recorded at a resolution of  
49  
50 0.5  $\text{cm}^{-1}$ , which have a better signal-to-noise ratio. Relative band strengths within a  
51  
52 given polyad have been obtained with an experimental uncertainty, estimated as  
53  
54 elsewhere described [16, 17], better than 15%.

### 3. Computational details

The information needed by VPT2 comprises the quadratic, cubic and semi-diagonal quartic force constants. For CHBrF<sub>2</sub> this information was calculated in the work of Ref. 11, in which high quality electronic structure calculations at the coupled cluster level of theory were carried out to compute equilibrium geometry and accurate force constants in the space of dimensionless normal coordinates. Here, the details of the computation will be only summarized.

All the calculations were performed at the CCSD(T) [18, 19] level of electronic correlation. Two basis sets of the correlation consistent family of Dunning and co-workers [20], were considered: these are cc-pVTZ and aug-cc-pVTZ. The latter was employed for the fluorine atoms, in both the geometry optimization and the second-order force constant calculations, in order to improve the overestimated C-F stretching frequency [21]; the former basis set (cc-pVTZ) was employed for the other atoms (H, C, Br). The cubic and semi-diagonal quartic force constants were calculated in the normal coordinate space using a finite difference procedure [22] involving displacements along the normal coordinates.

In the present work the VPT2 analysis of the vibrational states has been carried out starting from the resulting hybrid force field (i.e. HYB-2 of Ref. 11). In a first step, to reduce at most the differences between the calculated and observed fundamental wavenumbers, an empirical correction has been performed [23]. Specifically, the harmonic wavenumbers,  $\omega_i$ , have been corrected according to:

$$\omega_i = \omega_i^0 + \Delta \nu_i \quad (1)$$

1  
2  
3  
4  
5  
6  
7 where  $\omega_i^0$  are the *ab initio* calculated values and  $\Delta\nu_i$  represents the differences between  
8  
9  
10 the observed anharmonic wavenumbers and those obtained from VPT2. Therefore, the  
11  
12 *ab initio* cartesian harmonic force field has been transformed into a force field in terms  
13  
14 of internal coordinates ( $F_{ij}^0$ ) and scaled to the  $\omega_i$  :

$$F_{ij} = F_{ij}^0 \sqrt{s_i s_j} \quad (2)$$

15  
16  
17  
18  
19  
20  
21  
22  
23  
24  
25 where  $s_i$  denotes the scaling factors, and  $F_{ij}$  represents the improved force constants.  
26  
27  
28 Following this procedure, the only significant discrepancies (i.e. greater than  $1 \text{ cm}^{-1}$ ) are  
29  
30 found for  $\nu_2$  and  $\nu_7$ . These bands are indeed described as 100% of  $R_6 + R_7$  and 100% of  
31  
32  $R_6 - R_7$  (where  $R_6$  and  $R_7$  are the internal coordinates associated with the H-C-F angles),  
33  
34 respectively. Since the error in the computed wavenumber of  $\nu_2$  has opposite sign with  
35  
36 respect to the  $\nu_7$  one, any attempt to adjust the first value will introduce a larger error on  
37  
38 the second one.

#### 45 **4. The effective Hamiltonian for the analysis of the CH polyads**

46  
47  
48  
49  
50 The observed vibrational spectra have been analysed in the framework of a 3D  
51  
52 effective Hamiltonian, as defined by Quack and co-workers (see for example Ref. 24  
53  
54 and references therein), which takes explicitly into account Fermi and Darling-Dennison  
55  
56 resonances between the CH-stretching ( $\nu_1$ ,  $A'$  symmetry) and the two CH-bending  
57  
58 modes,  $\nu_2$  ( $A'$  symmetry) and  $\nu_7$  ( $A''$  symmetry), corresponding to the in-plane and out-  
59  
60

of-plane CH bending, respectively; in Figure 1 an approximate representation of these modes is shown. Being the frequency of the CH-stretching mode approximately twice the frequency of the CH-deformations, in the spectral region below  $3000 \text{ cm}^{-1}$  anharmonic resonances among the  $\nu_1$  fundamental and the first overtones of  $\nu_2$  and  $\nu_7$  can occur. Going to higher wavenumbers, these resonances may involve stretching overtones and stretching/bending combination bands, provided that they belong to the same symmetry species. According to this model, the vibrations involving the CH chromophore normal modes can be grouped into different polyads, each of them can be characterized by the polyad number  $N$  defined as:

$$N = \nu_1 + \frac{1}{2}(\nu_2 + \nu_7) \quad (3)$$

where  $\nu_1$ ,  $\nu_2$  and  $\nu_7$  are the vibrational quantum numbers for  $\nu_1$ ,  $\nu_2$  and  $\nu_7$ , respectively.

The number  $N$  acts as a sort of label for grouping vibrational states which, to a first approximation, have almost the same energy. Within each polyad the vibrational Hamiltonian has diagonal matrix elements (zero-order states of the polyad) expressed by the following equation

$$\begin{aligned} \langle \nu_1, \nu_2, \nu_7 | H^N | \nu_1, \nu_2, \nu_7 \rangle = & \tilde{\nu}_1' \nu_1 + \tilde{\nu}_2' \nu_2 + \tilde{\nu}_7' \nu_7 + x_{11}' \nu_1^2 + x_{22}' \nu_2^2 + x_{77}' \nu_7^2 + x_{12}' \nu_1 \nu_2 + \\ & + x_{17}' \nu_1 \nu_7 + x_{27}' \nu_2 \nu_7 \end{aligned} \quad (4)$$

where  $\nu_1$ ,  $\nu_2$ ,  $\nu_7$  are the above mentioned vibrational quantum numbers, and  $\tilde{\nu}_i'$  and  $x_{ij}'$  are vibrational wavenumbers and anharmonicities, respectively, treated as adjustable

1  
2  
3  
4 spectroscopic parameters (values in  $\text{cm}^{-1}$ ) which are refined by the fitting of  
5  
6 experimental data. This vibrational Hamiltonian, whose off-diagonal terms couple  
7  
8 vibrational states belonging to the same polyad, is block diagonal in  $N$  and it has  $(N+1)^2$   
9  
10 zero-order states for  $N$  integer and  $(N+1/2)(N+3/2)$  for half integer  $N$ . For a molecule  
11  
12 belonging to the  $C_s$  symmetry point group, each of these blocks, labelled by its own  $N$   
13  
14 number, can be further decomposed in two blocks, corresponding to vibrational states  
15  
16 having  $A'$  or  $A''$  symmetry. Within each block the off-diagonal matrix elements describe  
17  
18 the anharmonic resonances. The matrix elements corresponding to the Fermi resonance  
19  
20 in which one quantum of CH-stretching is exchanged for two quanta of CH-bending are  
21  
22 given by:  
23  
24  
25  
26  
27  
28  
29

$$\langle v_1, v_2, v_7 | H_F^N | v_1 - 1, v_2 + 2, v_7 \rangle = \frac{1}{2} k_{122}' \left[ \frac{1}{2} v_1 (v_2 + 1)(v_2 + 2) \right]^{1/2} \quad (5)$$

$$\langle v_1, v_2, v_7 | H_F^N | v_1 - 1, v_2, v_7 + 2 \rangle = \frac{1}{2} k_{177}' \left[ \frac{1}{2} v_1 (v_7 + 1)(v_7 + 2) \right]^{1/2}. \quad (6)$$

30  
31  
32  
33  
34  
35  
36  
37  
38  
39  
40  
41  
42  
43 Darling-Dennison resonances are taken explicitly into account by the inclusion of the  
44  
45 following off-diagonal matrix element:  
46  
47  
48  
49  
50

$$\langle v_1, v_2, v_7 | H_{D-D}^N | v_1, v_2 - 2, v_7 + 2 \rangle = \frac{1}{2} k_{2277}' [v_2 (v_2 - 1)(v_7 + 1)(v_7 + 2)]^{1/2}. \quad (7)$$

In equations 5 – 7  $k'_{ij}$  and  $k'_{iij}$  refer to effective spectroscopic resonance parameters.

Within each block, the resulting  $\mathbf{H}^N$  matrix is diagonalized:

$$\mathbf{Z}_N^{-1} \mathbf{H}^N \mathbf{Z}_N = \text{diag}(E_1^N, E_2^N, \dots) \quad (8)$$

thus giving the corresponding eigenvalues  $E_j^N$ , which can be compared to the wavenumbers of observed band centres, and the corresponding eigenvector matrix  $\mathbf{Z}_N$ .

The eigenstates are labelled by  $N_j$ , where by convention the index  $j$  equals to 1 for the highest eigenvalue and it increases with decreasing energy.

Within each polyad the experimental band strength for a given subband is computed according to the following equation:

$$G_j^N = \frac{1}{2.303 \cdot c \cdot l \cdot \tilde{\nu}_0} \int_{\tilde{\nu}_1}^{\tilde{\nu}_2} \log_{10} \left( \frac{I_0}{I} \right) d\tilde{\nu} \quad (9)$$

with  $c$  being the concentration (obtained from the pressure of the sample assuming the validity of the ideal gas law),  $l$  is the optical path length,  $\tilde{\nu}_0$  is the subband centre and the integration limits  $\tilde{\nu}_1$  and  $\tilde{\nu}_2$  refer to the wavenumbers where the absorption can be considered negligible. Following Amrein et al. [25], within each polyad block  $N(\Gamma)$  (where  $\Gamma = A'$  or  $A''$ , the symmetry species of the vibrational states) the observed relative band strengths  $g_j^N(\text{obs})$  are calculated from the experimental  $G_j^N$  employing the following expression:

$$g_j^N(\text{obs}) = \frac{G_j^N}{\sum_{N(\Gamma)} G_k^N} \quad (10)$$

These observed values can be compared with the corresponding relative intensities computed from the eigenvector matrix  $\mathbf{Z}^N$ . For each polyad labelled by an integer value of  $N$ , the chromophore state corresponds to the **zero-order** basis state having the largest value of  $v_1$ , the vibrational quantum number of the CH stretching mode; for the polyads with half integer value of  $N$  there are two of these **chromophore** states, one having  $v_1 = N - 1/2$ ,  $v_2 = 1$ ,  $v_7 = 0$  the other with  $v_1 = N - 1/2$ ,  $v_2 = 0$ ,  $v_7 = 1$ . For **the polyads having  $N = \text{integer}$ , one makes the assumption that only one state (i.e. the chromophore) carries zero-order intensity. The other bands of the polyad borrow their observed intensity entirely from anharmonic resonances with the chromophore. Under these hypotheses the relative intensity  $g_j^N$  of the transition from the ground state to the  $N_j$  vibrational level can be computed by considering the corresponding element of the eigenvector matrix  $\mathbf{Z}^N$ :**

$$g_j^N = |Z_{1j}^N|^2 \quad (11)$$

**For the polyads having  $N = \text{half integer}$ , the two chromophore states are assumed to carry oscillator strength. In this case, the relative intensities are computed employing the following weighted average [26]:**

$$g_j^N = \frac{|Z_{bj}^N|^2 + f|Z_{aj}^N|^2}{f+1} \quad (12)$$

where  $b$  and  $a$  are the indexes of the chromophore states having  $\nu_1 = N - 1/2$ ,  $\nu_2 = 1$ ,  $\nu_7 = 0$  and  $\nu_1 = N - 1/2$ ,  $\nu_2 = 0$ ,  $\nu_7 = 1$ , respectively. The weighting factor  $f$  is given by the experimental intensity ratio of the first two components of the  $N = 3/2$  polyad:

$$f = \frac{G_1^{3/2}}{G_2^{3/2}} \quad (13)$$

## 5. Results and discussion

An overall survey of spectra concerning the CH chromophore transitions observed in the present work is presented in Figure 2. As it can be seen, all the most relevant absorptions above  $4000 \text{ cm}^{-1}$  are associated to various CH polyads, thus confirming the relevance of the CH chromophore in the NIR region of the spectra of bromodifluoromethane, being the contributions of hot bands negligible. The two fundamentals  $\nu_2$  ( $A'$  symmetry) and  $\nu_7$  ( $A''$  symmetry) are shown in Figure 2(a). They are labelled as  $1/2_2$  and  $1/2_1$ , respectively and form the lowest polyad. Moving to higher wavenumbers, in the spectral range  $2500 - 3100 \text{ cm}^{-1}$  one can assign the  $N = 1$  polyad, illustrated in Figure 2(b). The strongest feature is assigned to the  $\nu_1$  fundamental ( $A'$  symmetry) and it corresponds to the CH-stretching mode. It is located at  $3020.9 \text{ cm}^{-1}$  and labelled as  $1_1$ . The other bands involved in this polyad, shown in the inset of Figure

1  
2  
3  
4 2(b), are  $2\nu_7$  ( $1_2$ ) at  $2676.1 \text{ cm}^{-1}$ ,  $\nu_2 + \nu_7$  ( $1_3$ ) and  $2\nu_2$  ( $1_4$ ) at  $2628.8$  and  $2544.2 \text{ cm}^{-1}$ ,  
5  
6  
7 respectively, with an intensity which is almost three orders of magnitude lower than  $\nu_1$ .  
8  
9  
10 The next two polyads,  $N = 3/2$  and  $N = 2$ , reported in Figure 2(c), account for almost  
11  
12 all the relevant absorptions falling in the range  $4000 - 6000 \text{ cm}^{-1}$ . Even if the  
13  
14 conventional nomenclature in terms of combinations of different normal modes is not  
15  
16 well suited when moving to higher wavenumbers, due to the relevant mixing among the  
17  
18 vibrational states, we have tried a possible labelling of each absorption in the polyads in  
19  
20 such manner. The  $\nu_1 + \nu_7$  ( $4349.9 \text{ cm}^{-1}$ ) and  $\nu_1 + \nu_2$  ( $4286.5 \text{ cm}^{-1}$ ) combination bands,  
21  
22 indicated respectively as  $3/2_1$  and  $3/2_2$ , are the first two components of the  $N = 3/2$   
23  
24 polyad, while the most intense components of the  $N = 2$  polyads, located at higher  
25  
26 wavenumbers, are clearly visible. The CH polyads  $N = 5/2$ ,  $N = 3$  and  $N = 7/2$  are  
27  
28 shown in Figure 2(d). In the  $N = 3$  polyad the most intense feature belongs to  $3\nu_1$  ( $3_1$ ) at  
29  
30  $8712.2 \text{ cm}^{-1}$ , while the weakest absorption assigned is  $\nu_1 + 4\nu_2$  ( $3_9$ ), reported in the inset  
31  
32 of the same Figure. It has an observed relative band strength approximately three orders  
33  
34 of magnitude lower than  $3\nu_1$ .

40

41 A total of 26 transitions belonging to different CH polyads (up to  $N = 7/2$ ) were  
42  
43 assigned in the present work. After having set up all the matrix elements of the effective  
44  
45 vibrational Hamiltonian for each of the considered polyads, the spectroscopic  
46  
47 parameters collected in Table 1 have been derived by least-square fitting the resulting  
48  
49 eigenvalues with all the corresponding wavenumbers of the experimentally observed  
50  
51 band centres. The column labelled Fit 1 lists the results computed letting all the twelve  
52  
53 parameters of the effective Hamiltonian free to vary. The reported values clearly show  
54  
55 the Fermi coupling between the CH-stretching and the CH-bending modes, being the  
56  
57 corresponding resonance parameters  $k'_{122}$  and  $k'_{177}$  equal to  $95$  and  $87.6 \text{ cm}^{-1}$ ,

respectively. In addition, also the value for the Darling-Dennison resonance term  $k'_{2277} = 10.4 \text{ cm}^{-1}$  suggests some effects of this coupling on the various overtones and combination bands within the polyads. The  $x'_{11}$  anharmonicity constant has a value  $(-61.8 \text{ cm}^{-1})$  very similar to those found for analogous halogenated methanes such as  $\text{CHClF}_2$  [25] and  $\text{CHCl}_2\text{F}$  [27] ( $x'_{11} = -63.8 \text{ cm}^{-1}$  and  $-63.1 \text{ cm}^{-1}$ , respectively). Without taking into account the Fermi resonances related to  $k'_{122}$  and  $k'_{177}$ , the values of  $x'_{11}$  and  $\tilde{\nu}'_1$  obtained from the fit of  $\nu_1$ ,  $2\nu_1$  and  $3\nu_1$  are  $-57.3$  and  $3075.7 \text{ cm}^{-1}$ , respectively. The small differences between these results and those obtained by introducing the off diagonal coupling terms can be rationalized by considering that in each polyad (with  $N = n$ ) the energy separation between the zero-order states  $n\nu_1$  and  $(n-1)\nu_1+2\nu_2$  or  $(n-1)\nu_1+2\nu_7$  is generally greater than the values of the corresponding off diagonal matrix elements. However, as before without considering explicitly the coupling terms, the comparison of the value of  $x'_{11}$  determined from  $2\nu_1$  and  $\nu_1$  ( $x'_{11} = -61.05 \text{ cm}^{-1}$ ) with that obtained from  $3\nu_1$  and  $\nu_1$  ( $x'_{11} = -58.4 \text{ cm}^{-1}$ ) suggests a trend understandable on the basis of an increasing ratio of the off diagonal matrix elements to the corresponding zero-order state energy differences.

The other diagonal anharmonicity constant values,  $x'_{22} = -6.8 \text{ cm}^{-1}$  and  $x'_{77} = -7.6 \text{ cm}^{-1}$ , are close to that expected for an isolated CH-chromophore, while the mixed anharmonicity constants  $x'_{12}$  and  $x'_{17}$  ( $-25.8$  and  $-25.7 \text{ cm}^{-1}$ , respectively) are in the range of the values obtained for other halogenated methane derivatives [24 – 28]. **A further evidence for the need of a global model is given by the comparison of the  $x'_{ij}$  constant values with those obtained by the differences  $(n\nu_i+\nu_j) - n\nu_j - \nu_j$  without taking**

1  
2  
3  
4 into account any interaction. For example, the anharmonicity constant  $x'_{17}$  obtained for  
5  
6  
7  $n = 1$  is  $-16.5 \text{ cm}^{-1}$ , while for  $n = 3$  it becomes  $-9.80 \text{ cm}^{-1}$ .  
8  
9

10 In general, all the parameters obtained are well determined, the only one whose  
11 uncertainty is within its magnitude is the anharmonicity constant  $x'_{27}$ , whose value is  
12 anyway close to zero. Therefore, we tried to fix this constant in the fitting procedure  
13 thus obtaining the parameters reported in the column Fit 2 of Table 1. There is not a  
14 significant difference between the values of Fit 1 and Fit 2, only a slight increase in the  
15 root-mean-square deviation, here calculated on the base of the sum of the squares of the  
16 deviations between the observed and the computed values, divided by the number of  
17 data, occurs (from  $1.26 \text{ cm}^{-1}$  for Fit 1 to  $1.33 \text{ cm}^{-1}$  for Fit 2). Table 2 reports the  
18 experimental and the predicted vibrational wavenumbers and relative intensities for all  
19 the observed bands. The agreement between the experimental data and those computed  
20 by the effective Hamiltonian is very good. For the band centres, the fit with 12 degrees  
21 of freedom (mean absolute error =  $0.896 \text{ cm}^{-1}$ , mean signed error =  $-0.0752 \text{ cm}^{-1}$ )  
22 and that with 11 degrees of freedom (mean absolute error =  $0.895 \text{ cm}^{-1}$ , mean signed  
23 error =  $-0.0425 \text{ cm}^{-1}$ ) perform equally well in predicting the experimental transitions.  
24 The predicted relative intensities were computed, as previously outlined, under the  
25 hypothesis that only the chromophore state carries oscillator strength; anyway, the  
26 model appears able to reproduce, at least semi-quantitatively, the observed values. The  
27 discrepancies can be ascribed not only to additional local resonances not explicitly  
28 considered by the Hamiltonian employed in the present study, but also to the presence,  
29 in some integration ranges, of other bands. The magnitude of the deviations is  
30 comparable to that reported by other authors [24, 26]. No significant differences  
31 between the values computed employing the fit with 12 degrees of freedom and those

obtained from the fit with 11 degrees of freedom have been found, therefore in Table 2 we reports the value derived from the former.

The model of the Hamiltonian here employed considers only intrapolyad resonances, thus not taking into account the possibility of interpolyad coupling among different blocks belonging to the same symmetry species. Nevertheless, the energy separation among consecutive polyads is so great compared to the coupling matrix elements to make it possible to neglect the corresponding perturbation effects.

The results obtained employing the above described least square analysis can be compared with those obtained from an *ab initio* study of the CH absorptions. Recalling that the CH chromophore comprises the  $\nu_1$ ,  $\nu_2$  and  $\nu_7$  vibrational modes and that these normal modes are expected to be in resonance, the diagonal matrix elements of the polyads are the wavenumbers obtained from:

$$\langle \mathbf{v} | H | \mathbf{v} \rangle = \sum_r \omega_r \left( \nu_r + \frac{1}{2} \right) + \sum_{r \leq s} x_{rs} \left( \nu_r + \frac{1}{2} \right) \left( \nu_s + \frac{1}{2} \right) \quad (14)$$

where the anharmonicity constants  $x_{rs}$  calculated from the *ab initio* force field must be replaced with  $x_{rs}^*$  constants, which exclude those second-order perturbation theory contributions that are included explicitly in the Fermi resonance model. The out diagonal terms are the Fermi resonances, through the  $\varphi_{rss}$  cubic force constants ( $r = 1, s = 2$  or  $7$ ),

$$\langle \nu_r, \nu_s | H_F | \nu_r - 1, \nu_s + 2 \rangle = \frac{\varphi_{rss}}{4} \left[ \frac{\nu_r (\nu_s + 1) (\nu_s + 2)}{2} \right]^{1/2} \quad (15)$$

and Darling-Dennison resonance interactions between the overtone levels of CH in-plane and out-of-plane deformations

$$\langle v_r + 2, v_s | H_{D-D} | v_r, v_s + 2 \rangle = \frac{K_{rrss}}{4} [(v_r + 1)(v_r + 2)(v_s + 1)(v_s + 2)]^{1/2} \quad (16)$$

where  $K_{rrss}$  ( $r = 2, s = 7$ ) is the Darling-Dennison coupling constant which is computed from cubic and quartic force constants, rotational constants, Coriolis terms and harmonic wavenumbers.

Removing the offending terms,  $\frac{\phi_{rss}^2}{(2\omega_s - \omega_r)}$ , from second order expressions, the anharmonicity constants result  $x_{12}^* = -58.106$ ,  $x_{17}^* = -60.610$ ,  $x_{22}^* = 2.906$ ,  $x_{77}^* = 2.451$  (in units of  $\text{cm}^{-1}$ ). The unperturbed values for the bands of  $A'$  symmetry involved in the  $N = 1$  polyad thus become  $2974 \text{ cm}^{-1}$  ( $\nu_1$ ),  $2542 \text{ cm}^{-1}$  ( $2\nu_2$ ) and  $2656 \text{ cm}^{-1}$  ( $2\nu_7$ ). The Hamiltonian matrix after diagonalization gives  $3026 \text{ cm}^{-1}$  ( $\nu_1$ ),  $2501 \text{ cm}^{-1}$  ( $2\nu_2$ ) and  $2645 \text{ cm}^{-1}$  ( $2\nu_7$ ). Whereas the  $\nu_1$  fundamental value is close to that obtained without considering the resonance and to the experimental one, the  $2\nu_2$  and  $2\nu_7$  computed wavenumbers are in disagreement with the experimental data. In addition, considering the higher overtones and combination bands,

$$(n\nu_1 + m\nu_2 + l\nu_7) = n(\nu_1) + m(\nu_2) + l(\nu_7) + n(n-1)x_{11}^* + m(m-1)x_{22}^* + l(l-1)x_{77}^* + (n \cdot m)x_{12}^* + (n \cdot l)x_{17}^* + (m \cdot l)x_{27}^* \quad (17)$$

1  
2  
3  
4 the Hamiltonian matrix after diagonalization gives wavenumbers having errors as large  
5  
6 as  $300 \text{ cm}^{-1}$  when compared to the observed ones. One of the reason is certainly due to  
7  
8 the large values of the *ab initio* cubic force constants  $\phi_{122} = -447.3 \text{ cm}^{-1}$  and  $\phi_{177} =$   
9  
10  $-409.0 \text{ cm}^{-1}$  that appear too large. The issue of unusually large values of cubic force  
11  
12 constants has been already pointed out in other investigations. Examples are given by  
13  
14 the studies carried out by Law and co-workers [29, 30], the calculation of spectroscopic  
15  
16 parameters of methanol performed by Hänninen and Halonen [31] as well as the VPT  
17  
18 approach of Matthews et al. to the stretching overtone levels of water vapour [32].

19  
20 Although Law and Duncan demonstrated that a better agreement between *ab initio*  
21  
22 cubic force constants and empirical Fermi parameters may be obtained by including  
23  
24 corrections from second order perturbation theory, they also emphasized that these  
25  
26 terms do not provide a complete description of the Fermi resonance. Therefore we have  
27  
28 investigated the possibility of higher-order effects in this model including the  
29  
30 dependence of the interacting levels from the vibrational quantum numbers into the  
31  
32 Fermi coupling constants. Although for the polyad with  $N = 1$  a slight improvement  
33  
34 could be observed, on average no significant improvements have been obtained from  
35  
36 this approach. If the presence of strong Fermi resonances could be easily recognized  
37  
38 from the unusual values of the anharmonicity constants, it is very difficult, if not  
39  
40 impossible, to find a simple criterion for the recognition of weak Fermi interactions. A  
41  
42 working expression for the estimate of higher order effects has been proposed by Martin  
43  
44 et al. [33] who, for type-1 Fermi resonance (i.e.  $\nu_1, 2\nu_1$ ), derived the quantity

addition, the small deviations of  $x_{11}$  in a so-called Birge-Sponer plot [34] suggest very weak resonances for this vibrational mode. This is in agreement with the experimental observation that neglecting Fermi resonances from the least squares analysis of the assigned absorptions has little effect on the value of  $x_{11}'$  anharmonicity constant.

On the basis of these observations, we have simplified the model by excluding Fermi resonances and taking into account all Darling-Dennison resonances between overtones and combinations of the CH bending modes within each polyad up to  $N = 7/2$ . The same approach has also been adopted by Hänninen and Halonen in their study on methanol [31] who have not been able “to obtain any improvement” by including higher order effects and hence, in the final calculation they excluded Fermi interaction between the OH stretch and CH bend. The calculated wavenumbers corresponding to the observed ones are reported under the *ab initio* column of Table 2. There is a general agreement between the observed and calculated values, even if, on average, the computed values fall at higher wavenumbers than the experimental ones (mean signed error =  $-7.7 \text{ cm}^{-1}$ ). Concerning the CH chromophore states up to  $N = 5/2$  the differences between the observed wavenumbers and those computed *ab initio* are generally within  $10 \text{ cm}^{-1}$ ; going to higher polyads these differences tend to increase but they still remain lower than  $20 \text{ cm}^{-1}$ .

## Conclusions

The vibrational analysis of the gas phase infrared spectra of bromodifluoromethane,  $\text{CHBrF}_2$ , performed by means of an effective Hamiltonian confirms the validity of the CH chromophore framework also for this molecule. The

1  
2  
3  
4 good agreement between the experimental and the predicted wavenumbers demonstrates  
5  
6 the usefulness of this model to quantitatively describe the most relevant resonances  
7  
8 affecting the absorptions in the overtone region up to  $10100\text{ cm}^{-1}$ . The approach here  
9  
10 followed is of central importance to understand the role of Fermi and Darling-Dennison  
11  
12 coupling terms between the CH-stretching and bending modes as well as in modelling  
13  
14 the features of the spectra of  $\text{CHBrF}_2$  in the near infrared region.  
15  
16  
17

18  
19 Employing the VPT2 spectroscopic parameters, the *ab initio* resonant model  
20  
21 used to describe the CH chromophore polyads, which excludes Fermi resonances due to  
22  
23 the high values of the computed cubic force constants  $\phi_{122}$  and  $\phi_{177}$ , and considers only  
24  
25 Darling-Dennison resonances between the overtones of  $\nu_2$  and  $\nu_7$ , leads to an overall  
26  
27 satisfactory agreement with the experimental data and also it could be useful to follow  
28  
29 the correct assignment of the bands here considered.  
30  
31  
32

33  
34 In conclusion, this work provides the first description of the different CH  
35  
36 chromophore polyads which accounts for almost all the most relevant absorptions of  
37  
38  $\text{CHBrF}_2$  up to the near infrared region of the spectra. The information here reported is  
39  
40 useful for successive studies which could better determine the resonances here analyzed.

Table 1. Spectroscopic parameters ( $\text{cm}^{-1}$ ) of  $\text{CHBrF}_2$  obtained from least square fitting to the model Hamiltonian <sup>a</sup>

Parameter	Fit 1 <sup>b</sup>	Fit 2 <sup>c</sup>
$\tilde{\nu}'_1$	3072.2(13)	3072.4(14)
$\tilde{\nu}'_2$	1289.5(15)	1288.9(15)
$\tilde{\nu}'_7$	1355.1(18)	1354.6(17)
$x'_{11}$	-61.8(11)	-61.9(11)
$x'_{12}$	-25.8(25)	-26.2(26)
$x'_{17}$	-25.7(26)	-26.5(27)
$x'_{22}$	-6.8(9)	-6.6(9)
$x'_{27}$	-1.0(8)	0 <sup>d</sup>
$x'_{77}$	-7.6(1.1)	-7.5(12)
$k'_{122}$	95(11)	95(12)
$k'_{177}$	87.6(77)	89.7(78)
$k'_{2277}$	10.4(16)	10.9(16)
N. data	26	26
RMS	1.26	1.33
$\sigma_{fit}$	1.71	1.76

<sup>a</sup> Figures in parentheses correspond to one standard deviation.

<sup>b</sup> Least square fitting with 12 degrees of freedom.

<sup>c</sup> Least square fitting with 11 degrees of freedom.

<sup>d</sup> Constrained.

<sup>a</sup> Figures in parentheses represent experimental errors.

<sup>b</sup> Predicted from parameters obtained by least square fitting with 12 degrees of freedom.

<sup>c</sup> Predicted from parameters obtained by least square fitting with 11 degrees of freedom.

<sup>d</sup> Predicted from *ab initio* hybrid force field: geometry and quadratic force constants at CCSD(T)/cc-pVTZ (for H, C, Br atoms) and CCSD(T)/aug-cc-pVTZ (F atoms); cubic and quartic force constants at CCSD(T)/cc-pVTZ.

<sup>e</sup> Observed relative intensities within a given polyad block.

<sup>f</sup> Relative intensities within a given polyad block predicted by least square fitting with 12 degrees of freedom.

**Figure captions**

Figure 1. Approximate description of  $\text{CHBrF}_2$  normal modes of vibration involving the C-H chromophore: (a)  $\nu_1$ , stretching; (b)  $\nu_2$ , in-plane bending; (c)  $\nu_7$ , out-of-plane bending. Vectors represent atomic displacements during vibrational motion.

Figure 2. Vibrational spectra of  $\text{CHBrF}_2$  in the regions of the  $\nu_1$ ,  $\nu_2$  and  $\nu_7$  fundamentals and their overtones.

(a)  $N = 1/2$  polyad in the  $1000 - 1400 \text{ cm}^{-1}$  spectral region (experimental conditions: pressure = 10.0 mbar; optical path = 13.4 cm; resolution =  $0.5 \text{ cm}^{-1}$ ; temperature = 298 K).

(b)  $N = 1$  polyad in the  $2000 - 3200 \text{ cm}^{-1}$  spectral region (experimental conditions: pressure = 30.9 mbar; optical path = 13.4 cm; resolution =  $0.5 \text{ cm}^{-1}$ ; temperature = 298 K); the inset shows a magnified view of overtones and combination bands belonging to this polyad.

(c)  $N = 3/2$  and  $N = 2$  polyads within the  $4000 - 6500 \text{ cm}^{-1}$  spectral region (experimental conditions: pressure = 33 mbar; optical path = 10.5 m; resolution =  $0.5 \text{ cm}^{-1}$ ; temperature = 298 K).

(d)  $N = 5/2$ ,  $N = 3$  and  $N = 7/2$  polyads in the  $6500 - 10000 \text{ cm}^{-1}$  spectral region (experimental conditions: pressure = 33 mbar; optical path = 77.5 m; resolution =  $0.5 \text{ cm}^{-1}$ ; temperature = 298 K). The inset shows a magnified view of the  $7900 - 8200 \text{ cm}^{-1}$  interval where  $N = 3_9$  ( $\nu_1 + \nu_4$ ) and  $N = 3_7$  ( $\nu_1$
