# On the number of numerical semigroups $\langle a, b\rangle$ of prime power genus 

Shalom Eliahou* and Jorge Ramírez Alfonsín ${ }^{\dagger}$

September 14, 2012

#### Abstract

Given $g \geq 1$, the number $n(g)$ of numerical semigroups $S \subset \mathbb{N}$ of genus $|\mathbb{N} \backslash S|$ equal to $g$ is the subject of challenging conjectures of Bras-Amorós. In this paper, we focus on the counting function $n(g, 2)$ of two-generator numerical semigroups of genus $g$, which is known to also count certain special factorizations of $2 g$. Further focusing on the case $g=p^{k}$ for any odd prime $p$ and $k \geq 1$, we show that $n\left(p^{k}, 2\right)$ only depends on the class of $p$ modulo a certain explicit modulus $M(k)$. The main ingredient is a reduction of $\operatorname{gcd}\left(p^{\alpha}+1,2 p^{\beta}+1\right)$ to a simpler form, using the continued fraction of $\alpha / \beta$. We treat the case $k=9$ in detail and show explicitly how $n\left(p^{9}, 2\right)$ depends on the class of $p \bmod$ $M(9)=3 \cdot 5 \cdot 11 \cdot 17 \cdot 43 \cdot 257$.

Keywords. Gap number; Sylvester's theorem; Special factorizations; Euclidean algorithm; Continued fractions; RSA.

## 1 Introduction

A numerical semigroup is a subset $S \subset \mathbb{N}$ containing 0 , stable under addition and with finite complement in $\mathbb{N}$. The cardinality of $\mathbb{N} \backslash S$ is then called the gap number or the genus of $S$. It is well known that, given $g \in \mathbb{N}$, there are only finitely many numerical semigroups of genus $g$. Yet the question of counting them seems to be a very hard problem, analogous to the one of

[^0]counting numerical semigroups by Frobenius number. See [1, 2] for some nice conjectures about it. The problem becomes more tractable when restricted to semigroups $S=\langle a, b\rangle=\mathbb{N} a+\mathbb{N} b$ with two generators. So, let us denote by $n(g, 2)$ the number of numerical semigroups $S=\langle a, b\rangle$ of genus $g$. On the one hand, determining $n(g, 2)$ is linked to hard factorization problems, like factoring Fermat and Mersenne numbers [3]. On the other hand, the value of $n(g, 2)$ is known for all $g=2^{k}$ with $k \geq 1$, and for all $g=p^{k}$ with $p$ an odd prime and $k \leq 8$. Indeed, exact formulas are provided in [3], showing in particular that $n\left(p^{k}, 2\right)$ for $k=1,2,3,4,5,6,7$ and 8 only depends on the class of $p$ modulo $3,1,15,7,255,31,36465$ and 27559 , respectively. See also Section 7, where these formulas are given in a new form.

Our purpose in this paper is to extend our understanding of $n\left(p^{k}, 2\right)$ to arbitrary exponents $k \in \mathbb{N}$. Giving exact formulas in all cases is out of reach since, for instance, a formula for $n\left(p^{4097}, 2\right)$ would require the still unknown factorization of the 12 th Fermat number $2^{2^{12}}+1$. However, what can and will be done here is to show that, for all $k \geq 1$, the value of $n\left(p^{k}, 2\right)$ only depends on the class of $p$ modulo some explicit modulus $M(k)$.

This result is formally stated and proved in Section 4. Here is how $M(k)$ is defined:

$$
M(k)=\operatorname{rad}\left(\prod_{i=1}^{k}\left(2^{i / \operatorname{gcd}(i, k)}-(-1)^{k / \operatorname{gcd}(i, k)}\right)\right),
$$

where $\operatorname{rad}(n)$ denotes the product of the distinct prime factors of $n$, i.e. the largest square-free divisor of $n$. We start by recalling in Section 2 that $n(g, 2)$ can be identified with the counting function of certain special factorizations of $2 g$. In Section 3, we reduce $\operatorname{gcd}\left(p^{\alpha}+1,2 p^{\beta}+1\right)$ for $\alpha, \beta \in \mathbb{N}$ to the simpler form

$$
\operatorname{gcd}\left(p^{\operatorname{gcd}(\alpha, \beta)} \pm 2^{\rho}, c\right)
$$

where $\rho, c \in \mathbb{Z}$ only depend on $\alpha, \beta$ and not on $p$. This reduction uses the continued fraction of $\alpha / \beta$ and directly leads to our main result in Section 4. In Section 5, we introduce basic binary functions $X_{a, q}$ which will serve as building blocks in our formulas. The case $k=9$ is treated in detail in Section 6, where we give an explicit formula for $n\left(p^{9}, 2\right)$ depending on the class of $p \bmod M(9)=3 \cdot 5 \cdot 11 \cdot 17 \cdot 43 \cdot 257$. We also provide a formula in the case $k=10$ with somewhat less details. Finally, in the last section we give and prove new formulas for $n\left(p^{k}, 2\right)$ with $k \leq 8$ in terms of the $X_{a, q}$.

Background information on numerical semigroups can be found in the books [4, 5].

## 2 Special factorizations of $2 g$

We first recall from [3] that $n(g, 2)$ can be identified with the counting number of factorizations uv of $2 g$ in $\mathbb{N}$ satisfying $\operatorname{gcd}(u+1, v+1)=1$. In formula:

$$
\begin{equation*}
n(g, 2)=\#\{\{u, v\} \subset \mathbb{N} \mid u v=2 g, \operatorname{gcd}(u+1, v+1)=1\} \tag{1}
\end{equation*}
$$

This follows from the classical theorem of Sylvester [6] stating that whenever $\operatorname{gcd}(a, b)=1$, the genus $g$ of the numerical semigroup $S=\langle a, b\rangle$ is given by

$$
g=\frac{(a-1)(b-1)}{2}
$$

For $g=p^{k}$ with $p$ an odd prime, an immediate consequence of (1) is the following formula.

Proposition 2.1 For any odd prime $p$ and exponent $k \geq 1$, we have

$$
n\left(p^{k}, 2\right)=\#\left\{0 \leq i \leq k \mid \operatorname{gcd}\left(p^{i}+1,2 p^{k-i}+1\right)=1\right\}
$$

Thus, in order to understand the behavior of $n\left(p^{k}, 2\right)$, we need to gain some control on

$$
\operatorname{gcd}\left(p^{\alpha}+1,2 p^{\beta}+1\right)
$$

for $\alpha, \beta \in \mathbb{N}$, and hopefully find ways to determine when this greatest common divisor equals 1 . This is addressed in the next section.

## $3 \quad \operatorname{On} \operatorname{gcd}\left(p^{\alpha}+1,2 p^{\beta}+1\right)$

Here is the key technical tool which will lead to our main result in Section 4. Given $\alpha, \beta \in \mathbb{N}$, we shall reduce the greatest common divisor

$$
\operatorname{gcd}\left(p^{\alpha}+1,2 p^{\beta}+1\right)
$$

to the simpler form

$$
\operatorname{gcd}\left(p^{\delta} \pm 2^{\rho}, c\right)
$$

where $\delta=\operatorname{gcd}(\alpha, \beta)$ and where $\rho, c \in \mathbb{Z}$ only depend on $\alpha, \beta$ and not on $p$. For this purpose, it is more convenient to work in the ring $\mathbb{Z}\left[2^{-1}\right]$ where 2 is made invertible. Moreover, one may effortlessly replace $\mathbb{Z}\left[2^{-1}\right]$ by any unique factorization domain $A$, and 2 by any invertible element $u$ in $A$. Of course then, the gcd is only defined up to invertible elements of $A$. The proof in this more general context remains practically the same.

Proposition 3.1 Let $A$ be a unique factorization domain and let $x, u \in A$ with $u$ invertible. Let $\alpha, \beta \in \mathbb{N}$ and set $\delta=\operatorname{gcd}(\alpha, \beta)$. Then there exists $\rho \in \mathbb{Z}$ such that

$$
\operatorname{gcd}\left(x^{\alpha}+1, u x^{\beta}+1\right)=\operatorname{gcd}\left(x^{\delta} \pm u^{\rho}, u^{\alpha / \delta}-(-1)^{(\alpha-\beta) / \delta}\right)
$$

The proof is based on a careful study of the successive steps in the Euclidean algorithm for computing gcd's.
Proof. First note that, since $u$ is invertible, we have

$$
\operatorname{gcd}\left(x^{\alpha}+1, u x^{\beta}+1\right)=\operatorname{gcd}\left(x^{\alpha}+1, x^{\beta}+u^{-1}\right) .
$$

Set $r_{0}=\alpha, r_{1}=\beta$. Consider the Euclidean algorithm to compute $\operatorname{gcd}\left(r_{0}, r_{1}\right)$ :

$$
\begin{equation*}
r_{i}=a_{i} r_{i+1}+r_{i+2} \tag{2}
\end{equation*}
$$

for all $0 \leq i \leq n-1$, where $0 \leq r_{i+1}<r_{i}$ for all $1 \leq i \leq n-1, r_{n+1}=0$, $r_{n}=\operatorname{gcd}\left(r_{0}, r_{1}\right)$. Of course, the $a_{i}$ 's are the partial quotients of the continued fraction $\left[a_{0}, a_{1}, \ldots, a_{n}\right]$ of $\alpha / \beta$. We have

$$
\binom{r_{i}}{r_{i+1}}=\left(\begin{array}{cc}
a_{i} & 1  \tag{3}\\
1 & 0
\end{array}\right)\binom{r_{i+1}}{r_{i+2}}
$$

for all $0 \leq i \leq n-1$. Set $\left(s_{0}, s_{1}\right)=(1,1)$ and $\left(t_{0}, t_{1}\right)=(0,-1)$. Then we have

$$
\begin{aligned}
x^{r_{0}}+1 & =x^{r_{0}}-(-1)^{s_{0}} u^{t_{0}}, \\
x^{r_{1}}+u^{-1} & =x^{r_{1}}-(-1)^{s_{1}} u^{t_{1}} .
\end{aligned}
$$

For $i=0, \ldots, n-1$, recursively define

$$
\begin{aligned}
s_{i+2} & =s_{i}-a_{i} s_{i+1}, \\
t_{i+2} & =t_{i}-a_{i} t_{i+1}
\end{aligned}
$$

Then as in (3), we have

$$
\begin{align*}
\binom{s_{i}}{s_{i+1}} & =\left(\begin{array}{ll}
a_{i} & 1 \\
1 & 0
\end{array}\right)\binom{s_{i+1}}{s_{i+2}}  \tag{4}\\
\binom{t_{i}}{t_{i+1}} & =\left(\begin{array}{cc}
a_{i} & 1 \\
1 & 0
\end{array}\right)\binom{t_{i+1}}{t_{i+2}} \tag{5}
\end{align*}
$$

for all $0 \leq i \leq n-1$. Finally, for all $0 \leq j \leq n+1$, set

$$
f_{j}=x^{r_{j}}-(-1)^{s_{j}} u^{t_{j}}
$$

Note that $f_{0}=x^{r_{0}}+1, f_{1}=x^{r_{1}}+u^{-1}$, and

$$
\begin{equation*}
f_{n+1}=1-(-1)^{s_{n+1}} u^{t_{n+1}} \tag{6}
\end{equation*}
$$

since $r_{n+1}=0$.
Claim. For all $0 \leq i \leq n-1$, we have

$$
\begin{equation*}
\operatorname{gcd}\left(f_{i}, f_{i+1}\right)=\operatorname{gcd}\left(f_{i+1}, f_{i+2}\right) \tag{7}
\end{equation*}
$$

Indeed, it follows from (2) that

$$
\begin{aligned}
f_{i} & =x^{r_{i}}-(-1)^{s_{i}} u^{t_{i}} \\
& =\left(x^{r_{i+1}}\right)^{a_{i}} x^{r_{i+2}}-(-1)^{s_{i}} u^{t_{i}} .
\end{aligned}
$$

Now, since

$$
x^{r_{i+1}} \equiv(-1)^{s_{i+1}} u^{t_{i+1}} \bmod f_{i+1}
$$

we find

$$
\begin{aligned}
f_{i} & \equiv\left((-1)^{s_{i+1}} u^{t_{i+1}}\right)^{a_{i}} x^{r_{i+2}}-(-1)^{s_{i}} u^{t_{i}} \bmod f_{i+1} \\
& \equiv(-1)^{a_{i} s_{i+1}} u^{a_{i} t_{i+1}} x^{r_{i+2}}-(-1)^{s_{i}} u^{t_{i}} \bmod f_{i+1} .
\end{aligned}
$$

Thus,

$$
\begin{aligned}
(-1)^{-a_{i} s_{i+1}} u^{-a_{i} t_{i+1}} f_{i} & \equiv x^{r_{i+2}}-(-1)^{s_{i}-a_{i} s_{i+1}} u^{t_{i}-a_{i} t_{i+1}} \bmod f_{i+1} \\
& \equiv x^{r_{i+2}}-(-1)^{s_{i+2}} u^{t_{i+2}} \bmod f_{i+1} \\
& \equiv f_{i+2} \bmod f_{i+1} .
\end{aligned}
$$

Consequently, we have $f_{i} \equiv(-1)^{a_{i} s_{i+1}} u^{a_{i} t_{i+1}} f_{i+2} \bmod f_{i+1}$. Using the equality

$$
\operatorname{gcd}(f, g)=\operatorname{gcd}(g, h)
$$

whenever $f \equiv h \bmod g$ for elements in $A$, we conclude that

$$
\begin{aligned}
\operatorname{gcd}\left(f_{i}, f_{i+1}\right) & =\operatorname{gcd}\left(f_{i+1},(-1)^{a_{i} s_{i+1}} u^{a_{i} t_{i+1}} f_{i+2}\right) \\
& =\operatorname{gcd}\left(f_{i+1}, f_{i+2}\right)
\end{aligned}
$$

since $(-1)^{a_{i} s_{i+1}} u^{a_{i} t_{i+1}}$ is a unit in $A$. This proves the claim.
As a first consequence, we get

$$
\begin{equation*}
\operatorname{gcd}\left(f_{0}, f_{1}\right)=\operatorname{gcd}\left(f_{n}, f_{n+1}\right) . \tag{8}
\end{equation*}
$$

Denote now

$$
A=\prod_{i=0}^{n-1}\left(\begin{array}{cc}
a_{i} & 1 \\
1 & 0
\end{array}\right)=\left(\begin{array}{ll}
\alpha_{11} & \alpha_{12} \\
\alpha_{21} & \alpha_{22}
\end{array}\right)
$$

We have $\operatorname{det} A=(-1)^{n}$, and it follows from repeatedly applying (3) that

$$
\binom{r_{0}}{r_{1}}=A\binom{r_{n}}{0} .
$$

This implies, in particular, that $\alpha_{11}=r_{0} / r_{n}$ and $\alpha_{21}=r_{1} / r_{n}$. Similarly, using (5) repeatedly, we have

$$
A^{-1}\binom{t_{0}}{t_{1}}=\binom{t_{n}}{t_{n+1}} .
$$

Since $A^{-1}=(-1)^{n}\left(\begin{array}{cc}\alpha_{22} & -\alpha_{12} \\ -\alpha_{21} & \alpha_{11}\end{array}\right)$ and $\binom{t_{0}}{t_{1}}=\binom{0}{-1}$, this implies that

$$
t_{n+1}=(-1)^{n+1} \alpha_{11}=(-1)^{n+1} r_{0} / r_{n}
$$

Finally, using (4) repeatedly, we have

$$
A^{-1}\binom{s_{0}}{s_{1}}=\binom{s_{n}}{s_{n+1}} .
$$

As above, and since $\binom{s_{0}}{s_{1}}=\binom{1}{1}$, we find that

$$
s_{n+1}=(-1)^{n}\left(-\alpha_{21}+\alpha_{11}\right)=(-1)^{n}\left(r_{0}-r_{1}\right) / r_{n} .
$$

Summarizing, it follows from the equality (8), the expression (6) for $f_{n+1}$, and the above values of $s_{n+1}, t_{n+1}$, that

$$
\begin{aligned}
\operatorname{gcd}\left(x^{\alpha}+1, u x^{\beta}+1\right) & =\operatorname{gcd}\left(f_{n}, f_{n+1}\right) \\
& =\operatorname{gcd}\left(x^{r_{n}}-(-1)^{s_{n}} u^{t_{n}}, 1-(-1)^{s_{n+1}} u^{t_{n+1}}\right) \\
& =\operatorname{gcd}\left(x^{\delta}-(-1)^{s_{n}} u^{t_{n}}, u^{\alpha / \delta}-(-1)^{(\alpha-\beta) / \delta}\right) .
\end{aligned}
$$

The special case of interest to us, namely where $A=\mathbb{Z}\left[2^{-1}\right]$ and $u=2$, reduces to the following statement.
Corollary 3.2 Let $1 \leq i \leq k$ be given integers, and set $\delta=\operatorname{gcd}(i, k)$. Then there exists $\rho \in \mathbb{Z}$ such that for any odd prime $p$, we have

$$
\operatorname{gcd}\left(p^{i}+1,2 p^{k-i}+1\right)=\operatorname{gcd}\left(p^{\delta} \pm 2^{\rho}, 2^{i / \delta}-(-1)^{k / \delta}\right)
$$

Proof. First observe that $\operatorname{gcd}\left(p^{i}+1,2 p^{k-i}+1\right)$ is odd since the second argument is, so we may as well work in $\mathbb{Z}\left[2^{-1}\right]$ when computing this gcd. Set $\alpha=i, \beta=k-i$. Since $\operatorname{gcd}(i, k-i)=\operatorname{gcd}(i, k)$, the values of $\delta$ in Proposition 3.1 and here are the same. Now $(\alpha-\beta) / \delta=(2 i-k) / \delta$, and so

$$
(-1)^{(\alpha-\beta) / \delta}=(-1)^{k / \delta} .
$$

The claimed formula for $\operatorname{gcd}\left(p^{i}+1,2 p^{k-i}+1\right)$ now follows directly from that in Proposition 3.1.

Consequently, given $1 \leq i \leq k$, an odd prime $p$ satisfies the condition

$$
\operatorname{gcd}\left(p^{i}+1,2 p^{k-i}\right)+1=1
$$

if and only if $p$ belongs to a certain union of classes $\bmod \left(2^{i / \delta}-(-1)^{k / \delta}\right)$, where as above $\delta=\operatorname{gcd}(i, k)$. This is the key to our main result below.

## 4 The main result

For a positive integer $n$, let $\operatorname{rad}(n)$ denote the radical of $n$, i.e. the product of the distinct primes factors of $n$. For instance, $\operatorname{rad}(4)=2$ and $\operatorname{rad}(6)=$ $\operatorname{rad}(12)=\operatorname{rad}(18)=6$. Given $k \geq 1$, let us define

$$
M(k)=\operatorname{rad}\left(\prod_{i=1}^{k}\left(2^{i / \operatorname{gcd}(i, k)}-(-1)^{k / \operatorname{gcd}(i, k)}\right)\right) .
$$

Note that if $k$ is odd, the formula becomes

$$
M(k)=\operatorname{rad}\left(\prod_{i=1}^{k}\left(2^{i / \operatorname{gcd}(i, k)}+1\right)\right)
$$

whereas if $k$ is even there is no such reduction in general, since the exponent $k / \operatorname{gcd}(i, k)$ may assume both parities. Here is our main result.

Theorem 4.1 For any odd prime $p$ and $k \geq 1$, the value of $n\left(p^{k}, 2\right)$ only depends on the class of $p$ modulo $M(k)$.

Proof. Recall the formula given by Proposition 2.1:

$$
\begin{equation*}
n\left(p^{k}, 2\right)=\#\left\{0 \leq i \leq k \mid \operatorname{gcd}\left(p^{i}+1,2 p^{k-i}+1\right)=1\right\} \tag{9}
\end{equation*}
$$

If $i=0$, then $\operatorname{gcd}\left(2,2 p^{k}+1\right)=1$ always, since $p$ is odd. Assume now $1 \leq i \leq k$, and set

$$
m_{k}(i)=2^{i / \operatorname{gcd}(i, k)}-(-1)^{k / \operatorname{gcd}(i, k)}
$$

By Corollary 3.2, the value of $\operatorname{gcd}\left(p^{i}+1,2 p^{k-i}+1\right)$ only depends on the class of $p \bmod m_{k}(i)$. Therefore, it follows from (9) and this property of $m_{i}(k)$ that if we set

$$
M(k)=\operatorname{rad}\left(\prod_{i=1}^{k} m_{k}(i)\right)
$$

the value of $n\left(p^{k}, 2\right)$ only depends on the class of $p \bmod M(k)$.
For concreteness, Table 1 gives the value of $M(k)$ for $1 \leq k \leq 10$. We have seen that $n\left(p^{k}, 2\right)$ only depends on the class of $p$ modulo $M(k)$. But $M(k)$ is not necessarily the smallest modulus with this property, only a multiple of it. For instance, we have $M(4)=21$, but the value of $n\left(p^{4}, 2\right)$ only depends on the class of $p \bmod 7$, as stated in the Introduction. However, for all odd $k$ in the range $1 \leq k \leq 9$, the modulus $M(k)$ actually turns out to be optimal for the desired property. (See [3] and Section 7.)

| $k$ | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $M(k)$ | 3 | 3 | 15 | 21 | 255 | 465 | 36465 | 82677 | 30998055 | 16548735 |

Table 1: First 10 values of $M(k)$.

## 5 The basic functions $X_{a, q}$

We now introduce numerical functions $X_{a, q}$, with values in $\{0,1\}$, which will subsequently serve as building blocks in our explicit formulas for $n\left(p^{k}, 2\right)$
with $k \leq 10$. Given integers $a, q$ with $q \geq 2$, the definition of

$$
X_{a, q}: \mathbb{Z} \rightarrow\{0,1\}
$$

depends on the distinct prime factors of $q$, as follows.

- If $q$ is prime, then $X_{a, q}$ is the indicator function of the complement of the subset $a+q \mathbb{Z}$ in $\mathbb{Z}$, i.e.

$$
X_{a, q}(n)= \begin{cases}1 & \text { if } n \not \equiv a \bmod q \\ 0 & \text { if } n \equiv a \bmod q .\end{cases}
$$

- If $q_{1}, \ldots, q_{t}$ are the distinct prime factors of $q$, then we set

$$
X_{a, q}=\prod_{i=1}^{t} X_{a, q_{i}} .
$$

In particular, since $X_{a, q}$ only depends on the prime factors of $q$, we have

$$
X_{a, q}=X_{a, \operatorname{rad}(q)} .
$$

Note that $X_{a, q}$ only depends on the class of $a \bmod q$. It is also plain that $X_{a, q}(n)$ only depends on the class of $n \bmod q$.

We now establish a few more properties of these functions. The first one links $X_{a, q}(n)$ with $\operatorname{gcd}(n-a, q)$, and so will be useful to capture occurrences of the equality $\operatorname{gcd}\left(p^{i}+1,2 p^{k-i}+1\right)=1$.

Proposition 5.1 Let $a, q$ be integers with $q \geq 2$. For all $n \in \mathbb{Z}$, we have

$$
X_{a, q}(n)= \begin{cases}1 & \text { if } \operatorname{gcd}(n-a, q)=1 \\ 0 & \text { if not. }\end{cases}
$$

Proof. Let $q_{1}, \ldots, q_{t}$ be the distinct prime factors of $q$. Then we have

$$
\begin{aligned}
X_{a, q}(n)=1 & \Longleftrightarrow X_{a, q_{i}}(n)=1 \forall i \\
& \Longleftrightarrow n \not \equiv a \bmod q_{i} \forall i \\
& \Longleftrightarrow \operatorname{gcd}\left(n-a, q_{i}\right)=1 \forall i \\
& \Longleftrightarrow \operatorname{gcd}(n-a, q)=1 .
\end{aligned}
$$

Since $X_{a, q}(n)$ only takes values in $\{0,1\}$, this implies that $X_{a, q}(n)=0$ if and only if $\operatorname{gcd}(n-a, q) \neq 1$.

Next, for determining $n\left(p^{k}, 2\right)$, we often need to evaluate $X_{a, q}\left(p^{s}\right)$ with $s \geq 2$. The next two properties help remove that exponent $s$. The first one reduces the task to the case where $s$ divides $q-1$. It suffices to consider the case where $q$ is prime.

Proposition 5.2 Let $q$ be a prime number, and let $a, s$ be integers with $s \geq 2$. Write $s=$ te with $t=\operatorname{gcd}(s, q-1)$, so that $\operatorname{gcd}(e, q-1)=1$. Let $d \in \mathbb{N}$ satisfy $d e \equiv 1 \bmod q-1$. Then

$$
X_{a, q}\left(n^{s}\right)=X_{a^{d}, q}\left(n^{t}\right)
$$

for all integers $n$.
Proof. This is the heart of the RSA cryptographic protocol, which relies on the fact that exponentiation to the power $e$ in $\mathbb{Z} / q \mathbb{Z}$ is a bijection, whose inverse is exponentiation to the power $d$. We have

$$
\begin{aligned}
X_{a, q}\left(n^{s}\right)=0 & \Longleftrightarrow n^{s} \equiv a \bmod q \\
& \Longleftrightarrow\left(n^{t}\right)^{e} \equiv a \bmod q \\
& \Longleftrightarrow\left(n^{t}\right)^{d e} \equiv a^{d} \bmod q \\
& \Longleftrightarrow n^{t} \equiv a^{d} \bmod q \\
& \Longleftrightarrow X_{a^{d}, q}\left(n^{t}\right)=0 .
\end{aligned}
$$

Thus, we may now assume that the exponent $s$ divides $q-1$.
Proposition 5.3 Let $q$ be a prime number, and let $a, s$ be integers with $s$ dividing $q-1$. Let $g \in \mathbb{N}$ be an integer whose class mod $q$ generates the multiplicative group of non-zero elements in $\mathbb{Z} / q \mathbb{Z}$. We have:

- If $a$ is not an $s$-power $\bmod q$, then $X_{a, q}\left(n^{s}\right)=1$ for all $n$.
- If $a$ in an $s$-power $\bmod q$, then $a \equiv g^{s i} \bmod q$ for some integer $i$ such that $0 \leq i \leq(q-1) / s-1$, and

$$
X_{a, q}\left(n^{s}\right)=\prod_{j=0}^{s-1} X_{g^{i+j(q-1) / s, q}}(n)
$$

for all integers $n$.

Proof. In the group $(\mathbb{Z} / q \mathbb{Z})^{*}$ of nonzero classes $\bmod q$, the set of $s$-powers is of cardinality $(q-1) / s$ and coincides with

$$
\left\{g^{s i} \bmod q \mid 0 \leq i \leq(q-1) / s-1\right\}
$$

First, if $a$ is not an $s$-power $\bmod q$, then $n^{s} \not \equiv a \bmod q$ for all $n$, implying $X_{a, q}\left(n^{s}\right)=1$ for all $n$. Assume now $a$ is an $s$-power $\bmod q$. By the above remark, there exists $0 \leq i \leq(q-1) / s-1$ such that $a \equiv g^{s i} \bmod q$. We have

$$
\begin{aligned}
X_{a, q}\left(n^{s}\right)=0 & \Longleftrightarrow n^{s} \equiv a \bmod q \\
& \Longleftrightarrow n^{s} \equiv g^{s i} \bmod q \\
& \Longleftrightarrow\left(\frac{n}{g^{i}}\right)^{s} \equiv 1 \bmod q .
\end{aligned}
$$

This means that $n / g^{i}$ is of order dividing $s$ in the group $(\mathbb{Z} / q \mathbb{Z})^{*}$. Now, the elements of order dividing $s$ in this group constitute a subgroup of order $s$ generated by $g^{(q-1) / s}$. Thus, there exists an integer $j$ such that $0 \leq j \leq s-1$ and satisfying

$$
\frac{n}{g^{i}} \equiv g^{j(q-1) / s} \bmod q,
$$

yielding

$$
X_{a, q}\left(n^{s}\right)=0 \Longleftrightarrow n \equiv g^{i+j(q-1) / s} \bmod q
$$

Summarizing, for $a \equiv g^{s i} \bmod q$, we have established the equivalence

$$
X_{a, q}\left(n^{s}\right)=0 \Longleftrightarrow \prod_{j=0}^{s-1} X_{g^{i+j(q-1) / s}, q}(n)=0
$$

whence the claimed equality $X_{a, q}\left(n^{s}\right)=\prod_{j=0}^{s-1} X_{g^{i+j(q-1) / s}, q}(n)$.
Example 5.4 In order to establish our formula for $n\left(p^{10}, 2\right)$ in Section 6, the term $X_{8,17}\left(p^{2}\right)$ turns out to be involved. Now 8 is a square mod 17, namely $8 \equiv 5^{2} \equiv 12^{2} \bmod 17$. Thus, the above result yields

$$
X_{8,17}\left(p^{2}\right)=X_{5,17}(p) X_{12,17}(p)
$$

## 6 The cases $k=9,10$

Explicit formulas for $n\left(p^{k}, 2\right)$ with $p$ an odd prime and $k \leq 6$ or $k=8$ are given in [3]. Here we go further and treat the case $k=9$ in detail. This will show how Corollary 3.2 can be applied, and will also give a sense of the increasing complexity of these formulas. We also briefly address the case $k=10$. The main ingredients are the basic functions $X_{a, q}$ defined in the preceding section.

Here comes our formula for $n\left(p^{9}, 2\right)$. The fact that it depends on the class of $p \bmod M(9)$ follows from this prime decomposition:

$$
M(9)=30998055=5 \cdot 17 \cdot 257 \cdot 3 \cdot 11 \cdot 43
$$

Theorem 6.1 Let $p$ be an odd prime. Then we have
$n\left(p^{9}, 2\right)=1+2 X_{3,5}(p)+X_{9,17}(p)+X_{128,257}(p)+X_{2,3}(p) \cdot\left(3+X_{2,11}(p)+X_{8,43}(p)\right)$.

Proof. By Proposition 2.1, in order to determine $n\left(p^{9}, 2\right)$, it suffices to count those exponents $i$ between 0 and 9 satisfying $\operatorname{gcd}\left(p^{i}+1,2 p^{9-i}+1\right)=1$. Using Corollary 3.2 and the calculations leading to it, these gcd's may be reduced as follows:

$$
\begin{aligned}
\operatorname{gcd}\left(p^{0}+1,2 p^{9}+1\right) & =1 \\
\operatorname{gcd}\left(p^{1}+1,2 p^{8}+1\right) & =\operatorname{gcd}(p+1,3) \\
\operatorname{gcd}\left(p^{2}+1,2 p^{7}+1\right) & =\operatorname{gcd}(2 p-1,5) \\
\operatorname{gcd}\left(p^{3}+1,2 p^{6}+1\right) & =\operatorname{gcd}\left(p^{3}+1,3\right)=\operatorname{gcd}(p+1,3) \\
\operatorname{gcd}\left(p^{4}+1,2 p^{5}+1\right) & =\operatorname{gcd}(2 p-1,17) \\
\operatorname{gcd}\left(p^{5}+1,2 p^{4}+1\right) & =\operatorname{gcd}(p-2,33) \\
\operatorname{gcd}\left(p^{6}+1,2 p^{3}+1\right) & =\operatorname{gcd}\left(2 p^{3}+1,5\right) \\
\operatorname{gcd}\left(p^{7}+1,2 p^{2}+1\right) & =\operatorname{gcd}(p-8,129) \\
\operatorname{gcd}\left(p^{8}+1,2 p^{1}+1\right) & =\operatorname{gcd}(2 p+1,257) \\
\operatorname{gcd}\left(p^{9}+1,2 p^{0}+1\right) & =\operatorname{gcd}\left(p^{9}+1,3\right)=\operatorname{gcd}(p+1,3) .
\end{aligned}
$$

Now, by Proposition 5.1 and the properties of the functions $X_{a, q}$, these equal-
ities imply the following equivalences:

$$
\begin{aligned}
& \operatorname{gcd}\left(p^{0}+1,2 p^{9}+1\right)=1 \quad \\
& \operatorname{gcd}\left(p^{1}+1,2 p^{8}+1\right)=1 \quad \Longleftrightarrow \quad X_{2,3}(p)=1 \\
& \operatorname{gcd}\left(p^{2}+1,2 p^{7}+1\right)=1 \quad \Longleftrightarrow \quad X_{3,5}(p)=1 \\
& \operatorname{gcd}\left(p^{3}+1,2 p^{6}+1\right)=1 \quad \Longleftrightarrow \quad X_{2,3}(p)=1 \\
& \operatorname{gcd}\left(p^{4}+1,2 p^{5}+1\right)=1 \quad \Longleftrightarrow \quad X_{9,17}(p)=1 \\
& \operatorname{gcd}\left(p^{5}+1,2 p^{4}+1\right)=1 \quad \Longleftrightarrow \quad X_{2,33}(p)=1 \\
& \operatorname{gcd}\left(p^{6}+1,2 p^{3}+1\right)=1 \quad \Longleftrightarrow \quad X_{3,5}(p)=1 \\
& \operatorname{gcd}\left(p^{7}+1,2 p^{2}+1\right)=1 \quad \Longleftrightarrow \quad X_{8,129}(p)=1 \\
& \operatorname{gcd}\left(p^{8}+1,2 p^{1}+1\right)=1 \quad \Longleftrightarrow \quad X_{128,257}(p)=1 \\
& \operatorname{gcd}\left(p^{9}+1,2 p^{0}+1\right)=1 \quad \Longleftrightarrow \quad X_{2,3}(p)=1 .
\end{aligned}
$$

Read sequentially, this table directly yields the following first formula for $n\left(p^{9}, 2\right)$, with 10 summands, in terms of the functions $X_{a, q}$ :

$$
\begin{aligned}
n\left(p^{9}, 2\right)= & 1+X_{2,3}(p)+X_{3,5}(p)+X_{2,3}(p)+X_{9,17}(p)+X_{2,33}(p) \\
& +X_{3,5}(p)+X_{8,129}(p)+X_{128,257}(p)+X_{2,3}(p) \\
= & 1+3 X_{2,3}(p)+2 X_{3,5}(p)+X_{9,17}(p)+X_{2,33}(p)+X_{8,129}(p) \\
& +X_{128,257}(p) .
\end{aligned}
$$

Among the moduli involved above, the only non-prime ones are $33=3 \cdot 11$ and $129=3 \cdot 43$. By definition of $X_{a, q}$ for non-prime $q$, we have

$$
\begin{aligned}
X_{2,33} & =X_{2,3} X_{2,11} \\
X_{8,129} & =X_{8,3} X_{8,43} .
\end{aligned}
$$

Moreover, since $X_{a, q}$ only depends on the class of $a \bmod q$, we have

$$
X_{8,3}=X_{2,3}
$$

Substituting these equalities in the above formula for $n\left(p^{9}, 2\right)$, we get $n\left(p^{9}, 2\right)=1+2 X_{3,5}(p)+X_{9,17}(p)+X_{128,257}(p)+X_{2,3}(p) \cdot\left(3+X_{2,11}(p)+X_{8,43}(p)\right)$, as claimed.

We now derive another version of our formula for $n\left(p^{9}, 2\right)$, from which its values are easier to read. Given positive integers $q_{1}, \ldots, q_{t}$, we denote by

$$
\rho_{q_{1}, \ldots, q_{t}}: \mathbb{Z} \rightarrow \mathbb{Z} / q_{1} \mathbb{Z} \times \cdots \times \mathbb{Z} / q_{t} \mathbb{Z}
$$

the canonical reduction morphism $\rho_{q_{1}, \ldots, q_{t}}(n)=\left(n \bmod q_{1}, \ldots, n \bmod q_{t}\right)$. Moreover, we write $n \equiv \neg a \bmod q$ instead of $n \not \equiv a \bmod q$. For example, the condition

$$
\rho_{5,17,257}(p)=(3, \neg 9, \neg 128)
$$

means $p \equiv 3 \bmod 5, p \not \equiv 9 \bmod 17$ and $p \not \equiv 128 \bmod 257$.
Corollary 6.2 Let $p$ be an odd prime. Consider the following functions of $p$ depending on its classes mod $5,17,257$ and 11,43 , respectively:

$$
\begin{aligned}
& \lambda(p)=\left\{\begin{array}{lll}
1 & \text { if } & \rho_{5,17,257}(p)=(3,9,128) \\
2 & \text { if } & \rho_{5,17,257}(p) \in\{(3,9, \neg 128),(3, \neg 9,128)\} \\
3 & \text { if } & \rho_{5,17,257}(p) \in\{(3, \neg 9, \neg 128),(\neg 3,9,128)\} \\
4 & \text { if } & \rho_{5,17,257}(p) \in\{(\neg 3,9, \neg 128),(\neg 3, \neg 9,128)\} \\
5 & \text { if } & \rho_{5,17,257}(p)=(\neg 3, \neg 9, \neg 128),
\end{array}\right. \\
& \mu(p)=\left\{\begin{array}{lll}
3 & \text { if } & \rho_{11,43}(p)=(2,8) \\
4 & \text { if } & \rho_{11,43}(p) \in\{(2, \neg 8),(\neg 2,8)\} \\
5 & \text { if } & \rho_{11,43}(p)=(\neg 2, \neg 8) .
\end{array}\right.
\end{aligned}
$$

Then we have

$$
n\left(p^{9}, 2\right)= \begin{cases}\lambda(p) & \text { if } p \equiv 2 \bmod 3 \\ \lambda(p)+\mu(p) & \text { if } p \not \equiv 2 \bmod 3\end{cases}
$$

Proof. This directly follows from the preceding result and the easy to prove equalities

$$
\begin{aligned}
& \lambda(p)=1+2 X_{3,5}(p)+X_{9,17}(p)+X_{128,257}(p) \\
& \mu(p)=3+X_{2,11}(p)+X_{8,43}(p) .
\end{aligned}
$$

It is still clearer now that $n\left(p^{9}, 2\right)$ is determined by the class of $p \bmod$ $M(9)=3 \cdot 5 \cdot 17 \cdot 257 \cdot 11 \cdot 43$, and that $M(9)$ is the smallest modulus with this property.

We close this section by briefly treating the case $k=10$. The formula obtained shows that $n\left(p^{10}, 2\right)$, for $p$ an odd prime, is determined by the class of $p$ modulo $M(10) / 15=7 \cdot 17 \cdot 73 \cdot 127$.

Theorem 6.3 Let $p$ be an odd prime. Then we have

$$
n\left(p^{10}, 2\right)=7+X_{3,7}(p)\left(1+X_{36,73}(p)\right)+X_{5,17}(p) X_{12,17}(p)+X_{123,127}(p)
$$

Proof. After reducing $\operatorname{gcd}\left(p^{i}+1,2 p^{10-i}+1\right)$ for $0 \leq i \leq 10$ as in Corollary 3.2, and using Proposition 5.1 involving the functions $X_{a, q}$, we obtain this first raw formula:

$$
\begin{aligned}
n\left(p^{10}, 2\right)= & 2+X_{-1,3}\left(p^{2}\right)+X_{3,7}(p)+X_{-2,5}\left(p^{2}\right)+1+X_{2,9}\left(p^{2}\right)+X_{123,127}(p) \\
& +X_{8,17}\left(p^{2}\right)+X_{255,511}(p)+X_{-1,3}\left(p^{10}\right)
\end{aligned}
$$

We now invoke Proposition 5.3 several times. Since -1 is not a square mod 3 , we have $X_{-1,3}\left(p^{2}\right)=1$. The same reason yields $X_{2,9}\left(p^{2}\right)=X_{-1,3}\left(p^{10}\right)=1$. Similarly, we have $X_{-2,5}\left(p^{2}\right)=1$ as -2 is not a square $\bmod 5$. As already explained in Example 5.4, we have $X_{8,17}\left(p^{2}\right)=X_{5,17}(p) X_{12,17}(p)$. Finally, since $511=7 \cdot 73$, and since 255 is congruent to $3 \bmod 7$ and to $36 \bmod 73$, we have

$$
X_{255,511}(p)=X_{3,7}(p) X_{36,73}(p)
$$

Inserting these reductions into the raw formula gives the stated one, where now the only argument of the various basic functions $X_{a, q}$ is $p$ and all involved $q$ 's are primes.

## 7 The cases $k \leq 8$ revisited

While explicit formulas for $n\left(p^{k}, 2\right)$ with $k \leq 6$ and $k=8$ are given in [3], we provide here new, shorter formulas in terms of the basic functions $X_{a, q}$ for $k \leq 8$, including $k=7$. The construction method is similar to the cases $k=9,10$ and relies on the reduction of $\operatorname{gcd}\left(p^{i}+1,2 p^{k-i}+1\right)$ provided by Corollary 3.2.

Theorem 7.1 Let $p$ be an odd prime. Then we have

$$
\begin{aligned}
& n\left(p^{1}, 2\right)=1+X_{2,3}(p) \\
& n\left(p^{2}, 2\right)=3 \\
& n\left(p^{3}, 2\right)=1+2 X_{2,3}(p)+X_{2,5}(p) \\
& n\left(p^{4}, 2\right)=4+X_{3,7}(p) \\
& n\left(p^{5}, 2\right)=1+3 X_{2,3}(p)+X_{3,5}(p)+X_{8,17}(p) \\
& n\left(p^{6}, 2\right)=6+X_{15,31}(p) \\
& n\left(p^{7}, 2\right)=1+X_{2,3}(p)\left(3+X_{7,11}(p)\right)+X_{2,5}(p)\left(1+X_{6,13}(p)\right)+X_{2,17}(p) \\
& n\left(p^{8}, 2\right)=6+X_{5,7}(p)+X_{23,31}(p)+X_{63,127}(p) .
\end{aligned}
$$

Proof. Corollary 3.2 and its proof method yield the following reductions of $\operatorname{gcd}\left(p^{i}+1,2 p^{k-i}+1\right)$ for $i=1, \ldots, k$. The case $i=0$ is omitted, as $\operatorname{gcd}\left(p^{0}+1,2 p^{k}+1\right)=1$ always. A few more arithmetical reductions are also applied. For instance, the equality $\operatorname{gcd}\left(p^{2}+1,3\right)=1$ below follows from the fact that -1 is not a square mod 3 . This is one easy case of Proposition 5.3.

$$
\begin{aligned}
k & =1: \\
\operatorname{gcd}\left(p^{1}+1,2 p^{0}+1\right) & =\operatorname{gcd}(p+1,3) \\
k & =2: \\
\operatorname{gcd}\left(p^{1}+1,2 p^{1}+1\right) & =\operatorname{gcd}(2 p+1,1)=1 \\
\operatorname{gcd}\left(p^{2}+1,2 p^{0}+1\right) & =\operatorname{gcd}\left(p^{2}+1,3\right)=1 \\
k & =3: \\
\operatorname{gcd}\left(p^{1}+1,2 p^{2}+1\right) & =\operatorname{gcd}(p+1,3) \\
\operatorname{gcd}\left(p^{2}+1,2 p^{1}+1\right) & =\operatorname{gcd}(2 p+1,5) \\
\operatorname{gcd}\left(p^{3}+1,2 p^{0}+1\right) & =\operatorname{gcd}\left(p^{3}+1,3\right)=\operatorname{gcd}(p+1,3) \\
k & =4: \\
\operatorname{gcd}\left(p^{1}+1,2 p^{3}+1\right) & =\operatorname{gcd}(p+1,1)=1 \\
\operatorname{gcd}\left(p^{2}+1,2 p^{2}+1\right) & =\operatorname{gcd}\left(2 p^{2}+1,1\right)=1 \\
\operatorname{gcd}\left(p^{3}+1,2 p^{1}+1\right) & =\operatorname{gcd}(2 p+1,7) \\
\operatorname{gcd}\left(p^{4}+1,2 p^{0}+1\right) & =\operatorname{gcd}\left(p^{4}+1,3\right)=1
\end{aligned}
$$

$$
\begin{aligned}
& k=5: \\
& \operatorname{gcd}\left(p^{1}+1,2 p^{4}+1\right)=\operatorname{gcd}(p+1,3) \\
& \operatorname{gcd}\left(p^{2}+1,2 p^{3}+1\right)=\operatorname{gcd}(2 p-1,5) \\
& \operatorname{gcd}\left(p^{3}+1,2 p^{2}+1\right)=\operatorname{gcd}(p-2,9) \\
& \operatorname{gcd}\left(p^{4}+1,2 p^{1}+1\right)=\operatorname{gcd}(2 p+1,17) \\
& \operatorname{gcd}\left(p^{5}+1,2 p^{0}+1\right)=\operatorname{gcd}\left(p^{5}+1,3\right)=\operatorname{gcd}(p+1,3) \\
& k=6: \\
& \operatorname{gcd}\left(p^{1}+1,2 p^{5}+1\right)=\operatorname{gcd}(p+1,1)=1 \\
& \operatorname{gcd}\left(p^{2}+1,2 p^{4}+1\right)=\operatorname{gcd}\left(p^{2}+1,3\right)=1 \\
& \operatorname{gcd}\left(p^{3}+1,2 p^{3}+1\right)=\operatorname{gcd}\left(2 p^{3}+1,1\right)=1 \\
& \operatorname{gcd}\left(p^{4}+1,2 p^{2}+1\right)=\operatorname{gcd}\left(2 p^{2}+1,5\right)=1 \\
& \operatorname{gcd}\left(p^{5}+1,2 p^{1}+1\right)=\operatorname{gcd}(2 p+1,31) \\
& \operatorname{gcd}\left(p^{6}+1,2 p^{0}+1\right)=\operatorname{gcd}\left(p^{6}+1,3\right)=1 \\
& k=7: \\
& \operatorname{gcd}\left(p^{1}+1,2 p^{6}+1\right)=\operatorname{gcd}(p+1,3) \\
& \operatorname{gcd}\left(p^{2}+1,2 p^{5}+1\right)=\operatorname{gcd}(2 p+1,5) \\
& \operatorname{gcd}\left(p^{3}+1,2 p^{4}+1\right)=\operatorname{gcd}(2 p-1,9) \\
& \operatorname{gcd}\left(p^{4}+1,2 p^{3}+1\right)=\operatorname{gcd}(p-2,17) \\
& \operatorname{gcd}\left(p^{5}+1,2 p^{2}+1\right)=\operatorname{gcd}(p+4,33) \\
& \operatorname{gcd}\left(p^{6}+1,2 p^{1}+1\right)=\operatorname{gcd}(2 p+1,65) \\
& \operatorname{gcd}\left(p^{7}+1,2 p^{0}+1\right)=\operatorname{gcd}\left(p^{7}+1,3\right)=\operatorname{gcd}(p+1,3) \\
& k=8: \\
& \operatorname{gcd}\left(p^{1}+1,2 p^{7}+1\right)=\operatorname{gcd}(p+1,1)=1 \\
& \operatorname{gcd}\left(p^{2}+1,2 p^{6}+1\right)=\operatorname{gcd}\left(p^{2}+1,1\right)=1 \\
& \operatorname{gcd}\left(p^{3}+1,2 p^{5}+1\right)=\operatorname{gcd}(p+2,7) \\
& \operatorname{gcd}\left(p^{4}+1,2 p^{4}+1\right)=\operatorname{gcd}\left(2 p^{4}+1,1\right)=1 \\
& \operatorname{gcd}\left(p^{5}+1,2 p^{3}+1\right)=\operatorname{gcd}(4 p+1,31) \\
& \operatorname{gcd}\left(p^{6}+1,2 p^{2}+1\right)=\operatorname{gcd}\left(2 p^{2}+1,7\right)=1 \\
& \operatorname{gcd}\left(p^{7}+1,2 p^{1}+1\right)=\operatorname{gcd}(2 p+1,127) \\
& \operatorname{gcd}\left(p^{8}+1,2 p^{0}+1\right)=\operatorname{gcd}\left(p^{8}+1,3\right)=1 .
\end{aligned}
$$

As in the case $k=9$, the claimed formulas follow by reading these tables sequentially and using properties of the functions $X_{a, q}$ from Section 5 .

In particular, these formulas confirm that for $k=1, \ldots, 8$, the value of $n\left(p^{k}, 2\right)$ at an odd prime $p$ is determined by the class of $p$ modulo $3,1,3 \cdot 5$, $7,3 \cdot 5 \cdot 17,31,3 \cdot 5 \cdot 11 \cdot 13 \cdot 17$ and $7 \cdot 31 \cdot 127$, respectively.

## 8 A question

We shall conclude this paper with an open question. On the one hand, we have obtained explicit formulas for $n\left(p^{k}, 2\right)$ in all cases $k \leq 10$. On the other hand, we know from [3] that no such formula can be expected in the case $k=4097$, at least as long as the prime factors of the 12th Fermat number $2^{2^{22}}+1$ remain unknown. Well then, what happens in the intermediate range $11 \leq k \leq 4096$ ? Are there fundamental obstacles which would prevent us to obtain exact formulas for $n\left(p^{k}, 2\right)$ all the way up to $k=4096$ ?
