10 Spatial Inequalities
11

12
13 Abstract. During the 1990s Finland's economy went from deep recession to becoming among
14 the most innovative and competitive within merely a decade. Economic recovery driven by the
15 surge of ICT-related industries with the active support of the higher education system gave way
16 also to growing inequalities among regions, especially within graduate workers. The paper
17 elaborates an empirical analysis of the returns to education of a cohort entering the labour
18 force between 1995 and 2005; our objective is to capture the extent of spatial and occupational
19 determinants on income distribution as Finland slid from its most troubled to most prosperous
20 times.

36 INTRODUCTION

37

38 The role of universities in the process of local and regional economic development has
39 attracted considerable interest among scholars and policy makers (Varga, 2000; Boucher et al,
40 2003). This strand of analysis initially centred on income-expenditure-employment effects (see
41 e.g. Brownrigg, 1973; Bleaney et al, 1992) has embraced new directions as universities'
42 capacity of incubators for new basic research and loci for learning gradually gained due
43 recognition (Malecki, 1985; Varga, 1998). Empirical evidence also indicates that the presence
44 of a skilled labour force fosters local development, either through productivity effects due to
45 local knowledge spillovers and human capital externalities (Howells, 1986; Glaeser et al, 1992;
46 Westhead and Storey, 1995), by attracting private sector R&D and investments in high-tech
47 activities (Malecki, 1991; Saxenian, 1994; Almeida and Kogut, 1997) or by further encouraging
48
49

51
52
53
54
55
56
57
58
59
60

1
2
3 immigration or retention of highly skilled workers (Herzog et al., 1986; Beeson and
4
5 Montgomery, 1993; Faggian and McCann, 2009). The organization of local labour markets, in
6
7 turn, brings to bear upon each of the foretold dimensions by either stimulating or hampering the
8
9 mobility of and the access to pools of skilled workers (Andersson et al, 1990; Malecki and
10
11 Bradbury, 1992).
12
13

14
15 The transformations unleashed by widespread diffusion of Information and Communication
16
17 Technologies (ICTs) during the 1990s added an important dimension to the class of
18
19 phenomena just outlined. ICT-driven technical change has been observed to trigger major
20
21 inequalities across geographical areas as well as educational groups, especially among more
22
23 educated workers (see Eckstein and Nagypal, 2004 on the US and Martins and Pereira, 2004
24
25 for a cross-country analysis). The most credited argument ascribes the latter to the intrinsic
26
27 skill-biased nature of ICTs (Acemoglu 1998; Machin and van Reenen, 1998; Piva et al, 2005)
28
29 combined with the renowned tendency of hi-tech activities to concentrate in selected
30
31 geographical areas (Acemoglu and Angrist, 1999; Moretti, 2004a). It is remarkable however
32
33 that inequality has an autocatalytic nature whereby imperfect geographical mobility prevents
34
35 the equalization of graduate premia across regions while, at the same time, non-convex returns
36
37 to education favour retention of skilled workers by more innovative regions. As a result the
38
39 latter remain close to the technological frontier while the others drift away (Aghion and Howitt,
40
41 1998). Add to this that while wage premia could be reasonably expected to diminish in regions
42
43 with abundance of skilled workers, the existence of human capital spillovers (due to clustering
44
45 of high-tech activities) tends to counteract the conventional demand-supply dynamic and to
46
47 accrue extra returns to highly educated workers (Moretti, 2004a).
48
49
50
51
52
53
54
55

56 As these transformations undermine the explanatory power of traditional variables like
57
58 observable worker characteristics – educational attainment, age, experience, etc – (see Juhn et
59
60 al. 1993; Goldin and Katz, 2008; Vona and Consoli, 2009) empirical research has probed

1
2
3 several new options in the attempt to enrich the wage equation with variables such as innate
4 abilities (Card, 1994); differences in university quality (Brewer et al, 1999; Dale and Krueger,
5
6 2002); job-skill mismatches (Green and McIntosh, 2007); firm-specific effects (Dunne et al,
7
8 2004; Faggio et al, 2007); and geographical location (Moretti 2004a; Glaeser and Maré, 1994).
9
10
11

12
13 The present paper elaborates a cross-regional analysis of earning differentials in Finland with a
14
15 view to contribute this debate, specifically by connecting two areas of scholarly research: on
16
17 the one hand it looks at the relationship between universities and regional economic
18
19 development through the lenses of labour market dynamics while at the same time it adds a
20
21 'regional' perspective to the labour economics literature on earning inequality. The remarkable
22
23 rebound that followed the recession of the mid 1990s and the related emergence of novel
24
25 phenomena like spatial and income inequalities make the recent history of Finland especially
26
27 interesting for our purposes (Asplund, 2001; Kautto, 2003). The proposed analysis uses an
28
29 original dataset containing detailed individual information on a cohort of labour market entrants
30
31 and seeks to tackle the following questions: (1) What is the wage premium associated to a
32
33 perfect job-degree match? (2) How do agglomeration effects impact earning distribution? And
34
35 (3) to what extent do spatial distributions of workers' characteristics affect cross-regional
36
37 differences in the returns to qualifications and occupations? By addressing these, the paper will
38
39 add novel empirical evidence to a growing area of empirical research that so far has focused
40
41 exclusively on Anglo-Saxon countries (Böckerman and Maliranta, 2007).

53 FRAMEWORK FOR ANALYSIS

54

55
56 The recent history of Finland offers a compelling illustration of the turbulences that follow major
57
58 regime transitions such as the emergence of new Information and Communication
59
60

1
2
3 Technologies (ICTs). This section reviews concisely key milestones of the country's long-term
4 economic development and connects them with the outlined conceptual framework.

6
7

8
9 *The 1990s in Finland: bust to boom*

10
11 The process of industrialization in Finland follows a typical pattern with the creation of
12 manufacturing and processing activities in the mid-1950s and the progressive reconversion
13 towards services in the late 1970s. The combined pressures of the oil crisis and of growing
14 foreign competition in the late 1970s. The combined pressures of the oil crisis and of growing
15 foreign competition in the 1980s stimulated the emergence of novel high-tech activities to
16 reduce dependence on transportation and energy supplies (Ollikainen, 1997). In the early
17 1990s Finland entered the most severe recession of its recent history, a storm which over its 5-
18 year course brought the country to a halt with record unemployment of 18% in 1993 (Rouvinen
19 and Ylä-Anttila, 2003). At the root of this was the uncontrolled financial deregulation of the late
20 1980s implemented as a response to the difficulties caused by the collapse of trade with the
21 Soviet Union. The legislation however favoured the accumulation of unsustainable private debt
22 thus leading to a cascade of bankruptcies (Kiander, 2004a; Kiander, 2004b).

26
27
28
29
30
31
32
33
34
35
36
37

38
39 Less than a decade later Finland was set on a different course, enjoying renewed prosperity
40 and falling unemployment. In the following years the country became a global leader in the ICT
41 sectors with over 6000 specialised firms (Paija and Rouvinen, 2003) and a wealth of resources
42 for research accounting for more than 50% of national industrial R&D (Castells and Himanen,
43 2002; Ylä-Anttila, 2005).¹ Let us offer a synthetic account of the changes that Finland went
44 through the decade 1995-2005 with the aid of Table 1 and Map 1. Consistent with various
45 accounts of the recent history of Finland, the Table paints a picture in which Southern regions
46 like Uusimaa (home to Helsinki), Eastern Uusimaa and Pirkanmaa (home to Tampere and
47 Nokia headquarters) capture more migrants and enjoy overall higher levels of Gross Value
48 Added (GVA) per capita and of employment recovery. North Ostrobothnia – whose main city is

14
15

16 17 18 19 *Higher Education and Labour Markets*

20
21
22 Beneath the remarkable transformations that bolstered recovery stand two pillars – both central
23
24 to the remit of this paper: higher education and the labour markets (OECD, 2004). Consistent
25
26 with egalitarian principles after which the higher education system has been modelled, in
27
28 Finland no fees are levied on full-time students, the ratio of university per inhabitant is rather
29
30 high (21 universities and 31 polytechnics with total population around 5 million) and
31
32 subsistence grants are widely available (Usher and Cervenán, 2005). Two significant pieces of
33
34 legislation are worth mentioning: the creation of new Universities between the 1960s and 1970s
35
36 which facilitated access to higher education for residents of remote areas, and the upgrading of
37
38 Polytechnics degree in the late 1990s to meet the growing demand for higher vocational skills
39
40 (Schienstock, 2004). The statistics available seem to confirm the efficacy of these reforms
41
42 considering that between 2000 and 2007 entry rates into Finnish tertiary education were about
43
44 70%, and that in the same period graduation rates for first degree programs and postgraduate
45
46 qualification were respectively 47% and 2.1% - both significantly above the OECD average
47
48 (OECD, 2008). Also data on average graduation times and PISA tests scores speak to the high
49
50 quality of the educational system (Väljörvi, et al, 2002; OECD, 2005).
51
52
53
54
55
56

57
58 Finland's labour market is organized around the canons of a traditional Nordic welfare system
59
60 with high labour taxes, extensive social benefits, elevated trade union membership (currently

1
2
3 70%, of the labour force down from more than 80% in the 1990s) which all together underpin a
4
5 traditionally compressed wage structure (Nickell and Layard, 1999). Wage bargaining involves
6
7 centralized framework agreements between unions and employers on a fixed-term basis
8
9 followed by union-level bargains.ⁱⁱ Despite high women participation the pay gap is higher in
10
11 Finland compared to the OECD average, mostly due to self-selection into low-wage careers
12
13 like teaching (Vartiainen, 2002; Böckerman, 2006). Consistent with the broader international
14
15 trend, the expansion of ICT-related activities has altered substantially the wage structure in
16
17 Finland by spurring fragmentation of local labour markets and the emergence of earning
18
19 inequalities within high-skilled workers. In relation to this Böckerman and Maliranta (2007)
20
21 observe that in spite of the extent of these transformations, only a few empirical studies have
22
23 thus far accounted properly for the effects of these new characteristics in Finland's labour
24
25 market.
26
27
28
29
30

31 32 *Economic growth and rising regional inequalities*

33
34
35 The rebound of the late 1990s contributes to the widely-held perception of Finland as
36
37 successful knowledge-intensive society, and fuels debates about the 'Finnish model' or 'Finnish
38
39 miracle' (Castells and Himanen 2002; Schienstock 2004). To be sure Finland reaped the
40
41 opportunities of the nascent ICT industry more effectively and rapidly than other European
42
43 countries thanks to a mix of forward-looking industrial policies and public investments in higher-
44
45 education and R&D which stimulated and supported ICT-complementary clusters in
46
47 manufacturing and service sectors (OECD, 2004; Honkapohja and Koskela, 1999; Honkapohja
48
49 et al, 2008). Empirical evidence confirms also that the industrial revitalization of the 1990s was
50
51 the backdrop to a story that has arguably attracted less attention: the emergence of significant
52
53 inequalities across regions.
54
55
56
57
58
59
60

1
2
3 Like the canonical examples commonly offered in the literature (see e.g. Krugman, 1991;
4
5 Feldman and Audretsch, 1999), the growth of specialised innovation activities in Finland was
6
7 strongly localized in some areas. A large number of empirical studies contribute to portray the
8
9 following picture: as the Southern regions joined the nascent high-tech trajectory the bulk of
10
11 industries located in the Central and Northern areas remained anchored to declining activities
12
13 like paper, pulp and metal processing. Hanell et al (2002) present evidence of massive
14
15 migration towards Helsinki and the South at the peak of the crisis; Kautto (2003) reports
16
17 significant and growing divergences in capital income shares and average household incomes
18
19 after 1994; Kangasharju and Pekkala (2004) show remarkable differences in sectoral
20
21 expansion between fast- and low-growing regions, especially in the business service sectors
22
23 (with a gap of 4,5% over the period 1995-2000); Loikkanen et al (2005) identify divergent
24
25 patterns of capital deepening, with the Helsinki region ahead of the Southern regions (+20% in
26
27 the period 1996-2000) and even more of the Central and Northern areas (+40%); Loikkanen
28
29 and Lönnqvist (2007) confirm post-recovery imbalances in the patterns of investments and
30
31 migration in favour, again, of the Southern regions and Helsinki.
32
33
34
35
36
37
38

39 Common to all these studies is the acknowledgement of growing inequalities in both
40
41 unemployment and earnings distribution (OECD, 2001; Asplund, 2001; Böckerman, 2002;
42
43 Tervo, 2005; Neubauer et al., 2007). Böckerman and Maliranta (2007), for example, show the
44
45 contrast between job destruction in Eastern and Northern Finland and hi-tech driven job
46
47 creation rates in Helsinki and the Southern regions, the net effect of which is signified by
48
49 widening spreads of wage differentials. Other empirical studies by Uusitalo (1999), Kyyrä
50
51 (2000) and Asplund and Leijola (2005) indicate that, in spite of centralised wage bargaining and
52
53 tight labour market regulation, unexplained wage dispersion among graduates increased
54
55 substantially after the mid-1990s. These phenomena are ascribed to the concurrence of
56
57 various factors. Empirical evidence suggests statistical association between earning
58
59
60

1
2
3 inequalities and the concentration of highly educated workers in the nascent ICT clusters of the
4 South (Kyyra, 2000; Asplund and Leijola, 2005). Some authors argue that regulation impeded
5 the adaptations demanded by the changing industrial structure thus amplifying the impact of
6 job-skill mismatches and agglomeration effects which triggered within-group inequality among
7 highly educated workers (Asplund and Lilja, 2000; Kyyra, 2000). Uusitalo (2002) on the other
8 hand stresses that in the mid-1990s, when income inequality increased, industry-level
9 bargaining partially replaced central agreement. Yet other works emphasise the impact of the
10 dual income tax system introduced by the fiscal reform of 1993 which, according to Riihela et al
11 (2008), created strong incentives to shift labour income to capital income for individuals in the
12 highest marginal tax brackets. The common denominator across all these studies is that the
13 aftermath of the crisis in Finland was the backdrop to the fastest growth in income inequality
14 among the OECD countries (OECD 2008).

35 DATA AND DESCRIPTIVE ANALYSIS

36
37
38 This section proposes an analysis of the relation between individual characteristics and their
39 earnings. As discussed in the introductory section, this paper has three empirical goals. First, to
40 assess the wage premium associated to a perfect job-degree match; secondly, to evaluate the
41 impact of agglomeration effects on earnings' distribution; and, lastly, to capture the extent to
42 which differential distributions of workers' characteristics across regions affect returns to
43 qualifications and occupations. Let us provide a brief illustration of the database and of the
44 criteria that guided the construction of specific variables.
45
46
47
48
49
50
51
52
53
54

55 *The dataset and construction of main variables*

56
57
58 The data source is the Longitudinal Census of Statistics Finland containing information on 8787
59 individualsⁱⁱⁱ [4292 men (49%); 4495 women (51%)] collected by means of a two-step survey: in
60

1
2
3 1995, year of enrolment at a Finnish University, and in 2005. Individual information includes (for
4
5 1995) gender; high-school mark; university of enrolment; field of study; degree aiming at; (for
6
7 2005) degree accomplished (if any); region of residence; occupational status; and income.^{iv} It is
8
9 worth reiterating the cohort under analysis entered the labour force as the crisis levelled off and
10
11 Finland's economy started to enjoy a new phase of expansion. Focussing on this particular
12
13 group reduces the turmoil typically associated to a phase of profound recession.
14
15

16
17
18 A key feature of the proposed analysis is the construction of ad-hoc variables to capture
19
20 occupational and spatial determinants (see Blundell et al., 1997; Robinson, 1997; Dearden et
21
22 al., 2002). For what concerns the former we matched the occupational categories listed by
23
24 Statistics Finland with the International Standard Classification of Occupations (ISCO).^v
25
26 Furthermore we create a job-degree dummy variable by comparing occupation-specific
27
28 requirements listed in ISCO with the content of each degree (second digit of degree codes),
29
30 and assigning 1 in case of perfect match and 0 otherwise.^{vi} To assess the influence of spatial
31
32 agglomeration we use region-specific human capital calculated as the weighted average of
33
34 educational attainment of the residing population^{vii} and the share of post-graduates within the
35
36 population. Since the analysis focuses on a cohort of labour market entrants we also include
37
38 variables for degree of experience in the local labour market, namely: relocation after
39
40 completing studies (Relocate), change of degree or drop-out (Shift) and duration of formal
41
42 schooling weighted by expected length of study in the field chosen (Years of Education).
43
44
45
46
47
48

49 *Descriptive Analysis*

50
51
52 Table 2 presents descriptive statistics for our main variables of interest. More than 90% of
53
54 individuals in the sample are employed in 2005 with high average educational attainment –
55
56 about 70% holding a Master's Degree. Among the most preferred areas of study are Business
57
58 and Social Sciences (23%), first among women, followed by Engineering (18%), first among
59
60

1
2
3 men. For what concerns occupations, lower half of the Table, the largest share of individuals
4 are employed in Medium-Skill Jobs (20%)^{viii} followed by Teachers (18%) – the first choice
5 among women. Finally, the population divides almost equally between those who took
6 residence in Helsinki and those who live elsewhere in Finland – a slight majority of the latter
7 being women.
8
9

10 11 12 13 14 15 TABLE TWO ABOUT HERE 16

17
18 The descriptive statistics of Table 3 illustrate the spatial distribution of our sample broken down
19 in two groups depending on area of residence in 2005. Here we note immediately that the
20 capital city features overall higher levels of human capital (Upper part of the Table). Further,
21 37.4% of the observations relocate to Helsinki after graduation while 54.4% to other regions.
22
23 When combined with information on the field of study we observe that Helsinki residents are
24 mostly graduates in Business Studies (note the difference with other regions), Engineering and
25 to a smaller extent Humanities while other regions feature comparatively more graduates in
26 Medicine, Information Sciences and Humanities. The breakdown by occupations shows that
27 medium-skill jobs have the highest share in Helsinki – recall the data concern labour market
28 entrants – followed Teachers, Public Service Professionals, Legal and Business Professionals
29 and Scientists; consistent with the previous distributions the workforce of other regions has its
30 peak with Teachers (more than twice as in Helsinki) and relatively more Medical doctors.
31
32

33
34 The lower-intermediate part of Table 3 shows that postgraduates residing in Helsinki earn more
35 compared to other areas while the opposite holds for Graduates. The breakdown by occupation
36 indicates that Helsinki residents enjoy a higher wage premium when employed as Managers
37 (+8%), Scientists (+11%), Legal and Business professionals (+20%), Medium-skill (+13%) and
38 low-skill workers (+15%). Looking at other regions, Teachers (+7%), Engineers (+1%) and
39 Medical Doctors (+2%) earn more compared to their peers in the capital city. The bottom of the
40 table shows that the distribution of individuals with perfect job-skill match does not displaying

9 TABLE THREE ABOUT HERE

10
11 Let us now turn to the empirical analysis of earnings distribution.
12
13

14 15 ECONOMETRIC ANALYSIS OF EARNINGS

16
17 This section presents an empirical analysis of the determinants of earnings (Log Monthly
18
19 Wage) among a cohort of individuals who enrolled at any of the Finnish Universities in 1995.
20
21

22 The basic wage model, a Mincer-type of regression, is progressively enriched by the addition of
23
24 controls and variables that capture job-skill match and agglomeration effects. Variables are
25
26 listed in the Appendix.
27
28

29 30 *OLS Estimates*

31
32 The basic model includes standard controls for individual characteristics^x and specific
33
34 occupation dummies. The first OLS regression (column 1, Table 4) yields positive and
35
36 significant returns to high qualifications with respect to university dropouts, ranging from 46%
37
38 for Master's degree to 68% for PhDs'.^x The estimated coefficients also indicate that Medical
39
40 doctors, Engineers, Legal professionals and Scientists enjoy relatively higher returns compared
41
42 to other occupations.^{xi} When dummy variables for Helsinki residence and job-skill match are
43
44 included (column 2) the estimates show that the former yields an extra premium of 6%, and
45
46 that being employed in a job that matches perfectly the educational background carries a 4%
47
48 higher monthly wage. Note that the Helsinki dummy is a first, albeit crude, indication of the
49
50 effect of location on wages that will be progressively refined.
51
52
53
54
55

56
57 The indications provided by the baseline model remain robust when 'Field of Study' is
58
59 controlled for (column 3). As might be expected, having a degree increases the wage
60
61 compared to individuals with no degree especially for Engineering, Business Studies and

Medicine degrees. The finding that returns to formal education are lower compared to the previous model resonates with studies showing that the type of specialisation acquired with a degree explains a large part of the educational premia (Asplund, 1993; Asplund and Leijola, 2005). In particular the higher coefficients for Engineering and Business Services studies compared to ICT-related degrees – such as Information Sciences – resonate with studies indicating that the wage premium of generic-to-specific computer skills had decreased during the late 1990s (Asplund, 1997). In fact, regional employment shares in private services are highly correlated with our human capital index and hence with wages.^{xii} In the enriched model coefficients for the job-skill match and the Helsinki dummies remain statistically significant.

TABLE FOUR ABOUT HERE

As anticipated earlier the Helsinki dummy captures in rather crude fashion the influence of spatial factors on earnings. As a matter of fact different issues are at stake when it comes to assess the impact of local characteristics on earnings. In general it is plausible that skilled workers sort themselves into metropolitan areas with high level of human capital (Glaeser and Maré, 2001); in such cases an observed positive correlation between wage levels and graduate share is ascribed to unobservable individual factors, like innate ability positively correlated with the skill of the workforce, rather than productivity differentials. On the other hand the positive association between earning levels and the share of graduates living in large cities may depend on unobservable characteristics of the location, such as the industrial mix: in this case the wage levels cause the increase of the skilled workers, not the other way round (Moretti, 2004a).

While our data do not allow a proper test of these concurrent hypotheses, agglomeration effects can be captured by taking the weighted average of educational attainment among residents as index of regional Human Capital (column 4). An increase of one standard deviation in the human capital in the region yields a remarkable 75% extra premium.^{xiii} Further, we focus on the effect of regional human capital and check whether the latter benefits more –

1
2
3 e.g. those with Master or more – or less skilled workers – e.g. Degree or less. Under the
4
5 traditional framework an increase of aggregate human capital bears two effects on local labor
6
7 markets. If there is imperfect substitution between educated and uneducated workers, an
8
9 increase in the number of educated workers will lower the wage of the educated and raise the
10
11 wage of uneducated workers. On the other hand, human capital spillovers can increase
12
13 productivity and the wage levels of both groups. In the estimates of columns (5) and (6) the
14
15 Human Capital coefficient is large and significant for both but twice as large for low-skilled
16
17 individuals. This suggests that human capital spillovers benefit relatively more those with lower
18
19 qualifications (less than post-graduate).
20
21
22
23
24

25 To further investigate location effects we consider interactions between being postgraduate and
26
27 region of residence in 2005. This interaction effect is included to check whether substantial
28
29 differences emerge in the returns to postgraduate qualifications across regions. Different from
30
31 previous studies employing a similar methodology (e.g. Moretti 2004b) the fine-grained
32
33 information contained in our dataset allows focussing on regional differences in returns to
34
35 postgraduate degrees. Note that in our sample of highly qualified workers a postgraduate
36
37 qualification is the characteristic that explains the greatest fraction of earning premium. The
38
39 coefficients for individual regions in column (1) (upper part of Table 5), for groups of regions by
40
41 GDP-per capita (column 2, intermediate part of Table) and by Levels of Human Capital (column
42
43 3, lower part of Table) all confirm that residing in Helsinki accrues a higher wage premium to
44
45 postgraduates.^{xiv}
46
47
48
49
50

51 TABLE FIVE ABOUT HERE
52
53

54 Overall these findings resonate with various accounts of the post-recession gap between fast-
55
56 growing regions located in the South of Finland and the remaining regions. At the onset of the
57
58 high-tech boom the uneven distribution of ICT-specific knowledge accrued early users an extra
59
60 wage premium. However as the technology entered a mature phase and the range of GPT-

1
2
3 related applications expanded, the demand for skills shifted towards those that match emergent
4 activities like Business Services, especially in Helsinki. This is also confirmed by evidence on
5
6 the higher wage premium commanded by postgraduates specialised in Engineering and
7
8 Business Science compared to those possessing narrow computing skills (see Asplund, 1997).
9
10 It is important to emphasise that such a process entails significant capacity in knowledge
11
12 systematization and adaptation of training to changing job content (Autor et al, 2003; Goldin
13
14 and Katz, 2008; Vona and Consoli, 2009; Consoli and Elche-Hortelano, 2010). In the case
15
16 under observation the regions that had joined early the party of hi-tech development managed
17
18 stay close to the frontier owing to the autocatalytic effects of high concentration of human
19
20 capital discussed earlier in the paper.
21
22
23
24
25
26

27 Let us now take a final step and check whether Finnish macro-regions, grouped by intensity of
28
29 human capital, respond to different models generating wage differentials across skill and
30
31 occupational groups. This exercise is particularly important in view of the wage policies
32
33 adopted in Finland to the effect of ensuring availability of certain professionals in remote
34
35 Northern areas. Moreover compositional effects such as differences in the regional
36
37 endowments of other individual controls can be relevant not only for human capital as well as
38
39 for managers or high skilled professionals. To this end we use that Oaxaca-Blinder (Blinder,
40
41 1973; Oaxaca, 1973) decomposition to check the extent to which regional differences explain
42
43 differences in returns to individual characteristics or differences in the endowments of these
44
45 characteristics (Table 6).^{xv} This technique, which was originally employed to decompose the
46
47 male-female wage differentials, is applied here to capture the regional wage gap in terms of (i)
48
49 a compositional effect due to cross-regional differences in individual characteristics that have a
50
51 positive effect on earnings; (ii) a price-component associated to different returns to
52
53 characteristics in each region; and (iii) an interaction term. This exercise allows disentangling
54
55 the sources of regional wage gap.
56
57
58
59
60

TABLE SIX ABOUT HERE

Taking Helsinki as the reference region for pair-wise comparison, predicted wages are always higher in Helsinki with respect to the other three macro-areas. With respect to other macro-areas, an important fraction of this gap is explained by a larger endowment of highly paid occupations, such as scientists and business professionals. However, the total endowment effect yields a penalty for residing in Helsinki –especially compared to middle- and low-human capital regions. This can be ascribed to the relatively smaller fraction of teachers and civil servants working in the capital area. To a lesser extent a negative endowment effect for engineers signals scarcity of these qualifications in the capital region.

Returns to characteristics that positively affect earnings are generally higher in Helsinki and explain more than 2/3 of the wage difference with the high-human capital macro-region.

Looking at this effect in detail, postgraduate workers receive significantly higher premia when employed there. By contrast, teachers, civil servants and, to a minor extent, doctors and engineers command lower wages. These patterns emerge with greater intensity among fast growing regions, e.g. Oulu, where also returns to being employed in medium-skill job are significantly larger compared to the capital area (comparison 2).

The large and positive interaction effect here is mostly due to Medical doctors and especially Teachers since both groups are less represented and less paid in Helsinki compared to other regions. These results resonate with the policy actions aimed at discouraging out-migration from Northern regions, especially among public sector professionals (see Kouvonen and Katainen, 2004).^{xvi} Similar rewards are also available to engineers and probably associated to the presence of Nokia and other high-tech firms in North Ostrobothnia (home to Oulu and hi-tech research facilities) and Pirkanmaa (home to Nokia headquarters).

CONCLUSIONS

Finland's recent history has a lot to contribute to the scholarly debate on both regional economic development and income inequality. Within merely a decade the country weathered a deep recession to become a central actor in the global knowledge economy thanks to the impressive expansion of ICT-related activities. In turn, the associated structural changes elicited far-reaching effects on the economic and social structure of the country. The empirical evidence unanimously indicates that the Southern regions of Finland played an active role in the development of high-tech sectors early on while other areas of the country remained behind. This process, combined with other events, gave way to persistent cross-regional differences in terms of migration flows, productivity, unemployment and income distribution.

Using a novel dataset containing individual information over the period 1995-2005 we show the impact of educational attainment, agglomeration and skill-job match on the wage premium. In so doing the paper contributes various areas of scholarly research. Direct observation of the impact of job-skill mismatches and agglomeration effects, both emblematic symptoms of radical technological change, enriches the existing debate on earning inequality. The finer disaggregation of educational levels adds to previous literature by showing the additional returns accrued by postgraduate degrees and are substantially higher in developed regions, closer to the technological frontier. Our empirical results also confirm the impact of local human capital on earnings, especially for less skilled workers. Finally, the paper captures novel important insights on the importance of job-skill mismatch in explaining an important fraction of the educational premium.

At this point it is important to emphasize some limitations of the current study. First, the data that are available to us contain information on one cohort only, which obviously precludes an appreciation of the inter-temporal aspects of the dynamics analysed here. We are seeking to acquire additional data to disentangle the long-term characteristics of spatial agglomeration

1
2
3 and to investigate the extent to which the expansion of higher education has affected
4
5 intergenerational mobility in Finland. Yet another limitation concerns the lack of information on
6
7 the sectoral dimension of regions in the data. Before concluding it is worth stressing that the
8
9 present paper invites reflections on what empirical studies on continental Europe might bring to
10
11 the debate on the relation between technological change, education and income distribution, a
12
13 debate so far limited to Anglo-Saxon countries. The inherent diversity of regions within the
14
15 European Union is perhaps an excellent opportunity to extend the debate further, and we hope
16
17 that this paper is but the first step in that promising direction.

Data Treatment

The original sample consists of 9713 observations. Observations with missing earnings were dropped after having checked that missing earnings were not correlated with individual characteristics (i.e. gender. education attainment). Observations with missing earnings also missed working months: when we had data on earnings we imputed the average number of working months of the income class to which the individual belongs. We excluded from the final sample 146 individuals with missing working months and zero earnings. For observations with 'zero' value for working months we assigned a fictitious 0.1 whereas we dropped those with positive income since working is not their main source of earning and they can distort our model specification. Moreover we created a specific category for those with missing job code. Finally we dropped observations where information on degrees was missing. The remaining sample was further reduced to 8787 after excluding earners above the 99% percentile.

i See also Daveri and Silva (2004) for a critical view of the impact of ICTs on economic expansion in Finland, as well as the critique towards the social model that emerged in association with ICT-related growth by Pelkonen (2005) and Häyriinen-Alestalo et al. (2005).

ii Böckerman and Maliranta (2007) attribute high union participation to the fact that membership fees are tax deductible and to the involvement of the unions in the administration of unemployment insurance benefits.

iii See data treatment in Appendix.

iv This representative sample accounts for 52% of all university entrants in 1995. See the appendix for details on data cleaning and treatment of missing data.

v <http://www.ilo.org/public/english/bureau/stat/isco/index.htm>

vi This method is appropriate in a context like Finland where educational programs have a manifest occupation-specific content (Asplund, 1993). Note that this measure of job-skill mismatch includes both over-educated workers as well as cases of perfect match. In a companion paper we analyse over-educated and perfect match separately and observe that results remain robust. For those observations listed as 'not employed' it is not possible to check for a mismatch we assign 1 if the educational attainment is higher than the minimum level and 0 otherwise. In future research we seek to disentangle the effect of over-(under-)education from that of qualitative match.

vii The index is obtained by assigning to the human capital of those with secondary education $\frac{1}{2}$ of the human capital of the graduate, whereas we weight 1.5 the human capital of the postgraduates and 0 the human capital of those with less than secondary education. Similar arbitrary scores are widely used in the literature (e.g. Katz and Murphy, 1992) as they stress more than, for example, the average of the years of education required to attend a degree the

difference associated to the attainment of a high qualification. Our results remain robust to different human capital indexes such as the weighted years of education.

viii Medium-High Skill Occupations include specialised professionals, like Matrons and ward sisters, Archivists, Librarians, as well as generic ones like Science associate professionals and technicians, Computer associate professionals, Instructors, Entertainment and sports professionals. Low-skill occupations include trades workers, painters, cleaners, metal workers, machinery mechanics and fitters, plant operators, machine operators, assemblers, drivers, caretakers, labourers and handlers.

ix Gender, age, High-School mark, proxy for tenure.

x The percentage values are calculated from the antilog of parameter estimates $(e^b - 1) * 100$, where b is the estimated coefficient in the log earnings equation. For further details see Gujrati (1988).

xi This result is sensitive to how occupations are grouped, indeed in an alternative specification with broader occupational classes (e.g. Managers, all Professionals, Medium-Skill Jobs, etc) the wage gap between professionals and medium skill jobs disappears. The finer specification employed here captures important details, namely the lower wage premium of some professional occupations compared to that of medium-skilled jobs. These alternative estimates are available by the authors. Note that the category 'medium skilled jobs' consists essentially of associate professionals.

xii We tried to control for the industry composition of regions to check the effect on wages independent from that captured by the skill composition of the labour force, i.e. our human capital index. Using Statistics Finland data we regressed a variation of the baseline model (Table 4, column 1) that includes employment shares for public sector, private services and high-medium tech manufacturing. This, however, did not affect our results. On one hand, the

share of employees in private services is highly correlated with the human capital index; on the other hand, the data available to us do not capture high-tech manufacturing and the ICT sector in each region in detail (like e.g. Böckerman, 2002). These additional regressions are available upon request. As for the share of private services, it is very likely that also the sectoral employment in high tech manufacturing is highly correlated with variables included in the regressions, such as the human capital index, the share of top occupations and that of postgraduates. We suspect that even if more refined information were available, our dataset would not be appropriate to disentangle the sectoral-composition effect from the agglomeration effect. A correct identification would require time-varying information on the evolution of these effects. We thank an anonymous referee for pointing out this issue.

xiii The regression with an alternative measure of Human Capital (share of Postgraduates in a region) produces broadly similar results. Estimates are available by the authors.

xiv The Åland Islands is an autonomous, Swedish-speaking archipelago in the Baltic Sea. It is the smallest region of Finland, with a population share of just 0.50%.

xv This methodology is not as robust as it would be for comparing groups that are purely exogenous, like male and female, but can nevertheless elucidate broader differences in local labour markets.

xvi Looking at medical doctors, Kouvonen and Katainen (2004) and Ruskoaho (2008) find that the wage premium for residents in areas where there is no faculty of medicine is higher, due to the local paucity of physicians. A recent report for the Finnish Ministry of Economic Affairs (2008) resonates with these results and emphasises the resistance of medical doctors and teachers to relocate in North Finland due to the geography and the climate of the areas.
