## Abstract

We discuss contemporaneous aggregation of independent copies of a triangular array of random-coefficient AR(1) processes with i.i.d. innovations belonging to the domain of attraction of an infinitely divisible law  $W$ . The limiting aggregated process is shown to exist, under general assumptions on  $W$  and the mixing distribution, and is represented as a mixed infinitely divisible moving-average  $\{\mathfrak{X}(t)\}$  in (1.4). Partial sums process of  $\{\mathfrak{X}(t)\}$  is discussed under the assumption  $EW^2 < \infty$  and a mixing density regularly varying at the “unit root”  $x = 1$  with exponent  $\beta > 0$ . We show that the above partial sums process may exhibit four different limit behaviors depending on  $\beta$  and the Lévy triplet of  $W$ . Finally, we study the disaggregation problem for  $\{\mathfrak{X}(t)\}$  in spirit of Leipus et al. (2006) and obtain the weak consistency of the corresponding estimator of  $\phi(x)$  in a suitable  $L_2$ -space.

*Keywords:* Aggregation; random-coefficient AR(1) process; triangular array; infinitely divisible distribution; partial sums process; long memory; disaggregation

## 1 Introduction

The present paper discusses contemporaneous aggregation of  $N$  independent copies

$$X_i^{(N)}(t) = a_i X_i^{(N)}(t-1) + \varepsilon_i^{(N)}(t), \quad t \in \mathbb{Z}, \quad i = 1, 2, \dots, N \quad (1.1)$$

of random-coefficient AR(1) process  $X^{(N)}(t) = aX^{(N)}(t-1) + \varepsilon^{(N)}(t)$ ,  $t \in \mathbb{Z}$ , where  $\{\varepsilon^{(N)}(t), t \in \mathbb{Z}\}$ ,  $N = 1, 2, \dots$  is a triangular array of i.i.d. random variables in the domain of attraction of an infinitely divisible law  $W$ :

$$\sum_{t=1}^N \varepsilon^{(N)}(t) \rightarrow_d W \quad (1.2)$$

and where  $a$  is a r.v., independent of  $\{\varepsilon^{(N)}(t), t \in \mathbb{Z}\}$  and satisfying  $0 \leq a < 1$  almost surely (a.s.). The limit aggregated process  $\{\mathfrak{X}(t), t \in \mathbb{Z}\}$  is defined as the limit in distribution:

$$\sum_{i=1}^N X_i^{(N)}(t) \rightarrow_{\text{fdd}} \mathfrak{X}(t). \quad (1.3)$$

Here and below,  $\rightarrow_d$  and  $\rightarrow_{\text{fdd}}$  denote the weak convergence of distributions and finite-dimensional distributions, respectively. A particular case of (1.1)-(1.3) corresponding to  $\varepsilon^{(N)}(t) = N^{-1/2}\zeta(t)$ , where  $\{\zeta(t), t \in \mathbb{Z}\}$

are i.i.d. r.v.'s with zero mean and finite variance, leads to the classical aggregation scheme of Robinson (1978), Granger (1980) and a Gaussian limit process  $\{\mathfrak{X}(t)\}$ . See also Gonçalves and Gouriéroux (1988), Zaffaroni (2004), Oppenheim and Viano (2004), Celov et al. (2007), Beran et al. (2010) on aggregation of more general time series models with finite variance. Puplinskaitė and Surgailis (2009, 2010) discussed aggregation of random-coefficient AR(1) processes with infinite variance and innovations  $\varepsilon^{(N)}(t) = N^{-1/\alpha}\zeta(t)$ , where  $\{\zeta(t), t \in \mathbb{Z}\}$  are i.i.d. r.v.'s in the domain of attraction of  $\alpha$ -stable law  $W$ ,  $0 < \alpha < 2$ . Aggregation and disaggregation of autoregressive random fields was discussed in Lavancier (2005, 2011), Lavancier et al. (2012), Puplinskaitė and Surgailis (2012), Leonenko et al. (2013).

The present paper discusses the existence and properties of the limit process  $\{\mathfrak{X}(t)\}$  in the general triangular aggregation scheme (1.1)-(1.3). Let us describe our main results. Theorem 2.6 (Sec. 2) says that under condition (1.2) and some mild additional conditions, the limit process in (1.3) exists and is written as a stochastic integral

$$\mathfrak{X}(t) := \sum_{s \leq t} \int_{[0,1)} x^{t-s} M_s(dx), \quad t \in \mathbb{Z}, \quad (1.4)$$

where  $\{M_s, s \in \mathbb{Z}\}$  are i.i.d. copies of an infinitely divisible (ID) random measure  $M$  on  $[0, 1)$  with control measure  $\Phi(dx) := P(a \in dx)$  and Lévy characteristics  $(\mu, \sigma, \pi)$  the same as of r.v.  $W$  ( $M \sim W$ ) in (1.2), i.e., for any Borel set  $A \subset [0, 1)$

$$\mathbb{E}e^{i\theta M(A)} = e^{\Phi(A)V(\theta)}, \quad \theta \in \mathbb{R}. \quad (1.5)$$

Here and in the sequel,  $V(\theta)$  denotes the log-characteristic function of r.v.  $W$ :

$$V(\theta) := \log \mathbb{E}e^{i\theta W} = \int_{\mathbb{R}} (e^{i\theta y} - 1 - i\theta y \mathbf{1}(|y| \leq 1)) \pi(dy) - \frac{1}{2} \theta^2 \sigma^2 + i\theta \mu, \quad (1.6)$$

where  $\mu \in \mathbb{R}$ ,  $\sigma \geq 0$  and  $\pi$  is a Lévy measure (see sec. 2 for details). In the particular case when  $W$  is  $\alpha$ -stable,  $0 < \alpha \leq 2$ , Theorem 2.6 agrees with Puplinskaitė and Surgailis (2010, Thm. 2.1). We note that the process  $\{\mathfrak{X}(t)\}$  in (1.4) is stationary, ergodic and has ID finite-dimensional distributions. According to the terminology in Rajput and Rosinski (1989), (1.4) is called a *mixed ID moving-average*.

Section 3 discusses partial sums limits and long memory properties of the aggregated process  $\{\mathfrak{X}(t)\}$  in (1.4) under the assumption that the mixing distribution  $\Phi$  has a probability density  $\phi$  varying regularly at  $x = 1$  with exponent  $\beta > 0$ :

$$\phi(x) \sim C(1-x)^\beta, \quad x \rightarrow 1 \quad (1.7)$$

for some  $C > 0$ . (1.7) is similar to the assumptions on the mixing distribution in Granger (1980), Zaffaroni (2004) and other papers. In the finite variance case  $\sigma_W^2 := \text{Var}(W) < \infty$  the aggregated process in (1.4) is covariance stationary provided  $\mathbb{E}(1-a^2)^{-1} < \infty$ , with covariance

$$r(t) := \text{Cov}(\mathfrak{X}(t), \mathfrak{X}(0)) = \sigma_W^2 \mathbb{E} \left[ \sum_{s \leq 0} a^{t-s} a^{-s} \right] = \sigma_W^2 \mathbb{E} \left[ \frac{a^t}{1-a^2} \right] \quad (1.8)$$

depending on  $\sigma_W^2$  and the mixing distribution only. It is well-known that for  $0 < \beta < 1$  (1.7) implies that  $r(t) \sim C_1 t^{-\beta}$  ( $t \rightarrow \infty$ ) with some  $C_1 > 0$ , in other words, the aggregated process  $\{\mathfrak{X}(t)\}$  has nonsummable covariances  $\sum_{t \in \mathbb{Z}} |r(t)| = \infty$ , or *covariance long memory*.

Long memory is often characterized by the limit behavior of partial sums. According to Cox (1984), a stationary process  $\{Y_t, t \in \mathbb{Z}\}$  is said to have *distributional long memory* if there exist some constants

$A_n \rightarrow \infty$  ( $n \rightarrow \infty$ ) and  $B_n$  and a (nontrivial) stochastic process  $\{J(\tau), \tau \geq 0\}$  with dependent increments such that

$$A_n^{-1} \sum_{t=1}^{[n\tau]} (Y_t - B_n) \xrightarrow{\text{fdd}} J(\tau). \quad (1.9)$$

In the case when  $\{J(\tau)\}$  in (1.9) has independent increments, the corresponding process  $\{Y_t, t \in \mathbb{Z}\}$  is said to have *distributional short memory*.

The main result of Sec. 3 is Theorem 3.1 which shows that under conditions (1.7) and  $EW^2 < \infty$ , partial sums of the aggregated  $\{\mathfrak{X}(t)\}$  in (1.4) may exhibit four different limit behaviors, depending on parameters  $\beta, \sigma$  and the behavior of the Lévy measure  $\pi$  at the origin. Write  $W \sim ID_2(\sigma, \pi)$  if  $EW = 0$ ,  $EW^2 = \sigma^2 + \int_{\mathbb{R}} x^2 \pi(dx) < \infty$ , in which case  $V(\theta)$  of (1.6) can be written as

$$V(\theta) = \int_{\mathbb{R}} (e^{i\theta y} - 1 - i\theta y) \pi(dy) - \frac{1}{2} \theta^2 \sigma^2. \quad (1.10)$$

The Lévy measure  $\pi$  is completely determined by two nonincreasing functions  $\Pi^+(x) := \pi(\{u > x\})$ ,  $\Pi^-(x) := \pi(\{u \leq -x\})$ ,  $x > 0$  on  $\mathbb{R}_+ = (0, \infty)$ . Assume that there exist  $\alpha > 0$  and  $c^\pm \geq 0$ ,  $c^+ + c^- > 0$  such that

$$\lim_{x \rightarrow 0} x^\alpha \Pi^+(x) = c^+, \quad \lim_{x \rightarrow 0} x^\alpha \Pi^-(x) = c^-. \quad (1.11)$$

Under these assumptions, the four limit behaviors of  $S_n(\tau) := \sum_{t=1}^{[n\tau]} \mathfrak{X}(t)$  correspond to the following parameter regions:

- (i)  $0 < \beta < 1$ ,  $\sigma > 0$ ,
- (ii)  $0 < \beta < 1$ ,  $\sigma = 0$ ,  $1 + \beta < \alpha < 2$ ,
- (iii)  $0 < \beta < 1$ ,  $\sigma = 0$ ,  $0 < \alpha < 1 + \beta$ ,
- (iv)  $\beta > 1$ .

According to Theorem 3.1, the limit process of  $\{S_n(\tau)\}$ , in the sense of (1.9) with  $B_n = 0$  and suitably growing  $A_n$  in respective cases (i) - (iv) is a

- (i) fractional Brownian motion with parameter  $H = 1 - (\beta/2)$ ,
- (ii)  $\alpha$ -stable self-similar process  $\Lambda_{\alpha, \beta}$  with dependent increments and self-similarity parameter  $H = 1 - (\beta/\alpha)$ , defined in (3.2) below,
- (iii)  $(1 + \beta)$ -stable Lévy process with independent increments,
- (iv) Brownian motion.

See Theorem 3.1 for precise formulations. Accordingly, the process  $\{\mathfrak{X}(t)\}$  in (1.4) has distributional long memory in cases (i) and (ii) and distributional short memory in case (iii). At the same time,  $\{\mathfrak{X}(t)\}$  has covariance long memory in all three cases (i)-(iii). Case (iv) corresponds to distributional and covariance short memory. As  $\alpha$  increases from 0 to 2, the Lévy measure in (1.11) increases its “mass” near the origin, the limiting case  $\alpha = 2$  corresponding to  $\sigma > 0$  or a positive “mass” at 0. We see from (i)-(ii) that distributional long memory is related to  $\alpha$  being large enough, or small jumps of the random measure  $M$  having sufficient high intensity. Note that the critical exponent  $\alpha = 1 + \beta$  separating the long and short memory “regimes” in

(ii) and (iii) decreases with  $\beta$ , which is quite natural since smaller  $\beta$  means the mixing distribution putting more weight near the unit root  $a = 1$ .

Since aggregation leads to a natural loss of information about aggregated “micro” series, an important statistical problem arises to recover the lost information from the observed sample of the aggregated process. In the context of the AR(1) aggregation scheme (1.1)-(1.3) this leads to the so-called the disaggregation problem, or reconstruction of the mixing density  $\phi(x)$  from observed sample  $\mathfrak{X}(1), \dots, \mathfrak{X}(n)$  of the aggregated process in (1.4). For Gaussian process (1.4), the disaggregation problem was investigated in Leipus et al. (2006) and Celov et al. (2010), who constructed an estimator of the mixing density based on its expansion in an orthogonal polynomial basis. In Sec. 4 we extend the results in Leipus et al. (2006) to the case when the aggregated process is a mixed ID moving-average of (1.4) with finite 4th moment and obtain the weak consistency of the mixture density estimator in a suitable  $L_2$ -space (Theorem 4.1).

The results of our paper could be developed in several directions. We expect that Theorem 3.1 can be extended to the aggregation scheme with common innovations and to infinite variance ID moving-averages of (1.4), generalizing the results in Puplinskaitė and Surgailis (2009, 2010). An interesting open problem is generalizing Theorem 3.1 to the random field set-up of Lavancier (2010) and Puplinskaitė and Surgailis (2012).

In what follows,  $C$  stands for a positive constant whose precise value is unimportant and which may change from line to line.

## 2 Existence of the limiting aggregated process

Consider random-coefficient AR(1) equation

$$X(t) = aX(t-1) + \varepsilon(t), \quad t \in \mathbb{Z}, \quad (2.1)$$

where  $\{\varepsilon(t), t \in \mathbb{Z}\}$  are i.i.d. r.v.'s with generic distribution  $\varepsilon$ , and  $a \in [0, 1)$  is a random coefficient independent of  $\{\varepsilon(t), t \in \mathbb{Z}\}$ . The following proposition is easy. See, e.g. Brandt (1986), Puplinskaitė and Surgailis (2009).

**Proposition 2.1** *Assume that  $E|\varepsilon|^p < \infty$  for some  $0 < p \leq 2$  and  $E\varepsilon = 0$  ( $p \geq 1$ ). Then there exists a unique strictly stationary solution to the AR(1) equation (2.1) given by the series*

$$X(t) = \sum_{k=0}^{\infty} a^k \varepsilon(t-k). \quad (2.2)$$

*The series in (2.2) converge conditionally a.s. and in  $L_p$  for a.e.  $a \in [0, 1)$ . Moreover, if*

$$E\left[\frac{1}{1-a}\right] < \infty \quad (2.3)$$

*then the series in (2.2) converges unconditionally in  $L_p$ .*

Write  $W \sim ID(\mu, \sigma, \pi)$  if r.v.  $W$  is infinitely divisible having the log-characteristic function in (1.6), where  $\mu \in \mathbb{R}, \sigma \geq 0$  and  $\pi$  is a measure on  $\mathbb{R}$  satisfying  $\pi(\{0\}) = 0$  and  $\int_{\mathbb{R}} (x^2 \wedge 1) \pi(dx) < \infty$ , called the Lévy measure of  $W$ . It is well-known that the distribution of  $W$  is completely determined by the (characteristic) triplet  $(\mu, \sigma, \pi)$  and vice versa. See, e.g., Sato (1999).

**Definition 2.2** Let  $\{\varepsilon^{(N)}, N \in \mathbb{N}^*\}$  be a sequence of r.v.'s tending to 0 in probability, and  $W \sim ID(\mu, \sigma, \pi)$  be an ID r.v. We say that the sequence  $\{\varepsilon^{(N)}\}$  belongs to the domain of attraction of  $W$ , denoted  $\{\varepsilon^{(N)}\} \in D(W)$ , if

$$(\mathcal{C}_N(\theta))^N \rightarrow \mathbb{E}e^{i\theta W}, \quad \forall \theta \in \mathbb{R}, \quad (2.4)$$

where  $\mathcal{C}_N(\theta) := \mathbb{E} \exp\{i\theta \varepsilon^{(N)}\}$ ,  $\theta \in \mathbb{R}$ , is the characteristic function of  $\varepsilon^{(N)}$ .

**Remark 2.1** Sufficient and necessary conditions for  $\{\varepsilon^{(N)}\} \in D(W)$  in terms of the distribution functions of  $\varepsilon^{(N)}$  are well-known. See, e.g., Sato (1999), Feller (1966, vol. 2, Ch. 17). In particular, these conditions include the convergences

$$NP(\varepsilon^{(N)} > x) \rightarrow \Pi^+(x), \quad NP(\varepsilon^{(N)} < -x) \rightarrow \Pi^-(x) \quad (2.5)$$

at each continuity point  $x > 0$  of  $\Pi^+$ ,  $\Pi^-$ , respectively, where  $\Pi^\pm$  are defined as in (1.11).

**Remark 2.2** By taking logarithms of both sides, condition (2.4) can be rewritten as

$$N \log \mathcal{C}_N(\theta) \rightarrow \log \mathbb{E}e^{i\theta W} = V(\theta), \quad \forall \theta \in \mathbb{R}, \quad (2.6)$$

with the convention that the l.h.s. of (2.6) is defined for  $N > N_0(\theta)$  sufficiently large only, since for a fixed  $N$ , the characteristic function  $\mathcal{C}_N(\theta)$  may vanish at some points  $\theta$ . In the general case, (2.6) can be precised as follows: For any  $\epsilon > 0$  and any  $K > 0$  there exists  $N_0(K, \epsilon) \in \mathbb{N}^*$  such that

$$\sup_{|\theta| < K} |N \log \mathcal{C}_N(\theta) - V(\theta)| < \epsilon, \quad \forall N > N_0(K, \epsilon). \quad (2.7)$$

The following definitions introduce some technical conditions, in addition to  $\{\varepsilon^{(N)}\} \in D(W)$ , needed to prove the convergence towards the aggregated process in (1.3).

**Definition 2.3** Let  $0 < \alpha \leq 2$  and  $\{\varepsilon^{(N)}\}$  be a sequence of r.v.'s. Write  $\{\varepsilon^{(N)}\} \in T(\alpha)$  if there exists a constant  $C$  independent of  $N$  and  $x$  and such that one of the two following conditions hold: either

- (i)  $\alpha = 2$  and  $\mathbb{E}\varepsilon^{(N)} = 0$ ,  $N\mathbb{E}(\varepsilon^{(N)})^2 \leq C$ , or
- (ii)  $0 < \alpha < 2$  and  $NP(|\varepsilon^{(N)}| > x) \leq Cx^{-\alpha}$ ,  $x > 0$ ; moreover,  $\mathbb{E}\varepsilon^{(N)} = 0$  whenever  $1 < \alpha < 2$ , while, for  $\alpha = 1$  we assume that the distribution of  $\varepsilon^{(N)}$  is symmetric.

**Definition 2.4** Let  $0 < \alpha \leq 2$  and  $W \sim ID(\mu, \sigma, \pi)$ . Write  $W \in \mathcal{T}(\alpha)$  if there exists a constant  $C$  independent of  $x$  and such that one of the two following conditions hold: either

- (i)  $\alpha = 2$  and  $\mathbb{E}W = 0$ ,  $\mathbb{E}W^2 < \infty$ , or
- (ii)  $0 < \alpha < 2$  and  $\Pi^+(x) + \Pi^-(x) \leq Cx^{-\alpha}$ ,  $\forall x > 0$ ; moreover,  $\mathbb{E}W = 0$  whenever  $1 < \alpha < 2$ , while, for  $\alpha = 1$  we assume that the distribution of  $W$  is symmetric.

**Corollary 2.5** Let  $\{\varepsilon^{(N)}\} \in D(W)$ ,  $W \sim ID(\mu, \sigma, \pi)$ . Assume that  $\{\varepsilon^{(N)}\} \in T(\alpha)$  for some  $0 < \alpha \leq 2$ . Then  $W \in \mathcal{T}(\alpha)$ .

*Proof.* Let  $\alpha = 2$  and  $R_N$  denote the l.h.s. of (1.2). Then  $R_N^2 \rightarrow_d W^2$  and  $\mathbb{E}W^2 \leq \liminf_{N \rightarrow \infty} \mathbb{E}R_N^2 = \liminf_{N \rightarrow \infty} N\mathbb{E}(\varepsilon^{(N)})^2 < \infty$  follows by Fatou's lemma. Then, relation  $\mathbb{E}W = \lim_{N \rightarrow \infty} \mathbb{E}R_N = 0$  follows by the dominated convergence theorem. For  $0 < \alpha < 2$ , relation  $\Pi^\pm(x) \leq Cx^{-\alpha}$  at each continuity point  $x$  of  $\Pi^\pm$  follows from  $\{\varepsilon^{(N)}\} \in T(\alpha)$  and (2.5) and then extends to all  $x > 0$  by monotonicity. Verification of the remaining properties of  $W$  in the cases  $1 < \alpha < 2$  and  $\alpha = 1$  is easy and is omitted.  $\square$

The main result of this section is the following theorem. Recall that  $\{X_i(t) \equiv X_i^{(N)}(t)\}$ ,  $i = 1, 2, \dots, N$  are independent copies of AR(1) process in (2.1) with i.i.d. innovations  $\{\varepsilon(t) \equiv \varepsilon^{(N)}(t)\}$  and random coefficient  $a \in [0, 1)$ . Write  $M \sim W$  if  $M$  is an ID random measure on  $[0, 1)$  with characteristic function as in (1.5)-(1.6).

**Theorem 2.6** *Let condition (2.3) hold. In addition, assume that the generic sequence  $\{\varepsilon^{(N)}\}$  belongs to the domain of attraction of ID r.v.  $W \sim ID(\mu, \sigma, \pi)$  and there exists an  $0 < \alpha \leq 2$  such that  $\{\varepsilon^{(N)}\} \in T(\alpha)$ . Then the limiting aggregated process  $\{\mathfrak{X}(t)\}$  in (1.3) exists. It is stationary, ergodic, has infinitely divisible finite-dimensional distributions, and a stochastic integral representation as in (1.4), where  $M \sim W$ .*

*Proof.* We follow the proof of Theorem 2.1 in Puplinskaitė and Surgailis (2010). Fix  $m \geq 1$  and  $\theta(1), \dots, \theta(m) \in \mathbb{R}$ . Denote

$$\vartheta(s, a) := \sum_{t=1}^m \theta(t) a^{t-s} \mathbf{1}(s \leq t).$$

Then  $\sum_{t=1}^m \theta(t) X_i^{(N)}(t) = \sum_{s \in \mathbb{Z}} \vartheta(s, a_i) \varepsilon_i^{(N)}(s)$ ,  $i = 1, \dots, N$ , and

$$\mathbb{E} \exp \left\{ i \sum_{i=1}^N \sum_{t=1}^m \theta(t) X_i^{(N)}(t) \right\} = \left( \mathbb{E} \exp \left\{ i \sum_{t=1}^m \theta(t) X^{(N)}(t) \right\} \right)^N = \left( 1 + \frac{\Theta(N)}{N} \right)^N, \quad (2.8)$$

where

$$\Theta(N) := N \left( \mathbb{E} \left[ \prod_{s \in \mathbb{Z}} \mathcal{C}_N(\vartheta(s, a)) \right] - 1 \right).$$

From definitions (1.4), (1.6) it follows that

$$\mathbb{E} \exp \left\{ i \sum_{t=1}^m \theta(t) \mathfrak{X}(t) \right\} = e^\Theta, \quad \text{where } \Theta := \mathbb{E} \sum_{s \in \mathbb{Z}} V(\vartheta(s, a)). \quad (2.9)$$

The convergence in (1.3) to the aggregated process of (1.4) follows from (2.8), (2.9) and the limit

$$\lim_{N \rightarrow \infty} \Theta(N) = \Theta, \quad (2.10)$$

which will be proved below.

Note first that  $\sup_{a \in [0, 1), s \in \mathbb{Z}} |\vartheta(s, a)| \leq \sum_{t=1}^m |\theta(t)| =: K$  is bounded and therefore the logarithm  $\log \mathcal{C}_N(\vartheta(s, a))$  is well-defined for  $N > N_0(K)$  large enough, see (2.7), and  $\Theta(N)$  can be rewritten as

$$\Theta(N) = \mathbb{E} N \left( \exp \left\{ N^{-1} \sum_{s \in \mathbb{Z}} N \log \mathcal{C}_N(\vartheta(s, a)) \right\} - 1 \right).$$

Then (2.10) follows if we show that for each  $a \in [0, 1)$ ,

$$\lim_{N \rightarrow \infty} \sum_{s \in \mathbb{Z}} N \log \mathcal{C}_N(\vartheta(s, a)) = \sum_{s \in \mathbb{Z}} V(\vartheta(s, a)), \quad \forall a \in [0, 1) \quad (2.11)$$

and

$$\sum_{s \in \mathbb{Z}} |N \log \mathcal{C}_N(\vartheta(s, a))| \leq \frac{C}{1 - a^\alpha}, \quad \forall a \in [0, 1), \quad (2.12)$$

where  $C$  does not depend on  $N, a$ .

Let us prove (2.12). It suffices to check the bound

$$N|1 - \mathcal{C}_N(\theta)| \leq C|\theta|^\alpha. \quad (2.13)$$

Indeed, since  $|\mathcal{C}_N(\vartheta(s, a)) - 1| < \epsilon$  for  $N$  large enough (see above), so  $|N \log \mathcal{C}_N(\vartheta(s, a))| \leq CN|1 - \mathcal{C}_N(\vartheta(s, a))|$  and (2.13) implies

$$\sum_{s \in \mathbb{Z}} |N \log \mathcal{C}_N(\vartheta(s, a))| \leq C \sum_{s \in \mathbb{Z}} |\vartheta(s, a)|^\alpha \leq \frac{C}{1 - a^\alpha}, \quad (2.14)$$

see Puplinskaitė and Surgailis (2010, (A.4)), proving (2.12).

Consider (2.13) for  $1 < \alpha < 2$ . Since  $E\varepsilon^{(N)} = 0$  so  $\mathcal{C}_N(\theta) - 1 = \int_{\mathbb{R}} (e^{i\theta x} - 1 - i\theta x) dF_N(x)$  and

$$\begin{aligned} N|1 - \mathcal{C}_N(\theta)| &\leq N \left| \int_{-\infty}^0 (e^{i\theta x} - 1 - i\theta x) dF_N(x) \right| + N \left| \int_0^\infty (e^{i\theta x} - 1 - i\theta x) d(1 - F_N(x)) \right| \\ &= |\theta| \left( \left| \int_{-\infty}^0 NF_N(x)(e^{i\theta x} - 1) dx \right| + \left| \int_0^\infty N(1 - F_N(x))(e^{i\theta x} - 1) dx \right| \right) \\ &\leq C|\theta| \int_0^\infty x^{-\alpha} ((|\theta|x) \wedge 1) dx \leq C|\theta|^\alpha, \end{aligned} \quad (2.15)$$

since  $NF_N(x)\mathbf{1}(x < 0) + N(1 - F_N(x))\mathbf{1}(x > 0) \leq C|x|^{-\alpha}$  and the integral

$$\int_0^\infty x^{-\alpha} ((|\theta|x) \wedge 1) dx = |\theta| \int_0^{1/|\theta|} x^{1-\alpha} dx + \int_{1/|\theta|}^\infty x^{-\alpha} dx = |\theta|^{\alpha-1} \left( \frac{1}{2-\alpha} + \frac{1}{\alpha-1} \right)$$

converges. In the case  $\alpha = 2$ , we have  $N|\mathcal{C}_N(\theta) - 1| \leq \frac{1}{2}\theta^2 NE(\varepsilon^{(N)})^2 \leq C\theta^2$  and (2.13) follows.

Next, let  $0 < \alpha < 1$ . Then

$$N|1 - \mathcal{C}_N(\theta)| \leq N \int_{-\infty}^0 |e^{i\theta x} - 1| dF_N(x) + N \int_0^\infty |e^{i\theta x} - 1| d(1 - F_N(x)) =: I_1 + I_2.$$

Here,  $I_1 \leq 2N \int_{-\infty}^0 ((|\theta||x|) \wedge 1) dF_N(x) = 2N \int_{-\infty}^{-1/|\theta|} dF_N(x) + 2N|\theta| \int_{-1/|\theta|}^0 |x| dF_N(x) =: 2(I_{11} + I_{12})$ . We have  $I_{11} = NF_N(-1/|\theta|) \leq C|\theta|^\alpha$  and

$$\begin{aligned} I_{12} &= -|\theta|N \int_{-1/|\theta|}^0 x dF_N(x) = -|\theta|N \left( xF_N(x) \Big|_{x=-1/|\theta|}^{x=0} - \int_{-1/|\theta|}^0 F_N(x) dx \right) \\ &= |\theta|N \left( -\frac{F_N(-1/|\theta|)}{|\theta|} + \int_{-1/|\theta|}^0 F_N(x) dx \right) \\ &\leq C|\theta|^\alpha + C|\theta| \int_{-1/|\theta|}^0 |x|^{-\alpha} dx \leq C|\theta|^\alpha. \end{aligned}$$

Since  $I_2$  can be evaluated analogously, this proves (2.13) for  $0 < \alpha < 1$ .

It remains to prove (2.13) for  $\alpha = 1$ . Since  $\int_{\{|x| \leq 1/|\theta|\}} x dF_N(x) = 0$  by symmetry of  $\varepsilon^{(N)}$ , so  $\mathcal{C}_N(\theta) - 1 = J_1 + J_2 + J_3 + J_4$ , where  $J_1 := \int_{-\infty}^{-1/|\theta|} (e^{i\theta x} - 1) dF_N(x)$ ,  $J_2 := \int_{-1/|\theta|}^0 (e^{i\theta x} - 1 - i\theta x) dF_N(x)$ ,  $J_3 := \int_0^{1/|\theta|} (e^{i\theta x} - 1 - i\theta x) dF_N(x)$ ,  $J_4 := \int_{1/|\theta|}^\infty (e^{i\theta x} - 1) dF_N(x)$ . We have  $N|J_1| \leq 2NF_N(-1/|\theta|) \leq C|\theta|$  and a similar bound follows for  $J_i, i = 2, 3, 4$ . This proves (2.13). Then (2.11) and the remaining proof of (2.10) and Theorem 2.6 follow as in Puplinskaitė and Surgailis (2010, proof of Thm. 2.1).  $\square$

Theorem 2.6 applies in the case of innovations in the domain of attraction of  $\alpha$ -stable law, see below.

**Definition 2.7** Let  $0 < \alpha \leq 2$  and  $\zeta$  be a r.v. Write  $\zeta \in D(\alpha)$  if

(i)  $\alpha = 2$  and  $E\zeta = 0$ ,  $E\zeta^2 < \infty$ , or

(ii)  $0 < \alpha < 2$  and there exist some constants  $c_1, c_2 \geq 0, c_1 + c_2 > 0$  such that

$$\lim_{x \rightarrow \infty} x^\alpha P(\zeta > x) = c_1 \quad \text{and} \quad \lim_{x \rightarrow -\infty} |x|^\alpha P(\zeta \leq x) = c_2;$$

moreover,  $E\zeta = 0$  whenever  $1 < \alpha < 2$ , while, for  $\alpha = 1$  we assume that the distribution of  $\zeta$  is symmetric.

**Corollary 2.8** Let  $\varepsilon^{(N)} = N^{-1/\alpha}\zeta$ , where  $\zeta \in D(\alpha)$ ,  $0 < \alpha \leq 2$ . Then  $\{\varepsilon^{(N)}\} \in T(\alpha)$  and  $\{\varepsilon^{(N)}\} \in D(W)$ , where  $W$  is  $\alpha$ -stable r.v. with the characteristic function

$$Ee^{i\theta W} = e^{-|\theta|^\alpha \omega(\theta; \alpha, c_1, c_2)}, \quad \theta \in \mathbb{R}, \quad (2.16)$$

where

$$\omega(\theta; \alpha, c_1, c_2) := \begin{cases} \frac{\Gamma(2-\alpha)}{1-\alpha} \left( (c_1 + c_2) \cos(\pi\alpha/2) - i(c_1 - c_2) \text{sign}(\theta) \sin(\pi\alpha/2) \right), & \alpha \neq 1, 2, \\ (c_1 + c_2)(\pi/2), & \alpha = 1, \\ \sigma^2/2, & \alpha = 2. \end{cases} \quad (2.17)$$

In this case, the statement of Theorem 2.6 coincides with Puplinskaitė and Surgailis (2010, Thm. 2.1).

### 3 Long memory properties of the aggregated process

In this section we study partial sums limits and distributional long memory property of the aggregated mixed ID moving-average in (1.4) under condition (1.7) on the mixing density  $\phi$ . More precisely, we shall assume that  $\phi$  has the form

$$\phi(x) = \psi(x) (1-x)^\beta, \quad x \in (0, 1), \quad (3.1)$$

where  $\beta > 0$  and  $\psi(x)$  is an bounded function having a finite limit  $\psi(1) := \lim_{x \rightarrow 1} \psi(x) > 0$ .

Consider an independently scattered  $\alpha$ -stable random measure  $N(dx, ds)$  on  $(0, \infty) \times \mathbb{R}$  with control measure  $\nu(dx, ds) := \psi(1)x^{\beta-\alpha} dx ds$  and characteristic function  $Ee^{i\theta N(A)} = e^{-|\theta|^\alpha \omega(\theta; \alpha, c^+, c^-) \nu(A)}$ ,  $\theta \in \mathbb{R}$ , where  $A \subset (0, \infty) \times \mathbb{R}$  is a Borel set with  $\nu(A) < \infty$  and  $\omega$  is defined at (2.17). For  $1 < \alpha \leq 2$ ,  $0 < \beta < \alpha - 1$ , introduce the process

$$\Lambda_{\alpha, \beta}(\tau) := \int_{\mathbb{R}_+ \times \mathbb{R}} (f(x, \tau - s) - f(x, -s)) N(dx, ds), \quad \tau \geq 0, \quad \text{where} \quad (3.2)$$

$$f(x, t) := \begin{cases} 1 - e^{-xt}, & \text{if } x > 0 \text{ and } t > 0, \\ 0, & \text{otherwise} \end{cases}$$

defined as a stochastic integral with respect to the above random measure  $N$ . The process  $\Lambda_{\alpha, \beta}$  was introduced in Puplinskaitė and Surgailis (2010). It has stationary increments,  $\alpha$ -stable finite-dimensional distributions, a.s. continuous sample paths and is self-similar with parameter  $H = 1 - \frac{\beta}{\alpha} \in (\frac{1}{\alpha}, 1)$ . Note that for  $\alpha = 2$ ,  $\Lambda_{2, \beta}$  is a fractional Brownian motion. Write  $\rightarrow_{D[0,1]}$  for the weak convergence of random processes in the Skorohod space  $D[0, 1]$  endowed with the  $J_1$ -topology.

**Theorem 3.1** Let  $\{\mathfrak{X}(t)\}$  be the aggregated process in (1.4), where  $M \sim W \sim ID_2(\sigma, \pi)$  and the mixing distribution satisfies (3.1).

(i) Let  $0 < \beta < 1$  and  $\sigma > 0$ . Then

$$\frac{1}{n^{1-\frac{\beta}{2}}} \sum_{t=1}^{\lfloor n\tau \rfloor} \mathfrak{X}(t) \rightarrow_{D[0,1]} B_H(\tau), \quad (3.3)$$

where  $B_H$  is a fractional Brownian motion with parameter  $H := 1 - \frac{\beta}{2}$  and variance  $EB_H^2(\tau) = \sigma^2 \psi(1) \Gamma(\beta - 2) \tau^{2H}$ .

(ii) Let  $0 < \beta < 1$ ,  $\sigma = 0$  and there exist  $1 + \beta < \alpha < 2$  and  $c^\pm \geq 0$ ,  $c^+ + c^- > 0$  such that (1.11) hold. Then

$$\frac{1}{n^{1-\frac{\beta}{\alpha}}} \sum_{t=1}^{\lfloor n\tau \rfloor} \mathfrak{X}(t) \rightarrow_{D[0,1]} \Lambda_{\alpha,\beta}(\tau), \quad (3.4)$$

where  $\Lambda_{\alpha,\beta}$  is defined in (3.2).

(iii) Let  $0 < \beta < 1$ ,  $\sigma = 0$ ,  $\pi \neq 0$  and there exists  $0 < \alpha < 1 + \beta$  such that

$$\int_{\mathbb{R}} |x|^\alpha \pi(dx) < \infty. \quad (3.5)$$

Then

$$\frac{1}{n^{\frac{1}{1+\beta}}} \sum_{t=1}^{\lfloor n\tau \rfloor} \mathfrak{X}(t) \rightarrow_{\text{fdd}} L_{1+\beta}(\tau), \quad (3.6)$$

where  $\{L_{1+\beta}(\tau), \tau \geq 0\}$  is an  $(1 + \beta)$ -stable Lévy process with log-characteristic function given in (3.22) below.

(iv) Let  $\beta > 1$ . Then

$$\frac{1}{n^{1/2}} \sum_{t=1}^{\lfloor n\tau \rfloor} \mathfrak{X}(t) \rightarrow_{\text{fdd}} \sigma_\Phi B(\tau), \quad (3.7)$$

where  $B$  is a standard Brownian motion with  $EB^2(1) = 1$  and  $\sigma_\Phi$  is defined in (3.23) below. Moreover, if  $\beta > 2$  and  $\pi$  satisfies (3.5) with  $\alpha = 4$ , the convergence  $\rightarrow_{\text{fdd}}$  in (3.7) can be replaced by  $\rightarrow_{D[0,1]}$ .

**Remark 3.1** Note that the normalization exponents in Theorem 3.1 decrease from (i) to (iv):

$$1 - \frac{\beta}{2} > 1 - \frac{\beta}{\alpha} > \frac{1}{1 + \beta} > \frac{1}{2}.$$

Hence, we may conclude that the dependence in the aggregated process decreases from (i) to (iv). Also note that while  $\{\mathfrak{X}(t)\}$  has finite variance in all cases (i) - (iv), the limit of its partial sums may have infinite variance as it happens in (ii) and (iii). Apparently, the finite-dimensional convergence in (3.6) cannot be replaced by the convergence in  $D[0, 1]$  with the  $J_1$ -topology. See Mikosch et al. (2002, p.40), Leipus and Surgailis (2003, Remark 4.1) for related discussion.

*Proof.* (i) The statement is true if  $\pi = 0$ , or  $W \sim \mathcal{N}(0, \sigma^2)$ . In the case  $\pi \neq 0$ , split  $\mathfrak{X}(t) = \mathfrak{X}_1(t) + \mathfrak{X}_2(t)$ , where  $\mathfrak{X}_1(t), \mathfrak{X}_2(t)$  are defined following the decomposition of the measure  $M = M_1 + M_2$  into independent random measures  $M_1 \sim W_1 \sim ID_2(\sigma, 0)$  and  $M_2 \sim W_2 \sim ID_2(0, \pi)$ . Let us prove that

$$S_{n2} := \sum_{t=1}^n \mathfrak{X}_2(t) = o_p(n^{1-\frac{\beta}{2}}). \quad (3.8)$$

Let  $V_2(\theta) := \log \mathbb{E} e^{i\theta W_2} = \int_{\mathbb{R}} (e^{i\theta x} - 1 - i\theta x) \pi(dx)$ . Then

$$|V_2(\theta)| \leq C\theta^2 \quad (\forall \theta \in \mathbb{R}) \quad \text{and} \quad |V_2(\theta)| = o(\theta^2) \quad (|\theta| \rightarrow \infty). \quad (3.9)$$

Indeed, for any  $\epsilon > 0$ ,  $|V_2(\theta)| \leq \theta^2 I_1(\epsilon) + 2|\theta| I_2(\epsilon)$ , where  $I_1(\epsilon) := \theta^{-2} \int_{|x| \leq \epsilon} |e^{i\theta x} - 1 - i\theta x| \pi(dx) \leq \int_{|x| \leq \epsilon} x^2 \pi(dx) \rightarrow 0$  ( $\epsilon \rightarrow 0$ ) and  $I_2(\epsilon) := (2|\theta|)^{-1} \int_{|x| > \epsilon} |e^{i\theta x} - 1 - i\theta x| \pi(dx) \leq \int_{|x| > \epsilon} |x| \pi(dx) < \infty$  ( $\forall \epsilon > 0$ ). Hence, (3.9) follows.

Relation (3.8) follows from  $J_n := \log \mathbb{E} \exp \{i\theta n^{-1+\frac{\beta}{2}} S_{n2}\} = o(1)$ . We have

$$J_n = \sum_{s \in \mathbb{Z}} \int_0^1 V_2 \left( \theta n^{-1+\beta/2} \sum_{t=1}^n (1-z)^{t-s} \mathbf{1}(t \geq s) \right) z^\beta \psi(1-z) dz = J_{n1} + J_{n2},$$

where  $J_{n1} := \sum_{s \leq 0} \int_0^1 V_2(\dots) z^\beta \psi(1-z) dz$ ,  $J_{n2} := \sum_{s=1}^n \int_0^1 V_2(\dots) z^\beta \psi(1-z) dz$ . By change of variables:  $nz = w$ ,  $n-s+1 = nu$ ,  $J_{n2}$  can be rewritten as

$$\begin{aligned} J_{n2} &= \sum_{s=1}^n \int_0^1 V_2 \left( \frac{\theta(1 - (1-z)^{n-s+1})}{n^{1-\beta/2} z} \right) z^\beta \psi(1-z) dz \\ &= \frac{1}{n^\beta} \int_{1/n}^1 du \int_0^n V_2 \left( \frac{\theta n^{\beta/2} (1 - (1 - \frac{w}{n})^{[un]})}{w} \right) w^\beta \psi \left( 1 - \frac{w}{n} \right) dw \\ &= \theta^2 \int_0^1 du \int_0^\infty G_n(u, w) w^{\beta-2} \psi \left( 1 - \frac{w}{n} \right) dw, \end{aligned}$$

where

$$G_n(u, w) := \left( 1 - \left( 1 - \frac{w}{n} \right)^{[un]} \right)^2 \kappa \left( \frac{\theta n^{\beta/2} (1 - (1 - \frac{w}{n})^{[un]})}{w} \right) \mathbf{1}(1/n < u < 1, 0 < w < n)$$

and where  $\kappa(\theta) := V_2(\theta)/\theta^2$  is a bounded function vanishing as  $|\theta| \rightarrow \infty$ ; see (3.9). Therefore  $G_n(u, w) \rightarrow 0$  ( $n \rightarrow \infty$ ) for any  $u \in (0, 1], w > 0$  fixed. We also have  $|G_n(u, w)| \leq C \left( 1 - \left( 1 - \frac{w}{n} \right)^{[un]} \right)^2 \leq C(1 - e^{-wu})^2 =: \bar{G}(u, w)$ , where  $\int_0^1 du \int_0^\infty \bar{G}(u, w) w^{\beta-2} dw < \infty$ . Thus,  $J_{n2} = o(1)$  follows by the dominated convergence theorem. The proof  $J_{n1} = o(1)$  using (3.9) follows by a similar argument. This proves  $J_n = o(1)$ , or (3.8). The tightness of the partial sums process in  $D[0, 1]$  follows from  $\beta < 1$  and Kolmogorov's criterion since  $\mathbb{E}(\sum_{t=1}^n \mathfrak{X}(t))^2 = O(n^{2-\beta})$ , the last relation being an easy consequence of  $r(t) = O(t^{-\beta})$ , see (1.8) and the discussion below it.

(ii) Let  $S_n(\tau) := \sum_{t=1}^{[n\tau]} \mathfrak{X}(t)$ . Let us prove that for any  $0 < \tau_1 < \dots < \tau_m \leq 1$ ,  $\theta_1 \in \mathbb{R}, \dots, \theta_m \in \mathbb{R}$

$$J_n := \log \mathbb{E} \exp \left\{ i \frac{1}{n^{1-\frac{\beta}{\alpha}}} \sum_{j=1}^m \theta_j S_n(\tau_j) \right\} \rightarrow J, \quad \text{where} \quad (3.10)$$

$$J := -\psi(1) \int_{\mathbb{R}_+ \times \mathbb{R}} \left| \sum_{j=1}^m \theta_j (f(w, \tau_j - u) - f(w, -u)) \right|^\alpha \omega \left( \sum_{j=1}^m \theta_j (f(w, \tau_j - u) - f(w, -u)); \alpha, c^+, c^- \right) \frac{dw du}{w^{\alpha-\beta}}.$$

We have  $J = \log \mathbb{E} e^{i \sum_{j=1}^m \theta_j \Lambda_{\alpha, \beta}(\tau_j)}$  by definition (3.2) of  $\Lambda_{\alpha, \beta}$ . We shall restrict the proof of (3.10) to  $m = \tau_1 = 1$ , since the general case follows analogously. Let  $V(\theta)$  be defined as in (1.10), where  $\sigma = 0$ . Then,

$$\begin{aligned} J_n &= \sum_{s \in \mathbb{Z}} \int_0^1 V \left( \theta \frac{1}{n^{1-\frac{\beta}{\alpha}}} \sum_{t=1}^n (1-z)^{t-s} \mathbf{1}(t \geq s) \right) z^\beta \psi(1-z) dz \\ &= \sum_{s \leq 0} \int_0^\epsilon V(\dots) z^\beta \psi(1-z) dz + \sum_{s=1}^n \int_0^\epsilon V(\dots) z^\beta \psi(1-z) dz + \sum_{s \in \mathbb{Z}} \int_\epsilon^1 V(\dots) z^\beta \psi(1-z) dz \\ &=: J_{n1} + J_{n2} + J_{n3}, \end{aligned}$$

Similarly, split  $J = J_1 + J_2$ , where

$$\begin{aligned} J_1 &:= -|\theta|^\alpha \psi(1) \omega(\theta; \alpha, c^+, c^-) \int_{-\infty}^0 du \int_0^\infty (f(w, 1-u) - f(w, -u))^\alpha w^{\beta-\alpha} dw, \\ J_2 &:= -|\theta|^\alpha \psi(1) \omega(\theta; \alpha, c^+, c^-) \int_0^1 du \int_0^\infty (f(w, u))^\alpha w^{\beta-\alpha} dw. \end{aligned}$$

To prove (3.10) we need to show  $J_{n1} \rightarrow J_1$ ,  $J_{n2} \rightarrow J_2$ ,  $J_{n3} \rightarrow 0$ . We shall use the following facts:

$$\lim_{\lambda \rightarrow +0} \lambda V(\lambda^{-1/\alpha} \theta) = -|\theta|^\alpha \omega(\theta; \alpha, c^+, c^-), \quad \forall \theta \in \mathbb{R} \quad (3.11)$$

and

$$|V(\theta)| \leq C|\theta|^\alpha, \quad \forall \theta \in \mathbb{R} \quad (\exists C < \infty). \quad (3.12)$$

Here, (3.12) follows from (1.11),  $\int_{\mathbb{R}} x^2 \pi(dx) < \infty$  and integration by parts. To show (3.11), let  $\chi(x)$ ,  $x \in \mathbb{R}$  be a bounded continuously differentiable function with compact support and such that  $\chi(x) \equiv 1$ ,  $|x| \leq 1$ . Then the l.h.s. of (3.11) can be rewritten as

$$\lambda V(\lambda^{-1/\alpha} \theta) = \int_{\mathbb{R}} (e^{i\theta y} - 1 - i\theta y \chi(y)) \pi_\lambda(dy) + i\theta \mu_{\chi, \lambda},$$

where  $\pi_\lambda(dy) := \lambda \pi(d\lambda^{1/\alpha} y)$ ,  $\mu_{\chi, \lambda} := \int_{\mathbb{R}} y(\chi(y) - 1) \pi_\lambda(dy)$ . The r.h.s. of (3.11) can be rewritten as

$$-|\theta|^\alpha \omega(\theta; \alpha, c^+, c^-) = V_0(\theta) := \int_{\mathbb{R}} (e^{i\theta y} - 1 - i\theta y \chi(y)) \pi_0(dy) + i\theta \mu_{\chi, 0},$$

where  $\pi_0(dy) := -c^+ dy^{-\alpha} \mathbf{1}(y > 0) + c^- d(-y)^{-\alpha} \mathbf{1}(y < 0)$ ,  $\mu_{\chi, 0} := \int_{\mathbb{R}} y(\chi(y) - 1) \pi_0(dy)$ . Let  $C_b$  be the class of all bounded continuous functions on  $\mathbb{R}$  vanishing in a neighborhood of 0. According to Sato (1999, Thm. 8.7), relation (3.11) follows from

$$\lim_{\lambda \rightarrow 0} \int_{\mathbb{R}} f(y) \pi_\lambda(dy) = \int_{\mathbb{R}} f(y) \pi_0(dy), \quad \forall f \in C_b, \quad (3.13)$$

$$\lim_{\lambda \rightarrow 0} \mu_{\chi, \lambda} = \mu_{\chi, 0}, \quad \lim_{\epsilon \downarrow 0} \lim_{\lambda \rightarrow 0} \int_{|y| \leq \epsilon} y^2 \pi_\lambda(dy) = 0. \quad (3.14)$$

Relations (3.13) is immediate from (1.11) while (3.14) follows from (1.11) by integration by parts.

Coming back to the proof of (3.10), consider the convergence  $J_{n2} \rightarrow J_2$ . By change of variables:  $nz = w$ ,  $n - s + 1 = nu$ ,  $J_{n2}$  can be rewritten as

$$\begin{aligned} J_{n2} &= \int_{1/n}^1 du \int_0^{\epsilon n} n^{-\beta} V\left(\theta n^{\frac{\beta}{\alpha}} \frac{1 - (1 - \frac{w}{n})^{[un]}}{w}\right) w^\beta \psi\left(1 - \frac{w}{n}\right) dw \\ &= -|\theta|^\alpha \omega(\theta; \alpha, c^+, c^-) \int_0^1 du \int_0^\infty \left(\frac{1 - e^{-wu}}{w}\right)^\alpha \kappa_{n2}(\theta; u, w) w^\beta \psi\left(1 - \frac{w}{n}\right) dw, \end{aligned}$$

where  $\kappa_{n2}(u, w)$  is written as

$$\begin{aligned} \kappa_{n2}(\theta; u, w) &:= -\left(\frac{1 - e^{-wu}}{w}\right)^{-\alpha} n^{-\beta} \frac{V\left(\theta n^{\frac{\beta}{\alpha}} w^{-1} (1 - (1 - \frac{w}{n})^{[un]})\right)}{|\theta|^\alpha \omega(\theta; \alpha, c^+, c^-)} \mathbf{1}(n^{-1} < u \leq 1, 0 < w < \epsilon n) \\ &= \frac{\lambda V(\lambda^{-1/\alpha} \theta)}{-|\theta|^\alpha \omega(\theta; \alpha, c^+, c^-)} \left(\frac{1 - (1 - \frac{w}{n})^{[un]}}{1 - e^{-wu}}\right)^\alpha \mathbf{1}(n^{-1} < u \leq 1, 0 < w < \epsilon n) \end{aligned} \quad (3.15)$$

with

$$\lambda \equiv \lambda_n(u, w) := n^{-\beta} \left( \frac{w}{1 - (1 - \frac{w}{n})^{[un]}} \right)^\alpha \rightarrow 0$$

for each  $u \in (0, 1], w > 0$  fixed. Hence and with (3.11) in mind, it follows that  $\kappa_{n2}(\theta; u, w) \rightarrow 1$  for each  $\theta \in \mathbb{R}, u \in (0, 1], w > 0$  and therefore the convergence  $J_{n2} \rightarrow J_2$  by the dominated convergence theorem provided we establish a dominating bound

$$|\kappa_{n2}(\theta; u, w)| \leq C \quad (3.16)$$

with  $C$  independent of  $n, u \in (0, 1], w \in (0, \epsilon n)$ . From (3.12) it follows that the first ratio on the r.h.s. of (3.15) is bounded by an absolute constant. Next, for any  $0 \leq x \leq 1/2, s > 0$  we have  $1 - x \geq e^{-2x} \implies (1 - x)^s \geq e^{-2xs} \implies 1 - (1 - x)^s \leq 2(1 - e^{-xs})$  and hence  $\frac{1 - (1 - \frac{w}{n})^{[un]}}{1 - e^{-wu}} \leq \frac{1 - (1 - \frac{w}{n})^{un}}{1 - e^{-wu}} \leq 2$  for any  $0 \leq w \leq n/2, u > 0$  so that the second ratio on the r.h.s. of (3.15) is also bounded by 2, provided  $\epsilon \leq 1/2$ . This proves (3.16) and concludes the proof of  $J_{n2} \rightarrow J_2$ . The proof of the convergence  $J_{n1} \rightarrow J_1$  is similar and is omitted. Using inequality (3.12) it is not difficult to prove that  $|J_{n3}| < Cn^{\beta - (\alpha - 1)}$ . Since  $\beta - (\alpha - 1) < 0, J_{n3} \rightarrow 0$ . This concludes the proof of (3.10), or finite-dimensional convergence in (3.4).

To prove the tightness part of (3.4), it suffices to verify the well-known criterion in Billingsley (1968, Thm.12.3): there exists  $C > 0$  such that, for any  $n \geq 1$  and  $0 \leq \tau < \tau + h \leq 1$

$$\sup_{u > 0} u^\alpha \mathbb{P}(n^{\frac{\beta}{\alpha} - 1} |S_n(\tau + h) - S_n(\tau)| > u) < Ch^{\alpha - \beta}, \quad (3.17)$$

where  $\alpha - \beta > 1$ . By stationarity of increments of  $\{\mathfrak{X}(t)\}$  it suffices to prove (3.17) for  $\tau = 0, h = 1$ , in which case it becomes

$$\sup_{u > 0} u^\alpha \mathbb{P}(|S_n| > u) < Cn^{\alpha - \beta}, \quad S_n := S_n(1). \quad (3.18)$$

The proof of (3.18), below, requires inequality in (3.19) for tail probabilities of stochastic integrals w.r.t. ID random measure. Let  $L^\alpha(\mathbb{Z} \times (0, 1))$  be the class of measurable functions  $g : \mathbb{Z} \times (0, 1) \rightarrow \mathbb{R}$  with  $\|g\|_\alpha^\alpha := \sum_{s \in \mathbb{Z}} \mathbb{E}|g(s, a)|^\alpha < \infty$ . Also, introduce the weak space  $L_w^\alpha(\mathbb{Z} \times (0, 1))$  of measurable functions  $g : \mathbb{Z} \times (0, 1) \rightarrow \mathbb{R}$  with  $\|g\|_{\alpha, w}^\alpha := \sup_{t > 0} t^\alpha \sum_{s \in \mathbb{Z}} \mathbb{P}(|g(s, a)| > t) < \infty$ . Note  $L^\alpha(\mathbb{Z} \times (0, 1)) \subset L_w^\alpha(\mathbb{Z} \times (0, 1))$  and  $\|g\|_{\alpha, w}^\alpha \leq \|g\|_\alpha^\alpha$ . Let  $\{M_s, s \in \mathbb{Z}\}$  be the random measure in (1.4),  $M \sim W \sim ID_2(0, \pi)$  with zero mean and the Lévy measure  $\pi$  satisfying the assumptions in (ii). It is well-known (see, e.g., Surgailis (1981)) that the stochastic integral  $M(g) := \sum_{s \in \mathbb{Z}} \int_{(0, 1)} g(s, a) M_s(da)$  is well-defined for any  $g \in L^p(\mathbb{Z} \times (0, 1)), p = 1, 2$  and satisfies  $\mathbb{E}M^2(g) = C_2 \|g\|_2^2, \mathbb{E}|M(g)| \leq C_1 \|g\|_1$  for some constants  $C_1, C_2 > 0$ . The above facts together with Hunt's interpolation theorem, see Reed and Simon (1975, Theorem IX.19) imply that  $M(g)$  extends to all  $g \in L_w^\alpha(\mathbb{Z} \times (0, 1)), 1 < \alpha < 2$  and satisfies the bound

$$\sup_{u > 0} u^\alpha \mathbb{P}(|M(g)| > u) \leq C \|g\|_{\alpha, w}^\alpha \leq C \|g\|_\alpha^\alpha, \quad (3.19)$$

with some constant  $C > 0$  depending on  $\alpha, C_1, C_2$  only. Using (3.19) and the representation  $S_n = M(g)$  with  $g(s, a) = \sum_{t=1}^n a^{t-s} \mathbf{1}(t \geq s)$  we obtain

$$\sup_{u > 0} u^\alpha \mathbb{P}(|S_n| > u) \leq C \sum_{s \leq n} \mathbb{E} \left( \sum_{t=1}^n a^{t-s} \right)^\alpha = O(n^{\alpha - \beta}),$$

where the last relation is proved in Puplinskaitė and Surgailis (2010, proof of Theorem 3.1). This proves (3.18) and part (ii).

(iii) It suffices to prove that for any  $0 < \tau_1 < \dots < \tau_m \leq 1$ ,  $\theta_1 \in \mathbb{R}, \dots, \theta_m \in \mathbb{R}$

$$J_n := \log \mathbb{E} \exp \left\{ i \frac{1}{n^{1/(1+\beta)}} \sum_{j=1}^m \theta_j S_n(\tau_j) \right\} \rightarrow J := \log \mathbb{E} \exp \left\{ i \sum_{j=1}^m \theta_j L_{1+\beta}(\tau_j) \right\}. \quad (3.20)$$

Similarly as in (i)-(ii), we shall restrict the proof of (3.20) to the case  $m = 1$  since the general case follows analogously. Then

$$J_n = \sum_{s \in \mathbb{Z}} \int_0^1 V \left( n^{-1/(1+\beta)} \theta \sum_{t=1}^{[n\tau]} (1-z)^{t-s} \mathbf{1}(t \geq s) \right) z^\beta \psi(1-z) dz = J_{n1} + J_{n2},$$

where  $J_{n1} := \sum_{s \leq 0} \int_0^1 V(\dots) z^\beta \psi(1-z) dz$ ,  $J_{n2} := \sum_{s=1}^{[n\tau]} \int_0^1 V(\dots) z^\beta \psi(1-z) dz$ . Let  $\theta > 0$ . By the change of variables:  $n^{1/(1+\beta)} z = \theta/y$ ,  $[n\tau] - s + 1 = nu$ ,  $J_{n2}$  can be rewritten as

$$\begin{aligned} J_{n2} &= \sum_{s=1}^{[n\tau]} \int_0^1 V \left( \frac{\theta(1 - (1-z)^{[n\tau]-s+1})}{n^{1/(1+\beta)} z} \right) z^\beta \psi(1-z) dz \\ &= \theta^{1+\beta} \int_0^\tau du \int_0^\infty \frac{dy}{y^{\beta+2}} V \left( y \left( 1 - \left( 1 - \frac{\theta}{n^{1/(1+\beta)} y} \right)^{[un]} \right) \right) \psi \left( 1 - \frac{\theta}{n^{1/(1+\beta)} y} \right) \mathbf{1}_n(\theta; y, u), \end{aligned} \quad (3.21)$$

where  $\mathbf{1}_n(\theta; y, u) := \mathbf{1}(1/n < u < [n\tau]/n, y > \theta n^{-1/(1+\beta)}) \rightarrow \mathbf{1}(0 < u < \tau, y > 0)$ . As  $(1 - \frac{\theta}{n^{1/(1+\beta)} y})^{un} \rightarrow 0$  for any  $u, y > 0$  due to  $n/n^{1/(1+\beta)} \rightarrow \infty$ , we see that the integrand in (3.21) tends to  $y^{-\beta-2} V(y) \psi(1)$ . We will soon prove that this passage to the limit under the sign of the integral in (3.21) is legitimate. Therefore,

$$\begin{aligned} J_{n2} &\rightarrow J := \tau |\theta|^{1+\beta} \psi(1) \int_0^\infty V(y) y^{-\beta-2} dy = -\tau |\theta|^{1+\beta} \psi(1) \omega(\theta; 1 + \beta, \pi_\beta^-, \pi_\beta^+), \\ \pi_\beta^+ &:= \frac{1}{1+\beta} \int_0^\infty x^{1+\beta} \pi(dx), \quad \pi_\beta^- := \frac{1}{1+\beta} \int_{-\infty}^0 |x|^{1+\beta} \pi(dx), \end{aligned} \quad (3.22)$$

and the last equality in (3.22) follows from the definition of  $V(y)$  and Ibragimov and Linnik (1971, Thm. 2.2.2).

For justification of the above passage to the limit, note that the function  $V(y) = \int_{\mathbb{R}} (e^{iyx} - 1 - iyx) \pi(dx)$  satisfies  $|V(y)| \leq V_1(y) + V_2(y)$ , where  $V_1(y) := y^2 \int_{|x| \leq 1/|y|} x^2 \pi(dx)$ ,  $V_2(y) := 2|y| \int_{|x| > 1/|y|} |x| \pi(dx)$ . We have

$$\begin{aligned} \int_0^\infty (V_1(y) + V_2(y)) y^{-\beta-2} dy &\leq \int_{\mathbb{R}} x^2 \pi(dx) \int_0^{1/|x|} y^{-\beta} dy + 2 \int_{\mathbb{R}} |x| \pi(dx) \int_{1/|x|}^\infty y^{-1-\beta} dy \\ &\leq C \int_{\mathbb{R}} |x|^{1+\beta} \pi(dx) < \infty. \end{aligned}$$

Next,  $\sup_{1/2 \leq c \leq 1} V_1(cy) \leq y^2 \int_{|x| \leq 2/|y|} x^2 \pi(dx) =: \bar{V}_1(y)$ ,  $\sup_{1/2 \leq c \leq 1} V_2(cy) \leq V_2(y)$  and  $\int_0^\infty \bar{V}_1(y) y^{-\beta-2} dy < \infty$ . Denote  $\zeta_n(\theta; y, u) := (1 - \frac{\theta}{n^{1/(1+\beta)} y})^{[un]}$ . Then  $\zeta_n(\theta; y, u) \geq 0$  and we split the integral in (3.21) into two parts corresponding to  $\zeta_n(\theta; y, u) \leq 1/2$  and  $\zeta_n(\theta; y, u) > 1/2$ , viz.,  $J_{n2} = J_{n2}^+ + J_{n2}^-$ , where

$$\begin{aligned} J_{n2}^+ &:= \theta^{1+\beta} \int_0^\tau du \int_0^\infty y^{-\beta-2} dy V \left( y \left( 1 - \zeta_n(\theta; y, u) \right) \right) \psi \left( 1 - \frac{\theta}{n^{1/(1+\beta)} y} \right) \mathbf{1}(\zeta_n(\theta; y, u) \leq 1/2) \mathbf{1}_n(\theta; y, u), \\ J_{n2}^- &:= \theta^{1+\beta} \int_0^\tau du \int_0^\infty y^{-\beta-2} dy V \left( y \left( 1 - \zeta_n(\theta; y, u) \right) \right) \psi \left( 1 - \frac{\theta}{n^{1/(1+\beta)} y} \right) \mathbf{1}(\zeta_n(\theta; y, u) > 1/2) \mathbf{1}_n(\theta; y, u). \end{aligned}$$

Since  $|V(y(1 - \zeta_n(\theta; y, u))) \mathbf{1}(\zeta_n(\theta; y, u) \leq 1/2)| \leq \bar{V}_1(y) + V_2(y)$  is bounded by integrable function (see above), so  $J_{n2}^+ \rightarrow J$  by the dominated convergence theorem. It remains to prove  $J_{n2}^- \rightarrow 0$ . From inequalities

$1 - x \leq e^{-x}$  ( $x > 0$ ) and  $[un] \geq un/2$  ( $u > 1/n$ ) it follows that  $\zeta_n(\theta; y, u) \leq e^{-\theta un/2n^{1/(1+\beta)}y}$  and hence  $\mathbf{1}(\zeta_n(\theta; y, u) > 1/2) \leq \mathbf{1}(e^{-\theta un/2n^{1/(1+\beta)}y} > 1/2) = \mathbf{1}((u/y) < c_1 n^{-\gamma})$ , where  $\gamma := \beta/(1 + \beta) > 0$ ,  $c_1 := (2 \log 2)/\theta$ . Without loss of generality, we can assume that  $1 < \alpha < 1 + \beta$  in (3.5). Condition (3.5) implies

$$|V(y)| \leq \int_{|xy| \leq 1} |yx|^\alpha \pi(dx) + 2 \int_{|yx| > 1} |yx|^\alpha \pi(dx) \leq C|y|^\alpha, \quad \forall y \in \mathbb{R}.$$

Hence

$$|J_{n2}^-| \leq C \int_0^\tau du \int_0^\infty \mathbf{1}\left(\frac{u}{y} < c_1 n^{-\gamma}\right) \frac{dy}{y^{2+\beta-\alpha}} \leq K n^{-\gamma(1+\beta-\alpha)} \rightarrow 0$$

where  $K := C \int_0^\tau u^{\alpha-1-\beta} du < \infty$ . This proves  $J_{n2} \rightarrow J$ , or (3.22). The proof of  $J_{n1} \rightarrow 0$  follows similarly and hence is omitted.

(iv) The proof of finite-dimensional convergence is similar to Puplinskaitė and Surgailis (2010, proof of Thm. 3.1 (ii)). Below, we present the proof of the one-dimensional convergence of  $n^{-1/2}S_n = n^{-1/2} \sum_{t=1}^n \mathfrak{X}(t)$  towards  $\mathcal{N}(0, \sigma_\Phi^2)$  with  $\sigma_\Phi^2 > 0$  given in (3.23) below. Since the general case follows analogously. Similarly as above, consider  $J_n := \log \mathbb{E} \exp\{i\theta n^{-1/2}S_n\} = J_{n1} + J_{n2}$ , where  $J_{n1} := \sum_{s \leq 0} \mathbb{E}V(\theta n^{-1/2} \sum_{t=1}^n a^{t-s})$ ,  $J_{n2} := \sum_{s=1}^n \mathbb{E}V(\theta n^{-1/2} \sum_{t=s}^n a^{t-s})$ . We have

$$\begin{aligned} J_{n2} &= \sum_{k=1}^n \int_0^1 V\left(\theta \frac{1 - (1-z)^k}{zn^{1/2}}\right) \phi(1-z) dz \\ &= -\theta^2 \sigma_W^2 n^{-1} \sum_{k=1}^n \int_0^1 (1 - (1-z)^k)^2 z^{-2} \kappa_n(\theta; k, z) \phi(1-z) dz, \end{aligned}$$

where  $\kappa_n(\theta; k, z) := \kappa\left(\theta \frac{1 - (1-z)^k}{zn^{1/2}}\right)$  and the function  $\kappa(y) := -\frac{V(y)}{\sigma_W^2 y^2}$  satisfies  $\lim_{y \rightarrow 0} \kappa(y) = 1$ ,  $\sup_{y \in \mathbb{R}} |\kappa(y)| < \infty$ . These facts together with  $\beta > 1$  imply  $n^{-1} \sum_{k=1}^n \int_0^1 (1 - (1-z)^k)^2 z^{-2} \kappa_n(\theta; k, z) \phi(1-z) dz \rightarrow \int_0^1 z^{-2} \phi(1-z) dz$  and hence  $J_{n2} \rightarrow -(1/2)\theta^2 \sigma_\Phi^2$ , with

$$\sigma_\Phi^2 := 2\sigma_W^2 \int_0^1 z^{-2} \phi(1-z) dz = 2\sigma_W^2 \mathbb{E}(1-a)^{-2}. \quad (3.23)$$

The proof of  $J_{n1} \rightarrow 0$  follows similarly (see Puplinskaitė and Surgailis (2010) for details). This proves (3.7).

Let us prove the tightness part in (iv). It suffices to show the bound

$$\mathbb{E}S_n^4 \leq Cn^2. \quad (3.24)$$

We have  $S_n = M(g)$ , where  $M$  is the stochastic integral discussed in the proof of (ii) above and  $g \equiv g(s, a) = \sum_{t=1}^n a^{t-s} \mathbf{1}(t \geq s) \in L^2(\mathbb{Z} \times (0, 1))$ . Then  $\mathbb{E}M^4(g) = \text{cum}_4(M(g)) + 3(\mathbb{E}M^2(g))^2$ , where  $\mathbb{E}M^2(g) = \mathbb{E}S_n^2$  satisfies  $\mathbb{E}S_n^2 \leq Cn$  (the last fact follows by a similar argument as above). Hence,  $(\mathbb{E}M^2(g))^2 \leq Cn^2$  in agreement with (3.24). It remains to evaluate the 4th cumulant  $\text{cum}_4(S_n) = \text{cum}_4(M(g)) = \pi_4 \sum_{s \in \mathbb{Z}} \mathbb{E}g^4(s, a)$ , where  $\pi_4 := \int_{\mathbb{R}} x^4 \pi(dx)$ . Then  $\text{cum}_4(S_n) = \pi_4(L_{n1} + L_{n2})$ , where

$$L_{n1} := \sum_{s \leq 0} \mathbb{E}\left(\sum_{t=1}^n a^{t-s}\right)^4, \quad L_{n2} := \sum_{s=1}^n \mathbb{E}\left(\sum_{t=s}^n a^{t-s}\right)^4.$$

We have

$$L_{n2} \leq n \sum_{k=1}^n \mathbb{E}\left(\sum_{t=0}^k a^t\right)^3 \leq n \sum_{k=1}^n \int_0^1 z^{\beta-3} \psi(1-z) dz \leq Cn^2$$

since  $\beta > 2$ . Similarly,

$$L_{n1} \leq n^2 \sum_{s \leq 0} \mathbb{E} \left( \sum_{t=1}^n a^{t-s} \right)^2 \leq n^2 \int_0^1 \frac{z^{\beta-2} \psi(1-z) dz}{1 - (1-z)^2} \leq Cn^2.$$

This proves (3.24) and part (iv). Theorem 3.1 is proved.  $\square$

## 4 Disaggregation

Following Leipus et al. (2006), let us define an estimator of  $\phi$ , the density of the mixing distribution  $\Phi$ . Its starting point is the equality (1.8), implying

$$\sigma_W^{-2}(r(k) - r(k+2)) = \int_0^1 x^k \phi(x) dx, \quad k = 0, 1, \dots, \quad (4.1)$$

where  $r(k) = \text{Cov}(\mathfrak{X}(k), \mathfrak{X}(0))$  and  $\sigma_W^2 = \text{Var}(W) = r(0) - r(2)$ . The l.h.s. of (4.1), hence the integrals on the r.h.s. of (4.1), or moments of  $\Phi$ , can be estimated from the observed sample, leading to the problem of recovering the density from its moments, as explained below.

For a given  $q > 0$ , consider a finite measure on  $(0, 1)$  having density  $w^{(q)}(x) := (1-x)^{q-1}$ . Let  $L_2(w^{(q)})$  be the space of functions  $h : (0, 1) \rightarrow \mathbb{R}$  which are square integrable with respect to this measure. Denote by  $\{J_n^{(q)}, n = 0, 1, \dots\}$  the orthonormal basis in  $L_2(w^{(q)})$  consisting of normalized Jacobi polynomials:

$$J_n^{(q)}(x) := \sum_{j=0}^n g_{n,j}^{(q)} x^j, \quad (4.2)$$

with coefficients

$$g_{n,j}^{(q)} := (-1)^{n-j} \frac{\sqrt{2n+q}}{\Gamma(n+q)} \frac{\Gamma(n+1)}{\Gamma(n-j+1)} \frac{\Gamma(q+n+j)}{\Gamma(j+1)^2}, \quad (4.3)$$

$0 \leq j \leq n$ . See Abramovitz and Stegun (1965, p.774, formula 22.2.2). Thus,

$$\int_0^1 J_j^{(q)}(x) J_k^{(q)}(x) w^{(q)}(x) dx = \begin{cases} 1 & \text{if } j = k, \\ 0 & \text{if } j \neq k. \end{cases} \quad (4.4)$$

Any function  $h \in L_2(w^{(q)})$  can be expanded in Jacobi's polynomials:

$$h(x) = \sum_{k=0}^{\infty} h_k J_k^{(q)}(x) \quad \text{with} \quad h_k = \int_0^1 h(x) J_k^{(q)}(x) w^{(q)}(x) dx = \sum_{j=0}^k g_{k,j}^{(q)} \int_0^1 h(x) x^j w^{(q)}(x) dx. \quad (4.5)$$

Below, we call (4.5) the  $q$ -Jacobi expansion of  $h$ .

Consider the function

$$\zeta(x) := \frac{\phi(x)}{(1-x)^{q-1}}, \quad \text{with} \quad \int_0^1 \zeta(x) (1-x)^{q-1} dx = \int_0^1 \phi(x) dx = 1. \quad (4.6)$$

Under the condition

$$\int_0^1 \frac{\phi(x)^2}{(1-x)^{q-1}} dx < \infty, \quad (4.7)$$

the function  $\zeta$  in (4.6) belongs to  $L_2(w^{(q)})$ , and has a  $q$ -Jacobi expansion with coefficients

$$\zeta_k = \sum_{j=0}^k g_{k,j}^{(q)} \int_0^1 \phi(x) x^j dx = \frac{1}{\sigma_W^2} \sum_{j=0}^k g_{k,j}^{(q)} (r(j) - r(j+2)), \quad k = 0, 1, \dots; \quad (4.8)$$

see (4.1). Equations (4.5), (4.8) lead to the following estimates of the function  $\zeta(x)$ :

$$\widehat{\zeta}_n(x) := \sum_{k=0}^{K_n} \widehat{\zeta}_{n,k} J_k^{(q)}(x), \quad \widetilde{\zeta}_n(x) := \sum_{k=0}^{K_n} \widetilde{\zeta}_{n,k} J_k^{(q)}(x), \quad (4.9)$$

where  $K_n, n \in \mathbb{N}^*$  is a nondecreasing sequence tending to infinity at a rate which is discussed below, and

$$\widehat{\zeta}_{n,k} := \frac{1}{\widehat{\sigma}_W^2} \sum_{j=0}^k g_{k,j}^{(q)} (\widehat{r}_n(j) - \widehat{r}_n(j+2)), \quad \widetilde{\zeta}_{n,k} := \frac{1}{\sigma_W^2} \sum_{j=0}^k g_{k,j}^{(q)} (\widehat{r}_n(j) - \widehat{r}_n(j+2)) \quad (4.10)$$

are natural estimates of the  $\zeta_k$ 's in (4.8) in the case when  $\sigma_W^2$  is unknown or known, respectively. Here and below,

$$\bar{\mathfrak{X}} := \frac{1}{n} \sum_{k=1}^n \mathfrak{X}(k), \quad \widehat{r}_n(j) := \frac{1}{n} \sum_{i=1}^{n-j} (\mathfrak{X}(i) - \bar{\mathfrak{X}})(\mathfrak{X}(i+j) - \bar{\mathfrak{X}}), \quad j = 0, 1, \dots, n \quad (4.11)$$

are the sample mean and the sample covariance, respectively, and the estimate of  $\sigma_W^2 = r(0) - r(2)$  is defined as

$$\widehat{\sigma}_W^2 := \widehat{r}_n(0) - \widehat{r}_n(2).$$

The corresponding estimator of  $\phi(x)$  is constructed following relation (4.6):

$$\widehat{\phi}_n(x) := \widehat{\zeta}_n(x)(1-x)^{q-1}, \quad \widetilde{\phi}_n(x) := \widetilde{\zeta}_n(x)(1-x)^{q-1}. \quad (4.12)$$

The above estimators were essentially constructed in Leipus et al. (2006) and Celov et al. (2010). The modifications in (4.12) differ from the original ones in the above mentioned papers by the choice of a more natural estimate (4.11) of the covariance function  $r(j)$ , which allows for non-centered observations and makes both estimators in (4.12) location and scale invariant. Note also that the first estimator in (4.12) satisfies  $\int_0^1 \widehat{\phi}_n(x) dx = 1$ , while the second one does not have this property and can be used only if  $\sigma_W^2$  is known.

**Proposition 4.1** *Let  $(\mathfrak{X}(t))$  be an aggregated process in (1.4) with finite 4th moment  $E\mathfrak{X}(0)^4 < \infty$  and  $M \sim W \sim ID(\mu, \sigma, \pi)$ . Assume that the mixing density  $\phi(x)$  satisfies conditions (2.3) and (4.7), with some  $q > 0$ . Let  $\widetilde{\zeta}_n(x)$  be the estimator of  $\zeta(x)$  as defined in (4.9), where  $K_n$  satisfy*

$$K_n = \lceil \gamma \log n \rceil \quad \text{with} \quad 0 < \gamma < (4 \log(1 + \sqrt{2}))^{-1}. \quad (4.13)$$

Then

$$\int_0^1 E(\widetilde{\zeta}_n(x) - \zeta(x))^2 (1-x)^{q-1} dx \rightarrow 0. \quad (4.14)$$

*Proof.* Denote  $v_n$  the l.h.s. of (4.14). From the orthonormality property (4.4), similarly as in Leipus et al. (2006, (3.3)),

$$v_n = \sum_{k=0}^{K_n} E(\widetilde{\zeta}_{n,k} - \zeta_k)^2 + \sum_{k=K_n+1}^{\infty} \zeta_k^2, \quad (4.15)$$

where the second sum on the r.h.s. tends to 0. By the location invariance mentioned above, w.l.g. we can assume below that  $E\mathfrak{X}(t) = 0$ . Let  $\widehat{r}_n^\circ(j) := \frac{1}{n} \sum_{i=1}^{n-j} \mathfrak{X}(i)\mathfrak{X}(i+j)$ ,  $0 \leq j < n$ , then  $E\widehat{r}_n^\circ(j) - r(j) = (j/n)r(j)$  and

$$\begin{aligned} E\{\widetilde{\zeta}_{n,k} - \zeta_k\}^2 &= \sigma_W^{-4} E\left\{ \sum_{j=0}^k g_{k,j}^{(q)} (\widehat{r}_n(j) - \widehat{r}_n(j+2) - r(j) + r(j+2)) \right\}^2 \\ &= \sigma_W^{-4} E\left\{ \sum_{j=0}^k g_{k,j}^{(q)} \left( \widehat{r}_n^\circ(j) - \widehat{r}_n^\circ(j+2) - r(j) + r(j+2) + 2n^{-1}\overline{\mathfrak{X}}^2 \right. \right. \\ &\quad \left. \left. - n^{-1}\overline{\mathfrak{X}}[\mathfrak{X}(n-j-1) + \mathfrak{X}(n-j) + \mathfrak{X}(j+1) + \mathfrak{X}(j+2)] \right) \right\}^2 \\ &\leq Ck \left( \max_{0 \leq j \leq k} |g_{k,j}^{(q)}| \right)^2 \sum_{j=0}^k \left( \frac{j^2}{n^2} + \text{Var}(\widehat{r}_n^\circ(j) - \widehat{r}_n^\circ(j+2)) + \frac{C}{n^2} \right), \end{aligned} \quad (4.16)$$

where we used the trivial bound  $E\overline{\mathfrak{X}}^4 < C$ . The rest of the proof of Proposition 4.1 follows from (4.15), (4.16) and Lemmas 4.1 and 4.2 below. See Leipus et al. (2006, pp.2552-2553) for details.  $\square$

Lemma 4.1 generalizes (Leipus et al., 2006, Lemma 4) for a non-Gaussian aggregated process with finite 4th moment.

**Lemma 4.1** *Let  $\{\mathfrak{X}(t)\}$  be an aggregated process in (1.4) with  $E\mathfrak{X}(0)^4 < \infty$ ,  $E\mathfrak{X}(0) = 0$ . There exists a constant  $C > 0$  independent of  $n, k$  and such that*

$$\text{Var}(\widehat{r}_n^\circ(k) - \widehat{r}_n^\circ(k+2)) \leq \frac{C}{n}. \quad (4.17)$$

*Proof.* Let  $D(k) := \mathfrak{X}(k) - \mathfrak{X}(k+2)$ . Similarly as in Leipus et al. (2006, p.2560),

$$\text{Var}(\widehat{r}_n^\circ(k) - \widehat{r}_n^\circ(k+2)) \leq Cn^{-2} \left( \text{Var} \left( \sum_{j=1}^{n-k-2} \mathfrak{X}(j)D(j+k) \right) + 1 \right).$$

Here,  $\text{Var} \left( \sum_{j=1}^{n-k-2} \mathfrak{X}(j)D(j+k) \right) = \sum_{j,l=1}^{n-k-2} \text{Cov}(\mathfrak{X}(j)D(j+k), \mathfrak{X}(l)D(l+k))$ , where

$$\begin{aligned} \text{Cov}(\mathfrak{X}(j)D(j+k), \mathfrak{X}(l)D(l+k)) &= \text{Cum}(\mathfrak{X}(j), D(j+k), \mathfrak{X}(l), D(l+k)) \\ &\quad + E[\mathfrak{X}(j)\mathfrak{X}(l)]E[D(j+k)D(l+k)] + E[\mathfrak{X}(j)D(k+l)]E[\mathfrak{X}(l)D(j+k)]. \end{aligned}$$

The two last terms in the above representation of the covariance are estimated in Leipus et al. (2006). Hence the lemma follows from

$$\sum_{j,l=1}^{n-k-2} \text{Cum}(\mathfrak{X}(j), D(j+k), \mathfrak{X}(l), D(l+k)) \leq Cn. \quad (4.18)$$

We have for  $k_1, k_2 \geq 0, l \geq j$

$$\begin{aligned} \text{Cum}(\mathfrak{X}(j), \mathfrak{X}(j+k_1), \mathfrak{X}(l), \mathfrak{X}(l+k_2)) &= \pi_4 E \left[ \sum_{s \leq j} a^{j-s} a^{j-s+k_1} a^{l-s} a^{l-s+k_2} (1-a^2)^2 \right] \\ &= \pi_4 E \left[ \frac{a^{k_1+k_2+2(l-j)} (1-a^2)^2}{1-a^4} \right] \end{aligned}$$

and hence

$$c_{j,l,k} := \text{Cum}(\mathfrak{X}(j), D(j+k), \mathfrak{X}(l), D(l+k)) = \pi_4 E \left[ \frac{a^{2k+2(l-j)} (1-a^2)}{1+a^2} \right]$$

where  $\pi_4 := \int_{\mathbb{R}} x^4 \pi(dx)$ . Then

$$\begin{aligned} \sum_{j,l=1}^{n-k-2} |c_{j,l,k}| &\leq C \sum_{1 \leq j \leq l \leq n} \mathbb{E} \left[ \frac{(1-a^2)}{1+a^2} a^{2(l-j)} \right] \\ &\leq C \sum_{1 \leq j \leq n} \mathbb{E} \left[ \frac{1}{1+a^2} \right] \leq Cn, \end{aligned}$$

proving (4.18) and the lemma, too.  $\square$

**Lemma 4.2** Consider the coefficients  $g_{n,j}^{(q)}$  (4.3) of the normalized Jacobi polynomial  $J_n^{(q)}$  in (4.2). There exists a constant  $C_q > 0$  such that for all sufficiently large  $n$ ,

$$G_n^{(q)} := \max_{0 \leq j \leq n} |g_{n,j}^{(q)}| \leq C_q n^{13/2} e^{n\kappa} \quad \text{with} \quad \kappa := 2 \log(1 + \sqrt{2}).$$

*Proof* is similar to Leipus et al. (2006, proof of Lemma 5). We have

$$\left| \frac{g_{n,n-(m+1)}^{(q)}}{g_{n,n-m}^{(q)}} \right| = R(m), \quad \text{where} \quad R(z) := \frac{(n-z)^2}{(z+1)(q+2n-z-1)}. \quad (4.19)$$

The roots  $z_-, z_+$  of  $|R(z)| = 1$ , or  $(n-z)^2 - (z+1)(q+2n-z-1) = 0$ , are equal

$$z_{\pm} = n + \frac{q-2}{4} \pm n \frac{\sqrt{2}}{2} \sqrt{1 + \frac{p}{n} + \frac{q^2 + 4q - 4}{8n^2}}.$$

A straightforward verification shows that for any  $q > 0$  and all sufficiently large  $n$  the following bounds are true:

$$n \left( 1 - \frac{\sqrt{2}}{2} \right) - \frac{(\sqrt{2}-1)p}{4} - 1 \leq z_- \leq n \left( 1 - \frac{\sqrt{2}}{2} \right) - \frac{(\sqrt{2}-1)p}{4} =: z^*. \quad (4.20)$$

Since  $z_-$  is the only root satisfying  $0 \leq z_- \leq n$  and

$$|R(z)| \geq 1 \quad \text{for} \quad z \leq z_-; \quad |R(z)| \leq 1 \quad \text{for} \quad z_- \leq z \leq n, \quad (4.21)$$

(4.20)–(4.21) imply that  $G_n^{(q)} = \max_{0 \leq m \leq n} |g_{n,n-m}^{(q)}| = \max(|g_{n,n-m^*}^{(q)}|, |g_{n,n-(m^*+1)}^{(q)}|)$ , where  $m^*$  is the integer satisfying  $m^* \leq z_- \leq m^* + 1$ . Hence the statement of the lemma follows from Stirling's formula similarly to Leipus et al. (2006). Lemma 4.2 is proved.  $\square$

The main result of this sec. is the following theorem.

**Theorem 4.1** Let  $\{\mathfrak{X}(t)\}$ ,  $\phi(x)$  and  $K_n$  satisfy the conditions of Proposition 4.1, and  $\widehat{\phi}_n(x), \widetilde{\phi}_n(x)$  be the estimators of  $\phi(x)$  as defined in (4.12). Then

$$\int_0^1 \frac{(\widehat{\phi}_n(x) - \phi(x))^2}{(1-x)^{q-1}} dx \rightarrow_p 0 \quad \text{and} \quad \int_0^1 \frac{\mathbb{E}(\widetilde{\phi}_n(x) - \phi(x))^2}{(1-x)^{q-1}} dx \rightarrow 0. \quad (4.22)$$

*Proof.* The second relation in (4.22) is immediate from (4.12) and (4.14). Next,

$$\widehat{\phi}_n(x) - \phi(x) = \frac{\sigma_W^2}{\widehat{\sigma}_W^2} (\widetilde{\phi}_n(x) - \phi(x)) + \phi(x) \left( \frac{\sigma_W^2}{\widehat{\sigma}_W^2} - 1 \right),$$

where

$$\hat{\sigma}_W^2 = \hat{r}_n(0) - \hat{r}_n(2) = (g_{0,0}^{(q)})^{-1} \sigma_W^2 \tilde{\zeta}_{n,0} = \sigma_W^2 \int_0^1 \tilde{\zeta}_n(x) (1-x)^{q-1} dx,$$

see (4.4), (4.5), (4.9), (4.10). Hence the first relation in (4.22) follows from the second one and the fact that  $\hat{\sigma}_W^2 - \sigma_W^2 \rightarrow_p 0$ . We have

$$\begin{aligned} \mathbb{E}(\hat{\sigma}_W^2 - \sigma_W^2)^2 &= \sigma_W^4 \mathbb{E} \left( \int_0^1 (\tilde{\zeta}_n(x) - \zeta(x)) (1-x)^{q-1} dx \right)^2 \\ &\leq \sigma_W^4 \mathbb{E} \left( \int_0^1 (\tilde{\zeta}_n(x) - \zeta(x))^2 (1-x)^{q-1} dx \int_0^1 (1-x)^{q-1} dx \right) \\ &= \frac{\sigma_W^4}{q} \int_0^1 \mathbb{E}(\tilde{\zeta}_n(x) - \zeta(x))^2 (1-x)^{q-1} dx \rightarrow 0, \text{ as } n \rightarrow \infty, \end{aligned}$$

see (4.14). Theorem 4.1 is proved. □

**Remark 4.1** The optimal choice of  $q$  (minimizing the integrated MISE in (4.22)) is not clear. If  $\phi$  satisfies (3.1) then (4.7) is satisfied with any  $0 < q < 2 + 2\beta$ . Simulations in Leipus et al. (2006) and Celov et al. (2010) show the “optimal” choice of  $q$  might be close to  $\beta$  which is generally unknown.

**Remark 4.2** An interesting open question is asymptotic normality of the mixture density estimators in (4.12) for non-Gaussian process  $\{\mathfrak{X}(t)\}$  (1.4), extending Theorem 2.1 in Celov et al. (2010). The proof of the last result relies on a central limit theorem for quadratic forms of moving-average processes due to Bhansali et al. (2007). Generalizing this theorem to mixed ID moving averages is an open problem at this moment.
