# RELATIVE ENTROPY FOR THE FINITE VOLUME APPROXIMATION OF STRONG SOLUTIONS TO SYSTEMS OF CONSERVATION LAWS 

CLÉMENT CANCÈS, HÉLÈNE MATHIS, NICOLAS SEGUIN

#### Abstract

We study in this paper the finite volume approximation of strong solutions to systems of conservation laws. We derive error estimates in the multidimensional case, using the relative entropy between the strong solution and its finite volume approximation. The error terms are carefully studied, leading to a classical $h^{1 / 2}$ estimate under a $B V$ assumption on the numerical approximation.

## 1. Systems of conservation Laws

1.1. Strong, weak, and entropy weak solutions. We consider a system of $m$ conservation laws

$$
\begin{equation*}
\partial_{t} u(x, t)+\sum_{\alpha=1}^{d} \partial_{\alpha} f_{\alpha}(u)(x, t)=0 . \tag{1}
\end{equation*}
$$

The system (1) is set on the whole space $x \in \mathbb{R}^{d}$, and for any time $t \in[0, T], T>0$. We assume that there exists a convex bounded subset of $\mathbb{R}^{m}$, denoted by $\Omega$ and called set of the admissible states such that

$$
\begin{equation*}
u(x, t) \in \Omega, \quad \forall(x, t) \in \mathbb{R}^{d} \times[0, T] \tag{2}
\end{equation*}
$$

The system (1) is complemented with the initial condition

$$
\begin{equation*}
u(x, 0)=u_{0}(x) \in \Omega, \quad \forall x \in \mathbb{R}^{d} \tag{3}
\end{equation*}
$$

We assume for all $\alpha \in\{1, \ldots, d\}$ the functions $f_{\alpha}: \mathbb{R}^{m} \rightarrow \mathbb{R}^{m}$ to belong to $C^{2}\left(\bar{\Omega} ; \mathbb{R}^{m}\right)$, and be such that $\nabla_{u} f_{\alpha}$ are diagonalizable with real eigenvalues, where
$\nabla_{u} \phi$ denotes the matrix of the differential of $\phi: u \mapsto \phi(u)$. Moreover, we assume that there exists $L_{f}>0$ such that

$$
\begin{equation*}
\operatorname{spec}\left(\frac{1}{2}\left(\nabla_{u} f_{\alpha}(u)+\nabla_{u} f_{\alpha}(u)^{T}\right)\right) \subset\left[-L_{f}, L_{f}\right], \quad \forall \alpha \in\{1, \ldots, d\}, \forall u \in \Omega \tag{4}
\end{equation*}
$$

The system (1) is endowed with a uniformly convex entropy $\eta \in C^{2}(\bar{\Omega} ; \mathbb{R})$ such that there exists $M \geq \beta>0$ so that

$$
\begin{equation*}
\operatorname{spec}\left(\nabla_{u}^{2} \eta(u)\right) \subset[\beta ; M], \quad \forall u \in \bar{\Omega}, \tag{5}
\end{equation*}
$$

and the corresponding entropy flux $\xi \in C^{2}\left(\bar{\Omega} ; \mathbb{R}^{d}\right)$ satisfies for all $\alpha \in\{1, \ldots, d\}$

$$
\begin{equation*}
\nabla_{u} \xi_{\alpha}=\left(\nabla_{u} \eta\right)^{T} \nabla_{u} f_{\alpha} \tag{6}
\end{equation*}
$$

The existence of the entropy flux $\xi$ amounts to assume the integrability condition

$$
\begin{equation*}
\nabla_{u}^{2} \eta \nabla_{u} f_{\alpha}=\left(\nabla_{u} f_{\alpha}\right)^{T} \nabla_{u}^{2} \eta \tag{7}
\end{equation*}
$$

Despite it is well-known that even for smooth initial data $u_{0}$, the solutions of (1)(3) may develop discontinuities after a finite time, our study is restricted to the approximation of smooth solutions $u \in C^{1}\left(\mathbb{R}^{d} \times \mathbb{R}_{+} ; \Omega\right)$ of (1)-(3). Such solutions are called strong solutions and they automatically satisfy the conservation of the entropy

$$
\begin{equation*}
\partial_{t} \eta(u)+\sum_{\alpha=1}^{d} \partial_{\alpha} \xi_{\alpha}(u)=0 \quad \text { in } \mathbb{R}^{d} \times \mathbb{R}_{+} \tag{8}
\end{equation*}
$$

We refer for example to [Daf10] for more details.
Assuming that $u_{0} \in L^{\infty}\left(\mathbb{R}^{d} ; \Omega\right)$, a function $u \in L^{\infty}\left(\mathbb{R}^{d} \times \mathbb{R}_{+} ; \Omega\right)$ is said to be a weak solution to (1)-(3) if, for all $\phi \in C_{c}^{1}\left(\mathbb{R}^{d} \times \mathbb{R}_{+} ; \mathbb{R}^{n}\right)$, one has

$$
\begin{equation*}
\iint_{\mathbb{R}^{d} \times \mathbb{R}_{+}} u \partial_{t} \phi d x d t+\int_{\mathbb{R}^{d}} u_{0} \phi(\cdot, 0) d x+\iint_{\mathbb{R}^{d} \times \mathbb{R}_{+}} \sum_{\alpha=1}^{d} f_{\alpha}(u) \partial_{\alpha} \phi d x d t=0 . \tag{9}
\end{equation*}
$$

Moreover, $u$ is said to be an entropy weak solution to (1)-(3) if $u$ is a weak solution, i.e., $u$ satisfies (9), and if, for all $\left.\psi \in C_{c}^{1}\left(\mathbb{R}^{d} \times \mathbb{R}_{+}\right) ; \mathbb{R}_{+}\right)$, it satisfies

$$
\begin{equation*}
\iint_{\mathbb{R}^{d} \times \mathbb{R}_{+}} \eta(u) \partial_{t} \psi d x d t+\int_{\mathbb{R}^{d}} \eta\left(u_{0}\right) \psi(\cdot, 0) d x+\iint_{\mathbb{R}^{d} \times \mathbb{R}_{+}} \sum_{\alpha=1}^{d} \xi_{\alpha}(u) \partial_{\alpha} \psi d x d t \geq 0 \tag{10}
\end{equation*}
$$

1.2. Relative entropy. In the scalar case, the comparison of two entropy weak solutions lies on the Kruzhkov's paper [Kru70] which has been extended to the comparison of an entropy weak solution with an approximate solution by Kuznetsov [Kuz76]. Several improvements can be found in [CCL94, Vil94, EGGH98, BP98, CH99, EGH00]. In the case of systems of conservation laws, these techniques no longer work. Basically, the family of entropy-entropy flux pair $(\eta, \xi)$ is not sufficiently rich to control the difference between two solutions. Nevertheless, let us assume that one of these solutions is a strong solution ( $u$ in the following definition) and introduce:

Definition 1.1 (Relative entropy). Let $u, v \in \Omega$, we define the relative entropy of $v$ w.r.t. u by

$$
H(v, u)=\eta(v)-\eta(u)-\left(\nabla_{u} \eta(u)\right)^{T}(v-u)
$$

while the corresponding relative entropy flux $Q: \mathbb{R}^{n} \times \mathbb{R}^{n} \rightarrow \mathbb{R}^{d}$ is defined by

$$
Q_{\alpha}(v, u)=\xi_{\alpha}(v)-\xi_{\alpha}(u)-\left(\nabla_{u} \eta(u)\right)^{T}\left(f_{\alpha}(v)-f_{\alpha}(u)\right), \quad \forall \alpha \in\{1, \ldots, d\}
$$

The notion of relative entropy for systems of conservation laws goes back to the early works of DiPerna and Dafermos (see [DiP79], [Daf79] and the condensed presentation in [Daf10]). It is also a powerful tool which has been extensively used for the study of hydrodynamic limits of kinetic equations (see the first works [Yau91] and [BGL93], but also [SR09] for more recent results). In the context of systems of conservation laws, it is easy to check that, given a strong solution $u$ and an entropy weak solution $v$ with respective initial data $u_{0}$ and $v_{0}$, one has

$$
\begin{equation*}
\partial_{t} H(v, u)+\sum_{\alpha=1}^{d} \partial_{\alpha} Q_{\alpha}(v, u) \leq-\sum_{\alpha=1}^{d}\left(\partial_{\alpha} u\right)^{T} Z_{\alpha}(v, u) \tag{11}
\end{equation*}
$$

in the weak sense, where

$$
\begin{equation*}
Z_{\alpha}(v, u)=\nabla_{u}^{2} \eta(u)\left(f_{\alpha}(v)-f_{\alpha}(u)-\left(\nabla_{u} f_{\alpha}(u)\right)^{T}(v-u)\right) . \tag{12}
\end{equation*}
$$

On the other hand, it follows from the definition of $H$ that

$$
\begin{equation*}
H(v, u)=\int_{0}^{1} \int_{0}^{\theta}(v-u)^{T} \nabla_{u}^{2} \eta(u+\gamma(v-u))(v-u) d \gamma d \theta \tag{13}
\end{equation*}
$$

which, together with (5), leads to

$$
\begin{equation*}
\frac{M}{2}(v-u)^{2} \geq H(v, u) \geq \frac{\beta}{2}(v-u)^{2}, \quad \forall u, v \in \Omega \tag{14}
\end{equation*}
$$

If $u$ is assumed to be a strong solution, its first and second derivatives are bounded and by a classical localization procedure $\grave{a}$ la Kruzhkov and a Gronwall lemma, one obtains a $L_{\text {loc }}^{2}$ stability estimate for any $r>0$

$$
\begin{equation*}
\int_{|x|<r}|v(x, T)-u(x, T)|^{2} d x \leq C(T, u) \int_{|x|<r+L_{f} T}\left|v_{0}(x)-u_{0}(x)\right|^{2} d x \tag{15}
\end{equation*}
$$

where the dependence of $C$ on $u$ reflect the needs of smoothness on $u$ ( $C$ blows up when $u$ becomes discontinuous). This inequality, rigorously proved in [Daf10], provides a weak-strong uniqueness result and similar (but more sophisticated) ideas have been recently applied to other fluid systems [FN12].
Remark 1.1. For general conservation laws, the relative entropy is not symmetric, i.e, $H(u, v) \neq H(v, u)$ and $Q(u, v) \neq Q(v, u)$. In the very particular case of Friedrichs systems, i.e. when there exist symmetric matrices $A_{\alpha} \in \mathbb{R}^{m \times m}$ $(\alpha \in\{1, \ldots, d\})$ such that $f_{\alpha}(u)=A_{\alpha} u$, then $u \mapsto|u|^{2}$ is an entropy and the corresponding entropy flux $\xi$ is $\xi_{\alpha}(u)=u^{T} A_{\alpha} u,(\alpha \in\{1, \ldots, d\})$. It is then easy to check that

$$
\begin{aligned}
H(v, u) & =|v-u|^{2}=H(u, v) \\
Q_{\alpha}(v, u) & =(v-u)^{T} A_{\alpha}(v-u)=Q_{\alpha}(v, u), \\
Z_{\alpha}(v, u) & =0
\end{aligned}
$$

for all $(u, v) \in \mathbb{R}^{m}$. As a consequence, inequality (11) becomes

$$
\partial_{t} H(v, u)+\sum_{\alpha=1}^{d} \partial_{\alpha} Q_{\alpha}(v, u) \leq 0
$$

even if $u$ is a weak solution since $H$ and $Q$ are symmetric functions. This allows to make use of the doubling variable technique [Kru70] to compare $u$ to $v$, recovering the classical uniqueness result for Friedrichs systems [Fri54].

Our aim is to replace the entropy weak solution $v$ in (11) by an approximate solution provided by finite volume schemes on unstructured meshes. Following the formalism introduced in [EGGH98], this makes appear in (11) bounded Radon measures which can be controlled, leading to error estimates in $h^{1 / 2}$ between a
strong solution and its finite volume approximation, $h$ being the characteristic size of the cells of the mesh.

Remark 1.2. In the context of Friedrichs systems, such error estimates can be obtained, even in the weak setting, for the sames reasons as those given in Remark 1.1, see [VV03, RJ05].

Remark 1.3. In [Tza05], Tzavaras studies the comparison of solutions of a hyperbolic system with relaxation with solutions of the associated equilibrium system of conservation laws. He also makes use of the relative entropy but, since he only focus on strong solutions (for both systems), he does not need to place himself in a weak setting with measure terms. Very similar questions have been adressed in [BV05, BTV09] for the convergence of kinetic equations towards the system of gas dynamics. Here again, only strong solutions of the Euler equations are considered. To finish the bibliographical review, let us mention the work by Leger and Vasseur [LV11] where the reference solution may include some particular discontinuities.
1.3. Organization of the paper. We first introduce in Section 2 the family of numerical schemes we consider for approximating the solution to the problem (1)(3). Some natural assumptions are made on the scheme, but also on the numerical solution on which we assume some reasonable stability property.

In order to compare the discrete solution (denoted by $u^{h}$ in the sequel of the paper) with the strong solution $u$, we write continuous weak and entropy formulations in Section 3, so that we can adapt the uniqueness proof proposed in [Daf10]. Nevertheless, the discrete solution $u^{h}$ is obviously not a weak entropy solution. Therefore, some error terms coming from the discretization have to be taken into account in the formulation, which take the form of positive locally bounded Radon measures, following [EGGH98]. A large part of Section 3 consists in making these measures explicit and to bound them with quantities tending towards 0 with the discretization size.

In Section 4, we make use of the weak and entropy weak formulations for the discrete solution (and of their corresponding error measures) to derive an error estimate. The distance between the strong solution $u$ and the discrete solution $u^{h}$ is quantified thanks to the relative entropy $H\left(u^{h}, u\right)$ introduced in Definition 1.1.

## 2. Entropy Satisfying finite volume schemes

2.1. Definition of the numerical scheme. Let $\mathcal{T}$ be a mesh of $\mathbb{R}^{d}$ such that $\mathbb{R}^{d}$ is the union of the closure of the elements of $\mathcal{T}$. We denote

$$
h=\sup \{\operatorname{diam}(K), K \in \mathcal{T}\}<\infty
$$

For all $K \in \mathcal{T}$, we denote by $|K|$ its $d$-dimensional Lebesgue measure, and by $\mathcal{N}(K)$ the set of its neighboring cells. For $L \in \mathcal{N}(K)$, the common interface between $K$ and $L$ is denoted by $\sigma_{K L}$ and $\left|\sigma_{K L}\right|$ is its $(d-1)$-Lebesgue measure. We assume that there exists $a>0$ such that

$$
\begin{equation*}
|K| \leq a h^{d} \quad \text { and } \quad|\partial K|:=\sum_{L \in \mathcal{N}(K)}\left|\sigma_{K L}\right| \leq \frac{h^{d-1}}{a}, \quad \forall K \in \mathcal{T} . \tag{16}
\end{equation*}
$$

The unit normal vector to $\sigma_{K L}$ from $K$ to $L$ is denoted $n_{K L}$. Let $\Delta t>0$ be the time step and we set $t^{n}=n \Delta t, \forall n \in \mathbb{N}$.

Remark 2.1. In order to avoid some additional heavy notations, we have chosen to deal with an uniform time discretization and a space discretization that does not depend on time. Nevertheless, it is possible, by following the path described in [KO00], to adapt our study to the case of time depending space discretizations and to non-uniform time discretizations. This would be mandatory for considering
a dynamic mesh adaptation procedure based on the a posteriori numerical error estimators that can be derived from our study.

For all $(K, L) \in \mathcal{T}^{2}, L \in \mathcal{N}(K)$, we consider the numerical flux $G_{K L} \in C^{2}(\Omega \times$ $\left.\Omega ; \mathbb{R}^{m}\right):(u, v) \rightarrow G_{K L}(u, v)$ which satisfies the following conditions:

$$
\begin{align*}
& G_{K L}(u, v)=-G_{L K}(v, u), \quad \forall(u, v) \in \Omega^{2}  \tag{17}\\
& G_{K L}(u, u)=f(u) \cdot n_{K L}, \quad \forall u \in \Omega . \tag{18}
\end{align*}
$$

We assume that there exists $\lambda^{\star}>0$ such that, for all $\lambda>\lambda^{\star}$, for all $K \in \mathcal{T}$, and for all $L \in \mathcal{N}(K)$,

$$
\begin{equation*}
u-\frac{1}{\lambda}\left[G_{K L}(u, v)-f(u) \cdot n_{K L}\right] \in \Omega, \quad \forall(u, v) \in \Omega^{2} \tag{19}
\end{equation*}
$$

We also assume there exists a numerical entropy flux $\xi_{K L}$ which is conservative

$$
\begin{equation*}
\xi_{K L}(u, v)=-\xi_{L K}(v, u), \quad \forall(u, v) \in \Omega^{2} \tag{20}
\end{equation*}
$$

and such that, for all $\lambda \geq \lambda^{\star}>0$, the following entropy inequality by interface is satisfied:
(21) $\quad \xi_{K L}(u, v)-\xi(u) \cdot n_{K L} \leq-\lambda\left(\eta\left(u-\frac{1}{\lambda}\left[G_{K L}(u, v)-f(u) \cdot n_{K L}\right]\right)-\eta(u)\right)$.

We additionally assume that the following CFL condition holds

$$
\begin{equation*}
\frac{\Delta t}{|K|} \lambda^{\star} \sum_{L \in \mathcal{N}(K)}\left|\sigma_{K L}\right| \leq 1, \quad \forall K \in \mathcal{T} \tag{22}
\end{equation*}
$$

In particular, the regularity of the mesh (16) implies that (22) holds if

$$
\begin{equation*}
\Delta t \leq \frac{a^{2}}{\lambda^{\star}} h . \tag{23}
\end{equation*}
$$

We have now introduced all the necessary material to define the numerical scheme we will consider in what follows.

Definition 2.1 (Finite volume scheme). Let us introduce $N_{T}=\max \{n \in \mathbb{N}, n \leq$ $T / \Delta t+1\}$ and define the discrete unknowns $u_{K}^{n}, K \in \mathcal{T}$ and $n \in\left\{0, \ldots, N_{T}\right\}$, by

$$
\begin{equation*}
\frac{u_{K}^{n+1}-u_{K}^{n}}{\Delta t}|K|+\sum_{L \in \mathcal{N}(K)}\left|\sigma_{K L}\right| G_{K L}\left(u_{K}^{n}, u_{L}^{n}\right)=0 \tag{24}
\end{equation*}
$$

together with the initial condition

$$
\begin{equation*}
u_{K}^{0}=\frac{1}{|K|} \int_{K} u_{0}(x) d x, \quad \forall K \in \mathcal{T} \tag{25}
\end{equation*}
$$

under assumptions (17)-(21) on the numerical flux $G_{K L}$ and under the CFL condition (23). The approximate solution $u^{h} \in L^{\infty}\left(\mathbb{R}^{d} \times \mathbb{R}_{+}\right)$provided by the finite volume scheme (24)-(25) is defined by

$$
\begin{equation*}
u^{h}(x, t)=u_{K}^{n}, \quad \text { for } x \in K, t^{n} \leq t<t^{n+1}, K \in \mathcal{T}, n \in\left\{0, \ldots, N_{T}\right\} \tag{26}
\end{equation*}
$$

An important property of such a numerical scheme is the preservation of the set of admissible states.

Lemma 2.2. Assume that (3), (19) and (22) holds, then, for all $K \in \mathcal{T}$, for all $n \in\left\{0, \ldots, N_{T}\right\}, u_{K}^{n}$ belong to $\Omega$.
Proof. Recall first that for all $K \in \mathcal{T}, u_{K}^{0}$ is defined by (25). Since, thanks to (2), $u_{0}$ takes its values in the convex set $\Omega$, then so does its spatial mean values on the cells $K \in \mathcal{T}$. This ensures that $u_{K}^{0}$ belongs to $\Omega$ for all $K \in \mathcal{T}$.

Now, let us notice that assumption (18) implies

$$
\begin{equation*}
\sum_{L \in \mathcal{N}(K)}\left|\sigma_{K L}\right| G_{K L}(u, u)=0, \quad \forall u \in \mathbb{R}^{m}, \forall K \in \mathcal{T} \tag{27}
\end{equation*}
$$

Assume now that for all $K \in \mathcal{T}, u_{K}^{n} \in \Omega$. Using (24) and (27), we know that for all $K \in \mathcal{T}$ and for all $n \in \mathbb{N}$, one has

$$
\begin{equation*}
u_{K}^{n+1}=\sum_{L \in \mathcal{N}(K)} \frac{\left|\sigma_{K L}\right|}{|\partial K|}\left(u_{K}^{n}-\frac{\Delta t|\partial K|}{|K|}\left(G_{K L}\left(u_{K}^{n}, u_{L}^{n}\right)-f\left(u_{K}^{n}\right) \cdot n_{K L}\right)\right) . \tag{28}
\end{equation*}
$$

Thanks to (19) and (22), $u_{K}^{n+1}$ is a convex combination of elements of the convex set $\Omega$, then it also belongs to $\Omega$.

Thanks to (21), we can derive entropy consistency properties on the numerical scheme.

Proposition 2.3. Let $u^{h}$ be defined by (24)-(26) (and thus, satisfying assumptions (17)-(21)). Then the numerical entropy flux $\xi_{K L}$ is consistent with $\xi$, i.e.

$$
\begin{equation*}
\xi_{K L}(u, u)=\xi(u) \cdot n_{K L}, \quad \forall u \in \Omega . \tag{29}
\end{equation*}
$$

Moreover, under the CFL condition (23), $u^{h}$ satisfies the discrete entropy inequality

$$
\begin{equation*}
\frac{m(K)}{\Delta t}\left(\eta\left(u_{K}^{n+1}\right)-\eta\left(u_{K}^{n}\right)\right)+\sum_{L \in \mathcal{N}(K)} \xi_{K L}\left(u_{K}^{n}, u_{L}^{n}\right) \leq 0 \tag{30}
\end{equation*}
$$

Proof. First we focus on the consistance property (29). We write the inequality (21) for $\xi_{K L}\left(u_{K}, u_{L}\right)$ and $\xi_{L K}\left(u_{L}, u_{K}\right)$ :

$$
\begin{aligned}
\xi_{K L}\left(u_{K}, u_{L}\right) \leq & \xi\left(u_{K}\right) \cdot n_{K L} \\
& -\lambda\left(\eta\left(u_{K}-\frac{1}{\lambda}\left[G_{K L}\left(u_{K}, u_{L}\right)-f\left(u_{K}\right) \cdot n_{K L}\right]\right)-\eta\left(u_{K}\right)\right), \\
\xi_{L K}\left(u_{L}, u_{K}\right) \leq & \xi\left(u_{L}\right) \cdot n_{L K} \\
& -\lambda\left(\eta\left(u_{L}-\frac{1}{\lambda}\left[G_{L K}\left(u_{L}, u_{K}\right)-f\left(u_{L}\right) \cdot n_{L K}\right]\right)-\eta\left(u_{L}\right)\right) .
\end{aligned}
$$

Setting $u_{K}=u_{L}=u$, then using the conservation property (20) and the consistency relation (18) lead to the consistency of the numerical entropy flux (29).

Applying $\eta$ to (28) and using its convexity yields

$$
\begin{equation*}
\eta\left(u_{K}^{n+1}\right) \leq \sum_{L \in \mathcal{N}(K)} \frac{\left|\sigma_{K L}\right|}{|\partial K|} \eta\left(u_{K}^{n}-\frac{\Delta t|\partial K|}{|K|}\left(G_{K L}\left(u_{K}^{n}, u_{L}^{n}\right)-f\left(u_{K}^{n}\right) \cdot n_{K L}\right)\right) \tag{31}
\end{equation*}
$$

Now, it follows from the CFL condition (23), the interface entropy condition (21) and

$$
\begin{equation*}
\sum_{L \in \mathcal{N}(K)}\left|\sigma_{K L}\right| \xi_{K L}(u, u)=0, \forall u \in \Omega \tag{32}
\end{equation*}
$$

that (30) holds.
2.2. Stability estimates and main result. In order to carry out an error estimate, we have to assume some "regularity" on the approximate solution $u^{h}$. In practice, we assume from now on that there exists $C_{B V}>0$ (that may depend at most on $r, T, u_{0}$ and on $\left.G_{K L}\right)$ such that

$$
\begin{equation*}
\sum_{n=0}^{N_{T}} \Delta t \sum_{(K, L) \in \mathcal{E}_{r}}\left|\sigma_{K L}\right|\left|G_{K L}\left(u_{K}^{n}, u_{L}^{n}\right)-f\left(u_{K}^{n}\right) \cdot n_{K L}\right| \leq C_{B V} \tag{33}
\end{equation*}
$$

Remark 2.2. Assumption (33) requires several comments.
(1) Since we consider explicit numerical schemes, the stability estimate (33) requires a CFL condition to be satisfied in order to prevent oscillations. One can reasonably assess that

$$
\begin{equation*}
\Delta t \leq C_{\text {stab }} h \tag{34}
\end{equation*}
$$

for some $C_{\text {stab }}>0$ which may depend on the same quantities as $C_{B V}$. We then have to choose $\Delta t$ small enough so that both (34) and (23) are satisfied.
(2) Assuming (33) is weaker than assuming that $u^{h} \in\left(B V_{\text {loc }}\left(\mathbb{R}_{+} \times \mathbb{R}^{d}\right)\right)^{m}$. Indeed, consider the simple linear transport case where $f(u)=u \otimes \mathbf{e}_{1}$ for $\mathbf{e}_{1}=(1,0)^{T}$ in $\mathbb{R}^{2}$ with a grid whose edges are along $\mathbf{e}_{1}$ and $\mathbf{e}_{2}=(0,1)^{T}$, and define $G_{K, L}$ as the upstream flux. Then (33) only requires $u^{h}$ to have a bounded variation in the direction of $\mathbf{e}_{1}$. We refer to [Des04, Lemma 5] for an example where $u^{h}$ is not uniformly bounded in $B V_{\text {loc }}\left(\mathbb{R}_{+} \times \mathbb{R}^{2}\right)$ but where (33) still holds.
(3) In the scalar case $m=1$, it is possible to recover estimate (33) on cartesian grids even for nonlinear flux functions $f: \mathbb{R} \rightarrow \mathbb{R}^{d}$ (cf. e.g. [CH99, EGGH98, GR91]). On unstructured grids, despite (33) seems to remain true in the numerical experiments (cf. [KO00]), only a weaker inequality can be proved, namely

$$
\sum_{n=0}^{N_{T}} \Delta t \sum_{(K, L) \in \mathcal{E}_{r}}\left|\sigma_{K L}\right|\left|G_{K L}\left(u_{K}^{n}, u_{L}^{n}\right)-f\left(u_{K}^{n}\right) \cdot n_{K L}\right| \leq \frac{C_{w B V}}{\sqrt{h}}
$$

for some $C_{w B V}>0$. This estimate, called weak-BV estimate in [EGGH98, CH99], relies on the quantification of the numerical diffusion introduced by the scheme [Vil94, CCL94].

Using the $B V$ assumption (33), one may derive entropy $B V$ estimates and time$B V$ estimates.

Lemma 2.4. Assume that (17)-(21) and (33) hold, then one has

$$
\begin{equation*}
\sum_{n=0}^{N_{T}} \Delta t \sum_{(K, L) \in \mathcal{E}_{r}}\left|\sigma_{K L}\right|\left|\xi_{K L}\left(u_{K}^{n}, u_{L}^{n}\right)-\xi\left(u_{K}\right) \cdot n_{K L}\right| \leq\left\|\nabla_{u} \eta\right\|_{L^{\infty}(\Omega)} C_{B V} \tag{35}
\end{equation*}
$$

Proof. This is a direct consequence of (21) in which the Lipschitz continuity of $\eta$ has been taken into account.

Lemma 2.5 (time- $B V$ estimates). Under Assumption (33), one has

$$
\begin{gather*}
\sum_{n=0}^{N_{T}} \sum_{K \in \mathcal{T}_{r}}|K|\left|u_{K}^{n+1}-u_{K}^{n}\right| \leq C_{B V},  \tag{36}\\
\sum_{n=0}^{N_{T}} \sum_{K \in \mathcal{T}_{r}}|K|\left|\eta\left(u_{K}^{n+1}\right)-\eta\left(u_{K}^{n}\right)\right| \leq\left\|\nabla_{u} \eta\right\|_{L^{\infty}(\Omega)} C_{B V} \tag{37}
\end{gather*}
$$

Proof. Thanks to the definition (24) of the scheme and thanks to the divergence free property (27), for all $K \in \mathcal{T}$ and all $n \in \mathbb{N}$, one has

$$
\left(u_{K}^{n+1}-u_{K}^{n}\right)|K|=-\Delta t \sum_{L \in \mathcal{N}(K)}\left|\sigma_{K L}\right|\left(G_{K L}\left(u_{K}^{n}, u_{L}^{n}\right)-f\left(u_{K}^{n}\right) \cdot n_{K L}\right),
$$

so that

$$
\left|u_{K}^{n+1}-u_{K}^{n}\right||K| \leq \Delta t \sum_{L \in \mathcal{N}(K)}\left|\sigma_{K L}\right|\left|G_{K L}\left(u_{K}^{n}, u_{L}^{n}\right)-f\left(u_{K}^{n}\right) \cdot n_{K L}\right| .
$$

Summing over $K \in \mathcal{T}_{r}$ and $n \in\left\{0, \ldots, N_{T}\right\}$ and using (33) provides (36). Inequality (37) then follows from the Lipschitz continuity of $\eta$.

Let us now state our main result.
Theorem 2.6. Assume that $u_{0} \in W^{1, \infty}\left(\mathbb{R}^{d}\right)$ and that the solution $u$ of the Cauchy problem (1)-(3) belongs to $W^{1, \infty}\left([0, T] \times \mathbb{R}^{d}\right)$. Assume also that (3), (16), (17)(21), (23), and identities (6)-(7) hold. Let $u^{h}$ defined by (24)-(26), and assume that the stability estimate (33) holds, then, for all $r>0$ and $T>0$ there exist $C$ depending only on $T, r, \Omega, a, \lambda^{\star}, u_{0}, G_{K L}, \eta$ and $f$, such that

$$
\int_{0}^{T} \int_{B\left(0, r+L_{f}(T-t)\right)}\left|u-u_{h}\right|^{2} d x d t \leq C h
$$

## 3. Continuous weak and entropy formulations for the discrete SOLUTION

In order to obtain the error estimate of Theorem 2.6, we aim at using the relative entropy of $u^{h}$ w.r.t. $u$. Since $u^{h}$ is only an approximate solution, it does not exactly satisfies neither the weak formulation (9) nor the entropy weak formulation (10). Some numerical error terms appear in these formulations, and thus also appear the inequality of the relative entropy

$$
\begin{align*}
\partial_{t} H\left(u^{h}, u\right)+\sum_{\alpha=1}^{d} \partial_{\alpha} Q_{\alpha}\left(u^{h}, u\right) \leq & -\sum_{\alpha=1}^{d}\left(\partial_{\alpha} u\right)^{T} Z_{\alpha}\left(u^{h}, u\right)  \tag{38}\\
& + \text { numerical error terms. }
\end{align*}
$$

As usual, these terms may be described by Radon measures - see [BP98, EGGH98, CH99, KO00] in the scalar case and [RJ05] in the case of Friedrichs systems. Note that for nonlinear systems of conservation laws, a function which satisfies the entropy inequality (10) is not necessarily a weak solution (9). This leads us to consider the measures not only in the entropy inequality of $u^{h}$ but also in the weak formulation of $u^{h}$. Let us first begin with the entropy formulation and the related measures.

For $X=\mathbb{R}^{d}$ or $X=\mathbb{R}^{d} \times \mathbb{R}^{+}$, we denote $\mathcal{M}(X)$ the set of locally bounded Radon measures on $X$, i.e., $\mathcal{M}(X)=\left(C_{c}(X)\right)^{\prime}$. If $\mu \in \mathcal{M}(X)$ we set

$$
\langle\mu, \varphi\rangle=\int_{X} \varphi d \mu, \forall \varphi \in C_{c}(X)
$$

Definition 3.1. For $\psi \in C_{c}\left(\mathbb{R}^{d}\right)$, $\varphi \in C_{c}\left(\mathbb{R}^{d} \times \mathbb{R}^{+}\right)$, we define $\mu_{0} \in \mathcal{M}\left(\mathbb{R}^{d}\right)$ and $\mu \in \mathcal{M}\left(\mathbb{R}^{d} \times \mathbb{R}^{+}\right)$by

$$
\begin{aligned}
\left\langle\mu_{0}, \psi\right\rangle= & \int_{\mathbb{R}^{d}}\left|\eta\left(u_{0}(x)\right)-\eta\left(u^{h}(x, 0)\right)\right| \psi(x) d x, \\
\langle\mu, \varphi\rangle= & \left\langle\mu_{\mathcal{T}}, \varphi\right\rangle+\sum_{n=0}^{\infty} \Delta t \sum_{(K, L) \in \mathcal{E}_{r}}\left|\sigma_{K L}\right|\left|\xi_{K L}\left(u_{K}^{n}, u_{L}^{n}\right)-\xi_{K L}\left(u_{K}^{n}, u_{K}^{n}\right)\right|\left\langle\mu_{K L}, \varphi\right\rangle \\
& +\sum_{n=0}^{\infty} \Delta t \sum_{(K, L) \in \mathcal{E}_{r}}\left|\sigma_{K L}\right|\left|\xi_{K L}\left(u_{K}^{n}, u_{L}^{n}\right)-\xi_{K L}\left(u_{L}^{n}, u_{L}^{n}\right)\right|\left\langle\mu_{L K}, \varphi\right\rangle,
\end{aligned}
$$

where

$$
\begin{aligned}
\left\langle\mu_{\mathcal{T}}, \varphi\right\rangle= & \sum_{n=0}^{\infty} \sum_{K \in \mathcal{T}_{r}}\left|\eta\left(u_{K}^{n+1}\right)-\eta\left(u_{K}^{n}\right)\right| \int_{t^{n}}^{t^{n+1}} \int_{K} \varphi(x, t) d x d t \\
\left\langle\mu_{K L}, \varphi\right\rangle= & \frac{1}{m(K) m\left(\sigma_{K L}\right)(\Delta t)^{2}} \\
& \times \int_{t^{n}}^{t^{n+1}} \int_{K} \int_{t^{n}}^{t^{n+1}} \int_{\sigma_{K L}} \int_{0}^{1}(h+\Delta t) \varphi(\gamma+\theta(x-\gamma), s+\theta(t-s)) d \theta d x d t d \gamma d s, \\
\left\langle\mu_{L K}, \varphi\right\rangle= & \frac{1}{m(L) m\left(\sigma_{K L}\right)(\Delta t)^{2}} \\
& \times \int_{t^{n}}^{t^{n+1}} \int_{L} \int_{t^{n}}^{t^{n+1}} \int_{\sigma_{K L}} \int_{0}^{1}(h+\Delta t) \varphi(\gamma+\theta(x-\gamma), s+\theta(t-s)) d \theta d x d t d \gamma d s .
\end{aligned}
$$

The measures $\mu$ and $\mu_{0}$ describe the error of approximation in the entropy formulation satisfied by $u^{h}$. Indeed, we have:
Lemma 3.2. Assume that (3), (16), (17)-(21), (23), and identities (6)-(7) hold. Let $u^{h}$ defined by (24)-(26), and assume that the stability estimate (33) holds, then, for all $r>0$ and $T>0$ there exist $C_{\mu_{0}}>0$, depending only on $u_{0},\left\|\nabla_{u} \eta\right\|_{L^{\infty}(\Omega)}:=$ $\sup _{u \in \Omega}\left|\nabla_{u} \eta(u)\right|$ and $r$, and $C_{\mu}>0$, depending only on $T, r, a, \lambda_{\star}, u_{0}, G_{K L}$ and $\eta$ such that, for all $h<r$,

$$
\begin{align*}
& \mu_{0}(B(0, r)) \leq C_{\mu_{0}} h,  \tag{39}\\
& \mu(B(0, r) \times[0, T]) \leq C_{\mu} h . \tag{40}
\end{align*}
$$

Proof. The measure $\mu_{0}$ is the measure of density $\left|\eta\left(u_{0}(x)\right)-\eta\left(u^{h}(x, 0)\right)\right|$ with respect to the Lebesgue measure. For all $r>0$ we have

$$
\lim _{h \rightarrow 0} \mu_{0}(B(0, r))=0
$$

For smooth $u_{0}: \mathbb{R}^{d} \rightarrow \mathbb{R}^{m}$, the measure $\mu_{0}$ satisfies

$$
\mu_{0}(B(0, r)) \leq h\left\|\nabla_{u} \eta\right\|_{L^{\infty}(\Omega)} \int_{B(0, r+h)}\left|\nabla u_{0}\right| d x .
$$

For $r>0$ and $T>0$ the measure $\mu_{\mathcal{T}}$ satisfies

$$
\mu_{\mathcal{T}}(B(0, r) \times[0, T])=\int_{0}^{T} \int_{B(0, r)} \sum_{n=0}^{N_{T}} \sum_{K \in \mathcal{T}_{r}}\left|\eta\left(u_{K}^{n+1}\right)-\eta\left(u_{K}^{n}\right)\right| \mathbf{1}_{K \times\left[t^{n}, t^{n+1}\right]} d x d t .
$$

Then, using the time $-B V$ estimate (37),

$$
\mu_{\mathcal{T}}(B(0, r) \times[0, T]) \leq \Delta t \sum_{n=0}^{N_{T}} \sum_{K \in \mathcal{T}_{r}}\left|K\left\|\eta\left(u_{K}^{n+1}\right)-\eta\left(u_{K}^{n}\right) \mid \leq \Delta t\right\| \nabla_{u} \eta \|_{L^{\infty}(\Omega)} C_{B V} .\right.
$$

It follows from (23) that

$$
\begin{equation*}
\mu_{\mathcal{T}}(B(0, r) \times[0, T]) \leq C_{\mu_{\mathcal{T}}} h, \tag{41}
\end{equation*}
$$

where

$$
C_{\mu \tau}:=\frac{a^{2}\left\|\nabla_{u} \eta\right\|_{L^{\infty}(\Omega)}}{\lambda^{\star}} C_{B V} .
$$

The measures $\mu_{K L}$ and $\mu_{L K}$ satisfy:

$$
\mu_{K L}\left(\mathbb{R}^{d} \times \mathbb{R}^{+}\right) \leq h+\Delta t, \quad \mu_{L K}\left(\mathbb{R}^{d} \times \mathbb{R}^{+}\right) \leq h+\Delta t .
$$

Therefore,

$$
\begin{aligned}
& \mu(B(0, r) \times[0, T]) \\
& \leq C_{\mu \mathcal{T}} h+(h+\Delta t) \sum_{n=0}^{N_{T}} \Delta t \sum_{(K, L) \in \mathcal{E}_{r}}\left|\sigma_{K L}\right|\left|\xi_{K L}\left(u_{K}^{n}, u_{L}^{n}\right)-\xi_{K L}\left(u_{K}^{n}, u_{K}^{n}\right)\right| \\
& \\
& +(h+\Delta t) \sum_{n=0}^{N_{T}} \Delta t \sum_{(K, L) \in \mathcal{E}_{r}}\left|\sigma_{K L}\right|\left|\xi_{K L}\left(u_{K}^{n}, u_{L}^{n}\right)-\xi_{K L}\left(u_{L}^{n}, u_{L}^{n}\right)\right| .
\end{aligned}
$$

Hence, using Lemma 2.4, the CFL condition (23) and the bound (41) provides the following bound:

$$
\mu(B(0, r) \times[0, T]) \leq C_{\mu} h
$$

where $C_{\mu}=C_{\mu \mathcal{T}}+2\left(1+\frac{a^{2}}{\lambda^{\star}}\right)\left\|\nabla_{u} \eta\right\|_{L^{\infty}(\Omega)} C_{B V}$.
Proposition 3.3. Assume (3), (16), (17)-(21), (23) and identities (6)-(7). Let u ${ }^{h}$ defined by (24)-(26), and assume that the stability estimate (33) holds. Let $\mu$ and $\mu_{0}$ be the measures introduced in Definition 3.1, then, for all $\varphi \in C_{c}^{1}\left(\mathbb{R}^{d} \times \mathbb{R}^{+} ; \mathbb{R}^{+}\right)$, one has
(42)

$$
\begin{aligned}
& \iint_{\mathbb{R}^{d} \times \mathbb{R}_{+}} \eta\left(u^{h}\right) \partial_{t} \varphi(x, t)+\sum_{\alpha=1}^{d} \xi_{\alpha}\left(u^{h}\right) \partial_{\alpha} \varphi(x, t) d x d t \\
& +\int_{\mathbb{R}^{d}} \eta\left(u_{0}(x)\right) \varphi(x, 0) d x \geq-\iint_{\mathbb{R}^{d} \times \mathbb{R}_{+}}\left(|\nabla \varphi|+\left|\partial_{t} \varphi\right|\right) d \mu(x, t)-\int_{\mathbb{R}^{d}} \varphi(x, 0) d \mu_{0}(x) .
\end{aligned}
$$

Proof. Let $\varphi \in C_{c}^{1}\left(\mathbb{R}^{d} \times \mathbb{R}^{+} ; \mathbb{R}^{+}\right)$. Let $T>0$ and $r>0$ such that $\operatorname{supp} \varphi \subset$ $B(0, r) \times[0, T)$. Let us multiply (30) by $\int_{t^{n}}^{t^{n+1}} \int_{K} \varphi(x, t) d x d t$ and sum over the control volumes $K \in \mathcal{T}_{r}$ and $n \leq N_{T}$. It yields

$$
\begin{equation*}
T_{1}+T_{2} \leq 0 \tag{43}
\end{equation*}
$$

where

$$
\begin{equation*}
T_{1}=\sum_{n=0}^{N_{T}} \sum_{K \in \mathcal{T}_{r}} \frac{1}{\Delta t}\left(\eta\left(u_{K}^{n+1}\right)-\eta\left(u_{K}^{n}\right)\right) \int_{t^{n}}^{t^{n+1}} \int_{K} \varphi(x, t) d x d t \tag{44}
\end{equation*}
$$

and

$$
\begin{equation*}
T_{2}=\sum_{n=0}^{N_{T}} \sum_{K \in \mathcal{T}_{r}} \frac{1}{|K|} \int_{t^{n}}^{t^{n+1}} \int_{K} \varphi(x, t) d x d t \sum_{L \in \mathcal{N}(K)}\left|\sigma_{K L}\right| \xi_{K L}\left(u_{K}^{n}, u_{L}^{n}\right) . \tag{45}
\end{equation*}
$$

The term $T_{1}$ corresponds to the discrete time derivative of $\eta\left(u^{h}\right)$ and $T_{2}$ to the discrete space derivative of $\xi\left(u^{h}\right)$. The proof relies on the comparison firstly between $T_{1}$ and $T_{10}$ and secondly between $T_{2}$ and $T_{20}$, where $T_{10}$ and $T_{20}$ denote respectively the temporal and spatial term in (42):

$$
\begin{align*}
T_{10} & =-\iint_{\mathbb{R}^{d} \times \mathbb{R}_{+}} \eta\left(u^{h}\right) \partial_{t} \varphi(x, t) d x d t-\int_{\mathbb{R}^{d}} \eta\left(u_{0}(x)\right) \varphi(x, 0) d x \\
T_{20} & =-\iint_{\mathbb{R}^{d} \times \mathbb{R}_{+}} \sum_{\alpha=1}^{d} \xi_{\alpha}\left(u^{h}\right) \partial_{\alpha} \varphi(x, t) d x d t . \tag{46}
\end{align*}
$$

Let us first focus on $T_{10}$. Following its definition (26), the approximate solution $u^{h}$ is piecewise constant, then so does $\eta\left(u_{h}\right)$. This yields

$$
\begin{aligned}
T_{10}= & -\sum_{n=0}^{N_{T}} \sum_{K \in \mathcal{T}_{r}} \eta\left(u_{K}^{n}\right) \int_{t^{n}}^{t^{n+1}} \int_{K} \partial_{t} \varphi d x d t-\int_{\mathbb{R}^{d}} \eta\left(u_{0}(x)\right) \varphi(x, 0) d x \\
= & -\sum_{n=0}^{N_{T}} \sum_{K \in \mathcal{T}_{r}} \eta\left(u_{K}^{n}\right) \int_{K}\left(\varphi\left(x, t^{n+1}\right)-\varphi\left(x, t^{n}\right)\right) d x-\int_{\mathbb{R}^{d}} \eta\left(u_{0}(x)\right) \varphi(x, 0) d x \\
= & \sum_{n=0}^{N_{T}} \sum_{K \in \mathcal{T}_{r}}\left(\eta\left(u_{K}^{n+1}\right)-\eta\left(u_{K}^{n}\right)\right) \int_{K} \varphi\left(x, t^{n+1}\right) d x \\
& -\int_{\mathbb{R}^{d}}\left(\eta\left(u_{0}(x)\right)-\eta\left(u^{h}(x, 0)\right)\right) \varphi(x, 0) d x \\
= & \sum_{n=0}^{N_{T}} \sum_{K \in \mathcal{T}_{r}}\left(\eta\left(u_{K}^{n+1}\right)-\eta\left(u_{K}^{n}\right)\right) \frac{1}{\Delta t} \int_{t^{n}}^{t^{n+1}} \int_{K} \varphi\left(x, t^{n+1}\right) d x d t \\
& -\int_{\mathbb{R}^{d}}\left(\eta\left(u_{0}(x)\right)-\eta\left(u^{h}(x, 0)\right)\right) \varphi(x, 0) d x
\end{aligned}
$$

Then we consider the quantity $\left|T_{1}-T_{10}\right|$ :

$$
\begin{aligned}
\left|T_{1}-T_{10}\right| \leq & \sum_{n=0}^{N_{T}} \sum_{K \in \mathcal{T}_{r}} \frac{\left|\eta\left(u_{K}^{n+1}\right)-\eta\left(u_{K}^{n}\right)\right|}{\Delta t} \int_{t^{n}}^{t^{n+1}} \int_{K}\left|\varphi(x, t)-\varphi\left(x, t^{n+1}\right)\right| d x d t \\
& +\int_{\mathbb{R}^{d}}\left|\eta\left(u_{0}(x)\right)-\eta\left(u^{h}(x, 0)\right)\right| \varphi(x, 0) d x \\
\leq & \sum_{n=0}^{N_{T}} \sum_{K \in \mathcal{T}_{r}}\left|\eta\left(u_{K}^{n+1}\right)-\eta\left(u_{K}^{n}\right)\right| \int_{t^{n}}^{t^{n+1}} \int_{K}\left|\partial_{t} \varphi\right| d x d t \\
& +\int_{\mathbb{R}^{d}}\left|\eta\left(u_{0}(x)\right)-\eta\left(u^{h}(x, 0)\right)\right| \varphi(x, 0) d x .
\end{aligned}
$$

Then, accounting from Definition 3.1, the inequality reads:

$$
\begin{equation*}
\left|T_{1}-T_{10}\right| \leq \iint_{\mathbb{R}^{d} \times \mathbb{R}_{+}}\left|\partial_{t} \varphi\right| d \mu \mathcal{T}(x, t)+\int_{\mathbb{R}^{d}} \varphi(x, 0) d \mu_{0}(x) . \tag{47}
\end{equation*}
$$

We now consider the terms $T_{2}$ and $T_{20}$. Performing a discrete integration by parts by reorganizing the sum, and using the properties (32) and (20) lead to

$$
\begin{equation*}
T_{2}=T_{2,1}+T_{2,2} \tag{48}
\end{equation*}
$$

with

$$
\begin{aligned}
T_{2,1} & =\sum_{n=0}^{N_{T}} \sum_{(K, L) \in \mathcal{E}_{r}} \frac{\left|\sigma_{K L}\right|}{|K|} \int_{t^{n}}^{t^{n+1}} \int_{K} \varphi(x, t)\left(\xi_{K L}\left(u_{K}^{n}, u_{L}^{n}\right)-\xi_{K L}\left(u_{K}^{n}, u_{K}^{n}\right)\right) d x d t, \\
T_{2,2} & =\sum_{n=0}^{N_{T}} \sum_{(K, L) \in \mathcal{E}_{r}} \frac{\left|\sigma_{K L}\right|}{|L|} \int_{t^{n}}^{t^{n+1}} \int_{L} \varphi(x, t)\left(\xi_{L K}\left(u_{L}^{n}, u_{K}^{n}\right)-\xi_{L K}\left(u_{L}^{n}, u_{L}^{n}\right)\right) d x d t .
\end{aligned}
$$

Gathering terms of $T_{20}$ by edges yields

$$
T_{20}=T_{20,1}+T_{20,2}
$$

where, thanks to (20), we have set

$$
\begin{aligned}
& T_{20,1}=\sum_{n=0}^{N_{T}} \sum_{(K, L) \in \mathcal{E}_{r}} \int_{t^{n}}^{t^{n+1}} \int_{\sigma_{K L}}\left(\xi_{K L}\left(u_{K}^{n}, u_{L}^{n}\right)-\xi\left(u_{K}^{n}\right) \cdot n_{K L}\right) \varphi(\gamma, t) d \gamma d t \\
& T_{20,2}=\sum_{n=0}^{N_{T}} \sum_{(K, L) \in \mathcal{E}_{r}} \int_{t^{n}}^{t^{n+1}} \int_{\sigma_{K L}}\left(\xi_{L K}\left(u_{L}^{n}, u_{K}^{n}\right)-\xi\left(u_{L}^{n}\right) \cdot n_{L K}\right) \varphi(\gamma, t) d \gamma d t .
\end{aligned}
$$

Let us now compare the terms $T_{2,1}$ and $T_{20,1}$ :

$$
\begin{aligned}
T_{2,1}-T_{20,1}= & \sum_{n=0}^{N_{T}} \Delta t \sum_{(K, L) \in \mathcal{E}_{r}}\left|\sigma_{K L}\right|\left(\xi_{K L}\left(u_{K}^{n}, u_{L}^{n}\right)-\xi\left(u_{K}^{n}\right) \cdot n_{K L}\right) \\
& \times\left(\frac{1}{|K| \Delta t} \int_{t^{n}}^{t^{n+1}} \int_{K} \varphi(x, t) d x d t\right. \\
& \left.\quad-\frac{1}{\left|\sigma_{K L}\right| \Delta t} \int_{t^{n}}^{t^{n+1}} \int_{\sigma_{K L}} \varphi(\gamma, s) d \gamma d s\right) .
\end{aligned}
$$

In order to handle the mean value of $\varphi$ over the cell $K$ and its mean value over the edge $\sigma_{K L}$, we write

$$
\begin{aligned}
& \frac{1}{|K|} \int_{t^{n}}^{t^{n+1}} \int_{K} \varphi(x, t) d x d t \\
& \\
& =\frac{1}{|K|\left|\sigma_{K L}\right| \Delta t} \int_{t^{n}}^{t^{n+1}} \int_{K} \int_{t^{n}}^{t^{n+1}} \int_{\sigma_{K L}} \varphi(x, t) d \gamma d s d x d t \\
& \frac{1}{\left|\sigma_{K L}\right|} \\
& \quad \int_{t^{n}}^{t^{n+1}} \int_{\sigma_{K L}} \varphi(\gamma, t) d \gamma d t \\
& \\
& =\frac{1}{|K|\left|\sigma_{K L}\right| \Delta t} \int_{t^{n}}^{t^{n+1}} \int_{K} \int_{t^{n}}^{t^{n+1}} \int_{\sigma_{K L}} \varphi(\gamma, s) d \gamma d s d x d t .
\end{aligned}
$$

Thus one has

$$
\begin{aligned}
T_{2,1}-T_{20,1}= & \sum_{n=0}^{N_{T}} \Delta t \sum_{(K, L) \in \mathcal{E}_{r}}\left|\sigma_{K L}\right|\left(\xi_{K L}\left(u_{K}^{n}, u_{L}^{n}\right)-\xi_{K L}\left(u_{K}^{n}, u_{K}^{n}\right)\right) \\
& \times \frac{1}{|K|\left|\sigma_{K L}\right|(\Delta t)^{2}} \int_{t^{n}}^{t^{n+1}} \int_{K} \int_{t^{n}}^{t^{n+1}} \int_{\sigma_{K L}}(\varphi(x, t)-\varphi(\gamma, s)) d \gamma d s d x d t .
\end{aligned}
$$

Writing a Taylor's expansion of $\varphi$ with the integral form of the remainder provides for all $(x, \gamma, t, s) \in K \times \sigma_{K L} \times\left[t^{n}, t^{n+1}\left[^{2}\right.\right.$
(49) $|\varphi(x, t)-\varphi(\gamma, s)| \leq \int_{0}^{1}(h+\Delta t)\left(|\nabla \varphi|+\left|\partial_{t} \varphi\right|\right)(\gamma+\theta(x-\gamma), s+\theta(t-s)) d \theta$.

Then using Definition 3.1 of the measure $\mu_{K L}$ we obtain the following estimate:
$\left|T_{2,1}-T_{20,1}\right| \leq \sum_{n=0}^{N_{T}} \Delta t \sum_{(K, L) \in \mathcal{E}_{r}}\left|\sigma_{K L}\right|\left|\xi_{K L}\left(u_{K}^{n}, u_{L}^{n}\right)-\xi_{K L}\left(u_{K}^{n}, u_{K}^{n}\right)\right|\left\langle\mu_{K L},\right| \nabla \varphi\left|+\left|\partial_{t} \varphi\right|\right\rangle$.
Similarly, one obtains that

$$
\begin{equation*}
\left|T_{2,2}-T_{20,2}\right| \leq \sum_{n=0}^{N_{T}} \Delta t \sum_{(K, L) \in \mathcal{E}_{r}}\left|\sigma_{K L}\right|\left|\xi_{L K}\left(u_{L}^{n}, u_{K}^{n}\right)-\xi_{L K}\left(u_{L}^{n}, u_{L}^{n}\right)\right|\left\langle\mu_{L K},\right| \nabla \varphi\left|+\left|\partial_{t} \varphi\right|\right\rangle, \tag{51}
\end{equation*}
$$

where the measure $\mu_{L K} \in \mathcal{M}\left(\mathbb{R}^{d} \times \mathbb{R}^{+}\right)$is given by Definition 3.1.
Bearing in mind the definition of $\mu \in \mathcal{M}\left(\mathbb{R}^{d} \times \mathbb{R}^{+}\right)$given in Definition 3.1, inequalities (43), (47), (48), (50) and (51), one has

$$
-T_{10}-T_{20} \geq-\iint_{\mathbb{R}^{d} \times \mathbb{R}_{+}}\left(|\nabla \varphi|+\left|\partial_{t} \varphi\right|\right) d \mu(x, t)-\int_{\mathbb{R}^{d}} \varphi(x, 0) d \mu_{0}(x)
$$

that concludes the proof.
The same kind of tools can be used to deduce how close is $u^{h}$ w.r.t. to a weak solution. For that purpose we define the following measures.
Definition 3.4. For $\psi \in C_{c}\left(\mathbb{R}^{d}\right)$ and $\varphi \in C_{c}\left(\mathbb{R}^{d} \times \mathbb{R}^{+}\right)$, we set

$$
\begin{aligned}
\left\langle\bar{\mu}_{0}, \psi\right\rangle= & \int_{\mathbb{R}^{d}}\left|u_{0}(x)-u^{h}(x, 0)\right| \psi(x) d x, \\
\langle\bar{\mu}, \varphi\rangle= & \left\langle\bar{\mu}_{\mathcal{T}}, \varphi\right\rangle+\sum_{n=0}^{\infty} \Delta t \sum_{(K, L) \in \mathcal{E}_{r}}\left|\sigma_{K L}\right|\left|G_{K L}\left(u_{K}^{n}, u_{L}^{n}\right)-G_{K L}\left(u_{K}^{n}, u_{K}^{n}\right)\right|\left\langle\bar{\mu}_{K L}, \varphi\right\rangle \\
& +\sum_{n=0}^{\infty} \Delta t \sum_{(K, L) \in \mathcal{E}_{r}}\left|\sigma_{K L}\right|\left|G_{K L}\left(u_{K}^{n}, u_{L}^{n}\right)-G_{K L}\left(u_{L}^{n}, u_{L}^{n}\right)\right|\left\langle\bar{\mu}_{L K}, \varphi\right\rangle,
\end{aligned}
$$

where

$$
\begin{aligned}
\left\langle\bar{\mu}_{\mathcal{T}}, \varphi\right\rangle= & \sum_{n=0}^{\infty} \sum_{K \in \mathcal{T}_{r}}\left|u_{K}^{n+1}-u_{K}^{n}\right| \int_{t^{n}}^{t^{n+1}} \int_{K} \varphi(x, t) d x d t \\
\left\langle\bar{\mu}_{K L}, \varphi\right\rangle= & \frac{1}{|K|\left|\sigma_{K L}\right| \Delta t^{2}} \times \\
& \int_{t^{n}}^{t^{n+1}} \int_{K} \int_{t^{n}}^{t^{n+1}} \int_{\sigma_{K L}} \int_{0}^{1}(h+\Delta t) \varphi(\gamma+\theta(x-\gamma), s+\theta(t-s)) d \theta d x d t d \gamma d s, \\
\left\langle\bar{\mu}_{L K}, \varphi\right\rangle= & \frac{1}{\left|L \|\left|\sigma_{K L}\right| \Delta t^{2}\right.} \times \\
& \int_{t^{n}}^{t^{n+1}} \int_{L} \int_{t^{n}}^{t^{n+1}} \int_{\sigma_{K L}} \int_{0}^{1}(h+\Delta t) \varphi(\gamma+\theta(x-\gamma), s+\theta(t-s)) d \theta d x d t d \gamma d s
\end{aligned}
$$

Remark 3.1. It follows from the definitions of the measures $\mu$ and $\bar{\mu}$ that they can be extended (in a unique way) into continuous linear forms defined on the set

$$
E:=\left\{\varphi \in L^{\infty}\left(\mathbb{R}^{d} \times \mathbb{R}^{+} ; \mathbb{R}\right) \mid \operatorname{supp}(\varphi) \text { is compact, and } \nabla \varphi \in \mathcal{M}\left(\mathbb{R}^{d} \times \mathbb{R}^{+}\right)^{d}\right\}
$$

Indeed, any $\varphi \in E$ admits traces on $\sigma_{K L}$, so that the quantities $\left\langle\mu_{K L}, \varphi\right\rangle,\left\langle\mu_{L K}, \varphi\right\rangle$, $\left\langle\bar{\mu}_{K L}, \varphi\right\rangle$ and $\left\langle\bar{\mu}_{L K}, \varphi\right\rangle$ are well defined. Moreover, one has

$$
|\langle\mu, \varphi\rangle| \leq\|\varphi\|_{L^{\infty}} \mu(\{\varphi \neq 0\}), \quad|\langle\bar{\mu}, \varphi\rangle| \leq\|\varphi\|_{L^{\infty}} \bar{\mu}(\{\varphi \neq 0\}), \quad \forall \varphi \in E .
$$

We now state a lemma and a proposition whose proofs are left to the reader, since they are similar to the proofs of Lemma 3.2 and Proposition 3.3 respectively as one uses the estimates (33) and (36) instead of (35) and (37).

Lemma 3.5. Assume that (3), (16), (17)-(21), (23), and identities (6)-(7) hold. Let $u^{h}$ defined by (24)-(26), and assume that the stability estimate (33) holds, then, for all $r>0$ and $T>0$ there exist $C_{\bar{\mu}_{0}}>0$, depending only on $u_{0}$ and $r$, and $C_{\bar{\mu}}>0$, depending only on $T, r, a, \lambda_{\star}, u_{0}, G_{K L}$ such that, for all $h<r$,

$$
\begin{align*}
\bar{\mu}_{0}(B(0, r)) & \leq C_{\bar{\mu}_{0}} h, \\
\bar{\mu}(B(0, r) \times[0, T]) & \leq C_{\bar{\mu}} h . \tag{52}
\end{align*}
$$

The quantities $C_{\bar{\mu}_{0}}$ and $C_{\bar{\mu}}$ are related to $C_{\mu_{0}}$ and $C_{\mu}$ by the relations

$$
C_{\mu_{0}}=\left\|\nabla_{u} \eta\right\|_{L^{\infty}(\Omega)} C_{\bar{\mu}_{0}}, \quad C_{\mu}=\left\|\nabla_{u} \eta\right\|_{L^{\infty}(\Omega)} C_{\bar{\mu}}
$$

where $C_{\mu_{0}}$ and $C_{\mu}$ have been explicitly calculated during the proof of Lemma 3.2.
We are now in position to provide the approximate weak formulation satisfied by $u^{h}$.

Proposition 3.6. Assume (3), (16), (17)-(21), (23) and identities (6)-(7). Let $u^{h}$ defined by (24)-(26), and assume that the stability estimate (33) holds. Let $\mu$ and $\mu_{0}$ be the measures introduced in Definition 3.1, then, for all $\varphi \in C_{c}^{1}\left(\mathbb{R}^{d} \times \mathbb{R}^{+} ; \mathbb{R}^{m}\right)$, one has

$$
\begin{align*}
\left|\iint_{\mathbb{R}^{d} \times \mathbb{R}_{+}}\left(u^{h}\right)^{T} \partial_{t} \varphi(x, t)+\sum_{\alpha=1}^{d} f_{\alpha}\left(u^{h}\right)^{T} \partial_{\alpha} \varphi(x, t) d x d t+\int_{\mathbb{R}^{d}} u_{0}(x)^{T} \varphi(x, 0) d x\right|  \tag{53}\\
\leq \iint_{\mathbb{R}^{d} \times \mathbb{R}_{+}}\left(|\nabla \varphi|+\left|\partial_{t} \varphi\right|\right) d \bar{\mu}(x, t)+\int_{\mathbb{R}^{d}}|\varphi(x, 0)| d \bar{\mu}_{0}(x)
\end{align*}
$$

Let us stress that $\varphi$ is a vector-valued function. This means that

$$
|\nabla \varphi|=\max _{\alpha \in\{1, \ldots, d\}}\left|\partial_{\alpha} \varphi\right|
$$

Nevertheless, the proof of Proposition 3.6 follows the same guidelines as the proof of Proposition 3.3 and is left to the reader.

## 4. Error estimate using the relative entropy

Thanks to the measures defined above and Propositions 3.3 and 3.6, we are now in position to provide the precise meaning of inequality (38) satisfied by the relative entropy $H\left(u^{h}, u\right)$ and conclude the proof of Theorem 2.6.

### 4.1. Relative entropy for approximate solutions.

Proposition 4.1. Assume (3), (16), (17)-(21), (23) and identities (6)-(7). Let $u^{h}$ defined by (24)-(26), and assume that the stability estimate (33) holds. Let $\mu$ and $\mu_{0}$ be the measures introduced in Definition 3.1, and let $\bar{\mu}$ and $\bar{\mu}_{0}$ be the measures introduced in Definition 3.4 then, for all $\varphi \in C_{c}^{1}\left(\mathbb{R}^{d} \times \mathbb{R}^{+} ; \mathbb{R}^{+}\right)$, one has

$$
\begin{align*}
& \iint_{\mathbb{R}^{d} \times \mathbb{R}_{+}}\left(H\left(u^{h}, u\right) \partial_{t} \varphi(x, t)+\sum_{\alpha=1}^{d} Q_{\alpha}\left(u^{h}, u\right) \partial_{\alpha} \varphi(x, t)\right) d x d t \geq \\
& -\iint_{\mathbb{R}^{d} \times \mathbb{R}_{+}}\left(|\nabla \varphi|+\left|\partial_{t} \varphi\right|\right) d \mu(x, t)-\int_{\mathbb{R}^{d}} \varphi(x, 0) d \mu_{0}(x) \\
& -\iint_{\mathbb{R}^{d} \times \mathbb{R}_{+}}\left(\left|\nabla\left[\varphi \nabla_{u} \eta(u)\right]\right|+\left|\partial_{t}\left[\varphi \nabla_{u} \eta(u)\right]\right|\right) d \bar{\mu}(x, t) \\
& -\int_{\mathbb{R}^{d}}\left[\varphi \nabla_{u} \eta(u)\right](x, 0) d \bar{\mu}_{0}(x)+\iint_{\mathbb{R}^{d} \times \mathbb{R}_{+}} \varphi \sum_{\alpha=1}^{d} \partial_{\alpha} u^{T} Z_{\alpha}\left(u^{h}, u\right) d x d t \tag{54}
\end{align*}
$$

where $Z_{\alpha}\left(u^{h}, u\right)=\nabla_{u}^{2} \eta(u)\left(f_{\alpha}\left(u^{h}\right)-f_{\alpha}(u)-\left(\nabla_{u} f_{\alpha}(u)\right)^{T}\left(u^{h}-u\right)\right)$.
Proof. Let $\varphi$ be any nonnegative Lipschitz continuous test function with compact support in $\mathbb{R}^{d} \times[0, T]$. Since $u$ is a classical solution of (1)-(3), it satisfies

$$
\iint_{\mathbb{R}^{d} \times \mathbb{R}_{+}} \eta(u) \partial_{t} \varphi(x, t)+\sum_{\alpha=1}^{d} \xi_{\alpha}(u) \partial_{\alpha} \varphi(x, t) d x d t+\int_{\mathbb{R}^{d}} \eta\left(u_{0}\right) \varphi(x, 0) d x=0
$$

Subtracting this identity to (42) yields

$$
\begin{array}{r}
\iint_{\mathbb{R}^{d} \times \mathbb{R}_{+}}\left(\eta\left(u^{h}\right)-\eta(u)\right) \partial_{t} \varphi(x, t)+\sum_{\alpha=1}^{d}\left(\xi_{\alpha}\left(u^{h}\right)-\xi_{\alpha}(u)\right) \partial_{\alpha} \varphi(x, t) d x d t  \tag{55}\\
-\geq \iint_{\mathbb{R}^{d} \times \mathbb{R}_{+}}\left(|\nabla \varphi|+\left|\partial_{t} \varphi\right|\right) d \mu(x, t)-\int_{\mathbb{R}^{d}} \varphi(x, 0) d \mu_{0}(x) .
\end{array}
$$

We now exhibit the relative entropy-relative entropy flux pair in the inequality (55) and obtain

$$
\begin{align*}
& \iint_{\mathbb{R}^{d} \times \mathbb{R}_{+}}\left(H\left(u^{h}, u\right) \partial_{t} \varphi+\sum_{\alpha=1}^{d} Q_{\alpha}\left(u^{h}, u\right) \partial_{\alpha} \varphi\right) d x d t \geq \\
- & \iint_{\mathbb{R}^{d} \times \mathbb{R}_{+}}|\nabla \varphi|+\left|\partial_{t} \varphi\right| d \mu(x, t)-\int_{\mathbb{R}^{d}} \varphi(x, 0) d \mu_{0}(x)  \tag{56}\\
- & \iint_{\mathbb{R}^{d} \times \mathbb{R}_{+}}\left(\nabla_{u} \eta(u)\right)^{T}\left(\left(u^{h}-u\right) \partial_{t} \varphi+\sum_{\alpha=1}^{d}\left(f_{\alpha}\left(u^{h}\right)-f_{\alpha}(u)\right) \partial_{\alpha} \varphi\right) d x d t .
\end{align*}
$$

Since $u$ is a strong solution of (1)-(3), it satisfies the following weak identity, $\forall \psi \in$ $C_{c}\left(\mathbb{R}^{d} \times \mathbb{R}^{+} ; \mathbb{R}^{m}\right)$

$$
\begin{equation*}
\iint_{\mathbb{R}^{d} \times \mathbb{R}_{+}} u \partial_{t} \psi(x, t)+\sum_{\alpha=1}^{d} f_{\alpha}(u) \partial_{\alpha} \psi(x, t) d x d t+\int_{\mathbb{R}^{d}} u_{0}(x) \psi(x, 0) d x=0 \tag{57}
\end{equation*}
$$

Then we combine (57) and (53) using the Lipschitz continuous vector field $\left[\varphi \nabla_{u} \eta(u)\right]$ as test function to get

$$
\begin{align*}
& -\iint_{\mathbb{R}^{d} \times \mathbb{R}_{+}}\left(\nabla_{u} \eta(u)\right)^{T}\left[\left(u^{h}-u\right) \partial_{t} \varphi+\sum_{\alpha=1}^{d}\left(f_{\alpha}\left(u^{h}\right)-f_{\alpha}(u)\right) \partial_{\alpha} \varphi\right] d x d t \geq  \tag{58}\\
& -\iint_{\mathbb{R}^{d} \times \mathbb{R}_{+}}\left|\nabla\left[\varphi \nabla_{u} \eta(u)\right]\right|+\left|\partial_{t}\left[\varphi \nabla_{u} \eta(u)\right]\right| d \bar{\mu}(x, t)-\int_{\mathbb{R}^{d}}\left[\varphi \nabla_{u} \eta(u)\right](x, 0) d \bar{\mu}_{0}(x) \\
& +\iint_{\mathbb{R}^{d} \times \mathbb{R}_{+}}\left(u^{h}-u\right) \varphi \partial_{t}\left(\nabla_{u} \eta(u)\right)+\sum_{\alpha=1}^{d}\left(f_{\alpha}\left(u^{h}\right)-f_{\alpha}(u)\right) \varphi \partial_{\alpha}\left(\nabla_{u} \eta(u)\right) d x d t .
\end{align*}
$$

Moreover identity (7) together with (1) gives

$$
\begin{aligned}
\partial_{t}\left(\nabla_{u} \eta(u)\right) & =\partial_{t} u^{T} \nabla_{u}^{2} \eta(u) \\
& =-\sum_{\alpha=1}^{d} \partial_{\alpha}\left(f_{\alpha}(u)\right)^{T} \nabla_{u}^{2} \eta(u) \\
& =-\sum_{\alpha=1}^{d} \partial_{\alpha} u^{T} \nabla_{u} f_{\alpha}(u)^{T} \nabla_{u}^{2} \eta(u) \\
& =-\sum_{\alpha=1}^{d} \partial_{\alpha} u^{T} \nabla_{u}^{2} \eta(u) \nabla_{u} f_{\alpha}(u) .
\end{aligned}
$$

Injecting (58) and (59) into (56) leads to conclusion.
Lemma 4.2. There exists $C_{Z}$ depending only on $f, \eta$ and $\Omega$ such that, for all $\alpha \in\{1, \ldots, d\}$,

$$
\begin{equation*}
\left|Z_{\alpha}\left(u^{h}, u\right)\right| \leq C_{Z}\left|u^{h}-u\right|^{2} . \tag{60}
\end{equation*}
$$

Proof. For $\mathbf{M}: \Omega \rightarrow \mathbb{R}^{m \times m}$ and $\Upsilon: \Omega \rightarrow \mathcal{L}\left(\mathbb{R}^{m} ; \mathbb{R}^{m \times m}\right)$, we set

$$
\|\mathbf{M}\|_{\infty, \infty}=\sup _{u \in \Omega}|\mathbf{M}(u)|_{\infty}, \quad\|\Upsilon\|_{\infty, 2}=\sup _{u \in \Omega}\left(\sup _{v \in \mathbb{R}^{m},|v|=1}|\Upsilon(u) \cdot v|_{2}\right)
$$

where $|\cdot|_{2}$ and $|\cdot|_{\infty}$ denote the usual matrix 2- and $\infty$-norms respectively. Using the Taylor expansion of $f_{\alpha}$ around $u$, we get that

$$
\left|f_{\alpha}\left(u^{h}\right)-f_{\alpha}(u)-\left(\nabla_{u} f_{\alpha}(u)\right)^{T}\left(u^{h}-u\right)\right| \leq \frac{1}{2}\left\|\nabla_{u}^{2} f_{\alpha}\right\|_{\infty, 2}\left|u_{h}-u\right|^{2}
$$

then, estimate (60) holds for $C_{Z}=\frac{1}{2}\left\|\nabla_{u}^{2} \eta\right\|_{\infty, \infty}\left\|\nabla_{u}^{2} f_{\alpha}\right\|_{\infty, 2}$.
We now prove the following lemma on the finite speed of propagation, which is usually assumed to be true in the literature [DiP79, Tza05, Daf10]. Actually, this result is the reason why we makes assumption (4).

Lemma 4.3. For all $s \geq L_{f}$, one has

$$
\begin{equation*}
s H\left(u^{h}, u\right)+\sum_{\alpha=1}^{d} \frac{x_{\alpha}}{|x|} Q_{\alpha}\left(u^{h}, u\right) \geq 0 . \tag{61}
\end{equation*}
$$

Proof. Denote by $w^{h}:=u^{h}-u$, then it follows from the characterization (13) of the relative entropy $H$ that

$$
\begin{equation*}
H=\int_{0}^{1} \int_{0}^{\theta}\left(w^{h}\right)^{T} \nabla_{u}^{2} \eta\left(u+\gamma w^{h}\right) w^{h} d \gamma d \theta \tag{62}
\end{equation*}
$$

Denoting by $\mathbb{A}_{\gamma}$ the symmetric definite positive matrix $\nabla_{u}^{2} \eta\left(u+\gamma w^{h}\right)$, and by $\langle\cdot, \cdot\rangle_{\mathbb{A}_{\gamma}}$ the scalar product on $\mathbb{R}^{n}$ defined by

$$
\langle u, v\rangle_{\mathbb{A}_{\gamma}}=u^{T} \mathbb{A}_{\gamma} v, \quad \forall u, v \in \mathbb{R}^{n}
$$

the relation (62) can be rewritten

$$
\begin{equation*}
H=\int_{0}^{1} \int_{0}^{\theta}\left\langle w^{h}, w^{h}\right\rangle_{\mathbb{A}_{\gamma}} d \gamma d \theta \tag{63}
\end{equation*}
$$

On the other hand, it follows from the definition (6) of the entropy flux $\xi$ that, for all $\alpha \in\{1, \ldots, d\}$,

$$
\begin{aligned}
Q_{\alpha} & =\int_{0}^{1}\left(\nabla_{u} \eta\left(u+\theta w^{h}\right)-\nabla_{u} \eta(u)\right)^{T}\left(\nabla_{u} f_{\alpha}\left(u+\theta w^{h}\right)\right)^{T} w^{h} d \theta \\
& =\int_{0}^{1} \int_{0}^{\theta}\left(w^{h}\right)^{T} \mathbb{A}_{\gamma}\left(\nabla_{u} f_{\alpha}\left(u+\theta w^{h}\right)\right)^{T} w^{h} d \gamma d \theta \\
& =\int_{0}^{1} \int_{0}^{\theta}\left\langle w^{h},\left(\nabla_{u} f_{\alpha}\left(u+\theta w^{h}\right)\right)^{T} w^{h}\right\rangle_{\mathbb{A}_{\gamma}} d \gamma d \theta .
\end{aligned}
$$

The Rayleigh quotient

$$
\begin{aligned}
& \left\langle w^{h},\left(\nabla_{u} f_{\alpha}\left(u+\theta w^{h}\right)\right)^{T} w^{h}\right\rangle_{\mathbb{A}_{\gamma}}=\left\langle w^{h}, \nabla_{u} f_{\alpha}\left(u+\theta w^{h}\right) w^{h}\right\rangle_{\mathbb{A}_{\gamma}} \\
& \quad=\left\langle w^{h}, \frac{1}{2}\left(\left(\nabla_{u} f_{\alpha}\left(u+\theta w^{h}\right)\right)^{T}+\nabla_{u} f_{\alpha}\left(u+\theta w^{h}\right)\right) w^{h}\right\rangle_{\mathbb{A}_{\gamma}}
\end{aligned}
$$

satisfies, thanks to (4),

$$
\left|\left\langle w^{h},\left(\nabla_{u} f_{\alpha}\left(u+\theta w^{h}\right)\right)^{T} w^{h}\right\rangle_{\mathbb{A}_{\gamma}}\right| \leq L_{f}\left\langle w^{h}, w^{h}\right\rangle_{\mathbb{A}_{\gamma}}
$$

Therefore, we obtain that

$$
\begin{align*}
\left|Q_{\alpha}\right| & \leq \int_{0}^{1} \int_{0}^{\theta}\left|\left\langle w^{h},\left(\nabla_{u} f_{\alpha}\left(u+\theta w^{h}\right)\right)^{T} w^{h}\right\rangle_{\mathbb{A}_{\gamma}}\right| d \gamma d \theta \\
& \leq L_{f} \int_{0}^{1} \int_{0}^{\theta}\left\langle w^{h}, w^{h}\right\rangle_{\mathbb{A}_{\gamma}} d \gamma d \theta=L_{f} H . \tag{64}
\end{align*}
$$

The fact that (61) holds is a straightforward consequence of (64).
4.2. End of the proof of Theorem 2.6. We now have all the preliminary tools required for comparing $u^{h}$ to $u$ via the relative entropy $H\left(u^{h}, u\right)$.

Let $\delta \in(0, T)$ be a parameter to be fixed later, and, for $k \in \mathbb{N}$, we define the nonincreasing Lipschitz continuous function $\theta_{k}: \mathbb{R}^{+} \rightarrow[0,1]$ by

$$
\theta_{k}(t)=\min \left(1, \max \left(0, \frac{(k+1) \delta-t}{\delta}\right)\right), \quad \forall t \geq 0
$$

Let us also introduce the Lipschitz continuous function $\psi: \mathbb{R}^{d} \times \mathbb{R}_{+} \rightarrow[0,1]$ defined by

$$
\psi(x, t)=1-\min \left(1, \max \left(0,|x|-r-L_{f}(T-t)+1\right)\right),
$$

where $L_{f}$ is so that (4) holds. The function $\varphi_{k}:(x, t) \in \mathbb{R}^{d} \times \mathbb{R}^{+} \mapsto \theta_{k}(t) \psi(x, t) \in$ $[0,1]$ can be considered as a test function in (54). Indeed, denoting by

$$
\mathcal{I}_{k}^{\delta}=[k \delta,(k+1) \delta], \quad \mathcal{C}_{r, T}(t)=\left\{(x, t)| | x \mid \in\left[r+L_{f}(T-t), r+L_{f}(T-t)+1\right]\right\},
$$

one has

$$
\begin{aligned}
\partial_{t} \varphi_{k}(x, t) & =-\frac{1}{\delta} \mathbf{1}_{\mathcal{I}_{k}^{\delta}}(t) \psi(x, t)-L_{f} \theta_{k}(t) \mathbf{1}_{\mathcal{C}_{r, T}(t)}(x), \\
\nabla \varphi_{k}(x, t) & =-\frac{x}{|x|} \theta_{k}(t) \mathbf{1}_{\mathcal{C}_{r, T}(t)}(x)
\end{aligned}
$$

so that both $\partial_{t} \varphi_{k}$ and $\left|\nabla \varphi_{k}\right|$ belong to the set $E$ defined in Remark 3.1. Then taking $\varphi_{k}$ as test function in (54) yields

$$
\begin{aligned}
& \frac{1}{\delta} \int_{\mathcal{I}_{k}^{\delta}} \int_{\mathbb{R}^{d}} H \psi d x d t+\int_{0}^{T} \theta_{k}(t) \int_{\mathbb{R}^{d}} \sum_{\alpha=1}^{d} \partial_{\alpha} u^{T} Z_{\alpha}\left(u^{h}, u\right) \psi d x d t \\
& \quad \leq-\int_{0}^{T} \theta_{k}(t) \int_{\mathcal{C}_{r, T}(t)}\left(L_{f} H+\sum_{\alpha=1}^{d} Q_{\alpha} \frac{x_{\alpha}}{|x|}\right) d x d t+R_{1}+R_{2}+R_{3}+R_{4},
\end{aligned}
$$

where

$$
\begin{aligned}
R_{1}= & \iint_{\mathbb{R}^{d} \times[0, T]}\left(\left|\nabla \varphi_{k}(x, t)\right|+\left|\partial_{t} \varphi_{k}(x, t)\right|\right) d \mu(x, t), \\
R_{2}= & \int_{\mathbb{R}^{d}} \psi(x, 0) d \mu_{0}(x), \\
R_{3}= & \iint_{\mathbb{R}^{d} \times[0, T]}\left|\nabla_{u} \eta(u)\right|\left(\left|\nabla \varphi_{k}(x, t)\right|+\left|\partial_{t} \varphi_{k}(x, t)\right|\right) d \bar{\mu}(x, t) \\
& +\iint_{\mathbb{R}^{d} \times[0, T]} \varphi_{k}(x, t)\left|\nabla_{u}^{2} \eta(u)(x, t)\right|_{\infty}\left(\left|\partial_{t} u\right|+|\nabla u|\right) d \bar{\mu}(x, t), \\
R_{4}= & \int_{\mathbb{R}^{d}} \psi(x, 0)\left|\nabla_{u} \eta\left(u_{0}\right)\right| d \bar{\mu}_{0}(x) .
\end{aligned}
$$

Thanks to Lemma 4.3, one has
(65)
$\frac{1}{\delta} \int_{\mathcal{I}_{k}^{\delta}} \int_{\mathbb{R}^{d}} H \psi d x d t+\int_{0}^{T} \theta_{k}(t) \int_{\mathbb{R}^{d}} \sum_{\alpha=1}^{d} \partial_{\alpha} u^{T} Z_{\alpha}\left(u^{h}, u\right) \psi d x d t \leq R_{1}+R_{2}+R_{3}+R_{4}$.
In view of the definition of $\varphi_{k}$, one has

$$
\begin{aligned}
& \operatorname{supp}\left(\varphi_{k}\right) \subset \bigcup_{t \in[0,(k+1) \delta]} B\left(0, r+L_{f}(T-t)+1\right) \times\{t\} \\
& \left\|\varphi_{k}\right\|_{\infty}=1, \quad\left\|\nabla \varphi_{k}\right\|_{\infty} \leq 1, \quad\left\|\partial_{t} \varphi_{k}\right\|_{\infty} \leq \frac{1}{\delta}+L_{f}
\end{aligned}
$$

This leads to

$$
R_{1} \leq\left(\frac{1}{\delta}+L_{f}+1\right) \mu\left(\operatorname{supp}\left(\nabla \varphi_{k}\right) \cup \operatorname{supp}\left(\partial_{t} \varphi_{k}\right)\right)
$$

Thanks to Lemma 3.2, we obtain that there exists $C_{\mu}^{k}$ (depending on $k, r, T, \delta, L_{f}$, $a, \lambda^{\star}, u_{0}, G_{K L}$ and $\eta$ ) such that

$$
\begin{equation*}
R_{1} \leq C_{\mu}^{k}\left(\frac{1}{\delta}+L_{f}+1\right) h \tag{66}
\end{equation*}
$$

It follows from similar arguments that there exists $C_{\mu_{0}}^{k}$ (depending on $k \eta, u_{0}, r$, $L_{f}, T$ and $\delta$ ) such that

$$
\begin{equation*}
R_{2} \leq C_{\mu_{0}}^{k} h \tag{67}
\end{equation*}
$$

and, thanks to Lemma 3.5, we obtain that there exists $C_{\bar{\mu}_{0}}^{k}$ (depending on $k$, $r, u_{0}, L_{f}, T$ and $\left.\delta\right)$ such that

$$
\begin{equation*}
R_{4} \leq C_{\mu_{0}}^{k}\left\|\nabla_{u} \eta\left(u_{0}\right)\right\|_{\infty} h \tag{68}
\end{equation*}
$$

Similarly, there exists $C_{\bar{\mu}}^{k}$ (depending on $k, T, r, L_{f}, a, \lambda^{\star}, u_{0}, G_{K L}$ and $\delta$ ) such that
(69) $R_{3} \leq C_{\bar{\mu}}^{k}\left(\left\|\nabla_{u} \eta(u)\right\|_{\infty}\left(\frac{1}{\delta}+L_{f}+1\right)+\left\|\nabla_{u}^{2} \eta\right\|_{\infty, \infty}\left(\left\|\partial_{t} u\right\|_{\infty}+\|\nabla u\|_{\infty}\right)\right) h$.

By using Lemma 4.2, and using that $0 \leq \theta_{k}(t) \leq 1$, we obtain

$$
\begin{align*}
& \int_{0}^{T} \theta_{k}(t) \int_{\mathbb{R}^{d}} \sum_{\alpha=1}^{d} \partial_{\alpha} u^{T} Z_{\alpha}\left(u^{h}, u\right) \psi d x d t \\
& \quad \geq-C_{Z}\|\nabla u\|_{\infty} \iint_{\mathbb{R}^{d} \times[0,(k+1) \delta]}\left|u^{h}(x, t)-u(x, t)\right|^{2} \psi(x, t) d x d t . \tag{70}
\end{align*}
$$

Since the entropy $\eta$ is supposed to be $\beta$-convex, we have

$$
\begin{equation*}
H(x, t) \geq \frac{\beta}{2}\left|u^{h}(x, t)-u(x, t)\right|^{2} \tag{71}
\end{equation*}
$$

Putting (66)-(70) together with (65) provides that

$$
\begin{align*}
& \left(\frac{\beta}{2 \delta}-C_{Z}\|\nabla u\|_{\infty}\right) \int_{\mathcal{I}_{k}^{\delta}} \int_{\mathbb{R}^{d}}\left|u^{h}-u\right|^{2} \psi d x d t \\
& \quad \leq C_{Z}\|\nabla u\|_{\infty} \iint_{\mathbb{R}^{d} \times[0, k \delta]}\left|u^{h}-u\right|^{2} \psi d x d t+C_{k} h \tag{72}
\end{align*}
$$

where

$$
\begin{aligned}
C_{k}= & C_{\mu}^{k}\left(\frac{1}{\delta}+L_{f}+1\right)+C_{\mu_{0}}^{k}+C_{\bar{\mu}_{0}}^{k}\left\|\nabla_{u} \eta\left(u_{0}\right)\right\|_{\infty} \\
& +C_{\bar{\mu}}^{k}\left(\left\|\nabla_{u} \eta(u)\right\|_{\infty}\left(\frac{1}{\delta}+L_{f}+1\right)+\left\|\nabla_{u}^{2} \eta\right\|_{\infty, \infty}\left(\left\|\partial_{t} u\right\|_{\infty}+\|\nabla u\|_{\infty}\right)\right)
\end{aligned}
$$

Choose now

$$
\delta=\frac{T}{p^{\star}+1}, \quad \text { where } p^{\star}=\min \left\{p \in \mathbb{N}^{\star} \left\lvert\, \frac{T}{p+1} \leq \frac{\beta}{2 C_{Z}\|\nabla u\|_{\infty}+2}\right.\right\}
$$

(note that neither $\delta$ nor $p^{\star}$ depend on $h$ ), so that (72) turns to

$$
\begin{equation*}
e_{k} \leq \omega \sum_{i=0}^{k-1} e_{i}+C_{k} h \tag{73}
\end{equation*}
$$

where

$$
e_{k}=\int_{\mathcal{I}_{k}^{\delta}} \int_{\mathbb{R}^{d}}\left|u^{h}-u\right|^{2} \psi d x d t, \quad \omega=C_{Z}\|\nabla u\|_{\infty}
$$

Denoting by $\mathbf{e}=\left(e_{0}, \ldots, e_{p^{\star}}\right)^{T}$, and $\mathbf{c}=\left(C_{0}, \ldots, C_{p^{\star}}\right)^{T}$, we deduce from (73) that

$$
\mathbb{M} \mathbf{e} \leq h \mathbf{c}, \quad \text { where } \quad \mathbb{M}=\left(\begin{array}{cccc}
1 & 0 & \ldots & 0 \\
-\omega & \ddots & \ddots & \vdots \\
\vdots & \ddots & \ddots & 0 \\
-\omega & \ldots & -\omega & 1
\end{array}\right)
$$

It is easy to verify that

$$
\left(\mathbb{M}^{-1}\right)_{i, j}= \begin{cases}0 & \text { if } j>i, \\ 1 & \text { if } j=i, \\ \omega(1+\omega)^{i-j-1} & \text { if } j<i\end{cases}
$$

and then, since $\left(\mathbb{M}^{-1}\right)_{i, j} \geq 0$, that

$$
\begin{equation*}
e_{k} \leq\left(C_{k}+\omega \sum_{j=0}^{k-1}(1+\omega)^{k-j} C_{j}\right) h . \tag{74}
\end{equation*}
$$

Define $\mathbf{v}=(1, \ldots, 1)^{T} \in \mathbb{R}^{p^{\star}+1}$, then

$$
\sum_{k=0}^{p^{\star}} e_{k}=(\mathbf{e} \mid \mathbf{v}) \leq h\left(\mathbb{M}^{-1} \mathbf{c} \mid \mathbf{v}\right)=h\left(\mathbf{c} \mid\left(\mathbb{M}^{-1}\right)^{T} \mathbf{v}\right)
$$

Since

$$
\left(\left(\mathbb{M}^{-1}\right)^{T} \mathbf{v}\right)_{k}=1+\omega \sum_{i=0}^{p^{\star}-k-1}(1+\omega)^{i}=(1+\omega)^{p^{\star}-k+1}-\omega
$$

we obtain that

$$
\begin{equation*}
\sum_{k=0}^{p^{\star}} e_{k}=h \sum_{k=0}^{p^{\star}} C_{k}\left((1+\omega)^{p^{\star}-k+1}-\omega\right) \tag{75}
\end{equation*}
$$

Noticing that $\psi(x, t)=1$ if $x \in B\left(0, r+L_{f}(T-t)\right)$, and that $\psi(x, t) \geq 0$ for all $(x, t) \in \mathbb{R}^{d} \times(0, T)$, ensure that

$$
\begin{equation*}
\int_{0}^{T} \int_{B(0, r-s t)}\left|u-u_{h}\right|^{2} d x d t \leq \int_{0}^{T} \int_{\mathbb{R}^{d}}\left|u-u_{h}\right|^{2} \psi(x, t) d x d t=\sum_{k=0}^{p^{\star}} e_{k} \tag{76}
\end{equation*}
$$

We conclude the proof by using using (75) in (76).

## 5. Concluding remarks

Our goal was to derive an error estimate for the finite volume approximation $u^{h}$. As mentioned above, we use the relative entropy which is not symmetric and we choose to use $H\left(u^{h}, u\right)$. If one decide to choose $H\left(u, u^{h}\right)$, the solution $u$ can be an entropy weak solution instead of a strong solution. Moreover, $u^{h}$ can be approximated by a continuous function $\tilde{u}^{h}$ such that $\tilde{u}^{h}\left(x_{K}, t\right)=u^{h}\left(x_{K}, t\right)$ for all cell $K \in \mathcal{T}$ where $x_{K}$ is the center of $K$. However, in that case, the right hand side of inequality (11) blows up when $h \rightarrow 0$ because of the space derivatives of $\tilde{u}^{h}$.

Acknowledgments. The authors would like to thank Frédéric Coquel and Edwige Godlewski for fruitful discussions. This work has been supported by the LRC Manon (Modélisation et approximation numérique orientées pour l'énergie nucléaire - CEA/DM2S-LJLL).
