What makes helium clusters interesting?

- Helium-helium interaction is of **weak van der Waals** type, closed shell atoms of very low polarisability, $D_e \approx 7.6 \text{ cm}^{-1}$
- Helium atoms have a relatively small mass.
- Large zero point energy effects (D_0 for $\text{He}_2 \approx 0.001 \text{ cm}^{-1}$).
- Helium clusters are small chunks of a quantum liquid.
- Quantum statistical effects: **bosonic** ^4He , fermionic ^3He .
- **Superfluidity** in bulk liquid ^4He below 2.17 K, in ^3He at mK level
- **A very special solvent: Is there a new chemistry?**

- Implantation of dopants through (multiple) inelastic collisions.
- Weak interactions with dopant.
- Binding energy and position of dopants depend on quantum effects.

Delicate balance between potential and quantum kinetic energy

Plenty of interesting experiments but theoretical difficulties!

Recent applications of helium clusters

- Matrix spectroscopy with minimal perturbations: **OCS, (HF)_n, biomolecules at 0.4 K, radicals**
- Reaction dynamics at very low temperatures: **$\text{Ba} + \text{N}_2\text{O} \rightarrow \text{BaO} + \text{N}_2$**
- Preparation of reactive intermediates: **$\text{HF} \cdots \text{CH}_3$, $\text{HCN} \cdots \text{CH}_3$ etc.**
- Preparation of high spin metal polymers: **Na_3 , K_3 , Rb_3 etc.**
- Assembly of cold clusters: **Ag_n , Mg_n**
- Thermodynamically unstable isomers: **linear $(\text{HCN})_n$**
- Nanomodels for molecule-surface interactions: **$\text{HCN} \cdots \text{Mg}_3$ etc.**

- Container for soft ionisation for analytical mass spectrometry?
- Energy dissipation by coupling to the bath?
- Confinement medium for cluster ignition and Coulomb explosion.
- Spacer for interatomic Coulombic decay (ICD).

A typical helium droplet experiment

Pair potentials involving helium and metals

Shallower well than **He-He** and larger equilibrium distance for He-M

Alkali-helium dimers

Coordination in the Gas Phase

DOI: 10.1002/anie.200604148

The Search for the Species with the Highest Coordination Number**

Andreas Hermann, Matthias Lein, and Peter Schwerdtfeger*

The question of the highest possible coordination number for an atom is addressed as this is related to the Gregory–Newton problem of kissing hard spheres.^[1] Using first-principles quantum chemical simulations we show that the interaction of Pb²⁺ with He atoms results in remarkably stable PbHe₁₅²⁺ with 15 atoms in the first coordination sphere forming a Frank–Kasper polyhedron.^[2] The Pb–He distances do not change significantly by subsequent filling of the first coordination shell as one expects for a hard-sphere model. Such high coordination numbers have been proposed only in liquid simulations so far.^[3]

The problem of how many spheres (N_{\max} , called the kissing number or Newton number) of a given radius R can be

conjunction with coordination numbers higher than 12 stabilized by the surrounding matrix.^[2]

Herein we take a different approach. We look for a single molecule MX_N in the gas phase of high coordination number N which can be experimentally verified. We choose a large positively charged central atom, M = Pb²⁺, and a very small ligand, X = He. Both atoms have reasonably small polarizabilities ($\alpha_{\text{He}} = 1.38 \text{ au}^{[10]}$ and $\alpha_{\text{Pb}^{2+}} = 14.1 \text{ au}^{[11]}$), and therefore fit the hard-sphere model quite well. The ionization potential of Pb⁺ (15.03 eV) is much smaller than that of He (24.58 eV).^[12] Hence, Pb²⁺–He does not undergo a Coulomb explosion and there is no (or minimal) charge transfer from He to Pb²⁺. Hence the Pb²⁺–He interaction $V(R)$ is mainly of

DFT result: $N=16$ starts a new shell

Modelling ions inside helium clusters

Alkali ions and **Pb²⁺** ions have closed electronic shells and an isotropic interaction potential with helium atoms.

Pb⁺ has an open shell s²p electronic configuration leading to **electronic anisotropy** and **X²Π** and **A²Σ⁺** states for **Pb⁺He**.

Similar systems of interest are **Ar⁺** ions (s²p⁵ valence shell, **X²Σ⁺** and **A²Π** states for **Ar⁺He**) and halogen atoms and ions interacting with helium, in particular **iodine**. Spin-orbit coupling between Σ and Π states has to be included in the model.

The road map:

Build reliable many body models for **He interacting with open shell species** by combining high level ab initio surfaces with accurate level predictions and comparison with spectroscopic or collision experiments.

Use an accurate quantum many body method for nuclear dynamics:

Diffusion quantum Monte Carlo (DMC)

Diffusion quantum Monte Carlo (DMC)

- Isomorphism between **time dependent Schrödinger equation** and a **multi dimensional diffusion equation** (Fermi, Ulam)
- Exact solution except for statistical errors

KFU Graz 1936-38

$$i\hbar \frac{\partial \Psi(\vec{r}, t)}{\partial t} = \left\{ -\frac{\hbar^2}{2} \sum_{j=1}^n \frac{1}{m_j} \nabla_j^2 + \{ \textcircled{V(\vec{r})} - E_{ref} \} \right\} \Psi(\vec{r}, t)$$

$$\frac{\partial C(\vec{r}, t)}{\partial t} = \left\{ \sum_{j=1}^n D_j \nabla_j^2 - k(\vec{r}) \right\} C(\vec{r}, t) .$$

Solution by propagation of an ensemble of random walkers in imaginary time
Cartesian coordinates, precision $\sigma_E/E = 10^{-6} - 10^{-3}$

Radial densities for $\text{Pb}^{2+}\text{He}_n$

Ground state energies for Pb^+He_n

Radial densities for Pb^+He_n

DMC calculations for I@He_n

Motivation: Photodissociation of $\text{CH}_3\text{I} \rightarrow \text{CH}_3 + \text{I}$ inside He_n.

We need global potential energy surfaces for ground and excited $\text{CH}_3\text{I}@He_n$ and for the relevant fragments $\text{CH}_3@He_n$ and $\text{I}@He_n$

Potential model:

Anisotropy due to I s^2p^5 valence shell $\rightarrow \text{X}^2\Sigma^+$ and $\text{A}^2\Pi$ states for I-He.
RCCSD(T) calculations with aug-cc-pVXZ basis sets and relativistic pseudopotential (ECP) from K. Petersen.

Ab initio points fitted to extended Tang-Toennies analytical form.

Very strong spin-orbit interaction in I:

Non additive many body potential model with additional spin-orbit mixing using atomic Δ_I (complex 6 x 6 matrix to diagonalise in each DMC step).

Δ_{SO} dominates so much over E_{vdW} that SO mixing is almost perfect!

CO^+-He and $CO^+@He_n$

CO^+He ions have been observed several times in drift tube experiments.

Mixed cluster ions of the composition CO^+He_n should be accessible in drift tube experiments, mixed gas expansions coupled to electric discharges, or CO ionization inside large He clusters.

Ionisation of CO barely changes the rotational constants but strongly affects the interaction with helium: $CO@He_n$ and CO^+He_n are an ideal pair to understand **rotation in helium clusters** by separating effects due to mass and interaction.

Potential surface can be checked by ion depletion spectroscopy (see $N_2^+He_n$).

Astrophysical motivation

CO is a relatively abundant molecule in interstellar space and CO^+ has been identified in 1993. Low energy collisions with its second most abundant collision partner, helium atoms, are governed by the weak intermolecular interaction leading to the van der Waals complex $He-CO^+$.

Marius Lewerenz

TU Graz, 15.12.2011

34

Interaction and structure, what to expect?

Electrostatics/induction:

Charge – induced dipole: isotropic $\sim 1/R^4$

Permanent dipole – induced dipole: anisotropic $\sim 1/R^5 \rightarrow$ linear complex

Quadrupole moment – induced dipole: anisotropic $\sim 1/R^6 \rightarrow$ T-shaped

Dispersion: anisotropic $\sim 1/R^k$, $k \geq 6$

Result: Compromise between linear and T-shaped at short range,
linear long range approach: **Floppy, quasilinear?**

Ab initio CCSD(T) equilibrium structure of $\text{He-CO}^+(\text{X}^2\Sigma^+)$ and the dipole moment vector μ .

Helium density from DMC

Sum over CO⁺He and He-He pairs and induced dipole interaction between He atoms.

Vib. frequency shift $\approx 0.3 \text{ cm}^{-1}$ per He atom for small clusters

CO⁺@He₂₀: helium density from DMC

CH₃-He

- Ab initio **RCCSD(T)** calculations with **aug-cc-pVXZ** basis sets (**X=D,T,Q,5**)
- **CH₃** keeping **C_{3v}** symmetry and fixed C-H distance: only **umbrella angle α**
- **He** position relative to **CH₃** center of mass in **spherical coordinates R, θ, ϕ**
- Several 3D surfaces assembled into 4D surface including **CH₃** relaxation
- Overall about 3000 potential energy points

Analytical representation with **angle dependent HFD** form expanded over real spherical harmonics T_{lm} with symmetry restrictions on l, m :

$$V(R, \theta, \phi) = A \exp\{-b(\theta, \phi) [R - R_e(\theta, \phi)]\} - \sum_k C_k(\theta, \phi)/R^k$$

$$X(\theta, \phi) = \sum_{lm} x_{lm} T_{lm}(\theta, \phi) \quad X = b, R_e, C_k$$

500-1000 points per 3D cut are fitted with 38 parameters and rms < 0.1 cm⁻¹

Outlook

- **Vibrational shifts and effective rotational constants for CO⁺ in helium (DMC/PIMC in collaboration with P. N. Roy).**
- **CH₃ radicals in helium, reactive complexes.**
- **Photodissociation of CH₃I and CF₃I (ZPAD, DMC etc.)**
- **Dopant spectroscopy (Mg^{*}, Ag^{*}, Ag⁺ etc.).**
- **Transport properties (Mg⁺, Na⁺).**
- **DMC and ZPAD calculations on Xe_nHe_m.**
- **DMC with constraints ((H₂)_n, He_n(H₂)_m possible).**
- **SBDMC: soft body DMC allowing feedback between dopant and bath vibrations**

ANR project DYNHELIUM (Toulouse, Rennes, Paris)
