L’archive ouverte pluridisciplinaire HAL, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d’enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.
Advances in observer design for Takagi-Sugeno systems with unmeasurable premise variables

Dalil Ichalal, Benoît Marx, José Ragot, Didier Maquin

Abstract—This paper proposes a new approach of observer design for nonlinear systems described by a Takagi-Sugeno model. Its main contribution concerns models with premise variables depending on the system states which are completely or partially unknown. This case is more difficult than when the premise variables are known or measured. Indeed, in that case, weighting functions of the observer depend on state estimates and the state estimation error is then governed by a Lipschitz nonlinear system. Here, two main results are established. Firstly, relaxed stability conditions guaranteeing asymptotic stability of the observer by using a fuzzy Lyapunov function are provided. This aims to reduce the conservativeness compared to the existing works and enhance the maximal admissible Lipschitz constant for which the linear matrix inequality (LMI) conditions are feasible. Secondly, the Input-to-State Stability concept combined to a polyquadratic Lyapunov function are used for guaranteeing a bounded state estimation error which relaxes the conservativeness related to the Lipschitz constant. The robustness aspect is dealt with respect to some bounded modeling uncertainties and additive bounded perturbations. The stability conditions are expressed in terms of LMI.

Index Terms—Nonlinear systems, Takagi-Sugeno systems, unmeasurable premise variables, LMI, observer design, Input-to-state stability.

I. INTRODUCTION

Observer design for nonlinear systems is a challenging problem which is intensively studied in control and diagnosis fields. Indeed, many approaches have been proposed in order to estimate the states of such systems. Firstly, in [29], the author proposed a method for systems modeled by a linear part and a nonlinear Lipschitz one for which stability conditions were proposed. Thereafter, in [22], an iterative algorithm was proposed to deal with the problem of observer design, however the method may fail even if the system is observable. In [23], the $H_\infty$ formulation is exploited in order to provide necessary and sufficient conditions for stability of the state estimation error for Lipschitz systems. This work is extended in [21] for dynamic gain observer design for the same class of systems. Many other works were also proposed, namely, sliding mode observers which are interesting due to their insensitivity to modeling uncertainties and external perturbations [6], or high gain observer which are based on a mathematical transformation of the system by using immersion techniques [7], [8].

In these last years, the Takagi-Sugeno (T-S) approach, introduced in [26], offered an interesting tool for studying nonlinear systems. This structure may represent or approximate strongly nonlinear systems with a simple mathematical representation consisting in several linear submodels weighted by nonlinear functions satisfying the convex sum property. These weighting functions may depend on measurable premise variables (input, output of the system or external variable as linear parameter variable (LPV) systems), or and unmeasurable premise variables (UPV) as the state of the system. The T-S approach is interesting because it allows to extend some control and observation methods, previously dedicated to linear systems, to nonlinear ones [28].

The problem of state estimation of nonlinear systems using T-S model approach has been addressed with different methods, the most of the published works considered T-S models with measurable premise variables [1], [2], [16], [20]. Clearly the case of measurable premise variables offers a simpler way to generalize the methods already developed for linear systems. However, T-S models with UPV naturally arise when they are obtained from a nonlinear system ($x = f(x,u)$) by mathematical transformations. The most well-known is the so-called sector nonlinearity transformation providing an exact T-S model with no loss of information, in a compact set of the state space. Furthermore, the T-S models with UPV may represent a larger class of nonlinear systems compared to the T-S model with measurable premise variables [31].

However, T-S models with UPV are more difficult to deal with than those with measurable premise variables. Consequently, few works are devoted to this class of models despite of their advantages. Nevertheless, we can cite [5] which is the first work dealing with the problem of observer design for this class of nonlinear systems. Extensions of this approach have also been published in [4] and [19]. Let us also mention [31] where a filter estimating the state and minimizing the effect of disturbances is proposed. More recently, new approaches have been proposed in [10], [1], [11], [12], [13]. In [10], the differential mean value theorem is combined to sector nonlinearity transformation to re-write the state estimation error as an autonomous T-S system in order to be able to apply the classical stability studies developed for T-S systems. A similar problem is studied recently for a special case of discrete-time LPV systems with uncertain parameters in [9] and [17].

In this work, observer design approaches are proposed for estimating the state of nonlinear systems represented by a T-S model with UPV. The contributions of this paper concern:
where the matrices $y$ vector and $A$. Observer structure $x$ $x$ $x$ where the Lipschitz constant and finally, in the last section, conclusion combining polyquadratic Lyapunov function and ISS concept to ensure the bounded state estimation error which is used to deal with T-S systems with modeling uncertainties. The established inequalities are stated in an adequate form for applying several relaxations provided in the literature as Polya’s theorem [24], Tuan’s lemma [30], or the use of non quadratic Lyapunov functions [27]. The paper is organized as follows: In section II, an observer ensuring asymptotic convergence is proposed by using a polyquadratic Lyapunov function and the Lipschitz condition. In section III, an approach combining polyquadratic Lyapunov function and ISS concept is proposed in order to overcome the problem related to the Lipschitz constant and finally, in the last section, conclusion and future works are discussed.

II. ASYMPTOTIC OBSERVER DESIGN

Let us consider a nonlinear system described by the following T-S model

$$
\begin{align*}
\dot{x}(t) &= \sum_{i=1}^{r} \mu_i(x(t))(A_i x(t) + B_i u(t)) \\
y(t) &= C x(t)
\end{align*}
$$

(1)

where $x(t) \in \mathbb{R}^n$ is the state vector, $u(t) \in \mathbb{R}^m$ is the input vector and $y(t) \in \mathbb{R}^p$ represents the output vector. $A_i \in \mathbb{R}^{n \times n}$, $B_i \in \mathbb{R}^{n \times m}$, $C_i \in \mathbb{R}^{p \times n}$ are known matrices and $r$ is the number of sub-models. The functions $\mu_i(x(t))$ are the weighting functions depending on the state variables $x(t)$ which are non measurable variables. These functions verify the so-called convex sum properties

$$
\sum_{i=1}^{r} \mu_i(x(t)) = 1, \quad 0 \leq \mu_i(x(t)) \leq 1 \quad \forall i \in \{1, \ldots, r\}
$$

(2)

The output equation is chosen to be linear with regard to the state, which is frequently the case in practice.

A. Observer structure

Let us first introduce the following notations

$$
\begin{align*}
X_{\mu} &= \sum_{i=1}^{r} \mu_i(x(t))X_i, \quad X_{\mu \mu} = \sum_{i=1}^{r} \sum_{j=1}^{r} \mu_i(x(t))\mu_j(x(t))X_{ij} \\
X_{\hat{\mu}} &= \sum_{i=1}^{r} \hat{\mu}_i(x(t))X_i, \quad X_{\hat{\mu} \hat{\mu}} = \sum_{i=1}^{r} \sum_{j=1}^{r} \hat{\mu}_i(x(t))\hat{\mu}_j(x(t))X_{ij}
\end{align*}
$$

(3)

(4)

where $X_i$ and $X_{ij}$ stands for any matrices, e.g. $A_i$ or $B_i$. Using these notations, the system (1) becomes

$$
\begin{align*}
\dot{x}(t) &= A_\mu x(t) + B_\mu u(t) \\
y(t) &= C x(t)
\end{align*}
$$

(5)

The proposed observer is given by

$$
\begin{align*}
\dot{\hat{x}}(t) &= A_{\hat{\mu}} \hat{x}(t) + B_{\hat{\mu}} u(t) + P_{\hat{\mu}}^{-1} L_{\hat{\mu}} (y(t) - \hat{y}(t)) \\
\hat{y}(t) &= C \hat{x}(t)
\end{align*}
$$

(6)

where the matrices $L_i$ and the symmetric positive definite matrices $P_i$ are to be determined. The state estimation error $\hat{e}(t) = x(t) - \hat{x}(t)$ is governed by the following nonlinear differential equation depending on the system state $x(t)$, its estimate $\hat{x}(t)$, the system input $u(t)$ and the state estimation error $\hat{e}(t)$

$$
\dot{\hat{e}}(t) = \Phi_{\hat{\mu}} \hat{e}(t) + \delta(x, \hat{x}, u)
$$

(7)

where

$$
\Phi_{\hat{\mu}} = A_{\hat{\mu}} - P_{\hat{\mu}}^{-1} L_{\hat{\mu}} C
$$

(8)

$$
\delta(x, \hat{x}, u) = f(\hat{x}, x, u) - f(x, x, u)
$$

(9)

$$
f(\hat{x}, x, u) = A_{\hat{\mu}} \hat{x}(t) + B_{\hat{\mu}} u(t)
$$

(10)

with $P_i = P_i^T > 0$. In this section, the following assumptions are made

- A1. The function $f$ in (10) is Lipschitz with respect to its first variable. Then, there exists a positive scalar $\eta$ such that $\delta^T(\hat{x}, x, u)\delta(x, \hat{x}, u) \leq \eta^2 \hat{e}^T(t)\hat{e}(t)$.
- A2. There exists positive scalars $\rho_i$ such that the weighting functions satisfy $|\mu_i(\hat{x})| \leq \rho_i$.

B. Stability analysis

First sufficient LMI conditions for asymptotic convergence of the state estimation error (7) are given in the next theorem.

Theorem 1: Under the assumptions A1 and A2, if there exists a matrix $P_0$, symmetric and positive definite matrices $P_i$, gain matrices $L_i$ and a positive scalar $\lambda$ satisfying the following LMI

$$
M_{ij} < 0, \quad i, j = 1, \ldots, r
$$

(11)

$$
P_i - P_0 \geq 0, \quad i = 1, \ldots, r
$$

(12)

where

$$
M_{ij} = \begin{pmatrix}
\Omega_{ij} & P_j \\
P_j^- & -\lambda I
\end{pmatrix}
$$

(13)

and

$$
\Omega_{ij} = A_i^T P_j + P_j A_i - C_i^T L_i^T - L_i C_i + \sum_{i=1}^{r} \rho_i (P_i - P_0) + \lambda \eta^2 I
$$

(14)

then the state estimation error asymptotically converges towards zero.

Proof: To prove the stability of the state estimation error (7), let us consider the fuzzy Lyapunov function

$$
V(\hat{e}(t)) = \hat{e}^T(t) P_{\hat{\mu}} \hat{e}(t)
$$

(15)

The matrices $P_i$ being symmetric positive definite and the weighting functions satisfying (2), the function $V(\hat{e}(t))$ is positive too. Its time derivative is given by

$$
\dot{V}(\hat{e}(t)) = \hat{e}^T(t) P_{\hat{\mu}} \dot{\hat{e}}(t) + \hat{e}^T(t) \dot{P}_{\hat{\mu}} \hat{e}(t) + \hat{e}^T(t) \dot{P}_{\hat{\mu}} \hat{e}(t)
$$

(16)

The derivative of $P_{\hat{\mu}}$ is given by

$$
P_{\hat{\mu}} = \sum_{i=1}^{r} \mu_i(\hat{x}) P_i
$$

(17)

Substituting $P_{\hat{\mu}}$ and (7) in (16), one obtains

$$
\dot{V}(\hat{e}(t)) = \hat{e}^T(t) \left( \Phi_{\hat{\mu}} P_{\hat{\mu}} + P_{\hat{\mu}} \Phi_{\hat{\mu}} + \dot{P}_{\hat{\mu}} \right) \hat{e}(t) + 2 \hat{e}^T(t) P_{\hat{\mu}} \delta(x, \hat{x}, u)
$$

(18)
With assumption A1 and since it is well known that the following inequality holds
\[ X^T Y + Y^T X \leq X^T \Sigma X + Y^T \Sigma^{-1} Y \] (19)
for any matrices \( X, Y \) and \( \Sigma = \Sigma^T > 0 \), then, for any positive \( \lambda \), it follows
\[ 2e^T(t)\Phi_{\mu} \delta(x, \hat{x}, u) \leq \lambda \eta^2 e^T(t) e(t) + \lambda^{-1} e^T(t) (P_{\mu} P_{\mu}) e(t) \]
and, with assumption A2, \( \dot{P}_{\mu} \) is bounded by
\[ \dot{P}_{\mu} \leq \sum_{i=1}^{r} |\mu_i(\hat{x})| P_i = \sum_{i=1}^{r} \rho_i P_i \]
Moreover, due to (2), it obviously follows
\[ \sum_{i=1}^{r} \mu_i(\hat{x}) = 0 \Rightarrow \sum_{i=1}^{r} \mu_i(\hat{x})P_i = 0 \] (21)
for any matrix \( P_i \) which is a slack variable introducing an additional degree of freedom [18]. In the remaining of the paper, \( P_i \) is chosen to be symmetric. Then, the time derivative of the Lyapunov function is bounded as follows
\[ \dot{V}(e(t)) \leq e^T(t) (\Phi_{\mu}^T P_{\mu} + P_{\mu} \Phi_{\mu}) + \sum_{i=1}^{r} \rho_i (P_i - P_0) + \lambda \eta^2 I + \lambda^{-1} P_{\mu} P_{\mu} e(t) \]
\[ \leq e^T(t) (A_{\mu}^T P_{\mu} + P_{\mu} A_{\mu} - C^T L_{\mu}^T - L_{\mu} C) + \sum_{i=1}^{r} \rho_i (P_i - P_0) + \lambda \eta^2 I + \lambda^{-1} P_{\mu} P_{\mu} e(t) \] (23)
where \( P_i - P_0 \geq 0 \). The negativity of \( \dot{V}(e(t)) \) is ensured if
\[ A_{\mu}^T P_{\mu} + P_{\mu} A_{\mu} - C^T L_{\mu}^T - L_{\mu} C + \sum_{i=1}^{r} \rho_i (P_i - P_0) + \lambda \eta^2 I + \lambda^{-1} P_{\mu} P_{\mu} < 0 \] (24)
This inequality can be expressed as follows using the Schur complement
\[ M_{\mu} \dot{P}_{\mu} < 0 \] (25)
where \( M_{\mu} \) is defined by (13). Since the weighting functions satisfy (2), the inequality (25) holds if the LMIs (11) are satisfied, which achieves the proof.\[ \square \]

C. Relaxed LMI formulation of stability conditions of the state estimation error

Note that the negativity of (25) is largely studied in the literature. An intuitive and first result on stability of T-S systems is the negativity of each term of the sum (25), leading to the result presented above. This result may be very conservative; relaxed stability conditions have been provided using various approaches like Tuan’s lemma [30] and Polya’s theorem [24]. Let us examine the use of Tuan’s lemma. Inequality (25) holds if the following following inequalities are satisfied
\[ \begin{cases} M_{\mu} < 0, i = 1, \ldots, r \\ \frac{1}{2} M_{\mu} + M_{ji} + M_{ji} < 0, j \neq i \end{cases} \] (26)
The power of this result is its significant conservatism reduction without adding slack variables to increase the number of degree of freedom.

Another less restrictive approach is given by simple manipulations of the sums in order to obtain the LMIs [24], [14], in instance, by multiplying by one sum, one obtains
\[ \begin{cases} M_{\mu} < 0, i = 1, \ldots, r \\ M_{ij} + M_{ji} + M_{ji} < 0, j \neq i \\ M_{ij} + M_{ji} + M_{ji} + M_{ik} + M_{jk} + M_{jk} < 0 \end{cases} \] (27)
Note also that most of relaxed stability approaches proposed recently are expressed as LMI with double summation indexes, as the LMI given in (25). Consequently, one of the advantages of using polyquadratic Lyapunov functions is, especially, to find an inequality with a double sum as shown in (25).

III. GUARANTEED BOUNDED RECONSTRUCTION ERROR

In this section, a robust observer is designed for T-S systems with UPV. The objective is to provide LMI conditions where the Lipschitz constant \( \eta \) is not needed. The second objective is to design a robust observer with respect to modeling uncertainties. For that purpose, a bounded estimation error convergence is proven instead of asymptotic one, by considering ISS.

A. Bounded estimation error

Let us consider the system (5) and the corresponding proposed observer (6). The state estimation error dynamics is given by (7). Consider also the same polyquadratic Lyapunov function defined in (15) as well as the following assumptions

- **A3.** The input \( u(t) \) is bounded
- **A4.** The system is input-to-state stable (ISS), i.e. the system state \( x(t) \) is bounded for bounded input \( u(t) \)
- **A5.** There exists positive scalars \( \rho_i \) such that the weighting functions satisfy \( |\mu_i(\hat{x})| \leq \rho_i \).

These assumptions lead to a bounded perturbation term \( \delta(x, \hat{x}, u) \). For the sake of clarity, this term will be noted \( \delta(t) \) in the following. One can note that the Lipschitz assumption of the function \( f(x, \hat{x}, u) \) is no longer needed. The convergence conditions of the state estimation error are established in the theorem 2.

**Definition 1:** [25] The system (7) is said to be ISS if there exists a \( \mathcal{K} \mathcal{L} \) function \( \beta : \mathbb{R}^{+} \times \mathbb{R} \rightarrow \mathbb{R} \) and a \( \mathcal{K} \) function \( \alpha : \mathbb{R} \rightarrow \mathbb{R} \) such that, for each input \( \delta(t) \) satisfying \( \| \delta(t) \|_{\infty} < \infty \) and each initial condition \( e(0) \in \mathbb{R}^{n} \), the trajectory of (7) associated with \( e(0) \) and \( \delta(t) \) satisfies
\[ \| e(t) \| \leq \beta (\| e(0) \|, \| t \|) + \alpha (\| \delta(t) \|_{\infty}), \forall t \] (28)

**Theorem 2:** Under the assumptions A3, A4 and A5, given a scalar \( \alpha > 0 \). If there exists a matrix \( P_0 \), symmetric and positive definite matrices \( P_0 \) gain matrices \( L_0 \) and a positive scalars \( \gamma \) and \( c \) solution to the following optimization problem
\[ \min_{P_0, P_i, L_i, \gamma} \gamma \]
where \( \xi_j \) is defined by
\[
\xi_{ij} = \begin{pmatrix}
A_i^T P_j + P_j A_i - L_i C - C^T L_i^T + \sum_{i=1}^{r} p_i (P_i - P_0) + \alpha P_j
\end{pmatrix} P_j
\]
where \( x, \alpha \gamma \) are positive scalars and \( \alpha \) is a positive scalar to minimize. Let us consider the following inequality
\[
V(e(t)) = e^T(t) \left( \Phi_{\hat{\alpha}}^T P_{\hat{\mu}} + P_{\hat{\mu}} \Phi_{\hat{\beta}} + \sum_{i=1}^{\hat{r}} P_i (P_i - P_0) \right) e(t)
\]
and the term \( \delta(t) \) is bounded. The inequality (35) is equivalent to
\[
V(e(t)) \leq c e^T(t) \xi_{\hat{\beta} \hat{\mu}} e_{\hat{\alpha}}(t) - \alpha e^T(t) P_{\hat{\mu}} e(t) + c \delta^T(t) \delta(t)
\]
where
\[
\xi_{\hat{\beta} \hat{\mu}} = \begin{pmatrix}
\Phi_{\hat{\beta}}^T P_{\hat{\mu}} + P_{\hat{\mu}} \Phi_{\hat{\beta}} + \sum_{i=1}^{\hat{r}} p_i (P_i - P_0) + 2 \alpha p_{\hat{\mu}} P_{\hat{\mu}}
\end{pmatrix}
\]
and \( x, \alpha \) are positive scalars and \( e_{\hat{\alpha}}(t) = [e^T(t) \delta^T(t)]^T \).
If the inequality (30) holds, the inequality \( \xi_{\hat{\beta} \hat{\mu}} < 0 \) is also satisfied, then it follows
\[
V(e(t)) \leq -\alpha e^T(t) P_{\hat{\mu}} e(t) + c \delta^T(t) \delta(t)
\]
One obtains
\[
V(e(t)) \leq V(0) e^{-\alpha t} + \int_0^t e^{-\alpha(t-s)} \| \delta(s) \|^2 ds
\]
Due to the fact that the weighting functions \( \mu_i(\xi) \) satisfy (2), then it is easy to derive that, for any \( e(t) \in \mathbb{R}^n \), it holds
\[
\alpha_1 \| e(t) \|^2 \leq V(e(t)) \leq \alpha_2 \| e(t) \|^2, \forall e(t) \in \mathbb{R}^n
\]
where \( \alpha_1 = \min_{1 \leq i \leq r} \lambda_{\min} (P_i) \) and \( \alpha_2 = \max_{1 \leq i \leq r} \lambda_{\max} (P_i) \), where \( \lambda_{\min}(M) \) (resp. \( \lambda_{\max}(M) \)) denotes the minimal (resp. maximal) eigenvalue of the matrix \( M \). The inequality (40) becomes
\[
\alpha_1 \| e(t) \|^2 \leq \alpha_2 \| e(0) \|^2 e^{-\alpha \gamma t} + c \| \delta(t) \|^2
\]
which leads to
\[
\alpha_1 \| e(t) \|^2 \leq \alpha_2 \| e(0) \|^2 e^{-\alpha \gamma t} + c \| \delta(t) \|^2
\]
Finally, using the square root on equation (43), on obtains
\[
\| e(t) \|_2 \leq \sqrt{\frac{c}{\alpha \alpha_1}} \| e(0) \|_2 e^{-\alpha \gamma t} + \sqrt{\frac{c}{\alpha \alpha_1}} \| \delta(t) \|_\infty
\]
From this equation, we conclude that if \( \| \delta(t) \|_\infty = 0 \) then \( \| e(t) \|_2 \to 0 \) when \( t \to \infty \). Moreover, in the presence of the perturbation \( \delta(t) \), the error \( \| e(t) \|_2 \) is bounded by \( \gamma \| \delta(t) \|_\infty \) where \( \gamma = \sqrt{\frac{c}{\alpha \alpha_1}} \) in the steady state. As a conclusion, the Input-To-State (ISS) stability is proven with the inequality (44).

Note that the size of the convergence set \( D \) depends on the selected matrices \( P_i \) and the parameters \( \alpha \) and \( c \). The set \( D \) should be made as small as possible to ensure a good accuracy of convergence. The choice of \( \alpha \), \( c \) and \( P \) providing a small set of convergence is not obvious because the problem is not convex. In the next, a technique is proposed to transform the non convex problem to a convex one under LMI constraints. Let us consider the following inequality
\[
\sqrt{\frac{c}{\alpha \alpha_1}} \leq \sqrt{T}
\]
where \( T \) is a positive scalar to minimize. Let us consider the assumption that \( P_i \geq I \), then \( \alpha_1 = \min_{1 \leq i \leq r} \lambda_{\min} (P_i) = 1 \). It follows, form (45) that
\[
c - \alpha \gamma \leq 0
\]
Then, by fixing the parameter \( \alpha > 0 \), the optimization problem given in the theorem 2 are obtained, which ends the proof.

B. Robustness with respect to modeling uncertainties

The observer proposed in the last section guarantees bounded estimation error. It is easy to prove that this observer is robust for some bounded modeling uncertainties. Indeed, the uncertainties can be included in the disturbance-like term obtained from the fact that the weighting functions of the T-S model are unmeasurable. Consider the uncertain system:
\[
\begin{align*}
\dot{x}(t) &= (A_0 + \Delta A_0)x(t) + (B_0 + \Delta B_0)u(t) \\
y(t) &= (C + D_0)x(t)
\end{align*}
\]
with the observer (6), the state estimation error obeys to the differential equation
\[
\dot{\hat{e}}(t) = \Phi_{\hat{\mu}} e(t) + \delta(x, \dot{x}, u)
\]
where $\Phi_{\mu \beta} = A_\beta - P_\beta^{-1}L_\beta C$ and

$$ \delta(x, \dot{x}, u) = \left( A_\mu - A_\beta + \Delta A_\mu - P_\beta^{-1}L_\beta \Delta C \right) x(t) + \left( B_\mu - B_\beta + \Delta B_\mu \right) u(t) \quad (49) $$

Note that the state estimation error (48) has the same form as that given in (7). All the uncertain terms are included in the disturbance-like term $\delta(x, \dot{x}, u)$. This fact allows to use the result obtained in the last section and hence to prove the ISS from $\delta$ to the state estimation error. The only difference concerns the bound of this perturbation term. Then by minimizing the effect of $\delta(x, \dot{x}, u)$ a robust observer is obtained with respect to some modeling uncertainties.

**Remark 1:** It is known that using a fuzzy Lyapunov function is less conservative than using a quadratic one, especially when the T-S model contains a large number of sub-models. Furthermore, the LMI problem can be solved for larger Lipschitz constant compared to the existing results (see the example) [3], [5], [15].

**Remark 2:** The second result aims to provide LMI conditions without needing any calculation of the Lipschitz constant. This can only be ensured for some values of the (assumed) Lipschitz property of the disturbance-like term. The time derivatives of $\delta(x, \dot{x}, u)$ include the disturbances as follows

$$ \delta(x, \dot{x}, u) = (A_\mu - A_\beta) x + (B_\mu - B_\beta) u + \omega + P_\beta^{-1}L_\beta v \quad (51) $$

For bounded $\omega(t)$ and $v(t)$, then $\delta(x, \dot{x}, u)$ is still bounded. In addition, the proposed observer can take into account uncertainties on the premise variables.

**Remark 3:** The proposed results are firstly given in the form of double sums inequalities represented in general by

$$ M_{\mu \beta} < 0 \quad (50) $$

This is an adequate form to use the recent result on conservatism reduction, namely the Polya’s theorem which provides asymptotic necessary and sufficient stability conditions. It is easy to derive these conditions (as given in the theorem 2) (for more details, the reader can refer to [14], [24]).

**Remark 4:** The ISS is also preserved if any bounded additive disturbances $\omega(t)$ and $v(t)$ respectively affect the state dynamics and measurement equations. Indeed, it can easily be seen that the term $\delta(x, \dot{x}, u)$ can include the disturbances as follows

$$ \delta(x, \dot{x}, u) = (A_\mu - A_\beta) x + (B_\mu - B_\beta) u + \omega + P_\beta^{-1}L_\beta v \quad (51) $$

For bounded $\omega(t)$ and $v(t)$, then $\delta(x, \dot{x}, u)$ is still bounded. In addition, the proposed observer can take into account uncertainties on the premise variables.

**Remark 5:** Note that the results are easily extended to systems with nonlinear output equation given by

$$ y(t) = \sum_{i=1}^{r} \mu_i(x) C_i x(t) \quad (52) $$

**Remark 6:** In the first proposed approach, asymptotic convergence of the state estimation error is sought, based on the (assumed) Lipschitz property of the disturbance-like term. This can only be ensured for some values of the Lipschitz constant (feasibility of the LMIs). In the second approach, the goal is no longer asymptotic convergence, but only convergence in a ball. In that case, the Lipschitz assumption is not needed.

### IV. Simulation Example

Due to space limitation, only the second approach is illustrated and discussed. Let us consider the Rossler chaotic system modeled in the form of (1) with two sub-models ($r = 2$) defined as follows

$$ A_1 = \begin{pmatrix} -10 & 10 & 0 \\ 28 & -1 & -x_{1 \text{max}} \\ 0 & x_{1 \text{max}} & -0.37 \end{pmatrix}, \quad A_2 = \begin{pmatrix} -10 & 10 & 0 \\ 28 & -1 & -x_{1 \text{min}} \\ 0 & x_{1 \text{min}} & -0.37 \end{pmatrix}, $$

$$ B_1 = B_2 = \begin{pmatrix} 0 \\ 0 \\ 0 \end{pmatrix}, \quad C = \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix} $$

The premise variable is $x_1(t)$ which is bounded by $x_{1 \text{min}} = -9.8693$ and $x_{1 \text{max}} = 13.8164$. The weighting functions are defined by

$$ \mu_1(x(t)) = \frac{x_1(t) - x_{1 \text{min}}}{x_{1 \text{max}} - x_{1 \text{min}}}, \quad \mu_2(x(t)) = \frac{x_{1 \text{max}} - x_1(t)}{x_{1 \text{max}} - x_{1 \text{min}}} $$

The time derivatives of $\mu_i(x), \ i \in \{1, 2\}$ are bounded by $\rho_1 = \rho_2 = 4.5$. The Lipschitz constant of the term $\delta(t)$ is computed and given by $\eta = 173.35$. The approach given in [3] does not provide any solution to this example, since solution can only be obtained for Lipschitz constant smaller than 29.73. The LMIs given in the theorem 1 of the present paper are feasible for a maximal value of the Lipschitz constant $\eta_{\text{max}} = 476.87$ which is larger than the real Lipschitz constant $\eta = 173.35$. Maximization of the Lipschitz constant can take into account some uncertainties in the nonlinear term $\delta(t)$. On the other hand, solving the optimization problem given in the theorem 2 with SEDUMI (YALMIP), the LMIs are feasible for $\alpha = 10$ and the attenuation level of the transfer of $\delta(t)$ towards $e(t)$ is $\gamma = 0.0549$ which is greater than or equal to $\sqrt{\alpha \eta_i}$ (in this example, the obtained $\gamma$ is exactly the same as the quantity $\sqrt{\frac{\alpha \eta_i}{\eta_i}}$). The result of the state estimation is depicted on figure 1.

**Fig. 1.** State variables (blue line) and their estimates (red dashed lines)

A second simulation is performed with a centered measurement noise $v(t)$ in the range $-0.33$ and 0.33. This case
corresponds to a perturbation term $\delta(t)$ given in equation (51) with $\omega(t) = 0$. The norms $\|e(t)\|_2$ and $\gamma\|\delta(t)\|_\infty$ are depicted in the figure 2 and illustrates that the norm of the error is always less than $\gamma\|\delta(t)\|_\infty$.

V. CONCLUSIONS AND FUTURE WORKS

In this paper, some advances in observer design for Takagi-Sugeno systems with UPV are proposed. A focus has been made on some problems, namely, the conservativeness of the existing results on observer design for T-S systems with UPV and the maximal admissible Lipschitz constant allowing to solve the LMI constraints, and the robustness with respect to bounded modeling uncertainties and bounded additive perturbations. The first problem is dealt with by using a polyquadratic Lyapunov function and asymptotic stability conditions are provided. For the second problem, the polyquadratic Lyapunov function and ISS concept are combined. The obtained results are expressed in terms of LMIs and optimization problem with LMI constraints. For future work, it is interesting to extend the results for both state and unknown input estimation for possible application in fault diagnosis and fault tolerant control of nonlinear systems. An extension of some recent results will be considered for LMI conditions independent from derivative bounds of the weighting functions.
