Abstract

We are given a sequence of items that can be packed into m unit size bins and the goal is to assign these items online to m bins while minimizing the stretching factor. Bins have infinite capacities and the stretching factor is the size of the largest bin. We present an algorithm with stretching factor 26/17 improving the best known algorithm by Kellerer and Kotov [1] with a stretching factor 11/7. Our algorithms has 2 stages and uses bunch techniques: we aggregate bins into batches sharing a common purpose.

Keywords: Bin stretching, Multiprocessor scheduling, Online algorithms, Bin packing

1. Introduction

In bin packing problems, a set of items is to be packed into identical bins of size one, minimizing the number of bins. We are interested in the case were the items arrive online: on arrival, each item must be assigned immediately and irrevocably to a bin, without any knowledge of the future. Recent research has focused on studying scenarios where some information is known in advance. We consider a semi-online version of this problem where we know in advance that the items can be packed into m of bins of size 1. The objective is then to propose an algorithm which packs the items on arrival into m stretched bins, *i.e.* bins of size at most α, a stretching factor. Formally speaking, a bin-stretching algorithm is defined to have a stretching factor α if, for every sequence of items that can be assigned to m unit size bins, the algorithm successfully packs the items into m bins of size α. This problem was introduced by Azar and Regev [2]. They described a practical application of transferring files on a remote system.

This problem can be seen as a semi-online version of makespan minimization on parallel machines where we know that there is a feasible schedule with makespan $C_{\max}$ (especially, we can have $C_{\max} = C^*_{\max}$, the optimal makespan). The set of jobs has to be scheduled online on the machines with maximum completion time at most the stretched makespan $\alpha C_{\max}$. The objective is to minimize the stretching factor α.

For the online parallel machine scheduling problem, Graham [3, 4] gave the first deterministic online algorithm. He showed that the famous List scheduling algorithm is $(2 - 1/m)$-competitive. A long list of improved algorithms has since been published, the best one is due to Fleishner and Wahl [5].

For the semi-online case, the algorithm is provided with some information on the job sequence or has some extra ability to process it such as decreasing order [4, 6, 7], known total processing time [8, 9, 10, 11], or known number of necessary bins [2] as in our case.

Recently Kellerer and Kotov [1] developed an algorithm with stretching factor $\frac{11}{7}$. This value is smaller than the lower bound of 1.585 by Albers and Hellwig [11] for semi-online scheduling with known total processing time. It shows the difference between known total processing time version and bin-stretching problems. To our knowledge, 4/3 is the best known lower bound for the bin stretching problem. This bound is obtained with 2 bins, on input (1/3, 1/3, 1) or (1/3, 1/3, 2/3, 2/3).

In this paper we present an algorithm that uses bunch techniques and provides a stretching factor $\frac{26}{17}$.

1.1. Problem definition and notation

We are given a set of m identical unit size bins and a sequence of n items. Item j has a weight $w_j > 0$ and each item has to be assigned online to a bin. We define the weight of a bin B, denoted by $w(B)$, as the sum of the weights of all items assigned to B. In the course of the algorithm, we define some structures made up of one or several bins. For a given structure S, we denote by $w(S)$ the sum of the weights of all items packed into the bins composing S and $|S|$ is the number of bins in S.

The number m of bins is given as part of the initial input and it is certified that all items can fit into m bins. However, we have no more information in the initial input (the total number of items n is unknown until the end of the input).

We divide the items into 4 disjoint classes as in Table 1. Items with weight in $(0; \frac{9}{34}]$ are called *tiny*, items in $(\frac{9}{34}; \frac{9}{17}]$ are called *small*, items in $(\frac{9}{17}; \frac{13}{17}]$ are called *medium* and items in $(\frac{13}{17}; 1]$ are called *large*.

Table 1: Item classes

Item class	*tiny*	*small*	*medium*	*large*
Item weight	$(0; 9/34]$	$(9/34; 9/17]$	$(9/17; 13/17]$	$(13/17; 1]$

In the sequel, we design an algorithm with stretching factor $\frac{26}{17}$. Hence, each bin has a capacity $\frac{26}{17}$ and we say that an item j *fits* into a bin B if $w(B) + w_j \leq \frac{26}{17}$.

1.2. Algorithm overview

We design a multi-stage algorithm. In the first stage, we *open* the bins and create *bunches* which we use to fit the items. In the second stage, we fit the items into the remaining *non-reduced* bins and bunches.

In the algorithm, we use different kinds of bin structures and qualify them as *open*, *closed* or *reduced*. A structure is a group of one or several bins associated with a qualifier. We say that it is *open* if it can be used as such during current stage of the algorithm. It is *closed* if it cannot be used anymore as such during current stage (but can be reopened and converted to a new structure) and *reduced* if it will not be used anymore. Any reduced structure S has the property that the sum of the weights of its items is greater than its number of bins: $w(S) \geq |S|$ and for any bin $B \in S$, $w(B) \leq \frac{26}{17}$. Notice that if all bins have been reduced then there is no item remaining and current solution stretching factor is at most $\frac{26}{17}$.

We denote respectively by tB, sB, mB and lB single bins intended to contain mainly (but not only) *tiny*, *small*, *medium* and *large* items. $\mathcal{SB}$ and $\mathcal{LB}$ denote bunches intended to contain respectively *small* and *large* items. A bunch is made up of 4 bins. The aim of these structures is to help fitting items with more flexibility and then reduce them when structure's total weight is greater than or equal to 4. When a new bunch is created, we first assign a single bin to the bunch, then a second one, a third one and eventually the fourth bin. Once 4 bins have been assigned to a bunch, we say that the bunch is *complete*. Otherwise, the bunch is *incomplete* and is denoted by $\mathcal{SB}^i$ where $i \leq 3$ is the number of bins currently assigned to the bunch.

In the following sections, we describe the different stages of the algorithm and show that any incoming item is packed into a *non-reduced* bin where it fits. This proves Theorem 1.

Theorem 1. *The algorithm further described in this paper has a stretching factor of* 26/17.

This means that the algorithm never fails and all of the weights of the bins are smaller than $\frac{26}{17}$. In the following sections, we describe the algorithm as a set of priority rules and prove its correctness.

2. Stage 1

At the beginning of the first stage, all bins are empty. Along the first stage, we open bins and organize them into different structures.

Given an item, check its class, then assign it according priority rules given Table 2: check if the required structure for rule 1 exists and is feasible ; if so, pack the item according to rule 1, otherwise, continue with rule 2 and so on. Once an item is packed into some structure, the structure turns into a new one (possibly the same) detailed Table 2. If no rule is feasible, then stage 1 ends and the algorithm goes into stage 2.

For instance, if the current item is *small* and an *open sB* exists, then the item is packed into an *open sB*. If the weight of the bin becomes greater than 1, then reduce it. Otherwise the bin remains an *open sB* and further *small* item can still be packed in it. If no *open sB* exists but there is an empty bin, then pack the current item into an empty bin which becomes an *open sB*. If there is no empty bin, then the algorithm goes into stage 2.

If there is no item remaining, the current solution is feasible and has a stretching factor smaller than or equal to $\frac{26}{17}$. Remark that the empty bin is in every set of rules. Hence, by the end of stage 1, there is no empty bin remaining.

Table 2: Stage 1 priority rules

Item	Pack in	New structure
large	1. *open* $\mathcal{LB}$	*reduced* $\mathcal{LB}$ or *open* $\mathcal{LB}$
	2. *closed* $\mathcal{SB}$	*open* $\mathcal{LB}$
	3. *open* $\mathcal{SB}^1$	*reduced bin* or *open* lB
	4. *open* $\mathcal{SB}^i$	*reduced bin* and *open* $\mathcal{SB}^{i-1}$
	5. *empty*	*open* lB
medium	1. *open* mB	*reduced bin*
	2. *empty*	*open* mB
small	1. *open* sB	*reduced bin* or *open* sB
	2. *empty*	*open* sB
tiny	1. *open* lB	*reduced bin* or *open* lB
	2. *open* $\mathcal{SB}^3$	*open* $\mathcal{SB}^3$ or *closed* $\mathcal{SB}$
	3. *open* $\mathcal{SB}^i$	*open* $\mathcal{SB}^i$ or *open* $\mathcal{SB}^{i+1}$
	4. *empty*	*open* $\mathcal{SB}^1$

We now explain how items are packed into bunches. *Complete* bunches are made up of 4 bins added one after another. Remark that, according to priority rules, only *tiny* items can be assigned to an incomplete bunch. Let us consider an incomplete bunch $\mathcal{SB}^k$ and denote its bins B_i, $i \in \{1, 2, 3\}$ (B_i denotes the i^{th} bin assigned to the bunch). While this bunch is incomplete, it has been assigned at most 3 bins. A *tiny* item j assigned to $\mathcal{SB}^k$ is packed into B_i where i is the smallest feasible index such that $w(B_i) + w_j \leq \frac{9}{17}$. If none is feasible, a new bin is assigned to the bunch and j is assigned to this bin. As soon as B_3 contains two items (and any two *tiny* items fit into B_3 with total weight smaller than $\frac{9}{17}$), an additional empty bin is added to the bunch which is now *complete*. $\mathcal{SB}^3$ becomes a closed $\mathcal{SB}$. If there is no empty bin remaining, stage 2 is triggered.

Remark that for any $\mathcal{SB}$ bunch, each bin (except B_4) contains at least two items. Denote j and k, the two items in B_3, we have:

$$w(\mathcal{SB}) = (w(B_1) + w_j) + (w(B_2) + w_k) > \frac{18}{17}$$

Once a bunch is *complete*, sort its bins by decreasing order of the weights: $w(B_1) \geq w(B_2) \geq w(B_3) \geq w(B_4) = 0$. Then, the following property holds:

Property 1. *When a bunch is complete, we have:*

$$w(B_1) \geq w(B_2) \geq \frac{6}{17}$$

Proof. $w(B_1)+w(B_2)+w(B_3) > \frac{18}{17}$. Hence the largest weight of a bin is greater than the mean: $w(B_1) \geq \frac{6}{17}$. Both of the two remaining bins are containing at least 2 items. One precedes the other in the original ordering. W.l.o.g suppose that B_2 was before B_3. Both bins are containing at least two items. Let i and j be two items from B_3. If $w_i \geq \frac{3}{17}$ and $w_j \geq \frac{3}{17}$ then $w(B_3) \geq \frac{6}{17}$. Otherwise, $\min(w_i, w_j) < \frac{3}{17}$ and did not fit into B_2, hence $w(B_2) > \frac{9}{17} - \frac{3}{17} = \frac{6}{17}$. □

If a *complete* bunch is reopened (as an $\mathcal{LB}$) during stage 1, items are packed into the first feasible bin by increasing order of bins indices. Remark that in a *closed* $\mathcal{SB}$, the remaining capacity in each bin is larger than 1. Hence, we can fit one *large* item into each bin. Then $w(\mathcal{LB}) > \frac{18}{17} + 4 \times \frac{13}{17} > 4$ and the bunch can be reduced.

Now it remains to state the reduction rules. For any structure composed of a single bin, reduce it once its weight exceeds 1. $\mathcal{LB}$ structures are reduced once they contain 4 *large* items.

Using the priority rules, one can now easily verify the following properties:

Lemma 1. *Anytime during stage 1, the following properties hold:*

- (*i*) *all of the weights of the bins are smaller than or equal to* $\frac{26}{17}$
- (*ii*) *there is at most one open* mB
- (*iii*) *there is at most one open* sB
- (*iv*) *there is at most one open* $\mathcal{LB}$
- (*v*) *there is at most one incomplete bunch*
- (*vi*) *there is either no open* lB *or no bunch (even incomplete)*
- (*vii*) *(Except rules 2 and 3 for a tiny item) packing an item into the first existing structure is always feasible and results in one of the corresponding structures stated Table 2*

Note that the exception on property (*vii*) from Lemma 1 is related to the fact that rules 2 and 3 for a *tiny* item may require an additional empty bin. In such case, if there is no empty bin, the algorithme goes into stage 2.

Remark that Property (*i*) from Lemma 1 proves Theorem 1 if the input ends before the algorithm goes into stage 2.

3. Stage 2

In the second stage, there is no empty bin remaining (except B_4 bins from bunches). We use the remaining space in the open and closed bins and bunches to pack the items. Moreover, there is either no *open* lB or no bunch.We deal with both of these cases separately.

In the following, we rely on the following property:

Property 2. *Let* $\mathcal{S}_r$ *be the set of reduced bins,* $|\mathcal{S}_r| = r$*. The total weight of the items which are not packed into* $\mathcal{S}_r$ *is at most* $m - r$*.*

Proof. If a structure $\mathcal{S}$ is reduced then $w(\mathcal{S}) \geq |\mathcal{S}|$. We sum this up on all reduced structures and obtain: $w(\mathcal{S}_r) \geq r$. Let $\mathcal{I}$ be the set of all items and $\mathcal{I}_r$ the set of items packed into the reduced bins. $w(\mathcal{S}_r) = \sum_{i \in \mathcal{I}_r} w_i = w(\mathcal{I}_r)$. Since all items can be packed into m bins with capacity 1, $w(\mathcal{I}) \leq m$. Hence $w(\mathcal{I}) - w(\mathcal{I}_r) \leq m - r$. □

3.1. There is no non-reduced bunch

If there is no non-reduced bunch remaining, then there are no *open* $\mathcal{SB}^i$ or *closed* $\mathcal{SB}$ or *open* $\mathcal{LB}$ remaining. At the end of stage 1, we have some of the following structures:

Reduced bins	*Reduced* $\mathcal{LB}$	
Open lB	*Open* mB (0 or 1)	*Open* sB (0 or 1)

Stage 2 algorithm is straightforward: pack any coming item into the largest feasible *open* lB. If none is feasible, pack the item into the largest feasible bin. Reduce any bin whose weight exceeds 1.

Remark that any *small* or *tiny* item can be packed into any non-reduced bin. Hence, while some lB are remaining, *open* mB or *open* sB are only used to pack *medium* or *large* items.

Lemma 2. *The algorithm does not fail and no bin is filled to more than* $\frac{26}{17}$.

Proof. Suppose that a remaining item j cannot be packed in the remaining open bins. For all $i \in \{1, \dots, m\}$, the following inequalities hold:

$$w(B_i) > \frac{9}{17} \tag{1}$$

$$w_j + w(B_i) > \frac{26}{17} \tag{2}$$

Inequality (2), together with the fact that the weight of a non reduced bin is smaller than 1, give $w_j > \frac{9}{17}$. Therefore j is *medium* or *large*.

If there is 0 or 1 open bin remaining, then (2) contradicts Property 2. Hence, there are at least two open bins remaining.

Suppose there is no *open* lB remaining. Then, there are exactly two bins remaining (*open* mB and *open* sB). We sum up inequalities (1) and (2) and get: $w(B_1) + w(B_2) + w_j > 35/17 > 2$ which contradicts Property 2. Therefore, there are some *open* lB's remaining.

Remark 1. During stage 1, tiny items can only be packed within lB bins or $\mathcal{SB}$ bunches. Since there were no bunches remaining at the beginning of stage 2, all bunches have been reduced to *reduced* $\mathcal{LB}$. Moreover, there are some *open* lB's remaining. Hence, during stage 2, all tiny items were packed into lB bins. Therefore, *tiny* items have been packed only into bins containing *large* items.

In any feasible solution to the bin packing problem, any bin containing a *large* item can only hold a few additional *tiny* items. Let p be the total number of large items and l the number of *large* items already packed. Since the problem is feasible, we can pack all *medium* and *small* items and any $p - l$ *large* items into $m - l$ bins (one bin for each large item and the medium and small items fit into the other bins).

Denote $B^1, \dots, B^l$, the bins containing *large* items in the current solution. Because of remark 1, we know that $B^{l+1}, \dots, B^m$ contain no tiny item. Hence we can pack j and all items from $B^{l+1}, \dots, B^m$ into $m - l$ bins. All bins which are not containing *large* items have been reduced (and hence their weight is greater than 1), except maybe an *open* mB and an *open* sB. From the fact that at least $m - l - 2$ bins are reduced, together with inequalities (1) and (2), we obtain:

$$w_j + \sum_{i=l+1}^{m} w(B_i) \geq m - l - 2 + \frac{9}{17} + \frac{26}{17} > m - l$$

Which contradictss Property 2. Therefore, there is no such item j. □

We have proved in this case that the algorithm never fails and always returns a solution using at most m bins, filled to at most $\frac{26}{17}$. It remains to show that Lemma 2 still holds.

Remark that if we define the classes: $(0; \frac{\alpha}{2}]$ (*tiny*), $(\frac{\alpha}{2}; \alpha]$ (*small*), $(\alpha; \frac{1+\alpha}{2}]$ (*medium*) and $(\frac{1+\alpha}{2}; 1]$ (*large*), then all of the previous results hold for any $\alpha > 0.5$.

3.2. There are some non-reduced bunches

If there are some non-reduced bunches remaining, then there is no *open* lB remaining by the end of stage 1. Stage 2 starts with some of the following structures:

Reduced bins	*Reduced* $\mathcal{LB}$	
Open mB (0 or 1)	*Open* sB (0 or 1)	
Open $\mathcal{SB}^i$ (0 or 1)	*Open* $\mathcal{LB}$ (0 or 1)	*Closed* $\mathcal{SB}$

During stage 2, closed bunches are reopened and used to pack some of the remaining items. In the meantime, some *buffer* bins are used to pack the other items. Using these buffers, help us ensure that only the largest items are packed into bunches.

Current *buffer* is called $\mathcal{X}$. Along with this buffer, we use up to 3 other single bins: $\mathcal{Z}_1$, $\mathcal{Z}_2$ and $\mathcal{Z}_3$. If there is an *Open* $\mathcal{SB}^i$ at the beginning of stage 2 we assign its bins to $\mathcal{Z}_1$ and possibly $\mathcal{Z}_2$ and $\mathcal{Z}_3$, by decreasing order of their weights. Whenever we have no $\mathcal{X}$ (stage 2 is beginning or $\mathcal{X}$ is reduced), the first existing structure among the following becomes $\mathcal{X}$:

$$\textit{open } sB,\ \textit{open } mB,\ \mathcal{Z}_3,\ \mathcal{Z}_2,\ \mathcal{Z}_1,\ \textit{closed } \mathcal{SB}$$

In all but the last case, we get $\mathcal{X}$ by renaming a bin. In the last case, we denote by B_1, B_2, B_3, B_4 the bins from the bunch, $w(B_1) \geq w(B_2) \geq w(B_3) \geq w(B_4)$. We assign: $\mathcal{X} \leftarrow B_4$, $\mathcal{Z}_1 \leftarrow B_1$, $\mathcal{Z}_2 \leftarrow B_2$ and $\mathcal{Z}_3 \leftarrow B_3$.

If we cannot get a new $\mathcal{X}$, then only a few bins are remaining. Stage 2 is terminated and the algorithm goes into a last stage, detailed in Section 3.2.2.

During stage 2, an additional kind of bunch, denoted by $\mathcal{MB}$ is used. These bunches are mostly intended to pack *medium* items.

The process is then very similar to stage 1: items are packed into bins according to priority rules and bins are reduced. Priority rules are given Table 3. There is however a slight difference with Table 2: it should be read as "Pack item j into structure $\mathcal{S}$ if $\mathcal{S}$ exists and packing item j into $\mathcal{S}$ is feasible and results in the new structure indicated Table 3". This difference only concerns rule (1) for *large* items. Indeed: $\mathcal{Z}_1$ was part of a (possibly incomplete) bunch. Therefore, at the end of stage 1, its weight was smaller than 9/17 and any item can be packed into $\mathcal{Z}_1$. However, we only pack an item into $\mathcal{Z}_1$ if we can reduce it afterwards. If $\mathcal{Z}_1$ is reduced, then $\mathcal{Z}_1 \leftarrow \mathcal{Z}_2$ and $\mathcal{Z}_2 \leftarrow \mathcal{Z}_3$ (if exists).

Table 3: Stage 2 priority rules

Item	Pack in	New structure
large	1. $\mathcal{Z}_1$	*reduced bin*
	2. *open* $\mathcal{LB}$	*reduced* $\mathcal{LB}$ or *open* $\mathcal{LB}$
	3. *closed* $\mathcal{SB}$	*open* $\mathcal{LB}$
	4. $\mathcal{X}$	*reduced bin* or $\mathcal{X}$
medium	1. *open* mB	*reduced bin*
	2. $\mathcal{X}$	*reduced bin* or $\mathcal{X}$
	3. *open* $\mathcal{MB}$	*reduced* $\mathcal{MB}$ or *open* $\mathcal{MB}$
	4. *closed* $\mathcal{SB}$	*open* $\mathcal{MB}$
small, *tiny*	1. $\mathcal{X}$	*reduced bin* or $\mathcal{X}$
	2. *open* $\mathcal{MB}$	*reduced* $\mathcal{MB}$ or *open* $\mathcal{MB}$

When an item is assigned to a single bin structure, if the weight of the bin becomes greater than 1, then the bin is reduced.

When an item is assigned to an *open* $\mathcal{LB}$, we try to pack it into B_3, then B_2, B_1 and eventually B_4. Once B_4 contains an item, we reduce the bunch. As seen in stage 1, structure's weight is indeed greater than 4. When a *medium* item is assigned to a *closed* $\mathcal{SB}$, it is packed into B_3. When an item is assigned to an *open* $\mathcal{MB}$ we try to pack it into B_3, then B_2 and eventually B_4. Since B_4 was empty at the end of stage 1, we can pack any two *medium* items into B_4. When B_4 contains 2 items, we reduce B_2, B_3, B_4 and $\mathcal{X}$ and $\mathcal{X} \leftarrow B_1$. The following property shows that these bins can indeed be reduced:

Property 3. *Once B_4 from an open $\mathcal{MB}$ contains two items, $w(\mathcal{X}) + w(B_2) + w(B_3) + w(B_4) > 4$.*

Proof. During stage 2, at least one item j which did not fit into B_3 has been packed into B_2. Hence, by

Property 1:

$$\begin{aligned} w(B_3) + w(B_2) &= (w(B_3) + w_j) + (w(B_2) - w_j) \\ &> 26/17 + 6/17 = 32/17 \end{aligned}$$

Therefore, $\max(w(B_3), w(B_2)) > 16/17$. Moreover, B_4 is containing two items k and l (with l the last item packed). Neither k, nor l fit into B_3 or B_2 and l does not fit into $\mathcal{X}$. Hence:

$$\begin{aligned} w(\mathcal{X}) + \min(w(B_3), w(B_2)) + w(B_4) \\ \geq (w(\mathcal{X}) + w_l) + (\min(w(B_3), w(B_2)) + w_k) \\ > 26/17 + 26/17 = 52/17 \end{aligned}$$

Eventually, summing this up with $\max(w(B_3), w(B_2))$ gives:

$$w(\mathcal{X}) + w(B_2) + w(B_3) + w(B_4) > 4$$

□

Remark that Property 3 does not assume anything on the classes of the items packed into $\mathcal{X}$, B_2 and B_3.

3.2.1. Termination stage

Stage 2 is completed, either when the input is over or no packing rule is feasible (or we cannot get a new $\mathcal{X}$ – in such case, refer to subsection 3.2.2). In the following, we consider the different cases and show that we can always fit remaining items into non-reduced bins with a 26/17 stretching factor.

If the algorithm finishes before an item cannnot be packed according to priority rules, then all items have been packed and none of the bins capacities exceeds 26/17. If all bins have been reduced, then the sum of all the weights of the bins is greater than m and hence all items have been packed.
Otherwise, no rule can be applied to pack the current item. Table 4 sums up the possibly remaining structures depending on the current item. Remark that for a *large* item, if Z_2 exists, then $w(Z_1) > \frac{9}{34} > \frac{4}{17}$ and since $w(Z_1) \leq \frac{9}{17}$, we can apply rule 1 for a *large* item. Hence if current item is *large* and no rule can be applied, then there is no $\mathcal{Z}_2$ remaining. The reader can easily verify remaining configurations for the other classes of items.

Table 4 does not take *open* mB into account. We deal with this case as follows: if an *open* mB is remaining, then no *medium* item came during stage 2. Hence, there is no $\mathcal{MB}$ bunch. Moreover, the current item j is *large* since any *tiny* or *small* item would fit into $\mathcal{X}$ and any *medium* into *open* mB. Hence, there is no $\mathcal{Z}_2$. The remaining bins are $\mathcal{X}$, *open* mB and possibly $\mathcal{Z}_1$. The remaining items are packed according to subsection 3.2.4.

Table 4: Remaining structures depending on the current item

Current item	Remaining bins
large	*open* $\mathcal{MB}$, $\mathcal{X}$, $\mathcal{Z}_1$
medium	*open* $\mathcal{LB}$, $\mathcal{X}$, $\mathcal{Z}_1$, $\mathcal{Z}_2$, $\mathcal{Z}_3$
small	*open* $\mathcal{LB}$
tiny	*open* $\mathcal{LB}$

If a bunch is remaining, we denote its bins by B_1, B_2, B_3 and B_4. Depending on the current configuration, we reduce some of the remaining bins as follows:

1. If we have an *open* $\mathcal{LB}$ containing 3 *large* items and no $\mathcal{Z}_3$. We reduce B_1, B_2 and B_3. It is indeed feasible because the bunch contains 3 *large* items and was a *closed* $\mathcal{SB}$ bunch before being reopened, hence its weight was greater than 18/17. Therefore:

$$w(B_1) + w(B_2) + w(B_3) \geq 18/17 + 3 \times 13/17 = 57/17 > 3$$

Then, we have at most 4 bins remaining: $B_4, \mathcal{X}, \mathcal{Z}_1$ and $\mathcal{Z}_2$.

2. If we have an *open* $\mathcal{LB}$ containing 3 *large* items and $\mathcal{Z}_3$. Pack all coming items into $\mathcal{X}$ until it is reduced and then reduce B_1, B_2 and B_3 as previously. Otherwise, current item j does not fit into $\mathcal{X}$. Since $\mathcal{Z}_3$ exists, we can use Property 1 for $\mathcal{Z}_1$:

$$w_j + w(\mathcal{X}) + w(\mathcal{Z}_1) + (w(B_1) + w(B_2) + w(B_3)) > \\ 26/17 + 6/17 + 57/17 > 5$$

   Pack j into $\mathcal{Z}_1$ and reduce $\mathcal{X}$, $\mathcal{Z}_1$, B_1, B_2 and B_3. Then, $\mathcal{Z}_1 \leftarrow \mathcal{Z}_2$, $\mathcal{Z}_2 \leftarrow \mathcal{Z}_3$ and we have exactly 3 bins remaining: $\mathcal{Z}_1$, $\mathcal{Z}_2$ and B_4.
3. If we have an *open* $\mathcal{MB}$ remaining, then current item j, is *large*. If j fits into B_2 then pack j into B_2 and resume with priority rules. Property 3 still holds. Otherwise, B_2 contains an item which does not fit into B_3. Hence, $w(B_2) + w(B_3) > \frac{26}{17} + \frac{6}{17} = \frac{32}{17}$. Pack j into B_1, then $w(B_1) + w(B_2) + w(B_3) > \frac{6}{17} + \frac{13}{17} + \frac{32}{17} = 3$. Reduce B_1, B_2 and B_3. There are at most 3 remaining bins: B_4, $\mathcal{X}$ and $\mathcal{Z}_1$.
4. If we have an *open* $\mathcal{LB}$ containing 1 or 2 *large* items remaining, we consider this bunch as an *open* $\mathcal{MB}$ and keep on applying priority rules and eventually previous point (3).
5. Otherwise, we have no bunch. There are at most 4 bins remaining: $\mathcal{X}, \mathcal{Z}_1, \mathcal{Z}_2$ and $\mathcal{Z}_3$.

After these reductions, we have at most 4 bins remaining. Let b be the number of remaining bins. In each cases, we explain how to use the remaining bins and then consider j, an item which does not fit into any of the remaining bins. We show that w_j plus the sum of the weights of the remaining bins is strictly greater than b which contradicts Property 2.

The cases with 0 or 1 bin remaining are trivial so we only deal with the other cases.

3.2.2. We cannot get a new $\mathcal{X}$

If we cannot get a new $\mathcal{X}$, then remaining bins are possibly an *open* $\mathcal{MB}$ and an *open* $\mathcal{LB}$. We keep on applying prority rules. However, when an item is packed into *open* $\mathcal{MB}$, we try to pack it into B_3, then B_2, then B_1 and eventually B_4. Hence, if the *open* $\mathcal{MB}$ is reduced, its 4 bins are reduced.

Once there is a single structure remaining, if it is the *open* $\mathcal{LB}$, then we reduce the bins and finish as presented subsection 3.2.1.

Otherwise there is an *open* $\mathcal{MB}$ remaining. Keep on applying priority rules and suppose some item j cannot be packed.

The item j cannot be packed. Hence B_1 and B_4 both contain an item which fits into neither B_2, nor B_3. Denote those items k and l. By Property 1: $w(B_1) - w_k \geq \frac{6}{17}$. Moreover, Property 3 holds. Therefore, B_4 contains a single item. Therefore, either l or j (or both) is *large*. Without loss of generality, suppose j is *large*, then:

$$\begin{aligned} w(B_1) + w(B_2) + w(B_3) + w(B_4) + w_j & \\ &\geq (w(B_1) - w_k) + (w(B_2) + w_k) + (w(B_3) + w_l) + w_j \\ &> 6/17 + 26/17 + 26/17 + 13/17 \\ &> 4 \end{aligned}$$

Which is a contradiction.

3.2.3. 4 bins remaining

If there are 4 remaining bins, the possibly remaining bins are detailed Table 5. We rename those bins L_1, L_2, L_3 and L_4. Remark that $w(L_2), w(L_3), w(L_4) \leq \frac{9}{17}$ at the beginning of this step. Hence we can fit at least one item in any of those three bins.

Pack any fitting item into L_1, otherwise L_2, then L_3 and eventually into L_4. Suppose j is an item which does not fit into any of the remaining bins. Denote k_i the last item packed into L_i and remark that, for $i = 2, 3, 4$, k_i does not fit into L_f for all $f < i$.

Table 5: Renaming scheme

New names	L_1	L_2	L_3	L_4
Old names	$\mathcal{X}$	B_4	$\mathcal{Z}_2$	$\mathcal{Z}_1$
	$\mathcal{X}$	$\mathcal{Z}_3$	$\mathcal{Z}_2$	$\mathcal{Z}_1$

If the weight of a bin is greater than 1, then:

$$\begin{aligned} w(L_1)+&w(L_2) + w(L_3) + w(L_4) + w_j \\ &>1 + 26/17 + 26/17 \\ &>4 \end{aligned}$$

Otherwise, all of the weights of the bins are smaller than one. Hence $w_j > \frac{9}{17}$. Moreover, at the beginning of this step, $w(L_3) + w(L_4) > \frac{9}{17}$.

$$\begin{aligned} w(L_1)+&w(L_2) + w(L_3) + w(L_4) + w_j \\ &\geq (w(L_1) + w_{k_3}) + (w(L_2) + w_{k_4}) + \\ &\quad (w(L_3) + w(L_4) - w_{k_3} - w_{k_4}) + w_j \\ &>26/17 + 26/17 + 9/17 + 9/17 \\ &>4 \end{aligned}$$

Which is a contradiction.

3.2.4. 3 bins remaining

Remark that if there are 3 bins remaining, $\mathcal{Z}_1$ is among them and $w(\mathcal{Z}_1) \leq \frac{9}{17}$. Rename it L_3 and the other bins are renamed L_1 and L_2. Pack any fitting item into L_1, otherwise L_2 and eventually L_3. Suppose that the item j does not fit into any of them and let k be the last item packed into L_3. There is at least one such item since $w(\mathcal{Z}_1) \leq \frac{9}{17}$ in the beginning.

$$\begin{aligned} w(L_1)+&w(L_2) + w(L_3) + w_j \\ &\geq (w(L_1) + w_j) + (w(L_2) + w_k) \\ &>26/17 + 26/17 \\ &>3 \end{aligned}$$

Which is a contradiction.

3.2.5. 2 bins remaining

In this case, denote one bin by L_1 and the other bin by L_2. Pack any fitting item into L_1, otherwise into L_2. If j does not fit into L_2, then $w(L_2) > \frac{9}{17}$.

$$w_j + w(L_1) + w(L_2) > 26/17 + 9/17 > 2$$

Which is a contradiction.

4. Complexity

We represent a bin and its content using a stack plus its current weight and use a dedicated data structure (a stack) for each kind of structure used in the algorithm. The overall space used is $O(m)$.

In order to pack any given item during stage 1, we need to check its class and try to pack it in at most 5 different structures with at most 3 bins tested for each one. Hence, any item is packed in $O(1)$ time. Therefore the overall complexity of the first stage is bounded by $O(n)$.

During stage 2, we need to sort the structures. Each structure has at most 4 bins. Hence, a structure is sorted in $O(1)$ time and we have at most $\frac{m}{4}$ structures to sort. Therefore, we sort all of them in $O(m)$ time. In order to pack any item, we need to check its class and try at most 4 different structures. Hence, any item is packed in $O(1)$ time and the overall complexity of this stage is bounded by $O(n)$.

Same goes for the termination stage. Moreover, additionnal operation, like renumbering the bins, are performed but there is a fixed number of different additionnal operations and all of them are performed in constant time.

Eventually, when $m \geq n$, at most n bins are used. Hence, the overall time and space complexity of the algorithm is $O(n)$.

5. Summary and future work

The presented algorithm has a stretching factor of $\frac{26}{17}$ and runs in linear time. Remark that this bound is tight with the input $m = 2$ and the items: $\{\frac{13}{17}, \frac{13}{17}\}$.

The techniques of combining bins into bunches with certain properties and analyzing the bunches has been successfully applied to other online and offline packing problems, see e.g. [12, 13].

It seems reasonable to hope that better worst-case behavior can be achieved by refining this approach. Based on this scheme, it might be possible to reduce the gap between lower and upper bound for both known total sum and bin-stretching problems. Improving lower bounds is also a challenging task.
