Existence result for the coupling problem of two scalar conservation laws with Riemann initial data

Benjamin Boutin Christophe Chalons
Pierre-Arnaud Raviart

January 6, 2010

Abstract

This paper is devoted to the coupling problem of two scalar conservation laws through a fixed interface located for instance at $x=0$. Each scalar conservation law is associated with its own (smooth) flux function and is posed on a half-space, namely $x < 0$ or $x > 0$. At interface $x = 0$ we impose a coupling condition whose objective is to enforce in a weak sense the continuity of a prescribed variable, which may differ from the conservative unknown (and the flux functions as well). We prove existence of a solution to the coupled Riemann problem using a constructive approach. The latter allows in particular to highlight interesting features like non uniqueness of both continuous and discontinuous (at interface $x = 0$) solutions. The behavior of some numerical scheme is also investigated.

Introduction

The coupling of partial differential equations is of increasing interest in the applied mathematics community, and of course of increasing importance for industrial applications. Such a coupling arises for instance in the simulation of nuclear reactors when different two-phase flow codes are used¹. In these codes, multiple modelling scales are applied to describe the flow. For instance, different thermal-hydraulic models can be used for each reactor component to take into account its specific behavior, or small scale models can be used, locally, to obtain a better resolution. When these models are put side to side, we face the problem of coupling. In addition to the definition of each model, such a problematic requires to be supplemented with an interfacial model in order to precise the nature of the information that must be exchanged at the coupling interface. This interfacial model may be formulated for instance when imposing the continuity of a given set of variables. It generally strongly affects the whole solution and must therefore be defined in order to achieve a physically coherent description of the whole operating device under consideration.

¹The authors of the present paper are involved in a joint research program on multiphase flows between CEA (French center for nuclear research) and University Pierre et Marie Curie-Paris6 (Laboratoire Jacques-Louis Lions) in the frame of the Neptune project [20]. See for instance [3, 4, 5, 6, 2, 11] and the references therein

Let us mention that similar situations appear in the modelling of networks and traffic flows which have received a certain interest in the last few years. We refer for instance the reader to [12, 8, 9], [16, 17, 21], and the references therein.

In this paper, we are interested in the one dimensional coupling problem of two scalar conservation laws through a fixed interface, say $x = 0$, and more precisely in the resolution of the coupled Riemann problem. Each scalar conservation law is associated with its own (smooth) flux function f_α , $\alpha = L, R$ and is posed on a half-space, namely $x < 0$ ($\alpha = L$) or $x > 0$ ($\alpha = R$). Note from now on that it will be implicitly assumed throughout the paper that the flux functions have at most a finite number of changes of convexity, which is often (is not always) the case for practical applications. At the coupling interface, we assume without further details that it is physically relevant to impose the continuity of a given function $v_\alpha = v_\alpha(u)$ of the solution u , meaning that u is expected to satisfy

$$v_\alpha(u(0_-, t)) = v_\alpha(u(0_+, t)), \quad t > 0. \quad (1)$$

Note that the v -variable generally depends on α .

This approach is fairly general and referred to as the *state coupling method*. The theoretical study of such coupling conditions was initiated in the pioneering papers [19, 18] in the case of scalar equations, linear systems, and the usual Lagrangian system as well. In particular, the continuity constraint (1) has been reformulated in a weak sense inspired by [13] for the sake of well-posedness. This results in considering two boundary value problems and imposing "as far as possible" the continuity of the v -variable at the interface. We also refer the reader to [5, 11] and the references therein. It is important to notice that this approach does not ensure the conservativity property of the coupling problem. It does therefore significantly differ from the *flux coupling method* where the continuity of the flux is imposed at the interface ($v_\alpha(u) = f_\alpha(u)$). See for instance [23, 24, 7] and [22].

This paper gives the first result of global existence of a solution to the coupled Riemann problem in this context of state coupling, using a constructive approach. Except the smoothness hypothesis, no specific assumption is made on the flux functions f_α , $\alpha = L, R$. It is worth noticing right now that the solution of the coupled Riemann problem can be either continuous or discontinuous in the v -variable at the coupling interface. In the first situation, the coupling condition (1) is satisfied in the classical sense, while in the other one, it is satisfied in a weak sense only (to be precised hereafter). In addition, the solution to the Riemann problem is shown to be not necessarily unique, since in particular, a 1-parameter family of continuous solutions at the coupling interface may exist for the same Riemann initial data. In this context, it is an open problem to know whether or not there exists any natural criterion based for instance on entropy or stability arguments for choosing one particular solution. Then, our approach is different from the ones adopted for instance in [1] or [15] where the authors give and study different concepts of physically admissible entropy weak solutions. So as to get for instance existence and uniqueness of the corresponding Riemann weak solutions.

The outline of the paper is as follows. In Section 1, we introduce the general framework of the state coupling method. Section 2 is devoted to the main result of this paper, namely the existence of a solution to the coupled Riemann problem. First of all, a geometrical description of the sets of admissible traces at the

interface is given. Then, a characterisation is given for the solutions satisfying the coupling condition either in the strong sense (the so-called v -continuous solutions) or in the weak sense (the so-called v -discontinuous solutions). At last, we deduce the existence of at least one self-similar solution to any coupled Riemann problem. Several situations of non-uniqueness are exhibited, and a first case of coupling of scalar conservation laws "with phase change" is treated theoretically. Section 3 is devoted to numerical simulations, using both a relaxation and a Godunov scheme as a building block for the derivation of the numerical strategy.

1 The state coupling method

Let $f_\alpha : \mathbb{R} \rightarrow \mathbb{R}$, $\alpha = L, R$, be two C^1 functions; given a function $u_0 : \mathbb{R} \rightarrow \mathbb{R}$, we want to find a function $u : (x, t) \rightarrow u(x, t) \in \mathbb{R}$ solution of

$$\frac{\partial u}{\partial t} + \frac{\partial}{\partial x} f_L(u) = 0, \quad x < 0, \quad t > 0 \quad (2)$$

$$\frac{\partial u}{\partial t} + \frac{\partial}{\partial x} f_R(u) = 0, \quad x > 0, \quad t > 0 \quad (3)$$

and satisfying the initial condition

$$u(x, 0) = u_0(x), \quad x \in \mathbb{R} \quad (4)$$

together with coupling constraints at $x = 0$ that we now define. Let $\theta_\alpha : \mathbb{R} \rightarrow \mathbb{R}$, $\alpha = L, R$, be two *strictly monotone* C^1 functions; we require the function u to satisfy "as far as possible" the continuity constraint

$$\theta_L^{-1}(u(0_-, t)) = \theta_R^{-1}(u(0_+, t)), \quad t > 0. \quad (5)$$

Setting

$$v(x, t) = \begin{cases} \theta_L^{-1}(u(x, t)), & x < 0 \\ \theta_R^{-1}(u(x, t)), & x > 0, \end{cases} \quad (6)$$

this constraint must be understood in the weak sense, following [13], [19] and [18]

$$\begin{cases} v(0_-, t) \in \tilde{\mathcal{O}}_L(v(0_+, t)) \\ v(0_+, t) \in \tilde{\mathcal{O}}_R(v(0_-, t)). \end{cases} \quad (7)$$

Let us recall the definition of the sets $\tilde{\mathcal{O}}_L(v_d)$ and $\tilde{\mathcal{O}}_R(v_g)$. Denoting by $w_\alpha(\frac{x}{t}; u_g, u_d)$ the self-similar solution of the Riemann problem

$$\frac{\partial u}{\partial t} + \frac{\partial}{\partial x} f_\alpha(u) = 0, \quad x \in \mathbb{R}, \quad t > 0$$

$$u(x, 0) = \begin{cases} u_g, & x < 0 \\ u_d, & x > 0 \end{cases}$$

and setting

$$z_\alpha(\frac{x}{t}; v_g, v_d) = \theta_\alpha^{-1}(w_\alpha(\frac{x}{t}; \theta_\alpha(v_g), \theta_\alpha(v_d)))$$

we have

$$\begin{cases} \tilde{\mathcal{O}}_L(v_d) = \{z_L(0_-; v, v_d); v \in \mathbb{R}\} \\ \tilde{\mathcal{O}}_R(v_g) = \{z_R(0_+; v_g, v); v \in \mathbb{R}\}. \end{cases}$$

2 Solving the coupled Riemann problem.

We consider the coupled Riemann problem which corresponds to the initial condition

$$u_0(x) = \begin{cases} u_g, & x < 0 \\ u_d, & x > 0. \end{cases} \quad (8)$$

We set

$$v_g = \theta_L^{-1}(u_g), \quad v_d = \theta_R^{-1}(u_d).$$

When the flux functions f_α , $\alpha = L, R$ are *strictly convex*, we are able to exhibit all the solutions of this coupled Riemann problem (2)-(4),(7),(8). This is indeed the goal of this section. Recall that in the general case, we always assume for simplicity that the flux functions have at most a finite number of changes of convexity.

2.1 Preliminaries.

Let us first recall and derive some preliminary results. Given a function $f \in C^1(\mathbb{R})$, we consider the scalar equation

$$\frac{\partial u}{\partial t} + \frac{\partial}{\partial x} f(u) = 0. \quad (9)$$

We denote by $w(\frac{x}{t}; u_g, u_d)$ the solution of the Riemann problem for (9) corresponding to the initial condition (8). In the case of a general flux function f , $w(\frac{x}{t}; u_g, u_d)$ consists of a *composite wave* composed of shock and rarefaction subwaves. It is constructed in the following way.

(i) For $u_d > u_g$, we introduce the lower convex envelope function f_c of f in the interval $[u_g, u_d]$. This interval is divided into rarefaction subintervals where the function f is strictly convex (so that $f_c = f$) separated by shock subintervals where the function f_c is affine (and the graph of f is located above the corresponding chord). Then $w(\frac{x}{t}; u_g, u_d)$ is made of a sequence of rarefaction waves in the rarefaction subintervals and shock waves in the shock subintervals. These waves are bordered on the left by the constant state u_g and on the right by the constant state u_d . These constant states are the only constant states which appear in the solution of the Riemann problem.

(ii) For $u_d < u_g$, we introduce the upper concave envelope function f^c of f in the interval $[u_d, u_g]$. Again this interval is divided into rarefaction subintervals where the function f is strictly concave (so that $f = f^c$) separated by shock intervals where f^c is affine (and the graph of f is located under the corresponding chord). Then, the solution of the Riemann problem then has the same structure as in the case (i).

We shall say that such a composite wave has a nonnegative (resp. nonpositive) speed if all of its subwaves (shocks or rarefactions) have nonnegative (resp. nonpositive) speeds. In order to characterize the composite waves $w(\cdot; u_g, u_d)$ whose speeds are nonnegative or nonpositive, we determine the minimal and

maximal speeds σ_{min} and σ_{max} of such a composite wave. Denote by $I(u_g, u_d)$ the closed interval whose end points are u_g and u_d . Then, we can state

Lemma 1 *We have*

$$\sigma_{min} = \min_{u \in I(u_g, u_d)} \frac{f(u) - f(u_g)}{u - u_g} \quad (10)$$

and

$$\sigma_{max} = \max_{u \in I(u_g, u_d)} \frac{f(u) - f(u_d)}{u - u_d} \quad (11)$$

with the following convention

$$\frac{f(u) - f(u_a)}{u - u_a} = f'(u_a) \text{ for } u = u_a, a = g, d. \quad (12)$$

Proof. Let us check (10) for instance. We begin by observing that σ_{min} is the speed of the left boundary of the fan of the composite wave $w(\cdot; u_g, u_d)$. Assume first $u_d > u_g$. If the left subwave of $w(\cdot; u_g, u_d)$ is a shock that connects u_g and a state u_1 , its speed is

$$\sigma_{min} = \frac{f(u_1) - f(u_g)}{u_1 - u_g}.$$

On the other hand, it is clear geometrically (cf. Fig. 1a) that we have for all $u \in (u_g, u_d]$

$$\frac{f(u) - f(u_g)}{u - u_g} > \frac{f(u_1) - f(u_g)}{u_1 - u_g}.$$

Hence, using the convention (12), we obtain

$$\sigma_{min} = \min_{u \in [u_g, u_d]} \frac{f(u) - f(u_g)}{u - u_g}. \quad (13)$$

If this left subwave is a rarefaction, σ_{min} is the speed of the left side of the rarefaction fan which is given by

$$\sigma_{min} = f'(u_g)$$

Again, it is obvious geometrically (cf. Fig. 1b) that we have for all $u \in (u_g, u_d]$

$$f'(u_g) < \frac{f(u) - f(u_g)}{u - u_g}.$$

Therefore (13) still holds.

Consider next the case where $u_g > u_d$. Using Fig. 2 and a fairly similar analysis, one can check that

$$\sigma_{min} = \min_{u \in [u_d, u_g]} \frac{f(u) - f(u_g)}{u - u_g}.$$

This proves (10). The property (11) is established exactly in the same way. \square

As a consequence of Lemma 1, we obtain that a (composite) wave $w(\cdot; u_g, u_d)$ has a nonnegative speed if and only if

$$\min_{u \in I(u_g, u_d)} \frac{f(u) - f(u_g)}{u - u_g} \geq 0$$

Figure 1: $u_g < u_d$ and the left subwave is a shock (a) or a rarefaction (b)

Figure 2: $u_g > u_d$ and the left subwave is a shock (a) or a rarefaction (b)

and a nonpositive speed if and only if

$$\max_{u \in I(u_g, u_d)} \frac{f(u) - f(u_d)}{u - u_d} \leq 0.$$

In other words, we get

$$\begin{cases} w(0_-; u_g, u_d) = u_g \iff \min_{u \in I(u_g, u_d)} \frac{f(u) - f(u_g)}{u - u_g} \geq 0, \\ w(0_+; u_g, u_d) = u_d \iff \max_{u \in I(u_g, u_d)} \frac{f(u) - f(u_d)}{u - u_d} \leq 0. \end{cases} \quad (14)$$

Now, given a state u_0 , we look for the set $\mathcal{E}^+(u_0)$ (resp. $\mathcal{E}^-(u_0)$) of all states $u \neq u_0$ which can be connected to u_0 *on the left* (resp. *on the right*) by a nontrivial (composite) wave $w(\cdot; u, u_0)$ (resp. $w(\cdot; u_0, u)$) whose speed is nonnegative (resp. nonpositive). The above results yield

Lemma 2 *We have*

$$\mathcal{E}^+(u_0) = \left\{ u \neq u_0; \min_{v \in I(u_0, u)} \frac{f(v) - f(u)}{v - u} \geq 0 \right\} \quad (15)$$

and

$$\mathcal{E}^-(u_0) = \left\{ u \neq u_0; \max_{v \in I(u_0, u)} \frac{f(v) - f(u)}{v - u} \leq 0 \right\}. \quad (16)$$

It remains to give a geometric characterization of the conditions (15) and (16). This is easily done when the flux function f is either *monotone* or *strictly convex*.

Example 2.1. the case of a monotone flux function. If the function f is strictly increasing so that

$$\frac{f(v) - f(u)}{v - u} > 0 \text{ for all } v \neq u,$$

we obtain

$$\mathcal{E}^+(u_0) = \mathbb{R} \setminus \{u_0\}, \quad \mathcal{E}^-(u_0) = \emptyset$$

while if the function f is strictly decreasing, we find

$$\mathcal{E}^+(u_0) = \emptyset, \quad \mathcal{E}^-(u_0) = \mathbb{R} \setminus \{u_0\}. \quad \square$$

Example 2.2. the case of a strictly convex flux function. When the function f is strictly convex, we denote by \bar{u} the *sonic state* of f characterized by $f'(\bar{u}) = 0$ with the convention that $\bar{u} = -\infty$ (resp. $\bar{u} = +\infty$) if the function f is strictly increasing (resp. strictly decreasing). With the state u_0 , we associate the state \tilde{u}_0 defined by

$$\begin{cases} f(\tilde{u}_0) = f(u_0), \tilde{u}_0 \neq u_0 & \text{if } \bar{u} \text{ exists,} \\ \tilde{u}_0 = \bar{u} = -\infty & \text{if } f \text{ is strictly increasing,} \\ \tilde{u}_0 = \bar{u} = +\infty & \text{if } f \text{ is strictly decreasing.} \end{cases} \quad (17)$$

Lemma 3 *Assume that the function f is strictly convex. Then*

$$\mathcal{E}^+(u_0) = \{u \neq u_0; u \geq \max(\bar{u}, \tilde{u}_0)\} \quad (18)$$

and

$$\mathcal{E}^-(u_0) = \{u \neq u_0; u \leq \min(\bar{u}, \tilde{u}_0)\}. \quad (19)$$

Proof. Let us check for instance the property (18). Given $u \in \mathbb{R}$, we define the function g by

$$g(v) = \frac{f(v) - f(u)}{v - u}, \quad v \neq u, \quad g(u) = f'(u).$$

Since

$$g'(v) = \frac{f(u) - f(v) + f'(v)(v - u)}{(v - u)^2}$$

and by the strict convexity of f

$$f(u) - f(v) + f'(v)(v - u) > 0, \quad v \neq u,$$

this function g is strictly increasing. Hence we obtain

$$\min_{v \in I(u_0, u)} g(v) = \begin{cases} g(u_0) = \frac{f(u_0) - f(u)}{u_0 - u} & \text{if } u_0 < u \\ g(u) = f'(u) & \text{if } u_0 > u \end{cases}$$

Figure 3: In bold-face, the sets $\mathcal{E}^-(u_0)$ (a) and $\mathcal{E}^+(u_0)$ (b), u_0 being excluded in both cases, and the other circle points being included

so that

$$\min_{v \in I(u_0, u)} g(v) \geq 0 \iff \begin{cases} f(u) \geq f(u_0) & \text{if } u_0 < u \\ f'(u) \geq 0 & \text{if } u_0 > u. \end{cases}$$

Now the condition $f(u) \geq f(u_0)$ for $u_0 < u$ holds trivially if $u_0 \geq \bar{u}$ but means $u \geq \tilde{u}_0$ if $u_0 \leq \bar{u}$. On the other hand, the condition $f'(u) \geq 0$ means $u \geq \bar{u}$. The property (18) is then proved. \square

In the above examples, $\mathcal{E}^\pm(u_0)$ is an interval or the whole real line, the state u_0 being excluded. In the case of a general flux function, $\mathcal{E}^\pm(u_0)$ consists of an interval or a union of disjoint intervals (cf. Fig. 3).

We next give another useful characterization of the sets $\mathcal{E}^\pm(u_0)$

Lemma 4 *We have*

$$\mathcal{E}^+(u_0) = \{u = w(0_-; y, u_0), y \in \mathbb{R}; u \neq u_0\} \quad (20)$$

and

$$\mathcal{E}^-(u_0) = \{u = w(0_+; u_0, y), y \in \mathbb{R}; u \neq u_0\}. \quad (21)$$

Proof. Let $u = w(0_-; y, u_0) \neq u_0$ for some $y \in \mathbb{R}$. Then, u is connected to u_0 by a wave $w(\cdot; u, u_0)$ whose speed is nonnegative, i.e., $u \in \mathcal{E}^+(u_0)$. Conversely, if $u \in \mathcal{E}^+(u_0)$, then $u = w(0_-; u, u_0) \neq u_0$ which proves (20). The property (21) is established in a similar way. \square

In the sequel, we will make use of the following sets:

$$\begin{cases} \mathcal{F}^+(u_0) = \{u = w(0_+; y, u_0), y \in \mathbb{R}; u \neq u_0\} \\ \mathcal{F}^-(u_0) = \{u = w(0_-; u_0, y), y \in \mathbb{R}; u \neq u_0\}. \end{cases} \quad (22)$$

that we now characterize.

Lemma 5 *We have*

$$\mathcal{F}^+(u_0) = \left\{ u \neq u_0; \frac{f(v) - f(u)}{v - u} > 0 \forall v \in I(u, u_0), v \neq u \right\}. \quad (23)$$

and

$$\mathcal{F}^-(u_0) = \left\{ u \neq u_0; \frac{f(v) - f(u)}{v - u} < 0 \forall v \in I(u, u_0), v \neq u \right\}. \quad (24)$$

Figure 4: $u \in \mathcal{F}^+(u_0)$, i.e. $u = w(0_+; y, u_0)$, $y \in \mathbb{R}$.

Proof. Let us check (23). We first prove

$$\mathcal{F}^+(u_0) = \{u \in \mathcal{E}^+(u_0); w(0_-; u, u_0) = w(0_+; u, u_0)\}.$$

Indeed, let $u \in \mathcal{F}^+(u_0)$; clearly u is connected to u_0 on the left by a wave whose speed is nonnegative (cf. Fig. 4) so that $u \in \mathcal{E}^+(u_0)$. In addition, we have

$$u = w(0_-; u, u_0) = w(0_+; u, u_0). \quad (25)$$

Conversely, if $u \in \mathcal{E}^+(u_0)$ satisfies (25), u belongs obviously to $\mathcal{F}^+(u_0)$. We next show that $u \in \mathcal{E}^+(u_0)$ satisfies (25) if and only if

$$\frac{f(v) - f(u)}{v - u} > 0 \quad \forall v \in I(u, u_0), v \neq u.$$

Observe that the equality $w(0_-; u, u_0) = w(0_+; u, u_0)$ holds if and only if the left subwave of $w(\cdot; u, u_0)$ is not a stationary shock. Since $u \in \mathcal{E}^+(u_0)$, we already know from Lemma 2 that (15) holds and therefore

$$f'(u) \geq 0, \quad \frac{f(u) - f(u_0)}{u - u_0} \geq 0.$$

Then, if we assume $u > u_0$, it is clear geometrically (cf. Fig. 5) that we must have

$$f(v) < f(u) \quad \forall v \in [u_0, u].$$

Indeed, we have a stationary shock if and only if it exists a state $u_1 \in [u_0, u]$ such that $f(u) = f(u_1)$. Hence, there does not exist such a stationary shock if and only if

$$\frac{f(v) - f(u)}{v - u} > 0 \quad \forall v \in [u_0, u].$$

Similarly, for $u < u_0$, a stationary shock does not exist if and only if

$$f(v) < f(u) \quad \forall v \in (u, u_0]$$

or equivalently

$$\frac{f(v) - f(u)}{v - u} > 0 \quad \forall v \in (u, u_0].$$

This proves (23). The characterization (24) of $\mathcal{F}^-(u_0)$ is obtained analogously.

□

Figure 5: In bold-face, the set $\mathcal{F}^+(u_0)$, u_0 being excluded, and the other circle points being included (note the difference with respect to Fig. 3b). Here $u \in \mathcal{F}^+(u_0)$.

Example 2.1. (contd.) If the flux function f is strictly increasing, we have

$$\mathcal{F}^+(u_0) = \mathcal{E}^+(u_0) = \mathbb{R} \setminus \{u_0\}, \quad \mathcal{F}^-(u_0) = \mathcal{E}^-(u_0) = \emptyset$$

while for a strictly decreasing function f

$$\mathcal{F}^+(u_0) = \mathcal{E}^+(u_0) = \emptyset, \quad \mathcal{F}^-(u_0) = \mathcal{E}^-(u_0) = \mathbb{R} \setminus \{u_0\}. \quad \square$$

Example 2.2. (contd.) Here we can state

Lemma 6 *Assume that the function f is strictly convex. Then*

$$\mathcal{F}^+(u_0) = \{u \neq u_0; u \geq \max(\bar{u}, \tilde{u}_0), u \neq \tilde{u}_0\} \quad (26)$$

and

$$\mathcal{F}^-(u_0) = \{u \neq u_0; u \leq \min(\bar{u}, \tilde{u}_0), u \neq \tilde{u}_0\}. \quad (27)$$

Proof. We check for instance the property (26). It follows from (20) that we have to restrict ourselves to the states $u \geq \max(\bar{u}, \tilde{u}_0)$. Assume first $u \geq \bar{u}$ so that $\bar{u} \geq \tilde{u}_0$. Then, we observe that, for $u \geq \bar{u}$, we have indeed

$$\frac{f(v) - f(u)}{v - u} > 0 \quad \forall v \in I(u_0, u), v \neq u$$

and thus $u \in \mathcal{F}^-(u_0)$. Consider next the case $\bar{u} \geq u_0$ for which $\tilde{u}_0 \geq \bar{u}$. For $u \geq \tilde{u}_0$, we obtain

$$\frac{f(v) - f(u)}{v - u} > 0 \quad \forall v \in [u_0, u)$$

if and only if $u > \tilde{u}_0$ (cf. Fig. 6) which proves (26). \square

Now, let $\theta \in C^1(\mathbb{R})$ be a strictly monotone function; only for the sake of convenience, we will assume that θ satisfies $\theta' > 0$ and maps \mathbb{R} onto itself. We

Figure 6: In bold-face, the set $\mathcal{F}^+(u_0)$, \tilde{u}_0 being excluded.

set $\tilde{f}(v) = f(\theta(v))$ and we denote by $z(\frac{x}{t}; v_g, v_d)$ the solution of the Riemann problem expressed in the variable $v = \theta^{-1}(u)$, i.e.,

$$z(\frac{x}{t}; v_g, v_d) = \theta^{-1}(w(\frac{x}{t}; \theta(v_g), \theta(v_d))).$$

With a given state v_0 we associate the sets of states

$$\begin{cases} \tilde{\mathcal{E}}^+(v_0) = \{v = z(0_-; y, v_0), y \in \mathbb{R}; v \neq v_0\} \\ \tilde{\mathcal{F}}^+(v_0) = \{v = z(0_+; y, v_0), y \in \mathbb{R}; v \neq v_0\} \end{cases} \quad (28)$$

and

$$\begin{cases} \tilde{\mathcal{E}}^-(v_0) = \{v = z(0_+; v_0, y), y \in \mathbb{R}; v \neq v_0\} \\ \tilde{\mathcal{F}}^-(v_0) = \{v = z(0_-; v_0, y), y \in \mathbb{R}; v \neq v_0\}. \end{cases} \quad (29)$$

Using Lemmas 2 and 5, we have

$$\begin{cases} \tilde{\mathcal{E}}^+(v_0) = \left\{ v \neq v_0; \min_{w \in I(v_0, v)} \frac{\tilde{f}(w) - \tilde{f}(v)}{w - v} \geq 0 \right\} \\ \tilde{\mathcal{F}}^+(v_0) = \left\{ v \neq v_0; \frac{\tilde{f}(w) - \tilde{f}(v)}{w - v} > 0 \quad \forall w \in I(v_0, v), w \neq v \right\} \end{cases} \quad (30)$$

and

$$\begin{cases} \tilde{\mathcal{E}}^-(v_0) = \left\{ v \neq v_0; \max_{w \in I(v_0, v)} \frac{\tilde{f}(w) - \tilde{f}(v)}{w - v} \leq 0 \right\} \\ \tilde{\mathcal{F}}^-(v_0) = \left\{ v \neq v_0; \frac{\tilde{f}(w) - \tilde{f}(v)}{w - v} < 0 \quad \forall w \in I(v_0, v), w \neq v \right\}. \end{cases} \quad (31)$$

Example 2.1. (contd.) If the function f is strictly increasing, we have

$$\tilde{\mathcal{E}}^+(v_0) = \tilde{\mathcal{F}}^+(v_0) = \mathbb{R} \setminus \{v_0\}, \quad \tilde{\mathcal{E}}^-(v_0) = \tilde{\mathcal{F}}^-(v_0) = \emptyset$$

while if f is strictly decreasing

$$\tilde{\mathcal{E}}^+(v_0) = \tilde{\mathcal{F}}^+(v_0) = \emptyset, \quad \tilde{\mathcal{E}}^-(v_0) = \tilde{\mathcal{F}}^-(v_0) = \mathbb{R} \setminus \{v_0\}. \quad \square$$

Example 2.2. (contd.) When the function f is strictly convex, we denote by $\bar{v} = \theta^{-1}(\bar{u})$ the sonic state of \tilde{f} . Given a state v_0 , we set $u_0 = \theta(v_0)$ and $\tilde{v}_0 = \theta^{-1}(\tilde{u}_0)$. Then we obtain

$$\tilde{\mathcal{E}}^+(v_0) = \{v \neq v_0; v \geq \max(\bar{v}, \tilde{v}_0)\}, \quad \tilde{\mathcal{F}}^+(v_0) = \{v \in \tilde{\mathcal{E}}^+(v_0); v \neq \tilde{v}_0\}$$

and

$$\tilde{\mathcal{E}}^-(v_0) = \{v \neq v_0; v \leq \min(\bar{v}, \tilde{v}_0)\}, \quad \tilde{\mathcal{F}}^-(v_0) = \{v \in \tilde{\mathcal{E}}^-(v_0); v \neq \tilde{v}_0\}. \quad \square$$

2.2 v-continuous solutions.

Let us now look for all possible *self-similar* solutions $u = u(\frac{x}{t})$ of the coupled Riemann problem. Again, for convenience, we assume that both functions θ_L and θ_R are strictly increasing and map \mathbb{R} onto itself. We begin with those self-similar solutions which are *v-continuous at the interface* (in the strong sense), i.e., which satisfy

$$v(0_-) = v(0_+) = v(0) \tag{32}$$

where v is defined from u as in (6), or equivalently which satisfy the constraint

$$v(0) \in \left(\{v_g\} \cup \tilde{\mathcal{F}}_L^-(v_g) \right) \cap \left(\{v_d\} \cup \tilde{\mathcal{F}}_R^+(v_d) \right). \tag{33}$$

Hence, besides the trivial solution corresponding to $v(0) = v_g = v_d$ ², we obtain three types of v-continuous solutions.

(i) The first type of v-continuous solution. If

$$v(0) = v_d \in \tilde{\mathcal{F}}_L^-(v_g),$$

the solution of the coupled Riemann problem coincides with the solution $z_L(\cdot; v_g, v_d)$ of the L-Riemann problem: it consists of a (composite) L-wave whose speed is nonpositive. Such a solution is characterized by

$$\frac{\tilde{f}_L(v) - \tilde{f}_L(v_d)}{v - v_d} < 0 \quad \forall v \in I(v_g, v_d), \quad v \neq v_d.$$

(ii) The second type of v-continuous solution. If

$$v(0) = v_g \in \tilde{\mathcal{F}}_R^+(v_d),$$

²which is excluded since, once for all, we have supposed $v_g \neq v_d$.

the solution of the coupled Riemann problem coincides with the solution $z_R(\cdot; v_g, v_d)$ of the R-Riemann problem: it consists of a (composite) R-wave whose speed is nonnegative. Such a solution is characterized by

$$\frac{\tilde{f}_R(v) - \tilde{f}_R(v_g)}{v - v_g} > 0 \quad \forall v \in I(v_g, v_d), v \neq v_g.$$

(iii) The third type of v-continuous solution. The general case is indeed obtained by choosing

$$v(0) \in \tilde{\mathcal{F}}_L^-(v_g) \cap \tilde{\mathcal{F}}_R^+(v_d)$$

Obviously, this requires the condition

$$\tilde{\mathcal{F}}_L^-(v_g) \cap \tilde{\mathcal{F}}_R^+(v_d) \neq \emptyset.$$

Then a solution of the coupled Riemann problem coincides with $z_L(\cdot; v_g, v(0))$ in the domain $(x < 0, t > 0)$ and with $z_R(\cdot; v(0), v_d)$ in the domain $(x > 0, t > 0)$. It consists of two (composite) waves: a L-wave whose speed is nonpositive and a R-wave whose speed is nonnegative. Such a solution is characterized by the conditions

$$\begin{cases} \frac{\tilde{f}_L(v) - \tilde{f}_L(v(0))}{v - v(0)} < 0 & \forall v \in I(v_g, v(0)), v \neq v(0) \\ \frac{\tilde{f}_R(v) - \tilde{f}_R(v(0))}{v - v(0)} > 0 & \forall v \in I(v(0), v_d), v \neq v(0). \end{cases}$$

We thus find a *one-parameter family* of solutions depending on the parameter $v(0) \in \tilde{\mathcal{F}}_L^-(v_g) \cap \tilde{\mathcal{F}}_R^+(v_d)$.

Let us notice that a solution of type (i) or type (ii) is that of a classical L or R-Riemann problem and may be viewed as a *quasi trivial* solution of this coupling problem.

We now apply these results to the case where both flux functions f_L and f_R are either strictly monotone or strictly convex.

Example 2.3. The case of strictly monotone flux functions.

(a) Suppose first that the functions f_L and f_R are strictly decreasing so that

$$\tilde{\mathcal{F}}_L^-(v_g) = \mathbb{R} \setminus \{v_g\}, \quad \tilde{\mathcal{F}}_R^+(v_d) = \emptyset.$$

Then, clearly the solution of type (i) alone is admissible.

(b) Similarly, if the functions f_L and f_R are strictly increasing so that

$$\tilde{\mathcal{F}}_L^-(v_g) = \emptyset, \quad \tilde{\mathcal{F}}_R^+(v_d) = \mathbb{R} \setminus \{v_d\},$$

the solution of type (ii) alone is admissible.

(c) Suppose next that f_L is strictly increasing and f_R is strictly decreasing. We have $\tilde{\mathcal{F}}_L^-(v_g) = \tilde{\mathcal{F}}_R^+(v_d) = \emptyset$. Then, none of the existence conditions of a v-continuous solution holds: there does not exist any v-continuous solution of the coupled Riemann problem (except the trivial solution corresponding to

$v(0) = v_g = v_d$.

(d) If f_L is strictly decreasing and f_R is strictly increasing, we have

$$\tilde{\mathcal{F}}_L^-(v_g) = \mathbb{R} \setminus \{v_g\}, \quad \tilde{\mathcal{F}}_R^+(v_d) = \mathbb{R} \setminus \{v_d\}.$$

Hence any above condition of existence of a v -continuous solution holds: there exists a one-parameter family of solutions of type (iii) depending on the parameter $v(0) \in \mathbb{R}$. Clearly this family contains the solution of type (i) and that of type (ii). Hence the coupled Riemann problem has an infinite number of v -continuous solutions and it is enough to specify $v(0)$ for determining the unique corresponding solution.

Example 2.4. The case of strictly convex flux functions with sonic states.

Here we assume that f_α , $\alpha = L, R$, is a strictly convex function and possesses a sonic state \bar{u}_α . We set: $\bar{v}_\alpha = \theta_\alpha^{-1}(\bar{u}_\alpha)$. With the pair (v_g, v_d) , we associate the pair $(\tilde{v}_g, \tilde{v}_d)$ defined by

$$\left\{ \begin{array}{l} \tilde{f}_L(\tilde{v}_g) = \tilde{f}_L(v_g), \tilde{v}_g \neq v_g \text{ if } v_g \neq \bar{v}_L \\ \tilde{v}_g = \bar{v}_L \text{ if } v_g = \bar{v}_L \end{array} \right\}, \quad \left\{ \begin{array}{l} \tilde{f}_R(\tilde{v}_d) = \tilde{f}_R(v_d), \tilde{v}_d \neq v_d \text{ if } v_d \neq \bar{v}_R \\ \tilde{v}_d = \bar{v}_R \text{ if } v_d = \bar{v}_R. \end{array} \right.$$

Using the results of Example 2.2, we thus have

$$\tilde{\mathcal{F}}_L^-(v_g) = \{v \neq v_g; v < \min(\bar{v}_L, \tilde{v}_g), v \neq \tilde{v}_g\}$$

$$\tilde{\mathcal{F}}_R^+(v_d) = \{v \neq v_d; v > \max(\bar{v}_R, \tilde{v}_d), v \neq \tilde{v}_d\}.$$

(a) If

$$v_d \in \tilde{\mathcal{F}}_L^-(v_g) \Leftrightarrow v_d \leq \min(\bar{v}_L, \tilde{v}_g), v_d \neq \tilde{v}_g,$$

there exists a solution of type (i) (a L-wave) to the coupled Riemann problem. This is the only solution of this kind.

(b) If

$$v_g \in \tilde{\mathcal{F}}_R^+(v_d) \Leftrightarrow v_g \geq \max(\bar{v}_R, \tilde{v}_d), v_g \neq \tilde{v}_d,$$

there exists a solution of type (ii) (a R-wave) to the coupled Riemann problem. This is the only solution of this type.

(c) When

$$\tilde{\mathcal{F}}_L^-(v_g) \cap \tilde{\mathcal{F}}_R^+(v_d) \neq \emptyset \Leftrightarrow \max(\bar{v}_R, \tilde{v}_d) \leq \min(\bar{v}_L, \tilde{v}_g),$$

we can construct a family of solutions of type (iii) (a L-wave followed by a R-wave) depending on the parameter $v(0) \in [\max(\bar{v}_R, \tilde{v}_d), \min(\bar{v}_L, \tilde{v}_g)]$. They are the only solutions of type (iii).

It is worthwhile to notice that, given a pair (v_g, v_d) , we may have v -continuous solutions of several types. For instance, if

$$v_d \leq \max(\bar{v}_R, \tilde{v}_d) \leq \min(\bar{v}_L, \tilde{v}_g)$$

solutions of types (i) and (iii) are valid.

Figure 7: A v -discontinuous solution to the coupled Riemann problem

2.3 v -discontinuous solutions.

We next look for the self-similar solutions of the coupled Riemann problem which are v -discontinuous at the interface $x = 0$. Setting

$$v_- = v(0_-), \quad v_+ = v(0_+),$$

the coupling constraints (7) read here

$$\begin{cases} v_- \in \tilde{\mathcal{O}}_L(v_+) \Leftrightarrow v_- = z_L(0_-; v_-, v_+), \\ v_+ \in \tilde{\mathcal{O}}_R(v_-) \Leftrightarrow v_+ = z_R(0_+; v_-, v_+). \end{cases}$$

Since we assume $v_- \neq v_+$, $z_L(\cdot; v_-, v_+)$ and $z_R(\cdot; v_-, v_+)$ are both non trivial waves. The coupling constraints mean that $z_L(\cdot; v_-, v_+)$ is a wave with a nonnegative speed while $z_R(\cdot; v_-, v_+)$ is a wave with a nonpositive speed.

On the other hand, any solution of the coupled Riemann problem consists necessarily of a L-wave whose speed is nonpositive and a R-wave whose speed is nonnegative. In other words, the wave $z_L(\cdot; v_g, v_-)$ has a nonpositive speed while $z_R(\cdot; v_+, v_d)$ has a non negative speed (see Fig. 7).

Let us then state

Lemma 7 *One of the two following situations holds:*

- (i) $v_- = v_g \Rightarrow \tilde{f}'_L(v_g) \geq 0$;
- (ii) $v_- \neq v_g \Rightarrow \tilde{f}'_L(v_-) = 0$ and the right subwave of $z_L(\cdot; v_g, v_-)$ is a rarefaction.

In the case (ii), it is worthwhile to notice that v_- is a sonic state of the right rarefaction subwave of $z_L(\cdot; v_g, v_-)$.

Proof. We begin by proving the lemma when $\theta_L = id$, i.e., when $v = u$ is the conservative variable. Since $w_L(\cdot; u_-, u_+)$ has a nonnegative speed, we have

$$\min_{u \in I(u_-, u_+)} \frac{f_L(u) - f_L(u_-)}{u - u_-} \geq 0$$

which implies $f'_L(u_-) \geq 0$. If we assume $u_- = u_g$, we obtain $f'_L(u_g) \geq 0$. Assume next $u_- \neq u_g$. Then $w_L(\cdot; u_g, u_-)$ has a nonpositive speed so that

$$\max_{u \in I(u_g, u_-)} \frac{f_L(u) - f_L(u_-)}{u - u_-} \leq 0$$

Figure 8: The first type of v-discontinuous solution : a stationary discontinuity.

which yields $f'_L(u_-) \leq 0$. Hence we find $f'_L(u_-) = 0$. As a consequence, the right subwave of $w_L(\cdot; u_g, u_-)$ is either a rarefaction with u_- as a sonic state or a stationary shock. But, since $w_L(0_-; u_g, u_-) = u_-$, a stationary shock is not allowed. This proves the lemma when $v = u$.

Let us now turn to the general case of a nonconservative variable v . Since $\tilde{f}'_L(v) = f'_L(\theta_L(v))\theta'_L(v)$ and $\theta'_L(v) > 0$, the above properties (i) and (ii) become respectively

$$\begin{aligned} v_- = v_g &\Rightarrow \tilde{f}'_L(v_g) \geq 0 \\ v_- \neq v_g &\Rightarrow \tilde{f}'_L(v_-) = 0 \end{aligned}$$

and the proof is complete. \square

Similarly, one can state

Lemma 8 *One of the two following situations holds:*

- (i) $v_+ = v_d \Rightarrow \tilde{f}'_R(v_d) \leq 0$;
- (ii) $v_+ \neq v_d \Rightarrow \tilde{f}'_R(v_+) = 0$ and the left subwave of $z_R(\cdot; v_+, v_d)$ is a rarefaction.

As a consequence of Lemmas 7 and 8, we find that the self-similar v-discontinuous solutions of the coupled Riemann problem are necessarily of the four following types.

(i) The first type of v-discontinuous solution (see Fig. 8). It consists of a stationary discontinuity with $v_- = v_g$ and $v_+ = v_d$. Such a solution exists if and only if we have

$$\tilde{f}'_L(v_g) \geq 0 \geq \tilde{f}'_R(v_d)$$

together with the coupling conditions which read here

$$\begin{aligned} \min_{v \in I(v_g, v_d)} \frac{\tilde{f}_L(v) - \tilde{f}_L(v_g)}{v - v_g} &\geq 0, \\ \max_{v \in I(v_g, v_d)} \frac{\tilde{f}_R(v) - \tilde{f}_R(v_d)}{v - v_d} &\leq 0. \end{aligned}$$

(ii) The second type of v-discontinuous solution (see Fig. 9). It consists of a L-wave whose right subwave is a rarefaction with v_- as a sonic state followed

Figure 9: The second type of v -discontinuous solution : a L -wave whose right subwave is a rarefaction, followed by a stationary discontinuity.

by a stationary discontinuity with $v_+ = v_d$. Such a solution exists under the following conditions. On the one hand, we have

$$\tilde{f}'_R(v_d) \leq 0$$

and there exists a sonic state \bar{v}_L of \tilde{f}_L , $\bar{v}_L \neq v_g$, such that

$$\max_{v \in I(v_g, \bar{v}_L)} \frac{\tilde{f}_L(v) - \tilde{f}_L(\bar{v}_L)}{v - \bar{v}_L} = \tilde{f}'_L(\bar{v}_L) = 0$$

and $v_- = \bar{v}_L$. On the other hand, we require the associated coupling conditions

$$\min_{v \in I(\bar{v}_L, v_d)} \frac{\tilde{f}_L(v) - \tilde{f}_L(\bar{v}_L)}{v - \bar{v}_L} \geq 0,$$

$$\max_{v \in I(\bar{v}_L, v_d)} \frac{\tilde{f}_R(v) - \tilde{f}_R(v_d)}{v - v_d} \leq 0.$$

(iii) The third type of v -discontinuous solution (see Fig. 10). It consists of a stationary discontinuity with $v_- = v_g$ followed by a R -wave whose left subwave is a rarefaction with v_+ as a sonic state. This solution exists under the following conditions. On the one hand, we have

$$\tilde{f}'_L(v_g) \geq 0$$

and there exists a sonic state \bar{v}_R of \tilde{f}_R , $\bar{v}_R \neq v_d$ such that

$$\min_{v \in I(\bar{v}_R, v_d)} \frac{\tilde{f}_R(v) - \tilde{f}_R(\bar{v}_R)}{v - \bar{v}_R} = \tilde{f}'_R(\bar{v}_R) = 0$$

and $v_+ = \bar{v}_R$. On the other hand, the associated coupling conditions read

$$\min_{v \in I(v_g, \bar{v}_R)} \frac{\tilde{f}_L(v) - \tilde{f}_L(v_g)}{v - v_g} \geq 0,$$

$$\max_{v \in I(v_g, \bar{v}_R)} \frac{\tilde{f}_R(v) - \tilde{f}_R(\bar{v}_R)}{v - \bar{v}_R} \leq 0.$$

Figure 10: The third type of v -discontinuous solution : a stationary discontinuity followed by a R -wave whose left subwave is a rarefaction.

Figure 11: The fourth type of v -discontinuous solution : a L -wave whose right subwave is a rarefaction, followed by a stationary discontinuity, itself followed by a R -wave whose left subwave is a rarefaction.

(iv) **The fourth type of v -discontinuous solution (see Fig. 11).** It consists of a L -wave whose right subwave is a rarefaction with v_- as a sonic state followed by a stationary discontinuity and a R -wave whose left subwave is a rarefaction with v_+ as a sonic state. For obtaining such a solution, the following conditions hold: there exist sonic states $\bar{v}_L \neq v_g$ and $\bar{v}_R \neq v_d$ of \tilde{f}_L and \tilde{f}_R respectively such that

$$\max_{v \in I(v_g, \bar{v}_L)} \frac{\tilde{f}_L(v) - \tilde{f}_L(\bar{v}_L)}{v - \bar{v}_L} = \tilde{f}'_L(\bar{v}_L) = 0,$$

$$\min_{v \in I(\bar{v}_R, v_d)} \frac{\tilde{f}_R(v) - \tilde{f}_R(\bar{v}_R)}{v - \bar{v}_R} = \tilde{f}'_R(\bar{v}_R) = 0$$

and $v_- = \bar{v}_L, v_+ = \bar{v}_R$. In addition, we require the coupling conditions

$$\min_{v \in I(\bar{v}_L, \bar{v}_R)} \frac{\tilde{f}_L(v) - \tilde{f}_L(\bar{v}_L)}{v - \bar{v}_L} \geq 0$$

and

$$\max_{v \in I(\bar{v}_L, \bar{v}_R)} \frac{\tilde{f}_R(v) - \tilde{f}_R(\bar{v}_R)}{v - \bar{v}_R} \leq 0.$$

Again we apply the above results to the cases where both flux functions are

either strictly monotone or strictly convex.

Example 2.3. The case of strictly monotone flux functions. (contd.)

(a) If the functions f_L and f_R are strictly decreasing, we have $\tilde{f}'_L \leq 0$ and $\tilde{f}'_R \leq 0$ and no v-discontinuous solution can exist. This is obvious for solutions of types (i) and (iii). On the other hand, due to the coupling conditions, solutions of types (ii) and (iv) are not admissible. For instance, in the case of a solution of type (ii), the first coupling condition implies the existence of a sonic state \bar{v}_L such that $\bar{v}_L = v_d$, i.e., $v_- = v_+$ which is clearly excluded.

(b) If f_L and f_R are strictly increasing, a similar analysis shows again that there cannot exist any v-discontinuous solution.

(c) If f_L is strictly increasing and f_R is strictly decreasing, only the v-discontinuous solution of type (i), i.e., a stationary discontinuity, is admissible. Indeed, such a solution is clearly admissible. On the other hand, a solution of type (ii) cannot exist since the condition

$$\max_{v \in I(v_g, \bar{v}_L)} \frac{\tilde{f}_L(v) - \tilde{f}_L(\bar{v}_L)}{v - \bar{v}_L} = \tilde{f}'_L(\bar{v}_L) = 0$$

implies $\bar{v}_L = v_g$ and therefore $v_- = v_g$ so that the L-wave does not exist. Using similar arguments, one can check that the solutions of types (iii) and (iv) are also excluded.

(d) If f_L is strictly decreasing and f_R is strictly increasing, no v-discontinuous solution may exist since the coupling conditions are never satisfied.

To summarize, a v-discontinuous solution exists only when f_L is strictly increasing and f_R is strictly decreasing. This is a stationary discontinuity. \square

Example 2.4.(contd.) Consider again the case where both flux functions f_L and f_R are strictly convex and possess sonic states \bar{u}_L and \bar{u}_R respectively. Since, for $\alpha = L, R$, the function θ_α is assumed to satisfy $\theta'_\alpha > 0$, the function \tilde{f}_α has a unique sonic state $\bar{v}_\alpha = \theta_\alpha^{-1}(\bar{u}_\alpha)$ and is strictly decreasing in $(-\infty, \bar{v}_\alpha)$ (resp. strictly increasing in $(\bar{v}_\alpha, +\infty)$). We introduce again the states \tilde{v}_g and \tilde{v}_d defined above. Note that, in this strictly convex case, the sonic state $\bar{v}_L \neq v_g$ of \tilde{f}_L satisfies the condition

$$\max_{v \in I(v_g, \bar{v}_L)} \frac{\tilde{f}_L(v) - \tilde{f}_L(v_g)}{v - v_g} = \tilde{f}'_L(\bar{v}_L) = 0$$

if and only if $v_g < \bar{v}_L$ or equivalently $\tilde{f}'_L(v_g) < 0$. Similarly, the sonic state $\bar{v}_R \neq v_d$ of \tilde{f}_R satisfies the condition

$$\min_{v \in I(\bar{v}_R, v_d)} \frac{\tilde{f}_R(v) - \tilde{f}_R(v_d)}{v - v_d} = \tilde{f}'_R(\bar{v}_R) = 0$$

if and only if $v_d > \bar{v}_R$ or equivalently $\tilde{f}'_R(v_d) > 0$.

On the other hand, for $v_a = v_g \geq \bar{v}_L$ or $v_a = \bar{v}_L$, a coupling condition of the form

$$\min_{I(v_a, v_b)} \frac{\tilde{f}_L(v) - \tilde{f}_L(v_a)}{v - v_a} \geq 0$$

holds if and only if $v_b \geq \tilde{v}_a$ where

$$\tilde{v}_a = \begin{cases} \tilde{v}_g & \text{if } v_a = v_g \\ \bar{v}_L & \text{if } v_a = \bar{v}_L. \end{cases}$$

Similarly, for $v_b = v_d \leq \bar{v}_R$ or $v_b = \bar{v}_R$, a coupling condition of the form

$$\max_{I(v_a, v_b)} \frac{\tilde{f}_R(v) - \tilde{f}_R(v_b)}{v - v_b} \leq 0$$

holds if and only if $v_a \leq \tilde{v}_b$ where

$$\tilde{v}_b = \begin{cases} \tilde{v}_d & \text{if } v_b = v_d \\ \bar{v}_R & \text{if } v_b = \bar{v}_R. \end{cases}$$

Then, it is an easy matter to check that a v-discontinuous solution exists in the following situations.

(a) If

$$\bar{v}_L \leq v_g \leq \tilde{v}_d, \quad \tilde{v}_g \leq v_d \leq \bar{v}_R,$$

we obtain a v-discontinuous solution of type (i), i.e., a stationary discontinuity.

(b) If

$$v_g < \bar{v}_L < v_d \leq \bar{v}_R,$$

we find a v-discontinuous solution of type (ii), i.e., a L-wave followed by a stationary discontinuity.

(c) If

$$\bar{v}_L \leq v_g < \bar{v}_R < v_d,$$

we obtain a v-discontinuous solution of type (iii), i.e., a stationary discontinuity followed by a R-wave.

(d) If

$$v_g < \bar{v}_L < \bar{v}_R < v_d,$$

we find a v-discontinuous solution of type (iv), i.e., a L-wave followed by a stationary discontinuity and a R-wave.

Note that each case (i)-(iv) is disclosed from the others and each v-discontinuous solution is uniquely defined. \square

2.4 Solution of the coupled Riemann problem.

We are now able to solve the coupled Riemann problem for all pair (u_g, u_d) or (v_g, v_d) . We begin with the cases where the flux functions f_α , $\alpha = L, R$, are either strictly monotone or strictly convex.

Example 2.3.(contd.) We first assume that f_α , $\alpha = L, R$ is a strictly monotone function. Combining the above results, we obtain the following conclusions.

(a) *The functions f_L and f_R are strictly decreasing.* The solution is v-continuous: it is a L-wave.

(b) *The functions f_L and f_R are strictly increasing.* The solution is v-continuous: it is a R-wave.

(c) *The function f_L is strictly increasing and the function f_R strictly decreasing.* The solution is v- discontinuous: it is a stationary discontinuity.

(d) *The function f_L is strictly decreasing and the function f_R is strictly increasing.* The solutions are v-continuous and form a one-parameter family depending on three parameter $v(0) \in \mathbb{R}$. For $v(0) \neq v_g, v_d$, we obtain a L-wave followed by a R-wave. For $v(0) = v_d$, we obtain a L-wave while, for $v(0) = v_g$, we get a R-wave.

To summarize, in this case, the coupled Riemann problem has always a solution. This solution is unique except in the subcase (d). Note that, as in [19], one could have obtained directly the above results by using a method of characteristics.

Example 2.4.(contd.) Assume now that the flux functions f_L and f_R are strictly convex and possess sonic states \bar{u}_L and \bar{u}_R respectively. Let us check that the coupled Riemann problem has at least one solution. First of all, we already know from the results of section 2.1.2 that a v-continuous solution exists in the following cases.

- (a) For $v_d \leq \min(\bar{v}_L, \tilde{v}_g)$, $v_d \neq \tilde{v}_g$, the solution is a L-wave.
- (b) For $v_g \geq \max(\bar{v}_R, \tilde{v}_d)$, $v_g \neq \tilde{v}_d$, the solution is a R-wave.
- (c) If $\max(\bar{v}_R, \tilde{v}_d) \leq \min(\bar{v}_L, \tilde{v}_g)$, we obtain a family of v-continuous solutions consisting of a L-wave followed by a R-wave and depending on the parameter $v(0) \in [\max(\bar{v}_R, \tilde{v}_d), \min(\bar{v}_L, \tilde{v}_g)]$.

It remains to exhibit a v-discontinuous solution when a v-continuous one does not exist, i.e., when the pair (v_g, v_d) satisfies the conditions

$$\begin{cases} v_d > \min(\bar{v}_L, \tilde{v}_g) \\ v_g < \max(\bar{v}_R, \tilde{v}_d) \\ \max(\bar{v}_R, \tilde{v}_d) > \min(\bar{v}_L, \tilde{v}_g). \end{cases} \quad (34)$$

In fact, it is convenient to distinguish the following cases:

$$(v_g \geq \bar{v}_L, v_d \leq \bar{v}_R), (v_g \geq \bar{v}_L, v_d > \bar{v}_R), (v_g < \bar{v}_L, v_d \leq \bar{v}_R), (v_g < \bar{v}_L, v_d > \bar{v}_R).$$

(d) For $(v_g \geq \bar{v}_L, v_d \leq \bar{v}_R)$, the conditions (34) become respectively

$$v_d < \tilde{v}_g, \quad v_g < \tilde{v}_d, \quad \tilde{v}_d > \tilde{v}_g.$$

This case is therefore characterized by

$$\bar{v}_L \leq v_g < \tilde{v}_d, \quad \tilde{v}_g < v_d \leq \bar{v}_R.$$

Then, applying the results of section 2.1.3, we obtain that the solution of the coupled Riemann problem is a stationary discontinuity.

(e) For $(v_g \geq \bar{v}_L, v_d > \bar{v}_R)$, the conditions (34) read

$$v_d > \tilde{v}_g, \quad v_g < \bar{v}_R, \quad \bar{v}_R > \tilde{v}_g$$

so that this case is characterized by

$$\bar{v}_L \leq v_g < \bar{v}_R < v_d.$$

This implies that the solution is a L-wave followed by a stationary discontinuity.

(f) For $(v_g < \bar{v}_L, v_d \leq \bar{v}_R)$, (34) gives

$$v_d > \bar{v}_L, \quad v_g < \tilde{v}_R, \quad \tilde{v}_d > \bar{v}_L.$$

This leads us to the characterization

$$v_g < \bar{v}_L < v_d \leq \bar{v}_R$$

and we obtain a solution consisting of a stationary discontinuity followed by a R-wave.

(g) For $(v_g < \bar{v}_L, v_d > \bar{v}_R)$, the conditions (34) become

$$v_d > \bar{v}_L, \quad v_g < \bar{v}_R, \quad \bar{v}_R > \bar{v}_L$$

and therefore

$$v_g < \bar{v}_L < \bar{v}_R < v_d.$$

We find a solution consisting of a L-wave followed by a stationary discontinuity and a R-wave.

Observe that, in each case (d)-(g), the conditions (34) are exactly the conditions obtained in the previous section which ensure the existence and uniqueness of a v-discontinuous solution. We thus have proved

Theorem 1 *Assume that the functions f_L and f_R are strictly convex and possess sonic states. Then the coupled Riemann problem has at least one solution. The solution is unique except in the case (c) where there exists a one-parameter family of v-continuous solutions. \square*

We pass to the general case of arbitrary flux functions. The situation is not as simple as in the above examples due to the possible presence of several sonic states. The purpose of the remaining part of this section is to prove

Theorem 2 *Assume that the flux functions f_L and f_R are C^1 functions. Then the coupled Riemann problem has at least one self-similar solution.*

We know already that we can construct a v-continuous solution in the following cases:

$$v_d \in \tilde{\mathcal{F}}_L^-(v_g), \quad v_g \in \tilde{\mathcal{F}}_R^+(v_d), \quad \tilde{\mathcal{F}}_L^-(v_g) \cap \tilde{\mathcal{F}}_R^+(v_d) \neq \emptyset.$$

It remains to construct at least one v-discontinuous solution of the coupled Riemann problem when

$$v_d \notin \tilde{\mathcal{F}}_L^-(v_g), \quad v_g \notin \tilde{\mathcal{F}}_R^+(v_d), \quad \tilde{\mathcal{F}}_L^-(v_g) \cap \tilde{\mathcal{F}}_R^+(v_d) = \emptyset. \quad (35)$$

We begin with the following remarks. The condition $v_d \notin \tilde{\mathcal{F}}_L^-(v_g)$ means that $z_L(\cdot; v_g, v_d)$ possesses a nontrivial subwave whose speed is nonnegative. Otherwise, we would get $z_L(\frac{x}{t}; v_g, v_d) = v_d$ for all $x \geq 0$ and therefore $v_d \in \tilde{\mathcal{F}}_L^-(v_g)$. Hence, we have

$$v_L(0_-) \stackrel{def}{=} z_L(0_-; v_g, v_d) \neq v_d.$$

Similarly, the condition $v_g \notin \tilde{\mathcal{F}}_R^+(v_d)$ means that $z_R(\cdot; v_g, v_d)$ possesses a nontrivial subwave whose speed is nonpositive so that

$$v_R(0_+) \stackrel{def}{=} z_R(0_+; v_g, v_d) \neq v_g.$$

Note that the hypotheses (35) imply $v_L(0_-) \neq v_R(0_+)$. Otherwise the function

$$z\left(\frac{x}{t}; v_g, v_d\right) = \begin{cases} z_L\left(\frac{x}{t}; v_g, v_L(0_-)\right), & \frac{x}{t} < 0 \\ z_R\left(\frac{x}{t}; v_R(0_+), v_d\right), & \frac{x}{t} > 0 \end{cases}$$

would be a v -continuous solution of the coupled Riemann problem. On the other hand, we have either $v_L(0_-) = v_g$ (resp. $v_R(0_+) = v_d$) or $v_L(0_-)$ (resp. $v_R(0_+)$) is a sonic state of \tilde{f}_L (resp. \tilde{f}_R). Hence, it appears fairly natural to consider the function

$$z\left(\frac{x}{t}; v_g, v_d\right) = \begin{cases} z_L\left(\frac{x}{t}; v_g, v_d\right), & x < 0 \\ z_R\left(\frac{x}{t}; v_g, v_d\right), & x > 0 \end{cases} \quad (36)$$

as a possible solution of the coupled Riemann problem. Indeed, we can state

Lemma 9 *Assume the hypotheses (35) together with*

$$\begin{cases} v_L(0_-) < v_R(0_+) & \text{if } v_g < v_d \\ v_L(0_-) > v_R(0_+) & \text{if } v_g > v_d. \end{cases} \quad (37)$$

Then (36) is a solution of the coupled Riemann problem.

Proof. We have only to check the coupling conditions which read here

$$\min_{v \in I(v_L(0_-), v_R(0_+))} \frac{\tilde{f}_L(v) - \tilde{f}_L(v_L(0_-))}{v - v_L(0_-)} \geq 0$$

and

$$\max_{v \in I(v_L(0_-), v_R(0_+))} \frac{\tilde{f}_R(v) - \tilde{f}_R(v_R(0_+))}{v - v_R(0_+)} \geq 0.$$

Assume for instance $v_d > v_g$. Since, in that case, $z_L(\cdot; v_g, v_d)$ and $z_R(\cdot; v_g, v_d)$ are monotonically increasing functions, we have by (37)

$$v_g \leq v_L(0_-) < v_R(0_+) \leq v_d.$$

Now, we observe that $z_L(\cdot; v_L(0_-), v_d)$ has a nonnegative speed, i.e.,

$$\min_{v \in I(v_L(0_-), v_d)} \frac{\tilde{f}_L(v) - \tilde{f}_L(v_L(0_-))}{v - v_L(0_-)} \geq 0$$

which implies the first coupling condition. On the other hand, $z_R(\cdot; v_g, v_R(0_+))$ has a nonpositive speed, i.e.,

$$\max_{v \in I(v_g, v_R(0_+))} \frac{\tilde{f}_R(v) - \tilde{f}_R(v_R(0_+))}{v - v_R(0_+)} \leq 0$$

which yields the second coupling condition. The case $v_g > v_d$ is analyzed in the same way. \square

Note that the proof of the above lemma only uses the first two hypotheses (35). Observe that this proof fails if the conditions (37) do not hold. It remains to construct a solution of the coupled Riemann problem when either

$$v_g < v_d \quad \text{and} \quad v_L(0_-) > v_R(0_+) \quad (38)$$

or

$$v_g > v_d \quad \text{and} \quad v_L(0_-) < v_R(0_+). \quad (39)$$

Assume first (38). Let us then check that there exists at least one sonic state of \tilde{f}_L in $[v_g, v_R(0_+)]$. It is here convenient to work with the conservative variable u : setting $u_g = \theta_L(v_g)$, $u_R(0_+) = \theta_L(v_R(0_+))$, we introduce the lower convex envelope of f_L in the interval $[u_g, u_R(0_+)]$. This envelope function cannot be strictly decreasing. Otherwise, $w_L(\cdot; u_g, u_R(0_+))$ and therefore $z_L(\cdot; v_g, v_R(0_+))$, would be a wave whose speed is negative. One then could exhibit a v -continuous solution of the coupled Riemann problem, namely

$$z\left(\frac{x}{t}; v_g, v_d\right) = \begin{cases} z_L\left(\frac{x}{t}; v_g, v_R(0_+)\right), & \frac{x}{t} < 0 \\ z_R\left(\frac{x}{t}; v_R(0_+), v_d\right), & \frac{x}{t} > 0. \end{cases}$$

Hence the above envelope function has either a unique minimum which is a sonic state of f_L or an interval of minima which contains such sonic states (at least the end points of this interval). Denote by \bar{u}_- the smallest of all sonic states of both f_L and its lower convex envelope in $[u_g, u_R(0_+)]$. Then, $\bar{v}_- = \theta_L^{-1}(\bar{u}_-)$ is a sonic state of \tilde{f}_L in $[v_g, v_R(0_+)]$. In the same way, there exists at least one sonic state of both f_R and its lower convex envelope in the interval $[u_L(0_-), u_d]$ and we denote by \bar{u}_+ the largest of all such sonic states. Then, $\bar{v}_+ = \theta_R^{-1}(\bar{u}_+)$ is a sonic state of \tilde{f}_R in $[v_L(0_-), v_d]$. Now, it appears natural to consider the functions

$$z\left(\frac{x}{t}; v_g, v_d\right) = \begin{cases} z_L\left(\frac{x}{t}; v_g, \bar{v}_-\right), & \frac{x}{t} < 0 \\ z_R\left(\frac{x}{t}; v_R(0_+), v_d\right), & \frac{x}{t} > 0 \end{cases} \quad (40)$$

and

$$z\left(\frac{x}{t}; v_g, v_d\right) = \begin{cases} z_L\left(\frac{x}{t}; v_g, v_L(0_-)\right), & \frac{x}{t} < 0 \\ z_R\left(\frac{x}{t}; \bar{v}_+, v_d\right), & \frac{x}{t} > 0 \end{cases} \quad (41)$$

as possible candidates to the solution of the coupled Riemann problem. In fact, we can state

Lemma 10 *Assume the hypotheses (35) and (38). Then (40) and (41) are solutions of the coupled Riemann problem.*

Proof. Let us show that (40) is indeed solution. Again, we have to check the associated coupling conditions

$$\bar{v}_- = z_L(0_-; \bar{v}_-, v_R(0_+)) \Leftrightarrow \bar{u}_- = w_L(0_-; \bar{u}_-, u_R(0_+))$$

and

$$v_R(0_+) = z_R(0_+; \bar{v}_-, v_R(0_+)) \Leftrightarrow u_R(0_+) = w_R(0_+; \bar{u}_-, u_R(0_+)).$$

The first coupling condition holds since, by construction, $w_L(\cdot; \bar{u}_-, u_R(0_+))$ is a monotonically increasing function in $[\bar{u}_-, u_R(0_+)]$ and the corresponding wave has a nonnegative speed. Consider next the second coupling condition. We

Figure 12: A typical example where $v_d \notin \tilde{\mathcal{F}}_L^-(v_g)$, $v_g \notin \tilde{\mathcal{F}}_R^+(v_d)$, $\tilde{\mathcal{F}}_L^-(v_g) \cap \tilde{\mathcal{F}}_R^+(v_d) = \emptyset$.

know that the lower convex envelope of f_R in $[u_g, u_d]$ is a monotonically decreasing function in the interval $[u_g, u_R(0_+)]$ and is strictly convex in an interval $[u_R(0_+), u_R(0_+) + \varepsilon]$, $\varepsilon > 0$ small enough (cf. Fig. 12). Then, as $u_g < \bar{u}_- < u_R(0_+)$, it is clear geometrically that the lower convex envelope of f_R in the interval $[\bar{u}_-, u_R(0_+)]$ is a monotonically decreasing function so that $u_R(0_+) = w_R(0_+; \bar{u}_-, u_R(0_+))$ and our assertion is proved.

By using similar arguments, one can prove that (41) is also solution. \square

Remark. At first glance it would seem natural to consider the function

$$z\left(\frac{x}{t}; v_g, v_d\right) = \begin{cases} z_L\left(\frac{x}{t}; v_g, \bar{v}_-\right), & \frac{x}{t} < 0 \\ z_R\left(\frac{x}{t}; \bar{v}_+, v_d\right), & \frac{x}{t} > 0 \end{cases}$$

as a possible solution of the coupled Riemann problem. However, this is not true since one can easily check that the coupling conditions

$$\bar{v}_- = z_L(0_-; \bar{v}_-, \bar{v}_+), \quad \bar{v}_+ = z_R(0_+; \bar{v}_-, \bar{v}_+)$$

are not satisfied in general (cf. Fig. 12). \square

We can also state the analogue of Lemma 10 whose proof follows the same lines as above.

Lemma 11 *Assume the hypotheses (35) and (39). Then the coupled Riemann problem has at least two v -discontinuous solutions.*

Theorem 3 is now an obvious consequence of Lemmas 10 and 11.

A natural question now arises: when the coupled Riemann problem possesses several solutions, does there exist any “reasonable” criterion based on entropy or stability arguments for choosing the “right solution”? As a first step in this direction, we conjecture that, if a v -continuous solution exists, the eventual v -discontinuous solutions should be considered as parasitic ones.

2.5 The coupled Riemann problem for two conservation laws “with phase change”.

One can extend the above results to the case where the flux functions f_α , $\alpha = L, R$, are only piecewise C^1 . For simplicity, we will restrict ourselves in this section to *continuous* functions f_α which satisfy the following properties:

- (i) f_α is a C^1 strictly increasing function in the intervals $(-\infty, a_\alpha)$ and $(b_\alpha, +\infty)$, $a_\alpha < b_\alpha$;
- (ii) f_α is constant in the interval $[a_\alpha, b_\alpha]$.

One can think of each flux function f_α as modeling a diphasic behavior: the states $u < a_\alpha$ and $u > b_\alpha$ correspond to different phases while the states $u \in [a_\alpha, b_\alpha]$ correspond to a mixture of the two phases.

Again for simplicity, we will restrict ourselves to the u-coupling method. Before constructing the solution of the coupled Riemann problem, let us recall the properties of the solution $w(\cdot; u_g, u_d)$ of the usual Riemann problem associated with such a function $f = f_\alpha$ ³. By introducing the lower convex envelope (resp. the upper concave envelope) of f between the states u_g and u_d if $u_g < u_d$ (resp. $u_g > u_d$), it is a simple matter to check the following properties of $w(\cdot; u_g, u_d)$:

- (i) the associated (composite) wave has a nonnegative speed;
- (ii) the function $x \rightarrow w(\frac{x}{t}; u_g, u_d)$ is continuous at $x = 0$ in the following cases

$$\begin{cases} u_g < a, & u_d \in \mathbb{R} \\ u_g = a, & u_d < a \\ u_g > b, & u_d \in \mathbb{R} \\ u_g = b, & u_d > b; \end{cases} \quad (42)$$

- (iii) the function $x \rightarrow w(\frac{x}{t}; u_g, u_d)$ is discontinuous at $x = 0$ in the following cases

$$\begin{cases} u_g, u_d \in [a, b] \\ u_g \in [a, b), & u_d > b \\ u_g \in (a, b], & u_d < a. \end{cases} \quad (43)$$

In the first case, $w(\cdot; u_g, u_d)$ consists of a stationary shock while, in the last two cases, $w(\cdot; u_g, u_d)$ is a composite wave whose left subwave is a stationary shock.

Let us now consider the coupled Riemann problem. Instead of establishing general results for piecewise C^1 flux functions, it is here far simpler to use a direct approach. Since the function f_L is monotonically increasing, the solution of the coupled Riemann problem cannot include a L-wave. Therefore a solution consists of a possible stationary shock wave connecting u_g and u_+ and a R-wave connecting u_+ and u_d .

Assume first $u_g = u_+$ so that the solution is continuous at the interface $x = 0$. Then, using (42), we know that this is indeed the case if and only if the pair (u_g, u_d) satisfies one of the following properties

$$\begin{cases} u_g < a_R, & u_d \in \mathbb{R} \\ u_g = a_R, & u_d < a_R \\ u_g > b_R, & u_d \in \mathbb{R} \\ u_g = b_R, & u_d > b_R. \end{cases} \quad (44)$$

Assume next $u_g \neq u_+$. This occurs if and only if, on the one hand, the coupling conditions hold and, on the other hand, $w_R(\cdot; u_+, u_d)$ is either a trivial wave

³we drop the subscript α for simplicity.

(i.e., $u_d = u_+$) or a wave whose speed is positive. Since the function f_L is monotonically increasing, the first coupling condition

$$\min_{u \in I(u_g, u_+)} \frac{f_L(u) - f_L(u_g)}{u - u_g} \geq 0$$

holds trivially. The second coupling condition

$$\max_{u \in I(u_g, u_+)} \frac{f_R(u) - f_R(u_+)}{u - u_+} \leq 0$$

means that the wave $w_R(\cdot; u_g, u_+)$ has a nonpositive speed. Hence $w_R(\cdot; u_g, u_+)$ is necessarily a stationary shock or equivalently (cf. property (iii) above) we have

$$u_g, u_+ \in [a_R, b_R].$$

If $u_+ = u_d$, we thus have an admissible stationary shock for the solution of the coupled Riemann problem as soon as

$$u_g, u_d \in [a_R, b_R], \quad u_g \neq u_d.$$

Consider next the case $u_+ \neq u_d$. For the speed of the wave $w_R(\cdot; u_+, u_d)$ to be positive, it follows from (42) that we must have either

$$u_+ = a_R, \quad u_d < a_R$$

or

$$u_+ = b_R, \quad u_d > b_R.$$

In both cases, one can easily check that the speed of the wave is indeed positive.

As a conclusion, we obtain that the coupled Riemann problem has a unique solution. This solution is u-continuous at the interface $x = 0$ in the cases (44) and is u-discontinuous otherwise, i.e., when either

$$u_g, u_d = u_+ \in [a_R, b_R], \quad u_g \neq u_d \tag{45}$$

or

$$\begin{cases} u_g \in (a_R, b_R], & u_+ = a_R, & u_d < a_R \\ u_g \in [a_R, b_R), & u_+ = b_R, & u_d > b_R. \end{cases} \tag{46}$$

This result is easily extended to the case of a v-coupling method. It may be viewed as a generalization of the results of Example 2.3 when both flux functions f_α are strictly increasing.

3 Numerical experiments

Our objective in this section is to illustrate numerically the theoretical results we obtained in the previous sections. For that, the following configurations will be considered :

- the case of two strictly monotone flux functions (example 2.3 above),
- the case of two strictly convex flux functions (example 2.4 above),

- a particular configuration where two discontinuous and none continuous (at the coupling interface) solutions are admissible,
- a particular configuration where several discontinuous solutions and continuous solutions exist,
- and the coupling of two conservation laws “with phase change”.

The situations leading to several admissible solutions (continuous or discontinuous at interface) are of particular interest since different numerical schemes may capture different solutions. We begin with a brief description of the proposed numerical strategy and then present some numerical results.

3.1 Numerical strategy

We consider a finite volume approach. Let Δx and Δt denote the uniform space and time steps and $\mathcal{C}_{j+1/2}$ be the cells defined by $\mathcal{C}_{j+1/2} = (x_j, x_{j+1})$ with $x_j = j\Delta x$ and whose centers are $x_{j+1/2} = (j + 1/2)\Delta x$ for all $j \in \mathbb{Z}$. We set $\lambda = \Delta t/\Delta x$ and $t_n = n\Delta t$ for $n \in \mathbb{N}$. The approximate solution is assumed to be piecewise constant on each cell $\mathcal{C}_{j+1/2}$ and at each time t^n and the corresponding value is denoted $u_{j+1/2}^n$.

To begin with, we set as usual

$$u_{j+1/2}^0 = \frac{1}{\Delta x} \int_{\mathcal{C}_{j+1/2}} u_0(x) dx, \quad j \in \mathbb{Z},$$

where u_0 denotes a given initial condition of the coupling problem.

Then, let G_α , $\alpha = L, R$ be two two-point numerical flux functions that we assume to be consistent with f_α , $\alpha = L, R$. We propose the following update formula for $u_{j+1/2}^{n+1}$:

$$\begin{aligned} u_{j-1/2}^{n+1} &= u_{j-1/2}^n - \lambda(G_{L,j}^n - G_{L,j-1}^n), & j \leq 0, \quad n \geq 0, \\ u_{j+1/2}^{n+1} &= u_{j+1/2}^n - \lambda(G_{R,j+1}^n - G_{R,j}^n), & j \geq 0, \quad n \geq 0, \end{aligned} \quad (47)$$

with $G_{\alpha,j}^n = G_\alpha(u_{j-1/2}^n, u_{j+1/2}^n)$ for $j \neq 0$. In other words, this consists in a classical finite volume scheme outside of the interface, and only both fluxes $G_{L,0}^n$ and $G_{R,0}^n$ remain to be precised in order to define the numerical coupling procedure at the interface. Following the previous works [19], [18], [3] (see also [4], [5]), we set

$$\begin{aligned} G_{L,0}^n &= G_L(u_{-1/2}^n, \theta_L(v_{1/2}^n)), \\ G_{R,0}^n &= G_R(\theta_R(v_{-1/2}^n), u_{1/2}^n), \end{aligned} \quad (48)$$

where ghost states $v_{\pm 1/2}^n$ are obtained as

$$\begin{aligned} v_{-1/2}^n &= \theta_L^{-1}(u_{-1/2}^n), \\ v_{1/2}^n &= \theta_R^{-1}(u_{1/2}^n). \end{aligned} \quad (49)$$

Note from now on that for convenience, we will restrict ourselves to the simple case $\theta_L = \theta_R = id$, so that condition (5) reads $u(t, 0^-) = u(t, 0^+)$ and the ghost states at the interface are simply

$$\begin{aligned} v_{-1/2}^n &= u_{-1/2}^n, \\ v_{1/2}^n &= u_{1/2}^n. \end{aligned} \quad (50)$$

At last and as far as the numerical flux functions G_α , $\alpha = L, R$ are concerned, we will consider the celebrated Godunov scheme :

$$G_\alpha(u, v) = \begin{cases} \min_{w \in [u, v]} f_\alpha(w), & u \leq v, \\ \max_{w \in [v, u]} f_\alpha(w), & v < u, \end{cases} \quad (51)$$

and a relaxation scheme (see for instance [25]) defined by :

$$G_\alpha(u, v) = \frac{1}{2}(f_\alpha(u) + f_\alpha(v)) + \frac{a(u, v)}{2}(u - v) \quad \text{with} \quad a(u, v) = \max_{[\min(u, v), \max(u, v)]} |f'|. \quad (52)$$

3.2 Numerical results

Let us now present the numerical tests and results.

Test 1. The case of strictly monotone flux functions.

As Riemann initial data, we take

$$u_0(x) = \begin{cases} u_g & \text{if } x < 0, \\ u_d & \text{if } x > 0, \end{cases}$$

with $u_g = -2$ and $u_d = 2$ and we consider the following cases :

- (a) $f_L(u) = -u$ and $f_R(u) = -2u$: the unique solution is continuous at the coupling interface.
- (b) $f_L(u) = u$ and $f_R(u) = 2u$: the unique solution is continuous at the coupling interface.
- (c) $f_L(u) = u$ and $f_R(u) = -2u$: there is no continuous solution but a unique discontinuous solution.
- (d) $f_L(u) = -u$ and $f_R(u) = 2u$: there is no discontinuous solution and a continuum of continuous solutions.

Numerical results, obtained for both relaxation and Godunov approaches, are presented on Fig.13. These results are in agreement with the above theoretical results. Note that in the last case both numerical schemes capture the same continuous solution.

Test 2. The case of strictly convex flux functions with sonic states.

We consider two different cases, according to the relative position of the sonic points \bar{v}_L and \bar{v}_R .

Test 2.1. $f_L(u) = u^2/2$, $f_R(u) = (u - 1)^2/2$.

The sonic points are $\bar{v}_L = 0$ and $\bar{v}_R = 1$ and we consider the following four Riemann problems :

- (a) $u_g = -1$ and $u_d = 2$: the unique solution is a discontinuous solution of the fourth type (composite wave consisting of a L-wave, a discontinuity and a R-wave).
- (b) $u_g = 2$ and $u_d = -1$: the unique solution is a discontinuous solution of the first type.

Figure 13: Monotone fluxes. 1000 pts. $t = 0.2$. $u_g = -2$, $u_d = 2$.

- (c) $u_g = 0.5$ and $u_d = -2$: the solutions are a continuous solution of the first type and a discontinuous solution of the first type.
- (d) $u_g = -1$ and $u_d = -1.5$: the solutions are a continuous solution of the first type and a discontinuous solution of the second type (that is not a monotonous solution).

Numerical solutions are presented on Fig.14. We observe that both numerical schemes select the continuous solutions when more are presents (cases (c) and (d)).

Test 2.2. $f_L(u) = u^2/2$, $f_R(u) = (u + 1)^2/2$.

The sonic points are $\bar{v}_L = 0$ and $\bar{v}_R = -1$ and we consider the following four Riemann problems. The numerical solutions are presented on Fig.15.

- (a) $u_g = -0.6$ and $u_d = -0.2$: the solutions are a continuous solution of the first, second or third type, and a discontinuous solution of the fourth type. Both numerical schemes capture the continuous solution of the third type, here with two rarefaction waves connecting a constant state, that slightly differs for both schemes.
- (b) $u_g = -0.2$ and $u_d = -0.6$: the solutions are a continuous solution of the first, second or third type, and a discontinuous solution of the fourth type. Both numerical schemes capture the continuous solution of the third type,

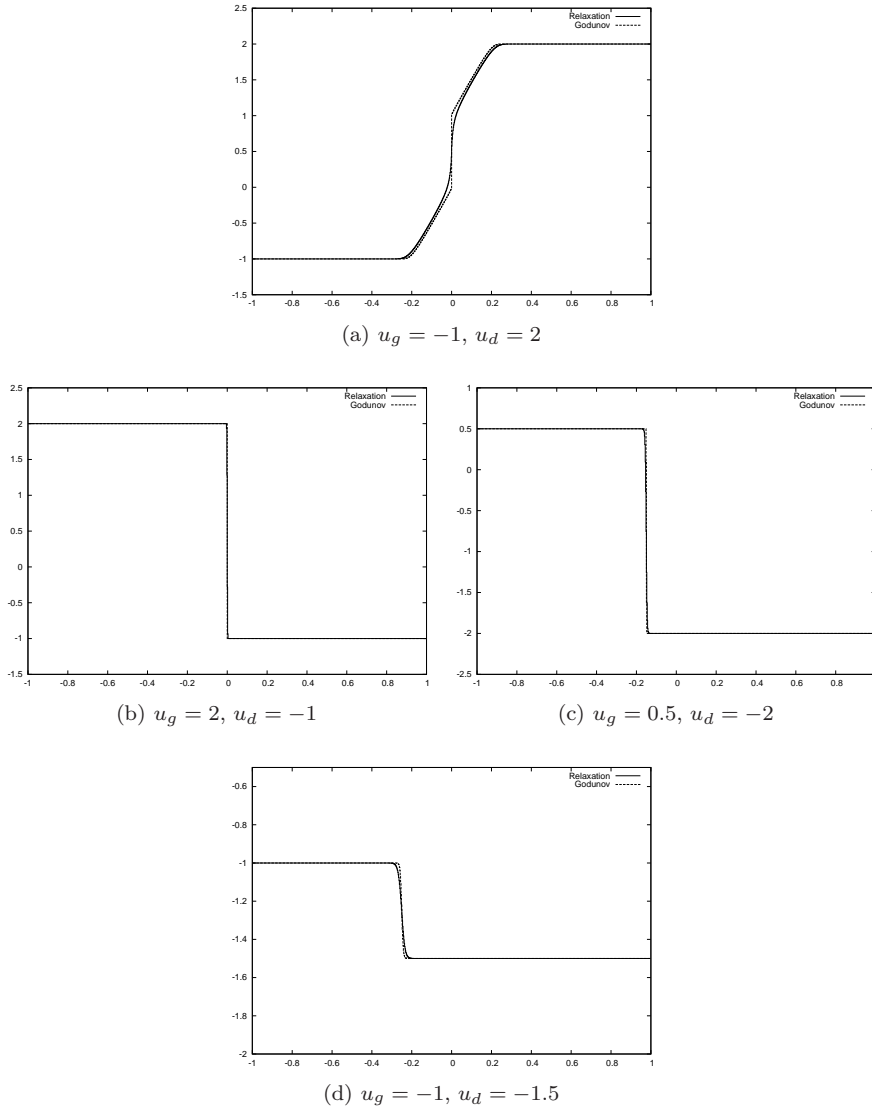

Figure 14: Convex fluxes. 1000 pts. $t = 0.2$

here with two shock waves connecting a constant state, that slightly differs for both schemes.

- (c) $u_g = 0.5$ and $u_d = 1$: the solutions are a continuous solution of the second type, and a discontinuous solution of the third type. Both numerical schemes capture the unique continuous solution of the second type.
- (d) $u_g = 1$ and $u_d = -1.5$: the solutions are a continuous solution of the first, second or third type, and a discontinuous solution of the first type. Both numerical schemes capture the continuous solution of the second type.

Test 3. A particular configuration where only two discontinuous solutions are admissible.

(a) $u_g = -0.6, u_d = -0.2$

(b) $u_g = -0.2, u_d = -0.6$

(c) $u_g = 0.5, u_d = 1$

(d) $u_g = 1, u_d = -1.5$

Figure 15: Convex fluxes. 1000 pts. $t = 0.2$

The flux functions f_L and f_R are defined from the derivatives f'_L and f'_R given by

$$f'_L(u) = (u+1)\left(u + \frac{1}{10}\right)(u-1),$$

$$f'_R(u) = -\left(u + \frac{1}{2}\right)\left(u - \frac{2}{5}\right)\left(u - \frac{3}{2}\right).$$

The sonic points are thus $u_L^- = -1$, $u_L^0 = -1/10$ and $u_L^+ = 1$ for the left flux f_L and $u_R^- = -1/2$, $u_R^0 = 2/5$ and $u_R^+ = 3/2$ for the right flux f_R . The Riemann initial data is such that $u_g = -1.25$ and $u_d = 1.75$. This configuration is such that $u_g \notin \tilde{\mathcal{F}}_R^+(u_d)$, $u_d \notin \tilde{\mathcal{F}}_L^-(u_g)$. Moreover the set $\tilde{\mathcal{F}}_L^-(u_g) \cap \tilde{\mathcal{F}}_R^+(u_d)$ is empty and therefore there is no continuous solution. Fig. 16 represents both fluxes

and in bold-face the sets $\tilde{\mathcal{F}}_R^+(u_d)$ and $\tilde{\mathcal{F}}_L^-(u_g)$.
The proposed coupled Riemann problem admits only discontinuous solutions,

Figure 16: A case where $u_g \notin \tilde{\mathcal{F}}_R^+(u_d)$, $u_d \notin \tilde{\mathcal{F}}_L^-(u_g)$, and $\tilde{\mathcal{F}}_R^+(u_d) \cap \tilde{\mathcal{F}}_L^-(u_g) = \emptyset$.

each one of the third type. More precisely, they are

- (a) a L-wave (whose speed is nonpositive) connecting u_g to u_L^+ , followed by a R-wave (whose speed is nonnegative) connecting u_R^+ to u_d ,
- (b) a L-wave (whose speed is nonpositive) connecting u_g to u_L^- , followed by a R-wave (whose speed is nonnegative) connecting u_R^- to u_d .

Numerical solutions are presented on Fig. 17. We observe that the Godunov scheme captures the solution (b), while the relaxation scheme captures the solution (a).

Figure 17: Multiple disc. solutions. 10000 pts. $u_L = -1.25$, $u_R = 1.75$, $t = 1.5$

Test 4. A particular configuration where several discontinuous solutions are admissible, and continuous solutions also exist.

Here again, both fluxes are obtained from the derivatives given by

$$f'_L(u) = (u+1)\left(u + \frac{1}{2}\right)(u-1),$$

$$f'_R(u) = -\left(u - \frac{5}{4}\right)\left(u - \frac{3}{4}\right)\left(u + \frac{3}{4}\right).$$

We take $u_g = -1.5$ and $u_d = 1.75$ so that $u_g \notin \tilde{\mathcal{F}}_R^+(u_d)$, $u_d \notin \tilde{\mathcal{F}}_L^-(u_g)$, but the set $\tilde{\mathcal{F}}_L^-(u_g) \cap \tilde{\mathcal{F}}_R^+(u_d)$ is not empty. Fig. 18 represents both fluxes and in bold-face the sets $\tilde{\mathcal{F}}_R^+(u_d)$ and $\tilde{\mathcal{F}}_L^-(u_g)$.

We can see that both numerical schemes capture the same continuous solution.

Figure 18: A case where $u_g \notin \tilde{\mathcal{F}}_R^+(u_d)$, $u_d \notin \tilde{\mathcal{F}}_L^-(u_g)$, and $\tilde{\mathcal{F}}_R^+(u_d) \cap \tilde{\mathcal{F}}_L^-(u_g) \neq \emptyset$.

Figure 19: Multiple disc. solutions. 10000 pts. $t = 0.5$. $u_L = -1.5$, $u_R = 1.75$.

Test 5. The coupling of two conservation laws “with phase change”

The rest of this section is devoted to the coupling of two scalar conservation

laws “with phase change”. We consider the following fluxes

$$f_L(u) = \begin{cases} -\frac{u^2-1}{2}, & u < -1, \\ 0, & -1 \leq u \leq 1, \\ \frac{u^2-1}{2}, & u > 1, \end{cases} \quad f_R(u) = f_L(u - 1/2) - 1,$$

that are represented on Fig. 20. The numerical solutions are shown on Fig.21

Figure 20: Scalar flux for the coupling “with phase change”.

for both relaxation and Godunov schemes and these match with the expected theoretical results. They correspond to the solution for the right-problem, that consists here in a shock transition wave connecting the left-state of the Riemann problem to the point of C^1 -discontinuity ($u = 3/2$), a constant part and finally a rarefaction wave to the right-state.

Figure 21: Phase change. 1000 pts. $u_L = -1.5$, $u_R = 2.0$, $t = 0.3$.
