Polymorphic Functions with Set-Theoretic Types

Part 2: Local Type Inference and Type Reconstruction

Abstract. This article is the second part of a two articles series about the definition of higher-order polymorphic functions in a type system with recursive types and set-theoretic type connectives (unions, intersections, and negations).

In the first part, presented in a companion paper, we defined and studied the syntax, semantics, and evaluation of the explicitly-typed version of a calculus, in which type instantiation is driven by explicit instantiation annotations. In this second part we present a local type inference system that allows the programmer to omit explicit instantiation annotations for function applications, and a type reconstruction system that allows the programmer to omit explicit type annotations for function definitions.

Categories and Subject Descriptors D.3.3 [Programming Languages]: Language Constructs and Features—Polymorphism

Keywords Types, XML, intersection types, type constraints.

1. Introduction

Many XML processing languages, such as XDuce, CDuce, XQuery, OcamlDuce, XHaskell, XAct, are statically-typed functional languages. However, none of them provides full-fledged parametric polymorphism even though this feature has been repeatedly requested in different standardization groups. A major stumbling block to such an extension — i.e., the definition of a subtyping relation for regular tree types with type variables — was lifted by Castagna and Xu [4]. In Part 1 of this work, presented in the previous edition of POPL [3], we described how to take full advantage of Castagna and Xu’s system by defining a calculus with higher-order polymorphic functions and recursive types with union, intersection, and negation connectives. The approach is general and goes well beyond the sole application to XML processing languages. As a matter of fact, the motivating example we gave in Part 1 [3] does not involve XML, but looks like a rather classic display of functional programming specimens:

map :: (α -> β) -> [α] -> [β]
map f l = case l of
  | [] -> []
  | (x : xs) -> (f x : map f xs)

even :: (Int -> Bool) ∧ ((γ\Int) -> (γ\Int)) ∧ ((γ\Int) -> [(γ\Int)\Bool])

since map even returns a function that when applied to a list of integers it returns a list of Booleans; when applied to a list that does not contain any integer, it returns a list of the same type (actually, the same list); and when it is applied to a list that may contain some integers (e.g., a list of reals), then it returns a list of the same type, without the integers but with some Booleans instead (in the case of reals, a list with Booleans and reals that are not integers).

Typing map even is difficult because it demands to infer several different instantiations1 of the type of map and then take their intersection. This is why the calculus in [3] includes explicit type substitutions: the programmer must explicitly provide the type-substitutions used to instantiate the types of the terms that form an application, a requirement that makes the system of [3] not usable in practice, yet. In this paper we remove this limitation by defining a sound and complete inference system that deduces the type substitutions that a programmer should insert in a program of [3] to make it type well-typed. In other words, we define “local

1For map even we need to infer just two instantiations, namely, \{(γ\Int)\_α, (γ\Int)\_β\} and \{(γ\Int)\_α, (γ\Int) \lor \ Bool\_β\}. The type in (1) is redundant since the first type of the intersection is an instance (eg, for γ=Int) of the third. We included it just for the sake of the presentation.
type inference\footnote{There are different definitions for local type inference. Here we use it with the meaning of finding the type of an expression in which not all type annotations are specified. This is the acceptation used in Scala where, like in C# and Java, type parameters for polymorphic/generic method calls can be omitted. In our specific problem, we will omit—and, thus, infer—the annotations that specify how the types of a function and of its argument can be made compatible. As explained in Section \ref{sec:ex} it is more general than Pierce and Turner’s local type inference for arguments types \cite{Pierce2007}.} for \cite{Castagna2014}, namely, we solve the problem of checking whether there exist some type-substitutions that make the types of a function and of its arguments compatible and, if so, of inferring the type of the application as we did for (1). In particular, we show that local type inference for \cite{Castagna2014} reduces to the problem of finding two sets of type substitutions \( \{ \sigma_i \mid i \in I \} \) and \( \{ \sigma'_j \mid j \in J \} \) such that for two given types \( s \) and \( t \) the relation \( \bigwedge_{i \in I} s \sigma_i \leq \bigwedge_{i \in I} s \sigma'_i \) holds, and we give a sound and complete algorithm for this problem. We also show how the same algorithm can be used to perform type reconstruction and infer types more precise than those inferred by the type systems of the ML family. All detailed proofs and complete definitions can be found in the Appendix. The system is fully implemented and, at the moment of writing, in alpha-test. It will be distributed in the next public release of the CDuce language \cite{CDuce}. In the meanwhile, the current version can be tested by compiling the master branch of the CDuce git repository: git clone https://git.cduce.org/cduce (we recommend to check the bugtracker for current issues).

Next section outlines the various problems to be faced in this research and succinctly describes the system of \cite{Castagna2014}. The reader acquainted with the work in \cite{Castagna2014} can skip directly to Section \ref{sec:ex}.

2. Overview

The aim of this research is the definition an XML processing functional language with high-order polymorphic functions, that is, in the specific, a polymorphic version of the language CDuce \cite{CDuce}. CDuce is a strongly-typed programming language that eases the manipulation of data in XML format. Issued from academic research it is used in production, available on different platforms, and included in all major Linux distributions. The essence of CDuce is a λ-calculus with parametrically explicitly-typed recursive functions and a type-case expression. Its types can be recursively defined and include basic, arrow, and product type constructors and the intersection, union, and negation type connectives. In this work we omit for brevity recursive functions and product types constructors and expressions (our results can be easily extended to them as sketched in Section \ref{sec:ex} and detailed in the appendices) and add type variables. So in the rest of this work we study a calculus whose types and expressions are described by the next two following definitions.

Definition 2.1 (Types). Types are the regular languages coinductively generated by the following productions:

\[
t ::=b \mid t \rightarrow t \mid t \land t \mid t \lor t \mid \neg t \mid 0 \mid 1 \mid \alpha
\]

and such that every infinite branch contains infinitely many occurrences of \(\neg\rightarrow\) constructor. We use \(\mathcal{T}\) to denote the set of all types.

In the definition, \(b\) ranges over basic types (eg, \texttt{Int}, \texttt{Bool}), \(\alpha\) ranges over type variables, and \(0\) and \(1\) respectively denote the empty (that types no value) and top (that types all values) types. Coinduction accounts for recursive types and the condition on infinite branches bars out ill-formed types such as \(t \rightarrow t \lor t\) (which does not carry any information about the set denoted by the type) or \(t \neg t\) (which cannot represent any set). It also ensures that the binary relation \(\triangleright\subseteq \mathcal{T}^2\) defined by \(t_1 \triangleright t_2 \triangleright t_3 \triangleright t_1 \land t_2 \triangleright t_4 \triangleright t_6 \triangleright \cdots\) is Noetherian. This gives an induction principle on \(\mathcal{T}\) that we will use without any further explicit reference to the relation. We use \(\var{t}\) to denote the set of type variables occurring in a type \(t\).

A type \(t\) is said to be ground or closed if and only if \(\var{t}\) is empty. The subtyping relation for these types is the one defined by Castagna and Xu \cite{Castagna2003}. For this work it suffices to consider that ground types are interpreted as sets of values (ie, either constants or \(\lambda\)-abstractions) that have that type, and that subtyping is set containment (a ground type \(s\) is a subtype of a ground type \(t\) if and only if \(t\) contains all the values of type \(s\)). In particular, \(\rightarrow\) contains all \(\lambda\)-abstractions that when applied to a value of type \(s\), if the computation terminates, then they return a result of type \(t\) (eg, \(0 \rightarrow 1\) is the set of all functions\footnote{Actually, for every type \(t\), all types of the form \(0 \rightarrow t\) are equivalent and each of them denotes the set of all functions.} and \(1 \rightarrow t\) is the set of functions that diverge on every argument). Type connectives (ie, union, intersection, negation) are interpreted as the corresponding set-theoretic operators (eg, \(s \lor t\) is the union of the values of the two types). For what concerns non-ground types (ie, types with variables occurring in them) all the reader needs to know for this work is that the subtyping relation of Castagna and Xu is preserved by substitution of the type variables. Namely, if \(s \leq t\), then \(\sigma \leq \tau\lor\sigma\) for every type-substitution \(\sigma\) (the converse does not hold in general, while it holds for semantic type-substitutions in convex models: see \cite{Hislop1991}). Two types are equivalent if they are subtype one of each other (type equivalence is denoted by \(\equiv\)). Finally, notice that in this system \(s \leq t\) if and only if \(s \wedge \neg t \leq 0\).

Definition 2.2 (Expressions). Expressions are the terms inductively generated by the following grammar:

\[
e ::= c \mid x \mid e \mid \lambda^{\alpha}(e_1 \rightarrow_{\sigma_1} e_1 . e_2) \mid e_1 ? : e_2
\]

and such that in every expression \(e_1 ? : e_2\) \(e_1\) the type is closed.

In the definition, \(c\) ranges over constants (eg, \texttt{true, false, 1, 2, ...}) which are values of basic types (we use \(b\) to denote the basic type of the constant \(c\); \(x\) ranges over expression variables; \(e_1 ? : e_2\) denotes the type-case expression that evaluates either \(e_1\) or \(e_2\) according to whether the value returned by \(e\) (if any) is of type \(t\) or not; \(\lambda^{\alpha}(e_1 \rightarrow_{\sigma_1} e_1 . e_2)\) is a value of type \(\lambda^{\alpha}(e_1 \rightarrow_{\sigma_1} e_1 . e_2)\) and denotes the function of parameter \(x\) and body \(e\). An expression has an intersection type if and only if it has all the types that compose the intersection. Therefore, intuitively, \(\lambda^{\alpha}(e_1 \rightarrow_{\sigma_1} e_1 . e_2)\) is a well-typed value if for all \(i \in I\) the hypothesis that \(x\) is of type \(s_i\) implies that the body \(e\) has type \(t_i\), that is to say, it is well typed if \(\lambda^{\alpha}(e_1 \rightarrow_{\sigma_1} e_1 . e_2)\) has type \(s_i \rightarrow t_i\) for all \(i \in I\).

As we said at the beginning of the section, the functional core of CDuce \cite{CDuce} has exactly the same types and expressions as the above except for two single differences: (i) its types do not contain type variables and (ii) it includes product types and recursive functions, which we omitted here for brevity. The reasons why in CDuce (and in its polymorphic extension we study here) there is a type-case expressions and why \(\lambda\)-expressions are explicitly annotated by their type-case expressions are explained in details in the companion paper that presents the first part of this work \cite{Castagna2014} and to which the reader can refer. The novelty of this research with respect to CDuce, thus, is to allow type variables to occur in the types that annotate \(\lambda\)-abstractions. It becomes thus possible to define the polymorphic identity function as \(\lambda^{\alpha}(\alpha \rightarrow t).x.x\), while the classic "auto-application" term is written as \(\lambda^{\alpha}(\alpha \rightarrow \alpha \rightarrow \alpha \rightarrow t).x.x.x\). The intended meaning of using a type variable, such as \(\alpha\), is that a (well-typed) \(\lambda\)-abstraction not only has the type specified in its label (and by subsumption all its super-types) but also all types obtained by instantiating the type variables occurring in its label. So \(\lambda^{\alpha}(\alpha \rightarrow t).x.x\) has not only type \(\alpha \rightarrow t\) but by subsumption also, for instance, the types \(\alpha \rightarrow \alpha\) (the type of all functions, which is a super-type of \(\alpha \rightarrow \alpha\)) and \(\alpha\) (the type of all non integer values), and by instantiation the types \(\alpha \rightarrow \alpha \rightarrow \alpha\) (\texttt{Int}→\texttt{Int}→\texttt{Bool}→\texttt{Bool}, etc. The addition of type variables and instantiation makes the calculus a full-fledged intersection...
which does not have explicit type-substitutions and, of type-substitutions, and sets must be explicitly propagated. That is, to apply annotation, thus any type-substitution of variables of an annotation type-case: we check the type of a function by checking its type explicitly-

expressions (to produce a particular expansion/instantiation of the body of a function since this may yield ill-typed terms. For instance, applied (relabeling is thus lazy). However, the new annotation is at the moment of the reduction, only if and when the function is instantiated as follows:

first "lazily" instantiate it as follows:

ular instance whose type is the one in the "interface" (to implement the lazy relabeling of the function body). This yields a calculus whose syntax is

e := c | x | e e | \text{for} \sigma | e e | e e | e e | e e

(7) where types are those in Definition 2.1 and with the restriction that the type tested in type-case expressions is closed. We call this calculus and its expressions the explicitly-typed calculus and expressions, respectively, in order to differentiate it from the one of Definition 2.2 which does not have explicit type-substitutions and, therefore, is called the implicitly-typed calculus.

Henceforth, given a \lambda-abstraction \lambda^\alpha \rightarrow x. x.e we call the type \lambda^\alpha \rightarrow x. x.e the interface of the function and the set of type-substitutions \sigma_j \in J the decoration of the function. We write \lambda^\alpha \rightarrow x. x.e for short when the decoration is a singleton containing just the empty substitution. We use \nu to range over values, that is, either constants or \lambda-abstractions. Let \e be an expression: we use \nu (e) and \nu (e) respectively to denote the sets of free expression variables and bound expression variables of the expression \e; we use \nu (e) to denote the set of type variables occurring in \e.

As customary, we assume bound expression variables to be pairwise distinct and distinct from any free expression variable occurring in the expressions under consideration. Polymorphic variables can be bound by interfaces, but also by decorations: for example, in \lambda^\alpha \rightarrow x. x.(x (\nu (e)) (x (\nu (e)) \e)), the \alpha occurring in the interface of the inner abstraction is "bound" by the decoration \nu (e), and the whole expression is \alpha-equivalent to \nu (e). If \nu (e) is a type variable bound by an outer abstraction, it cannot be instantiated; such a type variable is called monomorphic. We assume that polymorphic type variables are pairwise distinct and distinct from any monomorphic type variable in the expressions under consideration. In particular, when substituting a value \nu for a variable \nu in an expression \nu, we suppose the polymorphic type variables of \nu to be distinct from the monomorphic and polymorphic type variables of \nu thus avoiding unwanted capture.

Both static and dynamic semantics for the explicitly-typed expressions in (7) are defined in [3] in terms of a relabeling operation "\@\text{renaming}" which takes an expression \e and a set of type-substitutions \sigma_j \in J and pushes \sigma_j \in J down to all outermost \lambda-abstractions occurring in \e (and collects and composes with the sets of type-substitutions it meets). Precisely, \e \@ (\sigma_j) \in J is defined for \lambda-abstractions and applications of type-substitutions as

(\lambda^\alpha \rightarrow xy \rightarrow \e) \@ (\sigma_j) \in J \quad \equiv \quad \lambda^\alpha \rightarrow xy \rightarrow (e \circ (\sigma_j) \in J \in K) \e

(where \circ denotes the pairwise composition of all substitutions of the two sets). It erases the set of type-substitutions when \e is either a variable or a constant, and it is homomorphically applied on the remaining expressions (see [3] for comprehensive definitions). The dynamic semantics is given by the following notions of reduction (where \nu denotes a value), applied by a leftmost-outmost strategy:

\e (\sigma_j) \in J \quad \Rightarrow \quad \e \@ (\sigma_j) \in J

(8)

\lambda^\alpha \rightarrow xy \rightarrow (e \circ (\sigma_j) \in J \in K) \e \nu \quad \Rightarrow \quad (e \circ (\sigma_j) \in J \in K) \nu (\e) \nu (\sigma_j)

(9)

\nu \ni t \quad \nu \ni \e \quad \nu \ni \e \quad \nu \ni \e \quad \nu \ni \e \quad \nu \ni \e

\nu \ni t \quad \nu \ni \e

\nu \ni \e

\nu \ni \e

\nu \ni \e

\nu \ni \e

where in (9) we have P \ni (j \in J) \exists \nu \ni t \nu \ni \e.

The first rule (8) performs relabeling, that is, it propagates the sets of type-substitutions down into the decorations of the outermost \lambda-abstractions. The second rule (9) states the semantics of applications: this is standard call-by-value \beta-reduction, with the difference that the substitution of the argument for the parameter is performed on the relabeled body of the function. Notice that rela-
beings depends on the type of the argument and keeps only those type-substitutions that make the type of the argument match (at least one of) the input types defined in the interface of the function (ie, the set P which contains all substitutions σj such that the argument ν has type tiσj for some i in I: the type system statically ensures that P will never be empty). For instance, take the dafny identity function (4), instantiate it as in (6) by both Int and Bool, and apply it to 42 — ie, (λν∈I.x(ν→y.x)42),— then it reduces to (λν∈Int.x(ν→y.42)42), (which is observationally equivalent to (λν∈Int.y.42)42) since the reduction discards the {Bool|λ} substitution. Finally, the third rule (10) checks whether the value returned by the expression in the type-case matches the specified type and selects the branch accordingly.

The static semantics is given by the rules in Figure 1 which form an algorithmic system (as stressed by the subscripts in t ⇒j and by the names of the rules): in every case at most one rule applies, either because of the syntax of the term or because of mutually exclusive side conditions. We invite the reader to consult [3] for more details (there the reader will also find a non-algorithmic — and far more readable — system defined in terms of subsumption).

Here we just comment the rules interesting for this second part, that is, (ALG-ABSTR), (ALG-INST), and (ALG-APPL). First of all notice the presence of Δ in judgments. This is the set of monomorphic type variables, that is, the variables that occur in the type of some outer λ-abstraction and, as such, cannot be instantiated; this set must contain all the type variables occurring in Δ. Rule (ALG-ABSTR) checks that ν∈I.x(ν→y.x) has the type declared by (the combination of) its interface and its decoration, that is, ν∈I.x(ν→y.x) has the type obtained by applying the single type-substitution σj under consideration (ie, e(0[σj])), has a (sub)type of the corresponding output type.

Rule (ALG-INST) gives for e(σj)∈J the type obtained by applying the set of type-substitutions to the type of e, provided that the type-substitutions do not instantiate monomorphic variables (ie, for all j∈J, dom(σj) ∩ Δ = ⊘, noted as σj, Δ).

Rule (ALG-APPL) for applications checks that the type t of the function is a functional type (ie, t ≤ 0→1). Then it checks that the type of the argument is a subtype of the domain of t (denoted by dom(t)). Finally, it infers for the application the type t · s min{u | t ≤ s→u}, that is, the smallest result type that can be obtained by subsuming t to an arrow type with domain s.\(^4\)

\(^4\) For every type t such that t ≤ 0→1 and type s such that s ≤ dom(t), the type t · s exists and can be effectively computed.

The type system is sound (it satisfies both subject reduction and progress), it subsumes existing intersection type systems, and type inference is decidable. Furthermore the calculus can be compiled into an intermediate language which executes relabelling only by need and, thus, can be efficiently evaluated (again, see Part 1 [3]).

Before proceeding we stress again that in this calculus type-substitutions and, thus, instantiation are explicit: (λν∈I.x) has type Int→Int, but (λν∈I.x) does not (contrary to ML, the semantic subtyping relation ≤ does not account for instantiation).

\[\Delta \Gamma \vdash e : t\]
\[\Delta \Gamma \vdash x : \Gamma(x)\]
\[\Delta \Gamma \vdash e[σj]_{j∈J} : \bigwedge_{j∈J} \text{ts}_{j}\Delta\]
\[\Delta \Gamma \vdash e(σj)_{j∈J} : \bigwedge_{j∈J} \text{ts}_{j}\Delta\]

Figure 1. Typing algorithm

2.1 Overview and contributions of this article (Part 2)

Recall that we want the programmer to use the implicitly-typed expressions of grammar (3), and not those of grammar (7) which would require the programmer to write explicit type-substitutions. Therefore in Section 3 we define a local type inference system that, given an implicitly-typed expression produced by the grammar (3), checks whether and where some sets of type-substitutions can be inserted in this expression so as to make it a well-typed explicitly-typed expression of grammar (7). Thus, our local type inference consists of a type-substitution reconstruction system, insofar as it has to reconstruct the sets of type-substitutions that make an expression of grammar (3) a well-typed expression of grammar (7). In order to avoid ambiguity we reserve the word “reconstruction” for the problem of reconstructing type annotations (in particular, function interfaces) and speak of inference of type-substitutions for the problem of local type inference. In particular, we show that this problem can be reduced to the problem of deciding whether for two types s and t there exist two sets of type-substitutions [σj]∈I and [σj]∈J such that s[σj]∈I ≤ t[σj]∈J. We prove that when the cardinalities of I and J are given, the problem above is decidable and reduces to the problem of finding all substitutions σ such that s ≤ t′ for any given types s and t′. We dub this latter problem the tallying problem. We show how to produce a sound and complete set of solutions for the latter problem. This is done by generating sets of constraint-sets that are then normalized, merged, and solved. The solution of the tallying problem immediately yields a semi-decision procedure (that tries all the cardinalities for I, J) for the local type inference system. Henceforth, to enhance readability, we will systematically use the metavariable “α” to denote expressions of the implicitly-typed calculus (ie, those of grammar (3)) and reserve the metavariable “c” for expressions of the explicitly-typed calculus (ie, those of grammar (7)). Finally, in Section 4 we show that the theory and algorithms developed in Section 3 can be reused to do ML-like type reconstruction, that is, to infer the interface of unannotated λ-expressions in a pure λ-calculus with type-case.

In summary, the results of this paper make it possible to program in the implicitly-typed calculus (3), by compiling it into well-typed explicitly-typed expressions (7) defined in [3]. Let us show the details on the motivating example of the introduction. First, note
that in the implicitly-typed calculus (3) even can be defined as
\[
\lambda^{[\text{Int} \rightarrow \text{Bool}]} x . x \in \text{Int} \land (x \mod 2) = 0 : x
\] (11)
(where \(s/t\) is syntactic sugar for \(s \land t\)) while — with the products and recursive function definitions given in the appendix— map is
\[
\mu_{\mu}^{(\alpha \rightarrow \beta) 
\rightarrow (\alpha \rightarrow \beta)} f = 
\lambda^{(\alpha \rightarrow \beta)} \ell \cdot \text{ecnil?nil : f}(\ell(\pi t), mf(\pi x))
\] (12)
where the type nil tested in the type case denotes the singleton type that contains just the constant nil, and \(\alpha\) denotes the regular type that is the least solution of \(X = (\alpha \land \forall \gamma X) \lor \text{nil}\).

If we feed these two expressions to the type-checker (the rules in Figure 1 suffice since no local type inference is needed to type these two functions) it confirms that both are well typed and have the types declared in their interfaces. To apply (the expression (12) defining) map to (the expression (11) defining) even we need to instantiate map, that is, to perform local type inference. The type inference system of Section 3 infers the following set of type-checks (we subscripted the turnstile symbol by suffice since no local type inference is needed to type 1 and seeing that whenever a subtyping relation

\[

\text{Contributions:} & \\
& \text{The overall contribution of this work (Parts 1 and 2) is the definition of a statically-typed calculus with polymorphic higher-order functions in a type system with recursive types and union, intersection, and negation type connectives, and local type inference. The technical contributions of this Part 2 are:} \\
& \text{– the definition of an algorithm that for any pair of polymorphic regular tree types } t_1 \text{ and } t_2 \text{ produces a sound and complete set of solutions to the problem of deciding whether there exists a type-substitution } \sigma \text{ such that } t_1 \sigma \leq t_2 \sigma. \text{ This is obtained by using the set-theoretic interpretation of types to reduce the problem to a unification problem on regular tree types.} \\
& \text{– the definition of a type-substitution inference system sound and complete w.r.t. the system of the explicitly-typed calculus of (3).} \\
& \text{– the definition of a sound and complete algorithm for local type inference for the calculus. The algorithm yields a semi-decision procedure for the typeability of a } \lambda \text{-calculus with intersection and recursive types and with explicitly-typed } \lambda \text{-abstractions.} \\
& \text{– the definition of a type reconstruction algorithm that uses the machinery developed for local type inference and improves reconstruction defined for ML languages.} \\
& \text{We also provide two different implementations: a prototype implementation of the calculi presented here and the polymorphic extension of the compiler of CDuce, a production-grade language.} \\
\end{align*}
\]
the rules for constants and variables (omitted: they are the same as in Figure 1). Of particular interest is the rule (INF-ABSTR) which has become simpler than in Figure 1 since it works under the hypothesis that λ-abstractions have empty decorations, which uses the Δ ∪ Δ' set to compare the types of the body with the result types specified in the interface (s'_i ⊑ Δ ∪ Δ' // s_i) Notice that we do not require the sets of type-substitutions that make s'_i ⊑ Δ ∪ Δ' // s_i satisfied to be the same for all i ∈ I: this is not a problem since the case of different sets of type-substitutions corresponds to using their union as sets of type-substitutions (ie, to intersecting them point-wise: see Definition B.9 and Corollary B.12 — henceforth, references starting with letters refer to appendixes).

It still remains the most delicate rule, (INF-APPL), the one for application. It is difficult because not only it must find two distinct sets of type-substitutions (one for the function type the other for the argument type) but also because the set of type-substitutions for the function type must enforce two distinct constraints: the type resulting from applying the set of type-substitutions to the type of the function must be a subtype of 0 → t, and its domain must be compatible with (ie, a supertype of) the type inferred for the argument. In order to solve all these constraints we collapse them into a single definition which is the algorithmic counterpart of the set of types used in Section 2 to define the operation t · s occurring in the rule (ALG-APPL). Precisely, we define t • Δ s as the set of types for which there exist two sets of type-substitutions (for variables not in Δ) that make s compatible with the domain of t:

\[
\text{t • Δ s = } \{ u | \begin{array}{l}
| \sigma_j \rangle \in \Delta \implies t \subseteq \Delta \implies 0 \rightarrow t \\
| \sigma_j \rangle \in \Delta \implies s \subseteq \Delta \land \text{dom}(t[\sigma_j \rangle \in J) \\
\text{u = } t[\sigma_j \rangle \in J \cdot s[\sigma_i \rangle \in I
\end{array}\}
\]

In practice, this set takes all the pairs of sets of type-substitutions that make t a function type, and s an argument type compatible with t and collects all the possible result types. This set is closed by intersection (see Lemma B.8) which is an important property since it ensures that if we find two distinct solutions to type an application, then we can also use their intersection. Unfortunately, this property is not enough to ensure that this set has a minimum type (for that we also need to prove that the intersection of all the types in the set can be expressed as a finite intersection) which would imply the existence of a principal type (which is still an open problem). For the application of a function of type t to an argument of type s, the inference system deduces every type in t • Δ s. This yields the inference rule (INF-APPL) of Figure 2.

These type-substitution inference rules are sound and complete with respect to the typing algorithm, modulo the restriction that all the decorations in the λ-abstractions are empty. Both of these properties are stated in terms of the erase(.) function that maps expressions of the explicitly-typed calculus into expressions of the implicitly-typed one by erasing in the former all occurrences of sets of type-substitutions.

**Theorem 3.2 (Soundness of inference).** Let a be an implicitly-typed expression. If Δ ∪ Δ' ⊢ a : t, then there exists an explicitly-typed expression e such that erase(e) = a and Δ ∪ Δ' ⊢ e : t.

The proof of the soundness property is constructive: it builds along the derivation for the implicitly-typed expressions a an explicitly-typed expression e that satisfies the statement of the theorem; this expression is the one that is then compiled in the intermediate language we defined in Part I [3] and evaluated. Notice that ⊑Δ gauges the generality of the solutions found by the inference system: the smaller the type found, the more general the solution is. As a matter of fact, adding to the system in Figure 2 a subsumption rule that uses the relation ⊑Δ that is:

\[
\text{(SUBSUMPTION)} \quad \Delta \vdash a : t_1 \quad t_1 \subseteq \Delta t_2 \quad \Delta \vdash a : t_2
\]

is sound. This means that the set of solutions is upward closed with respect to ⊑Δ and that from smaller solutions it is possible (by such a subsumption rule) to deduce the larger ones. In that respect, the completeness theorem that follows states that the inference system can always deduce for the erasure of an expression a solution that is at least as good as the one deduced for that expression by the type system for the explicitly-typed calculus.

**Theorem 3.3 (Completeness of inference).** Let e be an (explicitly-typed) expression in which all decorations are empty. If Δ ∪ Δ' ⊢ e : t, then there exists a type t' such that Δ ∪ Δ' ⊢ erase(e) : t' and t' ⊑ Δ t.

The inference system is syntax directed and describes an algorithm that is parametric in the decision procedures for ⊑Δ and • Δ. The problem of deciding these two relations is tackled next.

### 3.2 Type Tallying

We define the tallying problem as follows.

**Definition 3.4 (Tallying problem).** Let C be a constraint-set, that is, a finite set of pairs of types (these pairs are called constraints), and Δ a finite set of type variables. A type-substitution σ is a solution for the tallying problem of C and Δ (noted σ ⊑Δ C) if σ ⊑Δ and for all (s, t) ∈ C, σs ≤ τt holds.

Thus a constraint-set corresponds to the logical conjunction of the constraints that compose it, and the tallying problem searches for a type-substitution that satisfies this conjunction. The definition of the tallying problem is the cornerstone of our type-substitution inference system, since every problem we have to solve to “implement” the rules of Figure 2 is reduced to different instances of this problem.

With the exception of (INF-APPL), it is not difficult to show that the “implementation” of the rules of the type-substitution inference system ⊢Δ corresponds to finding and solving a particular tallying problem. First, notice that for the remaining rules the problem we have to solve is to prove (or disprove) the relation s ⊑Δ t for given s and t. By definition this corresponds to finding a set of n type-substitutions |σ_i|≤n such that ∑_i≤n σ_i ≤ t. We can split each type-substitution σ_i in two: a renaming type-substitution ρ_i that maps each variable of s not in Δ into a fresh type variable, and a type substitution σ'_i such that σ_i = σ'_i ◦ ρ_i. Thus the inequation becomes ∑_i≤n (σ'_i ◦ ρ_i) ≤ t. The domains of σ'_i are...
by construction pairwise disjoint (they are formed of distinct fresh variables) and disjoint from the variables in \( t \); thus we can merge them into a single substitution \( \sigma = \bigcup_{i \in I} \sigma_i \) and apply it to \( t \) with no effect, yielding the inequation \( \bigwedge_{i \in I} \sigma_i \leq \sigma \). Let \( u_n = \bigwedge_{i \leq n} s_{\rho_{ij}} \), we have just transformed the problem of proving the relation \( s \subseteq \Delta \) into the problem of finding an \( n \) for which there exists a solution to the tallying problem for \( \{ u_n \leq t \} \) and \( \Delta \). The way to proceed to find \( n \) is explained in Section 3.2.3.

The (INF-APPL) rule deserves a special treatment since it needs to solve a more difficult problem. A “solution” for the (INF-APPL) rule problem is a pair of sets of type-substitutions \( [\sigma_i]_{i \leq I}, [\sigma_j]_{j \leq J} \) for variables not in \( \Delta \) such that both \( \bigwedge_{i \leq I} \sigma_i \leq 0 \to t \) and \( \bigwedge_{j \leq J} \sigma_j \leq \text{dom}(\bigwedge_{i \leq I} \sigma_i) \) hold. In this section we give an algorithm that produces a set of solutions for the (INF-APPL) rule problem that is sound (it finds only correct solutions) and complete (any other solution can be derived from those returned by the algorithm). To this end we proceed in three steps: (i) given a tallying problem, we show how to effectively produce a finite set of solutions that is sound (it contains only correct solutions) and complete (every other solution of the problem is less general—in the usual sense of unification, i.e., it is larger wrt \( \subseteq \) than some solution in the set); (ii) we show that if we fix the cardinalities of \( I \) and \( J \), then it is possible to reduce the (INF-APPL) rule problem to a tallying problem; (iii) from this we deduce a sound and complete algorithm to semi-decide the general (INF-APPL) rule problem and thus the whole inference system.

We solve each problem in one of the next subsections, but before we recall an important property of semantic subtyping systems [4, 12] which states that every type is equivalent to (and can be effectively transformed into) a type in disjunctive normal form, that is, a union of \( \text{uniform} \) intersections of \( \text{liters} \). A literal is either an arrow, or a basic type, or a type variable, or a negation thereof. An intersection is uniform if it is composed of literals with the same constructor, that is, either it is an intersection of arrows, type variables, and their negations or it is an intersection of basic types, type variables, and their negations. In summary, a disjunctive normal form is a union of summands of which form is either

\[
\bigwedge_{p \in P} b_p \land \bigwedge_{n \in N} \neg b_n \land \bigwedge_{q \in P'} \neg \alpha_q \land \bigwedge_{r \in N'} \neg \alpha_r
\]

or

\[
\bigwedge_{p \in P} (s_{p \to t_p}) \land \bigwedge_{n \in N} (s_n \to t_n) \land \bigwedge_{q \in P'} \alpha_q \land \bigwedge_{r \in N'} \alpha_r
\]

When either \( P' \) or \( N' \) is non empty, we call the variables \( \alpha_q's \) and \( \alpha_r's \) the top-level variables of the normal form.

### 3.2.1 Solution of the tallying problem.

In order to solve the tallying problem for given \( \Delta \) and \( C \), we first fix some total order \( \preceq \) —any will do— on the type variables occurring in \( C \) and not in \( \Delta \) (from now on, when speaking of type variables we will mean type variables not in \( \Delta \)), order that will be used to ensure that all inferred types satisfy the contractivity condition of Definition 2.1. Next, we produce sets of constraint-sets (as a single constraint-set corresponds to logical conjunction, so a set of constraint-sets corresponds to disjunction of the corresponding conjunctions) in a particular form by proceeding in four steps: first, we **normalize** the constraint-sets (so that at least one of the two types of every constraint is a type variable); second, we merge constraints that are on the same variables; third, we **solve** all these constraint-sets by producing soluble sets of equations equivalent to the original problem and then solving these equations; fourth, we combine these three steps into an **algorithm** that produces a sound and complete set of solutions of the tallying problem. To this end we define two operations on sets of constraint-sets:

**Definition 3.5.** Let \( \mathcal{A}_1, \mathcal{A}_2 \subseteq \mathcal{P}(\mathcal{F} \times \mathcal{F}) \) be two sets of constraint-sets. We define

\[
\mathcal{A}_1 \cap \mathcal{A}_2 \equiv \{ C_1 \cup C_2 : C_1 \in \mathcal{A}_1, C_2 \in \mathcal{A}_2 \}
\]

\[
\mathcal{A}_1 \cup \mathcal{A}_2 \equiv \mathcal{A}_1 \cup \mathcal{A}_2
\]

By convention the empty set of constraint-sets is unsolvable (it denotes failure in finding a solution), while the set containing the empty set is always satisfied.

We also define an auxiliary function single that singles out a given top-level variable of a normal form. More precisely, given a type \( t \) which is a summand of a normal form, that is, \( t = \bigwedge_{p \in P} b_p \land \bigwedge_{n \in N} \neg b_n \land \bigwedge_{q \in P'} \neg \alpha_q \land \bigwedge_{r \in N'} \neg \alpha_r \), and \( k \in P' \cup N' \), we define single\((\alpha_k, t)\) as the constraint equivalent to \( t \leq 0 \), in which \( \alpha_k \) is “singled-out”, that is,

\[
\bigwedge_{p \in P} b_p \land \bigwedge_{n \in N} \neg b_n \land \bigwedge_{q \in P'} \neg \alpha_q \land \bigwedge_{r \in N'} \neg \alpha_r \land \neg \alpha_k
\]

when \( k \) is not in \( N' \) and

\[
\bigwedge_{p \in P} b_p \land \bigwedge_{n \in N} \neg b_n \land \bigwedge_{q \in P'} \neg \alpha_q \land \bigwedge_{r \in N'} \neg \alpha_r \land \alpha_k
\]

when \( k \) is in \( P' \). Henceforth, to enhance readability we will often write \( s \leq t \) for the constraint \( (s, t) \), as we did above.

**Example.** We will show the various phases of the process by solving the tallying problem for the following constraint-set:

\[
C = \{ (\alpha \to \text{Bool}, \beta \to \beta), (\text{Int}\lor\text{Bool} \to \text{Int}, \alpha \to \beta) \}
\]

and assume that \( \alpha \preceq \beta \).

**1. Constraint normalization.** We define a function norm that takes a type \( t \) and generates a set of normalized constraint-sets —ie, constraint-sets formed by constraints whose form is either \( \alpha \leq s \) or \( s \leq \alpha \) — whose set of solutions is sound and complete w.r.t. the constraint \( t \leq 0 \). This function is parametric in a set \( M \) of visited types (needed to handle coinduction) and the algorithm to compute it is given in Figure 3. If the input type \( t \) is not in normal form, then the algorithm is applied to the disjunctive normal form \( t' \) of \( t \) (end of line 6). Since a union is empty if and only if every summand that is empty, then the algorithm generates a new constraint-set for the problem that equates all the summands of a normal form to 0 (beginning of line 6). If a summand contains a top-level variable, then the smallest (wrt \( \preceq \)) top-level variable is singled out (line 2). If there is no top-level variable and there are only basic types, then the algorithm checks

\[\text{Equivalence of } t \leq 0 \text{ and the two following constraints is easily derived from the De Morgan’s laws and the property } t_1 \leq t_2 \iff t_1 \land \neg t_2 \leq 0.\]
the constraint by calling the subtyping algorithm and, accordingly, it returns either the unsatisfiable set of constraint-sets (∅) or the one that is always satisfied ( ⋃ α ) (line 3). Finally, if there are only intersections of arrows and their negations, then the problem is decomposed into a set of subproblems by using the decomposition rule of the subtyping algorithm for semantic subtyping (see [12] for details), after having added t to the set M of visited types. The regularity of types ensures that the algorithm always terminates (see Lemma C.14). Notice that, in line 2 the algorithm always singles out the smallest variable. Therefore, by construction, if norm generates a constraint ( α , t ) or ( t , α ), then every variable smaller than or equal to α may occur in t only under an arrow (equivalently, every top-level variable of t is strictly larger than α).

**Remark 3.1.** There is the special case of ( α , t ) or ( t , α ) in which t is itself a variable. In that case we give priority to the smallest variable and consider the larger variable a bound for the lower one but not vice-versa. This point will be important for merge.

A constraint-set in which all constraints satisfy this property is said to be well ordered (cf. Definition C.16).

**Example (Cont’d).** The function norm works on single constraints (actually, on a type t representing the constraint t ≤ 0), so let us apply it on the first constraint of the example. We want to normalize the constraint α → Bool ≤ β → β, and thus we apply norm to the type ( α → Bool ) ∧ ¬ ( β → 3 ). Now, this constraint has two distinct solutions: either ( i ) β is the empty set, in which case the larger type becomes 0 → 0 that is the type of all functions (see Footnote 3) which contains every arrow type, in particular α → Bool, or ( ii ) the types satisfy the usual covariant-contravariant rule for arrows, that is, β ≤ α and Bool ≤ β.

Since there are two distinct solutions, then norm generates a set of two constraint-sets. Precisely norm( ( α → Bool ) ∧ ¬ ( β → 3 ) ) returns { { α → Bool , β → 3 } } . Both constraint-sets are normalized and are computed by Line 5 in Figure 3: the first constraint-set is computed by the rightmost recursive call of norm (notice that P' = ∅ since it ranges over the strict subsets of P which, in this case, is a singleton—so it requires s, n, e, to be empty), while the second constraint-set is obtained by the union of the first two recursive calls (which require s, n ≤ s, t, p ≤ t). In consequence, the application of merge to the first set leaves it unchanged. Merge on the second one returns an empty set of constraint-sets since at the second step it tries to solve Int ≤ 0. The same happens for the third since it first adds β ≤ 0 and at the recursive call tries to solve Bool ≤ 0. The fourth one is more interesting: in step 1 it replaces (Bool, β) and (Int, β) by (Int, Bool) and at the second step adds (Int, Bool) obtained from (β, α) and (α, Int, Bool) (it also checks (Int, Bool, Int, Bool) which is always satisfied). So after merge we have { { α , ( β , 3 ) } , { β , ( α , Int, Bool ) , ( Int, Bool, β ) , ( β , Int, Bool ) } } . Notice that we did not merge ( α , ( β , 3 ) ) and ( β , Int, Bool) into ( β , ( α , Int, Bool ) ) since α ≤ β, then α is not considered an upper bound of β (see Remark 3.1) and thanks to the following constraint-set is well ordered.

**3. Constraint solving.** norm and merge yield a set in which every constraint-set is of the form C = { s ≤ α ≤ t | i ∈ I } where α, are pairwise distinct variables and s and t, are respectively 0 or 1 whenever the corresponding constraint is absent. If there is a constraint on two variables, then again priority is given to the smaller variable. For instance, if α ≤ β, then { ( α , β ) } will be considered to represent { (0 ≤ α ≤ β) , (0 ≤ β ≤ 1) } . Thanks to this assumption the system so obtained is well ordered, that is, for every constraint s ≤ α ≤ t in it, the top-level variables of s and t are strictly larger than α. Notice that in doing this we do not lose any information: the bounds for larger variables are still recorded in those of smaller ones and any bound for larger variables obtained by transitivity on the smaller variables is already in the system by step 2 of merge.
The last step is to solve this constraint-set, that is, to transform it into a solvable set of equations that then we solve by a Unify algorithm that exploits the particular form of the equations obtained from a well-ordered constraint-set. Let $C$ be a well-ordered constraint-set of the above form; we define $\text{solve}(C)$ as follows:

$$\text{solve}(C) = \{ \alpha = (s \lor \beta) \land t \mid (s \leq \alpha \leq t) \in C, \beta \text{ fresh} \}$$

The function $\text{solve}(C)$ takes every constraint $s \leq \alpha \leq t$ in $C$ and replaces it by $\alpha = (s \lor \beta) \land t$ (with $\beta$ fresh). It is clear that the constraint-set $C$ has a solution for every possible assignment of $\alpha$ included between $s$ and $t$ if and only if the new constraint-set has a solution for every possible (unconstrained) assignment of $\beta$. At the end, the constraint-set $\{ s_i \leq \alpha \leq t_i \mid i \in I \}$ has become a set of equations of the form $\{ \alpha_i = u_i \mid i \in I \}$ where the $\alpha_i$’s are pairwise distinct. By construction, this set of equations has the property that every variable that is smaller than or equal to (wrt $\leq$) $\alpha_i$ may occur in $u_i$ only under an arrow (as for constraint-sets we say that the set of equations is well ordered). This last property ensures the correctness of the equation defining the smallest type variable. By Courcelle [7] (and Lemma C.44) there exists a solution of this set, namely, a substitution from the type variables $\alpha_1, \ldots, \alpha_n$ into (possibly recursive regular) types $t_1, \ldots, t_n$ whose variables are contained in the fresh $\beta_i$’s variables introduced by solve (all universally quantified, ie. no upper or lower bound) and the type variables in $\Delta$. This solution is given by the following Unify procedure in which we use $\mu$-notation to denote regular types and where $E$ is a well-ordered set of equations.

$$\text{Unify}(E) =$$

if $E = \emptyset$ then return $\{ \}$ else
- select in $E$ the equation $\alpha = t_a$ for the smallest $\alpha$ (wrt $\leq$)
- let $E'$ be the set of equations obtained by replacing in $E \setminus \{ \alpha = t_a \}$ every occurrence of $\alpha$ by $\mu X. (t_a (X / \alpha))$ ($X$ fresh)
- let $\sigma = \text{Unify}(E')$ in return $\{ \alpha = (\mu X. t_a (X / \alpha)) \land \beta \}$

Thanks to the well-ordering of $E$, Unify generates a set of solutions in which all types satisfy the contractivity condition on infinite branches of Definition 2.1. It solves the (contractive) recursive equation of the smallest variable $\alpha$ defined by $E$ (if $\alpha$ does not occur in $t_a$, then the $\mu$-abstraction can be omitted), replaces this solution in the remaining equations, solves this set of equations, and applies the solution so found to the solution of $\alpha$ so as to solve the other variables occurring in its definition.

4. The complete algorithm. The algorithm to solve the tallying problem for $C$ and variables not in $\Delta$, then, proceeds in three steps:

Step 1. Let $\mathcal{N} = \prod_{\varsigma \in \mathcal{C}} \text{norm}(\varsigma \land t, \emptyset)$ if $\mathcal{N} = \emptyset$ then fail else proceed to the next step.

Step 2. Let $\mathcal{M} = \bigcup_{\varsigma \in \mathcal{C}} \text{merge}(C, \emptyset)$. If $\mathcal{M} = \emptyset$ then fail else proceed to the next step.

Step 3. Let $\mathcal{F} = \bigcup_{\varsigma \in \mathcal{C}} \text{solve}(C)$. Return $\{ \text{Unify}(E) \mid E \in \mathcal{F} \}$.

Let $\text{Sol}_\Delta(C)$ denote the set of all substitutions obtained by the previous algorithm. They form a sound and complete set of solutions for the tallying problem:

**Theorem 3.6** (Soundness and completeness),

$$\sigma \in \text{Sol}_\Delta(C) \Rightarrow \sigma \vdash_\Delta C$$

$$\sigma \vdash_\Delta C \Rightarrow \exists \sigma' \in \text{Sol}_\Delta(C), \sigma'' , s.t. \sigma \approx \sigma'' \circ \sigma'$$

where $\approx$ means that the two substitutions map the same variable into equivalent types. Regularity of types ensures the termination of the algorithm and, hence, the decidability of the tallying problem (the proof of these properties combines proofs of soundness, completeness, and termination of each step: see Appendix C).

**Example (End).** After Step 1 and 2 our initial tallying problem $\{ (\alpha \rightarrow \text{Bool}, \beta \rightarrow \beta) , \{ \text{Int} \rightarrow \text{Bool} \rightarrow \text{Int}, \alpha \rightarrow \beta \} \}$ has become $\{ (\alpha, 0), (\beta, 0) \}, \{ (\beta, \alpha), (\alpha, \text{Int} \rightarrow \text{Bool}), (\beta, \text{Int} \rightarrow \text{Bool}), (\delta, \text{Int} \rightarrow \text{Bool}) \}$. Let us apply Step 3. The first constraint-set is trivial and it is easy to see that it yields the solution $\{ \{ \alpha, 0 \}, \{ \beta, 0 \} \}$. The second constraint-set is $\{ (\beta, 0) \in \text{Int} \rightarrow \text{Bool} \}$. We apply solve to the constraints for $\alpha$ obtaining $\{ \alpha = (\gamma \lor \beta) \land (\text{Int} \rightarrow \text{Bool}) \}$. We find the solution for $\beta$ (no need to substitute $\alpha$ since it does not occur in the constraints for $\beta$) which is $\{ \beta = \text{Int} \rightarrow \text{Bool} \}$. We replace $\beta$ in the solution of $\alpha$ obtaining $\{ \alpha = (\gamma \lor \text{Int} \rightarrow \text{Bool}) \land (\text{Int} \rightarrow \text{Bool}) \}$. The solution for this second constraint-set is then $\{ \text{Int} \rightarrow \text{Bool} / \alpha, \text{Int} \rightarrow \text{Bool} / \beta \}$, which with $\{ \alpha, 0, \beta, 0 \}$ forms a sound and complete set of solutions for our initial tallying problem.

Finally, solve introduces several fresh polymorphic variables which can be cleaned up after that the substitutions have been applied to obtain the types deduced by inference system: all variables that occur only in covariant (resp. contravariant) position in a type, can be replaced by 0 (resp. 1). This is what we implicitly did in our example to solve $\beta$ and eliminate $\gamma$ from the constraint of $\alpha$.

3.2.2 Solution for application with fixed cardinalities

It remains to solve the problem for the (INF-APPL) rule. We recall that given two types $s$ and $t$, a solution for this problem is a pair of sets of type-substitutions $\{ \sigma_i \mid i \in I \}, \{ \sigma_j \mid j \in J \}$ for variables not in $\Delta$ that make both of these two inequalities

$$\bigwedge_{i \in I} t_{\sigma_i} \leq 0 \rightarrow \text{Int} \quad \bigwedge_{j \in J} \sigma_j \leq \text{dom}(\bigwedge_{i \in I} t_{\sigma_i}) \quad (15)$$

hold. Two complications are to be dealt with: (i) we must find sets of type substitutions, rather than a single substitution as in the tallying problem and (ii) we have to get rid of the dom() function. If $I$ and $J$ have fixed cardinalities, then both difficulties can be easily surmounted and the whole problem is reduced to a tallying problem. To see how, consider the two inequations in (15). Since the two sets of substitutions are independent, then without loss of generality we can split each substitution $\sigma_k$ (for $k \in I \cup J$) in two substitutions: a renaming substitution $\rho_k$ that maps each variable in the domain of $\sigma_k$ into a different fresh variable, and a second substitution $\sigma_k'$ defined such that $\sigma_k = \sigma_k' \circ \rho_k$. The two inequations thus become $\bigwedge_{k \in I} (t_k (p_i)) \sigma_k' \leq 0 \rightarrow \text{Int}$ and $\bigwedge_{k \in J} (s_k (p_j)) \sigma_k' \leq \text{dom}(\bigwedge_{k \in I} (t_k (p_i)) \sigma_k')$. Since the variables $\rho_k$ (for $k \in I \cup J$) have disjoint domains, then we can take their union to get a single substitution $\sigma = \bigcup_{k \in I \cup J} \rho_k$, and the two inequations respectively become $\bigwedge_{k \in I \cup J} (t_k (p_i)) \sigma_k' \leq 0 \rightarrow \text{Int}$ and $\bigwedge_{k \in J} (s_k (p_j)) \sigma_k' \leq \text{dom}(\bigwedge_{k \in I \cup J} \rho_k)$. Now if we fix the cardinalities of $I$ and $J$ since the $p_k$ are generic renamings, we have just transformed the problem in (15) into the problem of finding for two given types $t_1$ and $t_2$ all substitutions $\sigma$ such that

$$t_1 \sigma \leq 0 \rightarrow \text{Int} \quad \text{and} \quad t_2 \sigma \leq \text{dom}(t_1 \sigma) \quad (16)$$

hold. Finally, we can prove (see Lemmas C.49 and C.50) that a type-substitution $\sigma$ solves (16) if and only if it solves

$$t_1 \sigma \leq 0 \rightarrow \text{Int} \quad \text{and} \quad t_2 \sigma \leq (t_2 \rightarrow \gamma) \sigma \quad (17)$$

with $\gamma$ fresh. We transformed the application problem (with fixed cardinalities) into the tallying problem for $\{(t_1, 0 \rightarrow 1), (t_2, t_2 \rightarrow \gamma)\}$, whose set of solutions is a sound and complete set of solutions for the (INF-APPL) rule problem when $I$ and $J$ have fixed cardinalities.

3.2.3 Solution of the application problem

The algorithm to solve the general problem for the (INF-APPL) rule explores all the possible combinations of the cardinalities of $I$

\footnote{Precisely, we have $t_1 = \bigwedge_{h \in 0, 1} t_1^h$ and $t_2 = \bigwedge_{h \in 0, 1} t_2^h$ where for $h = 1, 2$ each $t_i^h$ is obtained from $t_i$ by renaming the variables not in $\Delta$ into fresh variables.}
and \( J \) by, say, a dove-tail order. More precisely, we start with both \( I \) and \( J \) at cardinality 1 and:

**Step A:** Generate the constraint-set \( \left\{(t_1, t_2 \rightarrow \gamma)\right\} \) as explained in Subsection 3.2.2 (the constraint \( t_1 \leq \gamma \rightarrow t_2 \) is implied by this one since \( 0 \rightarrow \) contains every arrow type) and apply the tallying algorithm described in Subsection 3.2.1, yielding either a solution (a substitution for variables not in \( \Delta \)) or a failure.

**Step B:** If all the constraint-sets failed at Step 1 of the algorithm of Subsection 3.2.1, then fail (the expression is not typeable). If they all failed but at least one did not fail in Step 1, then increase the cardinalities of \( I \) and \( J \) to their successor in the dove-tail order and start from Step A again. Otherwise all substitutions found by the algorithm are solutions of the application problem.

Notice that the algorithm returns a failure only if all the constraint-sets fail at Step 1 of the algorithm for the tallying problem. The reason is that up to Step 1 all the constraints at issue are on distinct occurrences of type variables: if they fail, there is no possible expansion that can make the constraint-set satisfiable. In Step 2, instead, constraints of different occurrences of some variable are merged. Thus even if the constraints fail, it may be the case that they will be satisfied by expanding different occurrences of some variable into different variables. Therefore an expansion is tried. Solving the problem for \( s \subseteq a \ t \) is similar (there is just one set whose cardinality has to be increased at each step instead of two).

This constitutes a sound and complete semi-decision procedure for the application problem and, thus, for the type-substitution inference system (Theorem C.54). We defined some heuristics (omitted for space reasons: see Section C.2.3) to stop the algorithm when a solution seems unlikely. Whether these (or some coarser) halting conditions preserve completeness, that is, whether type-substitutions inference is decidable, is an open problem. We believe the system to be decidable. However, we fail to prove it when the type of the argument of an application is a union: its expansion distributes the union over the intersections thus generating new combinations of types. It comes as no surprise that the definitions of our heuristics are based on the cardinalities and depths of the unions occurring in the argument type.

Let us apply the algorithm to \( map \ even \). We start with the constraint set \( \left\{ (\alpha_1 \rightarrow \beta_1) \rightarrow \left[ \alpha_1 \rightarrow \beta_1 \right] \right\} \leq t \rightarrow \gamma \) where \( t = [\text{Int} \rightarrow \text{Bool}] \wedge (\alpha \rightarrow \text{Int} - \alpha) \rightarrow \) \( \text{Int} \) is the type of \( \text{even} \) (we just re-named the variables of the type of map). After Step A the algorithm generates a set of nine constraint-sets (see Section 10.2.2 of [25] for more details on this example): one is unsatisfiable since it contains the constraint \( t \leq 0 \) (an intersection of arrows is never empty since it always contains \( 1 \rightarrow 0 \) the type of the diverging functions); four of these are less general than some other (their solutions are included in the solutions of the other) and the remaining four are obtained by adding the constraint \( \gamma \geq (\alpha_1) \rightarrow \left[ \beta_1 \right] \) respectively to \( \{ \alpha_1 \leq 0 \} , \{ \alpha_1 \leq \text{Int} \rightarrow \text{Bool} \leq \beta_1 \} , \{ \alpha_1 \leq \alpha \rightarrow \text{Int} \rightarrow \alpha \rightarrow \text{Int} \} \rightarrow \text{Bool} \leq \beta_1 \} , \{ \alpha_1 \leq \alpha \rightarrow \text{Int} \rightarrow \alpha \rightarrow \text{Int} \} \rightarrow \text{Bool} \leq \beta_1 \} , \{ \alpha_1 \leq \alpha \rightarrow \text{Int} \rightarrow \alpha \rightarrow \text{Int} \} \rightarrow \text{Bool} \leq \beta_1 \} \), yielding the following four solutions for \( \gamma : \{ \gamma = [\text{Int} \rightarrow \text{Bool}] \} , \{ \gamma = \text{true} \rightarrow \} \rightarrow \}, \{ \gamma = \text{false} \rightarrow \} \rightarrow \}, \{ \gamma = \text{false} \rightarrow \} \rightarrow \}, \) of these solutions only the last two are minimal. Since both are valid we could stop here and take their intersection, yielding the type expected in the introduction. If instead we strictly follow the algorithm, then we have to perform a further iteration, expand the type of the function, yielding \( \{(\alpha_1 \rightarrow \beta_1) \rightarrow \left[ \alpha_1 \rightarrow \beta_1 \right] \wedge ((\alpha_2 \rightarrow \beta_2) \rightarrow \left[ \alpha_2 \rightarrow \beta_2 \right]) \leq t \rightarrow \gamma \} \) for which the minimal solution is, as expected:

\( \{ \gamma = \text{false} \rightarrow \} \rightarrow \}, \{ \gamma = \text{false} \rightarrow \} \rightarrow \} \rightarrow \} \rightarrow \} \rightarrow \}

A final remark on completeness. The theorem states that for every solution of the inference problem, our algorithm finds a solution that is more general. However this solution is not necessary the first one found by the algorithm: even if we find a solution, continuing with a further expansion may yield a more general solution. We have just seen that in the case of \( \text{map} \ even \) the good solution is the second one, although this solution could already have been deduced by intersecting the first minimal solutions we found. A simple example that shows that carrying on after a first solution may yield a better solution is the application of a function of type \( (\alpha \times \beta) \rightarrow (\beta \times \alpha) \) to an argument of type \( (\text{Int} \times \text{Bool}) \lor (\text{Bool} \times \text{Int}) \). For this applications our algorithm (extended with product types) returns after one iteration the type \( (\text{Int} \lor \text{Bool}) \times (\text{Int} \lor \text{Bool}) \) (since it unifies \( \alpha \) with \( \beta \)) while one further iteration would deduce the more precise type \( (\text{Int} \lor \text{Bool}) \lor (\text{Bool} \lor \text{Int}) \). Of course this raises the problem of the existence of principal types (notice that the type \( t \) in the statement of Theorem 3.3 is not unique): may an infinite sequence of increasingly general solutions exist? This is a problem we did not tackle in this work, but if the answer to the previous question were negative, then it would be easy to prove the existence of a principal type: since at each iteration there are only finitely many solutions, then the principal type would be the intersection of the minimal solutions of the last iteration.

Finally, notice that we did not give any reduction semantics for the implicitly-typed calculus. The reason is that its semantics is defined in terms of the semantics of the explicitly-typed calculus: the relabeling at run-time is an essential feature — independently from the fact that we started from an explicitly-typed expression or not — and we cannot avoid it. If we denote by \( erase^{-1}(a) \) the set of expressions \( e \) that satisfy the statement of Theorem 3.2, then the (big-step) semantics for an implicitly-typed expression \( a \) is given in terms of \( erase^{-1}(a) \): if an expression in \( erase^{-1}(a) \) reduces to \( v \), so does \( a \). As we see the result of computing an implicitly-typed expression is a value of the explicitly-typed calculus (so \( \lambda \)-abstractions may contain non-empty decorations) and this is unavoidable since it may be the result of a partial application (this can be made transparent for the programmer by returning just the type and the "value" \( \langle \text{fun} \rangle \) as in OCaml's toplevel). Also notice that the semantics is not univocally determined since different expressions in \( erase^{-1}(a) \) may yield different results. However this may happen only in one particular case, namely, when an occurrence of a polymorphic function flows into a type-case and its type is tested. For instance the application \( (\lambda [\text{Int} \rightarrow \text{Int}] \rightarrow \text{Bool}) f . f (\text{Bool} \rightarrow \text{Bool}) \text{true} : \text{false} \) \( (\alpha \rightarrow \alpha \rightarrow \alpha \times x) \) results into \( \text{true} \) or \( \text{false} \) according to whether the polymorphic identity at the argument is instantiated by \( [\text{Int} \rightarrow] \) or by \( [\text{Int} \rightarrow], [\text{Bool} \rightarrow] \). Once more this is unavoidable in a calculus that can dynamically test the types of polymorphic functions that admit several sound instantiations. This does not happen in practice since the inference algorithm always choose one particular instantiation (the existence of principal types would make this choice canonical and remove any residual latitude). So in practice the semantics is deterministic but implementation dependent.

In summary, programming in the implicitly-typed calculus corresponds to programming in the explicitly-typed one with the difference that we delegate to the system the task to write type-substitutions for us and with the caveat that by doing that we make the dynamic test of the type of a polymorphic function to be implementation dependent. Of course, forbidding the dynamic test of the type of polymorphic functions (or of functions \( \text{tout court} \) make this problem disappear (and yields much a simpler implementation).

### 3.3 Examples and experiments

We developed two implementations (see the last page of the appendix for download instructions), a complete but non-optimized prototype with products and arrow type constructors, and an extension of the full CDuce language which is highly optimized (types are stored in hash-consed binary decision trees to avoid the cost of normalization, pattern-matching has optimal implementation, static
In this section we show examples of the latter, that is of
analyzes to minimize the impact of polymorphism and
so on). In this section we show examples of the latter, that is of
CDuce syntax extended with type variables.3 In this extension map
has type \((\alpha \to \beta) \to (\alpha \to \beta)\) since in CDuce sequence types
are denoted by brackets whose content is described by a
regular expression on types. Functions are explicitly typed and thus must
be specified both their input and output types

```ocaml
let pretty (x: Int): String = string_of x
```

The type returned for the partial application `map even` is then
\(((\alpha \to \beta) \to (\alpha \to \beta))\to(\alpha \to \beta)\to(\alpha \to \beta)\))
 knapsack of distinct type variables, our inference algorithm also
deduces the special case \(\beta \to \beta\) because \(\alpha \to \beta\) and \(\alpha \to \alpha\) cannot, from any practical point of view, be distin-
guished seems a nice feature of our system. Nevertheless notice that
the same type deduction as for \(\alpha\) would have happened if in the
definition of `churchtrue` we had used \(\alpha\) instead of \(\beta\); in that case
\(\text{churchtrue} \, 42\, "3"\) would have been typed by the (less precise)
union type \(42\, |\, "3"\), too. Thus, in order to achieve precise typing, it is
important to use distinct type variables for distinct parameters.

Finally, we said in the introduction that the typing of `even`
follows a pattern that is common in programming functional data
structures. This can be seen by examining Okasaki's implementa-
tion of red-black trees [19]. These are balanced binary search
trees whose nodes are colored either in black or in red and such
that every red node has two (possibly empty) black children; a red
node with a red child is a "wrong" tree. Insertions must keep the
tree balanced and the key definition is a function balance which
transforms every "unbalanced" tree — i.e., a black-rooted tree with a
"wrong" child — into a red-rooted tree, and leaves all other trees
unchanged. Okasaki gives a very compact and elegant definition of
\textit{balance} consisting of a pattern matching with two cases (for a
union and for a capture variable), but current type systems are not
esspressive enough to verify that his code, without any modification,
satisfies color invariants. Our types, instead, can do it as follows:

```
let balance ( Unbal -> Rtree ; ( [ Rtree Rtree ] | [ ] ) ) -> ( [ Rtree Rtree ] | [ ] )
```

The only (irrelevant) difference of this definition with Okasaki's
definition of `balance` is that we used CDuce's syntax for trees, that is,
XML elements tagged by their color, with an attribute elem for their content,
and that define subsequences of two sub-trees.

The type of `balance` (which has the same form as the type of `even`)
precisely describes the behavior of the function and this type
information is enough to prove that the insertion function has type
\(\alpha \to \beta\). This is that, when it inserts an \(\alpha\)-element into a
well-formed black-rooted red-black it returns another well-formed
black-rooted red-black tree (see Appendix A for the complete code
and how to run it on the development version of CDuce).

Transposing the results and algorithms of this paper, to full-
fledged CDuce was not easy. Adapting the internal representation of
types and its algorithms is challenging (to give an idea of such
a challenge, consider that a simple type variable is internally rep-
resented as a hash-cased union of 7 binary decision diagrams each
intersecting the top type of a type constructor) and so are type pretty
printing and error message generation. For what is specific to this
work, the main challenge is not only to extend the typing rules of
Figure 2 to missing data structures and expressions (XML trees,
general pattern matching, products, ...), but, above all, to modify the
rules so that they return expressions decorated with sets of explicit
type substitutions. Also the various internal languages used by the
compiler must be modified (the CDuce compiler performs several
passes that translate each intermediate language into a lower level
one) and each transformation phase must be enriched with specific
static analyses to optimize the evaluation of polymorphic expres-

\footnote{Following the OCaml convention, in the concrete syntax type variables
start by a quote. To enhance readability here we pretty print them by Greek
letters and so write \(\alpha\) -> \(\beta\) rather than 'a' -> 'b.'}

3Have written. However, in a system with polymorphic union types a
more meaningful type for \(\max\) is \(\alpha \to \beta \to \max\); if we specify such a
type for \(\max\), then the type deduced for the partial application
\(\max\, 42\) is, more intuitively, \(\beta \to \beta\). The fact that \(\alpha \to \beta \to \max\) \(\beta\)
and \(\alpha \to \alpha \to \max\) cannot, from any practical point of view, be distin-
guished seems a nice feature of our system. Nevertheless notice that
the same type deduction as for \(\max\) would have happened if in the
definition of `churchtrue` we had used \(\alpha\) instead of \(\beta\); in that case
\(\text{churchtrue} \, 42\, "3"\) would have been typed by the (less precise)
union type \(42\, |\, "3"\), too. Thus, in order to achieve precise typing, it is
important to use distinct type variables for distinct parameters.

Finally, we said in the introduction that the typing of `even`
follows a pattern that is common in programming functional data
structures. This can be seen by examining Okasaki's implementa-
tion of red-black trees [19]. These are balanced binary search
trees whose nodes are colored either in black or in red and such
that every red node has two (possibly empty) black children; a red
node with a red child is a "wrong" tree. Insertions must keep the
tree balanced and the key definition is a function balance which
transforms every "unbalanced" tree — i.e., a black-rooted tree with a
"wrong" child — into a red-rooted tree, and leaves all other trees
unchanged. Okasaki gives a very compact and elegant definition of
\textit{balance} consisting of a pattern matching with two cases (for a
union and for a capture variable), but current type systems are not
esspressive enough to verify that his code, without any modification,
satisfies color invariants. Our types, instead, can do it as follows:

```
let balance ( Unbal -> Rtree ; ( [ Rtree Rtree ] | [ ] ) ) -> ( [ Rtree Rtree ] | [ ] )
```

The only (irrelevant) difference of this definition with Okasaki's
definition of `balance` is that we used CDuce's syntax for trees, that is,
XML elements tagged by their color, with an attribute elem for their content,
and that define subsequences of two sub-trees.

The type of `balance` (which has the same form as the type of `even`)
precisely describes the behavior of the function and this type
information is enough to prove that the insertion function has type
\(\alpha \to \beta\). This is that, when it inserts an \(\alpha\)-element into a
well-formed black-rooted red-black it returns another well-formed
black-rooted red-black tree (see Appendix A for the complete code
and how to run it on the development version of CDuce).

Transposing the results and algorithms of this paper, to full-
fledged CDuce was not easy. Adapting the internal representation of
types and its algorithms is challenging (to give an idea of such
a challenge, consider that a simple type variable is internally rep-
resented as a hash-cased union of 7 binary decision diagrams each
intersecting the top type of a type constructor) and so are type pretty
printing and error message generation. For what is specific to this
work, the main challenge is not only to extend the typing rules of
Figure 2 to missing data structures and expressions (XML trees,
general pattern matching, products, ...), but, above all, to modify the
rules so that they return expressions decorated with sets of explicit
type substitutions. Also the various internal languages used by the
compiler must be modified (the CDuce compiler performs several
passes that translate each intermediate language into a lower level
one) and each transformation phase must be enriched with specific
static analyses to optimize the evaluation of polymorphic expres-
sions. Finally, the propagation of type substitutions must be lazily implemented for all constructed values (ie, pairs and XML documents). The main modifications are summarized in Appendix E.

For what concerns performances, the results of some preliminary experiments are reported in Appendix F. In summary, we generated a test suite of 1 859 applications of higher-order polymorphic functions by taking all the 43 functions exported by the List module of OCaml, and cross applying one to each other. Whenever a given function can be applied (ie, the application type-checks in OCaml) to two other functions, then we applied it to their intersection and their union; whenever two functions can be applied to the same function then we applied their union and their intersection to it; and so on so forth up to a maximum of 15 top-level connectives. We also tested all applications resulting ill-typed in OCaml, so as to check cases in which local type-inference may fail. The results are significant and encouraging. The test suite was defined to maximize the possible exponential blow up (which is essentially due to the presence of arrows and intersections that may trigger multiple expansions). The combinations of the functions of the List module cover a wide range of use cases and involve recursive types (specifically, polymorphic lists), and the limit of 15 connectives on arrows more than doubles what we ever met in practice. To type check the 1 859 applications on an average laptop took 27 secs with an average time for application of 14ms and 2.1ms of median time. This means that apart from few pathological cases (which took a couple of seconds) our implementation performs local type inference within acceptable delays. We also verified that our implementation smoothly handles the application of curried functions to 20 arguments (cf., OCaml standard library whose functions have at most 5 arguments). Furthermore, the room for improvement is still important. Our implementation uses the highly-optimized data-structures of CDuce types and aggressive memoization, however normalization and constraint generation are implemented as described in this paper. In particular, as in Line 5 in Figure 3, normalization performs a full expansion. By modifying the algorithms so that, like in the subtyping algorithm, normalization and constraint generation are performed lazily, we hope to improve performance by an order of magnitude.

4. Type reconstruction

The theory of type tallying we developed in Section 3 can be reused to perform type reconstruction, that is, to assign a type to functions whose interface is not specified. The idea is to type the body of a function under the hypothesis that the function has the generic type \( \alpha \rightarrow \beta \) and deduce the corresponding constraints. Formally, we consider expressions produced by the following grammar:

\[
m ::= c \mid x \mid m \cdot m \mid \lambda x.m \mid m \in t? m : m
\]

together with the judgment \( \Gamma \vdash_{\text{R}} m : t \rightsquigarrow \mathcal{S} \) that states that under the typing environment \( \Gamma \), \( m \) has type \( t \) under the constraints in \( \mathcal{S} \), provided that \( \mathcal{S} \) is satisfiable (the turnstile subscript \( \Box \) indicates that this is a type Reconstruction system). These judgments are derived by the rules in Figure 4. These are quite standard apart from the fact that they derive multiple constraint-sets, rather than just one. This is due to the type reconstruction rule for type-cases, which explores four possible alternatives (\( \beta_0 \) diverges, it can match only the first, the second, or both cases). In this system the type of a well-typed expression is a type and a set of type-substitutions (ie, the set of all substitutions that are solutions of the satisfiable constraint-sets in \( \mathcal{S} \)) and thus it is an intersection type obtained by applying this set of type-substitutions to the type.

The soundness of this system is a consequence of the results on the type-substitution inference of the previous sections. As a matter of facts, this system is precisely the same system as the one in the previous sections with the only difference that all interfaces are of the form \( \alpha \rightarrow \beta \) and, to compensate that, we infer type-substitutions in decorations (we also used a different and more standard presentation to stress constraint generation). Of course, completeness does not hold: far from that. For instance, it is impossible, in general, to deduce for a function without type annotations the type \( \Pi \rightarrow \emptyset \) — the type of all diverging functions—since this would correspond to decide the halting problem (though our algorithm returns for \( \mu f.x = f(x) \) the same type as in ML, that is, \( \alpha \rightarrow \beta \). Likewise, completeness would imply decidability of reconstruction and thus imply decidability for intersection type systems, which are undecidable.

Similarly, our reconstruction system cannot type the paradoxical functions we pointed out in the first part of this work (see Section 2 in [3]). However, if a function can be typed in ML-like type systems, then our type reconstruction rules can deduce a type at least as good as the ML one. Indeed, if we restrict our attention to the first four rules, the system produces a singleton set of constraints that is the same as in ML system (cf. [21]) and when constraint-sets are not circular (ie, their solution does not require recursive types), then our constraint solving algorithm coincides with unification (all fresh variables introduced by solve are simplified as we described at the end of Section 3.2.1 and solve directly produces a set of equations that are, in Martelli and Montanari’s terminology [17], in solved form). Furthermore, since the types considered here are much richer than in ML (since they include unions, intersections, and negations), then our reconstruction may infer slightly better types. Type connectives alone bring, in particular, two advantages for type reconstruction: (i) the system deduces sets of type-substitutions (and thus deduces intersection types) and (ii) pattern matching (which can be seen as a type-case with singleton types) is typed more precisely (thanks in particular to intersections and negations).

For instance, and contrary to ML, our type reconstruction can type auto-application \( \lambda x.xx \) for which it returns the recursive type \( t = \mu X.(\alpha \rightarrow (X \rightarrow \beta)) \rightarrow \beta \). This type is a subtype of —thus, it is more precise than—the classic (non-recursive) typing of auto-application in intersection type systems \( t \leq (\alpha \land (\alpha \rightarrow \beta)) \rightarrow \beta \) (though it is not as precise as its subtype \( \mu X.((\alpha \lor (X \rightarrow \beta)) \rightarrow \beta \) which can also type auto-application). As a final example, if we apply our type reconstruction algorithm (extended with products and recursive functions) to the type erasure of the map function defined in equation (12), then we obtain the type (in CDuce’s syntax) \( \{ (\alpha \rightarrow \beta) \rightarrow [\alpha \rightarrow \beta] \} \land [(0 \rightarrow \beta) \rightarrow \emptyset] \) (see the complete unfolding of the algorithm in Appendix D). Thanks to the precise typing of the type-case, our type is slightly more accurate than the ML type, since it states that the application of map to any function and the empty list returns the empty list.

Finally, the “type” returned by the type reconstruction algorithm is not always very readable and often needs to be simplified. For instance, the type we showed for map was obtained after apply-
ing some simplifications —one of which was done by hand—, and defining an algorithm that does the right simplifications is not obvious (eg, how to detect that the type \((a \land \alpha \to \beta) \to \beta\) is much more readable than the type \(\mu X. (a \land (X \to \beta)) \to \beta\) as reconstructed for auto-application by our algorithm?). The simplification of types (or of type constraints) is a stand alone research topic that deserves further investigation. Nevertheless our reconstruction algorithm can already be used as is, to make type declaration of local functions optional. Indeed for local functions the system is not required to return a “readable” type to the programmer, but just to check whether there exists a typing for local functions that is compatible with their usage; and, for that, our system is enough, even though we will probably have to couple it with bidirectional typing techniques [9] to provide informative error messages when the check fails.

5. Extensions

In this presentation we omitted two key features; pairs and recursive functions. Recursive functions do not pose any particular problem in the inference of type-substitutions and are dealt with in a standard way, while pairs are more challenging. The rule for pairs in inference system \(\Gamma \vdash x : \tau\) is the same as in the explicitly-typed calculus (this corresponds to disregarding sets of type-substitutions applied inside a pair, as they can equivalently be inferred outside the pair: \(t_1 \neq 0 \land (t_1 \times t_2) \subseteq (s_1 \times s_2) \Rightarrow t_1 \subseteq s_1\)) Instead, as expected, the rule for projection \(\pi_e\) needs some special care since if the type inferred for \(e\) is say, \(t\), then we need to find a set of substitutions \(\sigma_i\) such that \(\forall i \leq n \; \sigma_i \leq t\times 1\). This problem can be solved by using the very same technique we introduced for \(\Delta\), namely by solving a sequence of tallying problems generated by increasing at each step the cardinality of \(I\) (see the appendix).

In the first part of this work [3] we studied the extension of the explicitly-typed calculus with \(\lambda\)-term-polymorphism, in particular, its typing and efficient execution (see Section 5.4 of [3]). There we distinguished \(\lambda\)-bound variables by underlining them. Reconstruction is mostly useful when combined with \(\lambda\)-term-polymorphism. To extend our reconstruction to \(\lambda\) we use a separate type environment \(\Phi\) for these variables (while we reserve \(\Gamma\) for \(\lambda\)-abstracted variables). As in Damas-Milner \(\W\) algorithm [8] we need to define \(\Gamma(t)\), the generalization (closure in [8]) of a type \(t\) wrt the type environment \(\Gamma\), that is, \(\Gamma(t) \equiv \{\forall \alpha \in \var(t) \exists \Gamma' [\alpha \in \var(\Gamma')]\}\) where \(\gamma_i\) are fresh. Then the rules for type reconstruction are

\[
\begin{align*}
\text{(let-var)} & \quad \Phi \vdash \Gamma \vdash x : \tau \quad \Phi \vdash \Gamma(\Phi(x)) \to \varnothing \\
\text{(let)} & \quad \Phi \vdash \Gamma \vdash x_1 : t_1 \to \varnothing \quad \Phi \vdash \Gamma(x : t_1) \vdash \Gamma \vdash e_2 : t_2 \to \varnothing' \\
& \quad \Phi \vdash \Gamma \vdash \lambda x.e \equiv \Gamma \vdash e_2 \to \varnothing' \land \Gamma \vdash x : \tau
\end{align*}
\]

Finally, we want to stress that there is at least a case in which we should have used more restrictive, that is, when an expression that is tested in a type-case has a polymorphic type. Our inference system may type it (by deducing a set of type-substitutions that makes it closed), even if this seems to go against the intuition: we are testing whether a polymorphic expression has a closed type. Although completeness ensures that in some cases it can be done, in practice it seems reasonable to consider ill-typed any type-case in which the tested expression has a polymorphic type (see Section B.3).

6. Related work

This section discusses related work on constraint-based type inference and inference for intersection/union type systems. Discussion about work on explicitly-typed intersection type systems and on XML processing languages can be found in Part 1 of this work [3].

Type inference in ML has essentially been considered as a constraint solving problem [18, 21]. We use a similar approach to solve the problem of type unification: finding a proper substitution that makes the type of the domain of a function compatible with \((ie, a \supertype of)\) the type of the argument it is applied to. Our type unification problem is essentially a specific set constraint problem [1].

This is applied in a much more complex setting with a complete set of type connectives and a rich set-theoretic subtyping relation. In particular, because of the presence of intersection types, solving the problem of application demands to find sets of substitutions rather than just one substitution. This is reflected by the definition of our \(\sqsubseteq\) relation which is much more thorough than the corresponding relation used in ML inference insofar as it encompasses instantiation, expansion, and subtyping. The important novelty of our work comes from the use of set-theoretic connectives, which allows us to turn sets of constraints of the form \(\alpha \leq \alpha \leq \tau\) into sets of equations of the form \(\alpha \equiv (\beta \lor s) \land \tau\), a technique that, in our ken, is original to our work. This set of equations is then solved using Courcelle’s work on infinite trees [7]. The use of type connectives also implies that we solve multiple sets of constraints, which account for different alternatives. Finally, it is worth noticing that [18, 21] use a richer language of constraints that includes binding. This allows separating constraint generation and constraint solving without compromising efficiency. Therefore an interesting direction of future research is either to re-frame our work into a richer language of constraints or to extend the work in [18, 21] to encompass our richer setting. This could be a first step towards the study of efficient constraint solving algorithms for our system.

Feature-wise the programming language closest to our language —ie, polymorphic C\(\text{Duce}\)— is Typed Racket [22, 23] since it has recursive types, union types, top and singleton types, subtyping, dynamic type-cases (called occurrence typing in [22, 23]), and explicitly-typed polymorphic functions. The goal of Typed Racket is to type an existing untyped programming language and it is superior to our system in that it allows the combination of both typed and untyped code in a single program. For what concerns typed features, however, Typed Racket is just a small fragment of our system: type-cases can only test basic types and tests for just some constructed types can be encoded by using Boolean connectives; there are no intersection types (thus, no overloaded functions); there are no negation or difference types; union types and their subtyping are quite naive (eg, a type is a subtype of a union of types only if it is a subtype of some type of the union, distribution laws over type constructors are absent, etc.). The typing of Typed Racket is internally defined in terms of propositional logic where atoms are the elements of a type environment (eg, \(x : \tau\)). The use of logical formulas coincides in C\(\text{Duce}\) to computing the types of capture variable of patterns (cf. the operator \(t/p\) in Appendix E or in [11]): the use of propositional logic corresponds to the use of Boolean connectives in C\(\text{Duce}\)’s patterns and unsatisfiability of a formula to type emptiness. This is why all the examples in the “Challenges” section of [23] can be easily defined and precisely typed in our system (straightforwardly with the syntactic sugar defined in the Appendix E of Part 1 [3]). Actually, these examples can already be defined and typed in monomorphic C\(\text{Duce}\) [2] since it already captures all the features characteristics of Typed Racket (recursive and union types, subtyping, occurrence typing, etc.) with the sole exception of polymorphism, a gap filled by this work. Typed Racket uses a limited form of local type inference: the application of a function to a polymorphic argument requires the application of an explicit type substitution to the argument. We do not have this limitation thanks to our tallying procedure that computes instantiations (type substitutions) both for the function and for its argument. It is not clear whether using generic SMT solvers for typing (as suggested by [23]) also in C\(\text{Duce}\) case (where subtyping is checked by type emptiness) would yield a better (sub)typing algorithm.
Local type inference was first formalized, as far as we know, by Pierce and Turner [20]. They consider (i) a type system with type variables, arrow, top, and bottom types, (ii) an internal language with explicitly typed polymorphic functions that, to be applied, must be explicitly instantiated, and (iii) an external language in which some or all such instantiations can be omitted. Then they show how to infer type instantiations for programs of the external language in order to obtain, when possible, well-typed programs of the internal language. Our work shares much of the philosophy and goals of Pierce and Turner [20]: expressions of grammar (3) form our external language, those of grammar (7) the internal one, and our sets of type-substitutions generalize Pierce and Turner’s instantiations. Our work extends and generalizes Pierce and Turner’s one in several ways. First, in an application we infer instantiation/type-substitutions both for the function \( \lambda x.x \) and for the argument, while [20] does just the former (Typed Racket does the same). As a consequence, the application of the polymorphic identity \( \lambda x.x \) to a function \( f \) of type \( (\text{Int} \to \text{Int}) \to \text{Int} \) can be typed in their systems (by inferring the instantiation \( (\text{Int} \to \text{Int}) \to \text{Int} / \alpha \)) the application of the same \( f \) to the polymorphic identity cannot be typed (while our system types it by instantiating the argument by the substitution \( (\text{Int} / \alpha) \)). Second, our system accounts for more expressive types, expressions, and subtyping relations. For instance, [20] essentially solves the tallying problem for simple constraint sets whose form is the same as those obtained after applying our merge; instead we manipulate sets of constraint sets (to account for alternatives generated to check whether the typing of type cases or the subtyping relation) and iterate the tallying problem with different cardinalities because of the presence of intersection types. Third, [20] synthesizes an instantiation for a type variable only if its occurrences are either all positive or all negative and fails otherwise, while our system, thanks to the use of type connectives and recursive types, always generates a set of solvable equations.

Finally, we want to stress as a caveat that works on type reconstruction for intersection type systems are weakly related to our study. The reason is that the core of our technique consists in solving (in-)equations by recursive types. With recursive types pure intersection type systems are trivially decidable since all terms can be typed by the type \( \mu X.X \to X \). The problem we tackle here, thus, is fundamentally different, namely, we check whether it is safe to apply to each other, expressions of two explicitly given (and possibly recursive) types in which some basic types may occur. There are however a few similarities with some techniques developed for pure intersection type systems that we briefly discuss next.

Coppo and Giannini [6] presented a decidable type checking algorithm for simple intersection type system where intersection is used in the left-hand side of an arrow and only a term variable is allowed to have different types in its different occurrences. They introduced labeled intersections and labeled intersection schemes, which are intended to represent potential intersections. During an application \( MN \), the labeled intersection schemes of \( M \) and \( N \) would be unified to make them match successfully, yielding a transformation, a combination of substitutions and expansions. An expansion expands a labeled intersection into an explicit intersection. The intersection here acts like a variable binding similar to a quantifier in logic. Our rule (ALG-INST) is similar to the transformation. We instantiated a quantified type into several instances according to different situations (ie, the argument types), and then combine them as an intersection type. The difference is that we instantiate a parametric polymorphic function into a function with intersection types, while Coppo and Giannini transform a potential intersection into an explicit intersection. Besides, as the general intersection type system is not decidable [5], to get a decidable type checking algorithm, Coppo and Giannini used the intersection in a limited way, while we give some explicit type annotations for functions. Likewise, Jim [14] proposed a type inference algorithm for a polar type system where intersection is allowed only in negative positions and System F-like quantification only in positive ones.

Restricting intersection types to finite ranks (using Leivant’s notion of rank) [16] also yields decidable systems. Van Bakel [24] gave the first unification-based inference algorithm for a rank 2 intersection type system. Jim [13] studied a decidable rank 2 intersection type system extended with recursion and parametric polymorphism. Kfoury and Wells proved decidability of type inference for intersection type systems of arbitrary finite rank [15]. As a future work, we want to investigate decidability of rank-restricted versions of our calculus.

7. Conclusion

The work presented here, together with the one in [3], provides the theoretical bases and all the algorithmic tools needed to design and implement polymorphic languages for semi-structured data and, more generally, generic functional languages with recursive types and set-theoretic unions, intersections, and negations. In particular, our results made the polymorphic extension of CDuce [2] possible and pave the way to the definition of a real type system for XQuery 3.0 [10] (not the current one in which all higher-order functions have type “function()”). Thanks to type reconstruction, these languages can have a syntax and semantics close to those of OCaml or Haskell, but also include primitives (in particular, complex patterns) that exploit the great expressive power of full-fledged set-theoretic types. Symmetrically, as the red-black trees and max examples in Section 3.3 demonstrates, OCaml and Haskell would certainly benefit from the addition of set-theoretic type connectives: we plan to study such an extension in the near future.

Some problems are still open, notably the decidability of type substitution inference, but these are of theoretical nature and, as our experiments hitherto confirm, should not have any impact in practice. The only problem open in this second part of the work, that is the non-determinism of the implicitly typed calculus, should have a negligible practical impact, insofar as it is theoretical (in practice, the semantics is deterministic but implementation dependent) and it concerns only the case when the type of (an instance of) a polymorphic function is tested at run-time: in our programming experience with CDuce we never met a single typecase for a function type. Nevertheless, it may be interesting to study how to remove such a constraint either by defining a canonical choice for the instances deduced by the inference system (a problem related to the existence of principal types), or by imposing reasonable restrictions, or by checking the flow of polymorphic functions by a static analysis.

On the practical side, by implementing the polymorphic extension of CDuce and applying it we realized that it would be useful to allow monomorphic type variables to occur in patterns (see Appendix A for examples) which in this work this would correspond to have a type case on types that may contain monomorphic type variables. How to do it is not straightforward and looks as a promising research direction. Other interesting practically-oriented directions of research are the study of heuristics to simplify types generated from constraints, so as to make type reconstruction for top-level functions human friendly; the generation of meaningful type error messages; the study of efficient implementation of constrained solving; the extension of the bridge between OCaml and CDuce to include polymorphic types and, later on, the inclusion of GADTs.

A. Examples of code

In this section we show examples of real code that follows the same pattern as the even function we defined in the introduction.

A.1 Red-Black trees

As a first example we show that the use of polymorphic set-theoretic types yields a better definition of Okasaki’s implementation of red-black trees.

A red and black tree is a colored binary search tree in which all nodes are colored either black or red and that satisfies 4 invariants:

1. the root of the tree is black
2. the leaves of the tree are black
3. no red node has a red child
4. every path from the root to a leaf contains the same number of black nodes

Thanks to our type system (and contrary to Okasaki’s version) the implementation below ensures by typing that the operations on red-black trees (notably, the insertion) satisfy the first three invariants, as well as, that the ins_aux function, local to insertion, never returns empty trees (yet another important property that, in ML/Haskell Okasaki’s version, types cannot ensure).

```haskell
let balance ( Unbalanced(α) -> Rtree(α) ; β(Unbalanced(α) -> β\Unbalanced(α) )
| ( <black (z)>[ <red (y)>[ <red (x)>[ a b ] c ] d ] |
<black (x)>[ a <red (y)>[ b c ] d ] |
<black (x)>[ a <red (y)>[ b red (z)>[ c d ] ] ] ) & Unbalanced(α)
→ <red (y)>[ <black (x)>[ a b ] <black (z)>[ c d ] ] |
| x → x

let insert (x : α) (t : Btree(α)) : Btree(α) =
let ins_aux ( [] -> Rtree(α);
Btree(α)[ ] → Rtree(α)[ ];
Rtree(α) → Rtree(α)|Wrongtree(α) )
| [] → <red elem=x>[
| (<<(color) elem=y>[ a b ] & z →
if x << y then balance <<(color) elem=y>[ (ins_aux a) b ]
else if x >> y then balance <<(color) elem=y>[ a (ins_aux b) ]
else z
in match ins_aux t with
| _ (y)>[ a b ] → <black (y)>[ a b ]
```

We invite the reader to refer to the excellent Okasaki’s monograph [19] for details about Okasaki’s algorithm—that our code faithfully follows—and the documentation of the language CDuce for details about the syntax we used, which is standard CDuce syntax apart from the presence of type variables.8 Let us instead spend some words to comment the types, since they are the real novelty and the added value of our definition. First, notice that we used the full palette of our types: unions, intersections, negations (difference), and type variables. Red-black trees (Btrees) are black-rooted RBtrees (invariant 1), which

---

8 For the reader convenience we recall that in CDuce XML types/pattern/expressions may have the form

```
<tag attr=type/pattern/expression ... attr=type/pattern/expression>[ sequence of types/patterns/expression ]
```

and that possibly recursive functions can be defined as

```
let name (type->type; ... ; type->type)
| pattern -> expression | ... | pattern -> expression
```

where the list of arrow types that follow the function name form the intersection type (ie, the interface) of the function.
are themselves black-rooted trees or red-rooted trees. The difference between the last two is that the latter cannot be leaves (invariant 2) and their children can only be black-rooted trees (invariant 3).

The \textit{insert} function takes an element \( x \) of type \( \alpha \), and returns a function that maps red-black trees into red-black trees.

\begin{verbatim}
insert :: \( \alpha \rightarrow \text{Btree}(\alpha) \rightarrow \text{Btree}(\alpha) \)
\end{verbatim}

By examining the code of \textit{insert} it is easy to see that if the argument tree is empty a red-rooted tree is returned, otherwise the element is inserted in the appropriate subtree and the whole tree is then balanced by the function \textit{balance}. This function has the following type (which follows the same typing pattern as the function \textit{even} defined in the introduction):

\begin{verbatim}
balance :: ( \text{Unbalanced}(\alpha) \rightarrow \text{Rtree}(\alpha) ) \& ( \text{\beta\Unbalanced}(\alpha) \rightarrow \text{\beta\Unbalanced}(\alpha) )
\end{verbatim}

This type states that \textit{balance} transforms an unbalanced tree into a (balanced) red-rooted tree and leaves all other trees (in particular the balanced ones) unchanged. The core of our definition is the type of \textit{ins_aux}:

\begin{verbatim}
is_aux :: ( [ ] \rightarrow \text{Rtree}(\alpha) ) \& ( \text{Btree}(\alpha) \& [ ] \rightarrow \text{RBtree}(\alpha) \& [ ] ) \& ( \text{Rtree}(\alpha) \rightarrow \text{Rtree}(\alpha) \| \text{Wrongtree}(\alpha) )
\end{verbatim}

which precisely describes the behaviour of the function. Notice that the domain of \textit{ins_aux} (which is the union of the three domains of the arrows forming its intersection type) is exactly \text{RBtree}(\alpha). The intersection type describes the behaviour of \textit{ins_aux} for each form of an \text{RBtree}—i.e, empty, black-rooted, and red-rooted—. The type system needs the full precision of this type to infer whether the calls to \textit{balance} in the body of \textit{ins_aux} are applied to a balanced or an unbalanced tree: even a slight approximation of this type, such as

\begin{verbatim}
is_aux :: ( \text{Btree}(\alpha) \& [ ] \rightarrow \text{RBtree}(\alpha) \& [ ] ) \& ( \text{Rtree}(\alpha) \& [ ] \rightarrow \text{Rtree}(\alpha) \& \text{Wrongtree}(\alpha) )
\end{verbatim}

makes type-checking fail. By examining the type of \textit{ins_aux} it is easy to see that \textit{ins_aux} always returns either a (balanced) black-rooted tree or a tree with a red root in which one of the children may be a \textit{Rtree}. In case of a tree with a red root, a (balanced) red-black tree is then obtained by changing the color of the root to black, as it is done in the last line of \textit{insert}.

The implementation above must be compared with the corresponding version in monomorphic \texttt{Cduce}:

\begin{verbatim}
type \text{RBtree} = \text{Btree} \mid \text{Rtree}

type \text{Btree} = [ ] \mid \langle \text{black elem=Int}\rangle \text{[ RBtree RBtree ]}

type \text{Rtree} = \langle \text{red elem=Int}\rangle \text{[ Btree Btree ]};;

type \text{Wrongtree} = \langle \text{Wrongleft} \mid \text{Wrongright}\rangle
type \text{Wrongleft} = \langle \text{red elem=Int}\rangle \text{[ Rtree Btree ]}

type \text{Wrongright} = \langle \text{red elem=Int}\rangle \text{[ Btree Rtree ]}

type \text{Unbalanced} = \langle \text{black elem=Int}\rangle \{( \text{Wrongtree RBtree } \& [ ] \& \text{RBtree Wrongtree } )
\end{verbatim}

\begin{verbatim}
let \text{balance} ( \text{Unbalanced}(\alpha) \rightarrow \text{Rtree}(\alpha) ) \& ( \text{\beta\Unbalanced}(\alpha) \rightarrow \text{\beta\Unbalanced}(\alpha) )\n\text{balance}\ ( \text{Unbalanced}(\alpha) \rightarrow \text{Rtree}(\alpha) ) \& ( \text{\beta\Unbalanced}(\alpha) \rightarrow \text{\beta\Unbalanced}(\alpha) )
\end{verbatim}

\begin{verbatim}
let \text{insert} (x : \text{Int}) (t : \text{Btree}) : \text{Btree} =
\end{verbatim}

\begin{verbatim}
let \text{ins_aux} ( [ ] \rightarrow \text{Rtree} ; \text{Btree}\&[ ] \rightarrow \text{RBtree}\&[ ] ; \text{Rtree} \rightarrow \text{Rtree}\&\text{Wrongtree})
\end{verbatim}

\begin{verbatim}
\text{let insert} (x : \text{Int}) (t : \text{Btree}) : \text{Btree} =
\end{verbatim}

\begin{verbatim}
which, besides being monomorphic, requires the introduction of several intermediate types (in particular \text{Wrongleft} and \text{Wrongright}) in order to describe the polymorphic behavior of \textit{balance}— whose type results, thus, much more obscure. Our implementation must also be compared with the version given by Rowan Davies in his PhD Thesis [9] which uses polymorphic intersection types and type inference. Contrary to our definition, Davies’s implementation \textit{(i)} does not statically verify invariant 1, \textit{(ii)} it introduces— as our monomorphic version does— several intermediate type definitions to specify the behavior of local
functions, and (iii) it does not faithfully reproduce Okasaki implementation since it needs the definition of several auxiliary functions absent from Okasaki’s (and our) formulation.

Likewise, there exist other implementations that are able to ensure/verify the first invariants of red-black trees (eg, by using GADTs or finite tree automata) but they all need extra definitions of intermediate functions or operations: as far as we know ours types are the only system that can statically ensure the invariants above simply by decorating (with types) the original Okasaki’s code without any further modification.

Notice that the definition of balance given above and the one in Section 3.3 differ for a couple of details. First, the name of the types require mandatory type parameters when their definitions contain free type variable (eg, we have to write RBtree(α) rather than just RBtree): this is the behavior implemented in the current development version of CDuce, and we omitted this detail in the code of Section 3.3 just for space reasons. More importantly, the union pattern of the first branch of the pattern matching is intersected with the type Unbalanced(α). The reason is that this type is strictly contained in the type accepted by the union pattern and, therefore, this branch can be selected for values that are not in Unbalanced(α) (notice that balance can be applied to any value). Now for these values the interfaces of balance declares that a result of the same type is returned, which is not true since the first branch is selected (and the latter transforms a black-rooted tree into a red-rooted one). This is why without the intersection in the pattern the type-checker rejects the definition by pointing out the problem. By adding the intersection we force the first branch to be selected only for values of type Unbalanced(α), and the function type-checks.

There is still a last glitch, at least to run the example on the current development version of CDuce. Notice that we used Unbalanced(α) in the pattern and that this type contains the monomorphic variable α. The current development version of CDuce does not allow monomorphic variables to occur in patterns, yet (this is listed as future work in Section 7). In order to execute balance on the current development version of CDuce there are (at least) three solutions, which are all as valid as the one presented before. The first solution is to restrict the domain of balance to Unbalanced(α) | RBtree(α). This can be done by declaring for balance the interface (Unbalanced(α) -> Rtree(α) ; β & RBtree(α) -> β & RBtree(α)) (notice that the intersection of Unbalanced(α) and RBtree(α) is empty so the difference in the interface and the intersection in the pattern are no longer necessary). The second solution is to use as intersection in the pattern the type Unbalanced(Any) to overapproximate Unbalanced(α). This however requires to modify the interface of balance accordingly into (Unbalanced(α) -> Rtree(α) ; β | Unbalanced(Any) -> β | Unbalanced(Any)) to capture the precise cases in which the second branch is selected. The third, more verbose, solution is to get rid again of the intersection pattern by declaring in the interface that the second arrow type applies only to values that are not in the accepted type of the first union pattern, that is, (Unbalanced(α) -> Rtree(α) ; β | UTree -> β | UTree), where UTree is the accepted type of the first union pattern, which is obtained by replacing in the pattern Any for every capture variable occurring in it, namely:

\[
\text{type UTree} = \begin{cases} 
\text{black (Any)} & [\text{red (Any)}] [\text{red (Any)}] [\text{Any Any }] [\text{Any Any }] \text{Any} \\
\text{black (Any)} & [\text{Any} \text{ red (Any)}] [\text{Any} \text{ red (Any)}] [\text{Any Any }] \text{Any} \\
\text{black (Any)} & [\text{Any red (Any)}] [\text{Any red (Any)}] [\text{Any Any }] \text{Any} \\
\text{black (Any)} & [\text{Any red (Any)}] [\text{Any red (Any)}] [\text{Any red (Any)}] [\text{Any Any }] \text{Any} \\
\end{cases}
\]

A.2 Soap envelopes

As a second usage example of the typing pattern followed by even we explore a typical XML application to process envelopes. Soap envelopes are a standardized format to communicate information wrapped in XML. An envelope contains a body and an optional header as described by the following type definitions.

\[
\text{type Envelope}(α, β) = \begin{cases} 
\text{Envelope} & [\text{Header}(β) \, \text{Body}(α) ] \\
\text{type Header}(β) = \begin{cases} 
\text{HEADER} & β \\
\text{type Body}(α) = \begin{cases} 
\text{Body} & α 
\end{cases} 
\end{cases} 
\end{cases}
\]

We define an enrich function which maps functions into a function with the same typing pattern as even (NOTE: in the current development version of CDuce this function cannot be executed because neither the : notation, nor monomorphic variables in patterns are implemented, yet).

\[
\text{(* enrich envelope headers with info computed by applying *)} \\
\text{(* the argument function f to the body of the envelope *)} \\
\text{enrich :: ( α -> β ) ->} \\
\begin{cases} 
\begin{cases} 
\text{Envelope}(α, β) & [ \text{Header}(β) \, \text{Body}(α) ] \\
\text{& ( γ | Envelope}(α, β) & [ \text{Body}(α) ] 
\end{cases} 
\end{cases} \\
\text{enrich f x = match x with} \\
\begin{cases} 
\text{| (Envelope} & [\text{Body} b ] & \text{Envelope}(α, β) & [\text{Header} f b] \, \text{Body} & (\text{enrich f b}) |
\end{cases} \\
\begin{cases} 
| (\text{Envelope} & [\text{Header} h & \text{Body} b ] & \text{Envelope}(α, β) & [\text{Header} & ((f b) @ h) \, \text{Body} & (\text{enrich f b}) ] |
\end{cases} \\
\begin{cases} 
\text{| lst & [ (AnyXML Envelope}(α, β)|Char]] & [\text{map lst with y -> enrich f y}) 
\end{cases} \\
\end{cases} 
\]

When applied to a function $f$, enrich returns a function that adds to the header of an envelope the result obtained by applying $f$ to the body of the envelope, and recursively applies this transformation inside the body and in possible subtrees. Once more, in the definition of enrich we used pattern with monomorphic variables, therefore the same considerations as for the red-black tree example apply, too. The function enrich can then be typically used as in

$$\text{xtransform anXMLdoc with}$$

$$| x & T \rightarrow \text{enrich } f_T x$$

$$| x & <\text{Envelope}> \rightarrow \text{enrich } f x$$

where $f_T$ is specific for type $T$ and $f$ is generic. The expression above transforms all the envelopes in the anXMLdoc document by preserving the type of all its subcomponents with the addition of the information on the headers, when it is missing.

Again this must be contrasted with the monomorphic version which must list all possible alternatives for the input type and in which the types of the contents of the envelope and the header are not preserved since they are subsumed to $\{(\text{AnyXml}|\text{Char})^*\}$:

$$\text{type Envelope} = <\text{Envelope}>[ \text{Header} \mid \text{Body} ]$$

$$\text{type Header} = <\text{Header}> B$$

$$\text{typeBody} = <\text{Body}> A$$

$$\text{type } A = [(\text{AnyXml}|\text{Char})^*]$$

$$\text{type } B = [(\text{AnyXml}|\text{Char})^*]$$

let enrich (f: A -> B): ( (Envelope -> <Envelope>[ Header Body]) & (A -> A) & (Char -> Char) & (AnyXml -> AnyXml)) =

$$(\text{fun } (\text{Envelope} \rightarrow <\text{Envelope}>[ \text{Header Body} ] ;$$

$$(A \rightarrow A) \& (\text{Char} \rightarrow \text{Char}) \& (\text{AnyXml} \rightarrow \text{AnyXml})) =$$

$$(\text{fun } (\text{Envelope} \rightarrow <\text{Envelope}>[ \text{Header Body} ] ;$$

$$( A \rightarrow A ; \text{Char} \rightarrow \text{Char} ; \text{AnyXml} \rightarrow \text{AnyXml})$$

$$(\text{fun } (\text{Envelope} \rightarrow <\text{Envelope}>[ \text{Body} b ] \rightarrow$$

$$(\text{fun } (\text{Envelope} \rightarrow <\text{Envelope}>[ \text{Header} (f b) \mid \text{Body}(\text{enrich } f b) ]$$

$$(\text{fun } (\text{Envelope} \rightarrow <\text{Envelope}>[ \text{Header} h \mid \text{Body} b ] \rightarrow$$

$$(\text{fun } (\text{Envelope} \rightarrow <\text{Envelope}>[ (\text{f b})@h \mid \text{Body}(\text{enrich } f b) ]$$

$$| \text{lst } & [ (\text{AnyXml}|\text{Char})^* ] \rightarrow (\text{map } \text{lst} \text{ with } y \rightarrow \text{enrich } f y)$$

$$| (\text{x})y \rightarrow (\text{x})(\text{enrich } f y)$$

$$| y \rightarrow y);$$

B. Implicitly-Typed Calculus

We want sets of type-substitutions to be inferred by the system, not written by the programmer. To this end, we define a calculus without type substitutions (called implicitly-typed, in contrast to the calculus in (7) in Section 2, which we henceforth call explicitly-typed), for which we define a type-substitutions inference system. As explained in Section 3, we do not try to infer decorations in $\lambda$-abstractions, and we therefore look for completeness of the type-substitutions inference system with respect to the expressions written according to the following grammar:

$$e ::= c \mid x \mid (e, e) \mid \pi_i(e) \mid e e \mid \lambda^{s_i \in T_i \rightarrow s_i} x.e \mid e \in t ? e : e | e[\sigma]_{\sigma \in J}.$$

We write $\mathcal{E}_0$ for the set of such expressions. The implicitly-typed calculus defined in this section corresponds to the type-substitution erasures of the expressions of $\mathcal{E}_0$. These are the terms generated by the grammar above without using the last production, that is, without the application of sets of type-substitutions. We then define the type-substitutions inference system by determining where the rule (A L G - INST) have to be used in the typing derivations of explicitly-typed expressions. Finally, we propose an incomplete but more tractable restriction of the type-substitutions inference system, which, we believe, is powerful enough to be used in practice.

B.1 Implicitly-typed Calculus

Definition B.1. An implicitly-typed expression $a$ is an expression without any type substitutions. It is inductively generated by the following grammar:

$$a ::= c \mid x \mid (a, a) \mid \pi_i(a) \mid a a \mid \lambda^{s_i \in T_i \rightarrow s_i} x.a \mid a \in t ? a : a$$

where $t_i, s_i$ range over types and $t \in T_0$ is a ground type. We write $\mathcal{E}_A$ to denote the set of all implicitly-typed expressions.

Clearly, $\mathcal{E}_A$ is a proper subset of $\mathcal{E}_0$.

The erasure of explicitly-typed expressions to implicitly-typed expressions is defined as follows:
Definition B.2. The erasure is the mapping from $E_0$ to $E_\Delta$ defined as

$$
erase(c) = c$$

$$
erase(x) = x$$

$$
erase(e_1, e_2) = (erase(e_1), erase(e_2))$$

$$
erase(\pi(e)) = \pi(erase(e))$$

$$
erase(\lambda x. e) = \lambda x. erase(e)$$

$$
erase(e_{1 t ? e_1 : e_2}) = erase(e)_{1 t ? e_1 : e_2}$$

$$
erase(e[\sigma]_1) = erase(e)$$

Prior to introducing the type inference rules, we define a preorder on types, which is similar to the type variable instantiation in ML but with respect to $\sqsubseteq$.

Definition B.3. Let $s$ and $t$ be two types and $\Delta$ a set of type variables. We define the following relations:

$$
[s]_{i \in I} \triangleright \triangleright s \sqsubseteq \Delta t \iff \bigwedge_{i \in I} s_{i} \leq t \text{ and } \forall i \in I, s_{i} \notin \Delta t
$$

$$
[s] \sqsubseteq \Delta t \iff \exists [s]_{i \in I} \text{ such that } [s]_{i \in I} \triangleright \triangleright s \sqsubseteq \Delta t
$$

We write $s \sqsubseteq \Delta t$ if it does not exist a set of type substitutions $[s]_{i \in I}$ such that $[s]_{i \in I} \triangleright \triangleright s \sqsubseteq \Delta t$. We now prove some properties of the preorder $\sqsubseteq$.

Lemma B.4. Let $t_1$ and $t_2$ be two types and $\Delta$ a set of type variables. If $t_1 \sqsubseteq \Delta s_1$ and $t_2 \sqsubseteq \Delta s_2$, then $(t_1 \times t_2) \sqsubseteq \Delta (s_1 \times s_2)$.

Proof. Let $[s]_{i \in I_1} \triangleright \triangleright t_1 \sqsubseteq \Delta s_1$ and $[s]_{j \in J_2} \triangleright \triangleright t_2 \sqsubseteq \Delta s_2$. Then

$$
\bigwedge_{i \in I_1 \cup J_2} (t_1 \times t_2)_{i} \sigma_{i} = \bigwedge_{i \in I_1 \cup J_2} (t_1 \sigma_{i}) \times (t_2 \sigma_{i})
$$

and

$$
\bigwedge_{i \in I_1 \cup J_2} (t_1 \times t_2)_{i} \sigma_{i} = \bigwedge_{i \in I_1 \cup J_2} (t_{1, i} \sigma_{i}) \times (t_{2, i} \sigma_{i})
$$

$$
\leq s_1 \times s_2
$$

Lemma B.5. Let $t_1$ and $t_2$ be two types and $\Delta$ a set of type variables such that $(\text{var}(t_1) \setminus \Delta) \cap \text{var}(t_2) \setminus \Delta) = \emptyset$. If $t_1 \sqsubseteq \Delta s_1$ and $t_2 \sqsubseteq \Delta s_2$, then $t_1 \triangleright \triangleright t_2 \sqsubseteq \Delta s_1 \lor s_2$.

Proof. Let $[s]_{i \in I_1} \triangleright \triangleright t_1 \sqsubseteq \Delta s_1$ and $[s]_{j \in J_2} \triangleright \triangleright t_2 \sqsubseteq \Delta s_2$. Then we construct another set of type substitutions $[\sigma_{1, i_2}, i_1, i_2]_{i \in I_1, j \in J_2}$ such that

$$
\sigma_{1, 2}(\alpha) = \begin{cases} 
\sigma_{1}(\alpha) & \text{if } \alpha \in (\text{var}(t_1) \setminus \Delta) \\
\sigma_{2}(\alpha) & \text{if } \alpha \in (\text{var}(t_2) \setminus \Delta) \\
\alpha & \text{otherwise}
\end{cases}
$$

So we have

$$
\bigwedge_{i \in I_1 \cup J_2} (t_1 \lor t_2)_{i} \sigma_{i_1, i_2} \leq \bigwedge_{i \in I_1 \cup J_2} (t_{1, i} \lor t_{2, i} \sigma_{i_1, i_2})
$$

Notice that two successive instantiations can be safely merged into one (see Lemma B.6). Henceforth, we assume that there are no successive instantiations in a given derivation tree. In order to guess where to insert sets of type-substitutions in an implicitly-typed expression, we consider each typing rule of the explicitly-typed calculus used in conjunction with the instantiation rule (ALG-INST). If instantiation can be moved through a given typing rule without affecting typability or changing the result type, then it is not necessary to infer type substitutions at the level of this rule.

Lemma B.6. Let $e$ be an explicitly-typed expression and $[\sigma_{1}]_{i \in I}, [\sigma_{j}]_{j \in J}$ two sets of type substitutions. Then

$$
\Delta \downarrow \Gamma \vdash_{df} (e[\sigma_{1}]_i)[\sigma_{j}]_j : t \iff \Delta \downarrow \Gamma \vdash_{df} e[\sigma_{j}]_j \circ [\sigma_{1}]_i : t
$$
Proof. $\Rightarrow$: consider the following derivation:

\[
\frac{\Delta_1 \Gamma \vdash e : \sigma_1 \not\in \Delta}{\Delta_3 \Gamma \vdash e[\sigma_1]_{i \in J} : \bigwedge_{j \in J} \sigma_i \not\in \Delta} \quad \frac{\Delta_3 \Gamma \vdash e[\sigma_1]_{i \in J} : \bigwedge_{j \in J} \sigma_i \not\in \Delta}{\Delta_1 \Gamma \vdash \epsilon(\bigwedge_{j \in J} \sigma_i)_{j \in J} : \bigwedge_{j \in J} (\bigwedge_{i \in I} \sigma_i)_{j \in J}}
\]

As $\sigma_1 \not\in \Delta$, $\sigma_j \not\in \Delta$ and $\text{dom}(\sigma_j \cup \sigma_i) = \text{dom}(\sigma_i) \cup \text{dom}(\sigma_j)$, we have $\sigma_j \circ \sigma_i \not\in \Delta$. Then by (ALG-INST), we have $\Delta_3 \Gamma \vdash e[\sigma_1]_{i \in J} : \bigwedge_{j \in J} (\bigwedge_{i \in I} \sigma_i)_{j \in J}$, that is $\Delta_3 \Gamma \vdash e[\sigma_1]_{i \in J} \circ (\bigwedge_{i \in I} \sigma_i)_{j \in J} : \bigwedge_{J \in J} (\bigwedge_{i \in I} \sigma_i)_{j \in J}$.

$\Leftarrow$: consider the following derivation:

\[
\frac{\Delta_1 \Gamma \vdash e : \sigma_j \circ \sigma_i \not\in \Delta}{\Delta_3 \Gamma \vdash e[\sigma_j \circ \sigma_i]_{i \in J} : \bigwedge_{j \in J} \sigma_i \not\in \Delta} \quad \frac{\Delta_3 \Gamma \vdash e[\sigma_j \circ \sigma_i]_{i \in J} : \bigwedge_{j \in J} \sigma_i \not\in \Delta}{\Delta_1 \Gamma \vdash \epsilon(\bigwedge_{j \in J} \sigma_i)_{j \in J} : \bigwedge_{j \in J} (\bigwedge_{i \in I} \sigma_i)_{j \in J}}
\]

As $\sigma_j \circ \sigma_i \not\in \Delta$ and $\text{dom}(\sigma_j \circ \sigma_i) = \text{dom}(\sigma_j) \cup \text{dom}(\sigma_i)$, we have $\sigma_j \not\in \Delta$ and $\sigma_i \not\in \Delta$. Then applying the rule (ALG-INST) twice, we have $\Delta_3 \Gamma \vdash e[\sigma_1]_{i \in J} [\sigma_j]_{j \in J} : \bigwedge_{j \in J} (\bigwedge_{i \in I} \sigma_i)_{j \in J}$, that is $\Delta_3 \Gamma \vdash e[\sigma_1]_{i \in J} [\sigma_j]_{j \in J} : \bigwedge_{J \in J} (\bigwedge_{i \in I} \sigma_i)_{j \in J}$. \hfill $\square$

First of all, consider a typing derivation ending with (ALG-PAIR) where both of its sub-derivations end with (ALG-INST):9

\[
\frac{\Delta_1 \Gamma \vdash e_1 : t_1 \quad \forall j \in J_1, \sigma_j \not\in \Delta}{\Delta_3 \Gamma \vdash e_1[\sigma_j]_{j \in J_1} : \bigwedge_{j \in J_1} t_1 \sigma_j \quad \forall j \in J_1, \sigma_j \not\in \Delta} \quad \frac{\Delta_1 \Gamma \vdash e_2 : t_2 \quad \forall j \in J_2, \sigma_j \not\in \Delta}{\Delta_3 \Gamma \vdash e_2[\sigma_j]_{j \in J_2} : \bigwedge_{j \in J_2} t_2 \sigma_j \quad \forall j \in J_2, \sigma_j \not\in \Delta} \quad \frac{\Delta_3 \Gamma \vdash e_1[\sigma_j]_{j \in J_1} \times e_2[\sigma_j]_{j \in J_2} : \bigwedge_{j \in J_1 \cup J_2} t_1 \sigma_1 \times t_2 \sigma_2 \quad \forall j \in J_1 \cup J_2, \sigma_j \not\in \Delta}{\Delta_3 \Gamma \vdash e : t \quad \forall j \in J, \sigma_j \not\in \Delta}
\]

We rewrite such a derivation as follows:

\[
\frac{\Delta_3 \Gamma \vdash e_1 : t_1 \quad \Delta_3 \Gamma \vdash e_2 : t_2 \quad \forall j \in J \cup J_2, \sigma_j \not\in \Delta}{\Delta_3 \Gamma \vdash e_1[\sigma_j]_{j \in J_1} \times e_2[\sigma_j]_{j \in J_2} : \bigwedge_{j \in J_1 \cup J_2} t_1 \sigma_1 \times t_2 \sigma_2 \quad \forall j \in J_1 \cup J_2, \sigma_j \not\in \Delta}
\]

Clearly, $\bigwedge_{j \in J_1 \cup J_2} (t_1 \times t_2) \sigma_j \leq \bigwedge_{j \in J_1} t_1 \sigma_1 \times \bigwedge_{j \in J_2} t_2 \sigma_2$. Then by subsumption we can deduce that $(e_1, e_2)[\sigma_j]_{j \in J_1 \cup J_2}$ also has the type $(\bigwedge_{j \in J_1 \cup J_2} t_1 \sigma_1 \times \bigwedge_{j \in J_2} t_2 \sigma_2)$. Therefore, we can disregard the sets of type substitutions that are applied inside a pair, since inferring them outside the pair is equivalent. Hence, we can use the following inference rule for pairs.

\[
\frac{\Delta_3 \Gamma \vdash a_1 : t_1 \quad \Delta_3 \Gamma \vdash a_2 : t_2}{\Delta_3 \Gamma \vdash (a_1, a_2) : t_1 \times t_2}
\]

Next, consider a derivation ending of (ALG-PROJ) whose premise is derived by (ALG-INST):

\[
\frac{\Delta_1 \Gamma \vdash e : t \quad \forall j \in J, \sigma_j \not\in \Delta}{\Delta_3 \Gamma \vdash e[\sigma_j]_{j \in J} : \bigwedge_{j \in J} t \sigma_j \quad \forall j \in J, \sigma_j \not\in \Delta} \quad \frac{\Delta_3 \Gamma \vdash \pi_i(e[\sigma_j]_{j \in J}) : \pi_i(\bigwedge_{j \in J} t \sigma_j)}{(\bigwedge_{j \in J} t \sigma_j) \leq 1 \times 1}
\]

According to Lemma C.8 in the companion paper [3], we have $\pi_i(\bigwedge_{j \in J} t \sigma_j) \leq \bigwedge_{j \in J} \pi_i(t \sigma_j)$, but the converse does not necessarily hold. For example, $\pi_i(\{\{1 \times 2\} \cup \{s_1 \times s_2\}) \{s_2 \sigma_2\}) = \{1 \times s_2 \sigma_2\}$ while $\{\pi_i(\{1 \times 2\} \cup \{s_1 \times s_2\}) \{s_2 \sigma_2\}) = \{1 \times \pi_i(s_2 \sigma_2\}$. So we cannot exchange the instantiation and projection rules without losing completeness. However, as $\{\bigwedge_{j \in J} t \sigma_j \leq 1 \times 1$ and $\forall j \in J, \sigma_j \not\in \Delta$, we have $t \subseteq \Delta \times \Delta$. This indicates that for an implicitly-typed expression $\pi_i(a)$, if the inferred type for $a$ is $t$ and there exists $[\sigma_j]_{j \in J}$ such that $[\sigma_j]_{j \in J} \vdash t \subseteq \Delta \times \Delta$, then we infer the type $\pi_i(\bigwedge_{j \in J} t \sigma_j)$ for $\pi_i(a)$.

Let $\Pi_\Delta(t)$ denote the set of such result types, that is,

\[
\Pi_\Delta(t) = \{ u | [\sigma_j]_{j \in J} \vdash t \subseteq \Delta \times \Delta, u = \pi_i(\bigwedge_{j \in J} t \sigma_j) \}
\]

Formally, we have the following inference rule for projections.

\[
\frac{\Delta_1 \Gamma \vdash a : t \quad u \in \Pi_\Delta(t)}{\Delta_3 \Gamma \vdash \pi_i(a) : u}
\]

The following lemma tells us that $\Pi_\Delta(t)$ is “morally” closed by intersection, in the sense that if we take two solutions in $\Pi_\Delta(t)$, then we can take also their intersection as a solution, since there always exists in $\Pi_\Delta(t)$ a solution at least as precise as their intersection.

Lemma B.7. Let $t$ be a type and $\Delta$ a set of type variables. If $u_1 \in \Pi_\Delta(t)$ and $u_2 \in \Pi_\Delta(t)$, then $\exists u_0 \in \Pi_\Delta(t)$, $u_0 \leq u_1 \wedge u_2$.

9 If one of the sub-derivations does not end with (ALG-INST), we can apply a trivial instance of (ALG-INST) with an identity substitution $\sigma_e$.\]
Proof. Let \([\sigma_{jk}]_{j \in J_k} \vdash t \equiv_\Delta 1 \times 1\) and \(u_k = \pi_j(\bigwedge_{j \in J_k} \tau_{jk})\) for \(k = 1, 2\). Then \([\sigma_j]_{j \in J_1 \cup J_2} \vdash t \equiv_\Delta 1 \times 1\). So \(\pi_j(\bigwedge_{j \in J_1 \cup J_2} \tau_{jk}) \in \Pi^\Delta(t)\). Moreover, by Lemma C.6 in the companion paper [3], we have
\[
\pi_i(\bigwedge_{j \in J_1 \cup J_2} \tau_{jk}) \leq \pi_i(\bigwedge_{j \in J_1} \tau_{jk}) \land \pi_i(\bigwedge_{j \in J_2} \tau_{jk}) = u_1 \land u_2
\]
\[
\square
\]

Since we only consider \(\lambda\)-abstractions with empty decorations, we can consider the following simplified version of (ALG-ABST) that does not use relabeling
\[
\forall i \in I. \Delta \cup \text{var}(\bigwedge_{i \in I} (t_i \rightarrow s_i))) \vdash \Gamma, x : t_i \vdash e : s_i' \text{ and } s_i' \leq s_i \quad (\text{ALG-ABST})
\]
Suppose the last rule used in the sub-derivations is (ALG-INST).
\[
\forall i \in I. \left\{ \begin{array}{l}
\Delta^\prime \vdash_x \lambda^\alpha \rightarrow \beta. e : s'_{i} \\
\forall j \in J, \sigma_j \notin \Delta^\prime
\end{array} \right.
\]
\[
\Delta^\prime = \Delta \cup \text{var}(\bigwedge_{i \in I} (t_i \rightarrow s_i))
\]
From the side conditions, we deduce that \(s_i' \subseteq \Delta^\prime \setminus \Delta\) for all \(i \in I\). Instantiation may be necessary to bridge the gap between the computed type \(s_i'\) for \(e\) and the type \(s_i\) required by the interface, so inferring type substitutions at this stage is mandatory. Therefore, we propose the following inference rule for abstractions.
\[
\forall i \in I. \left\{ \begin{array}{l}
\Delta \cup \text{var}(\bigwedge_{i \in I} (t_i \rightarrow s_i)) \vdash s_i' \\
\forall j \in J, \sigma_j \notin \Delta \vdash_x \lambda^\alpha \rightarrow \beta. e : s_i
\end{array} \right.
\]
In the application case, suppose both sub-derivations end with (ALG-INST):
\[
\Delta \vdash \pi \vdash e_1 : t \quad \forall j \in J_1, \sigma_{j1} \notin \Delta \vdash \pi \vdash e_2 : s \quad \forall j \in J_2, \sigma_{j2} \notin \Delta
\]
\[
\bigwedge_{j \in J_1} \tau_{j1} \leq 0 \rightarrow 1 \quad \bigwedge_{j \in J_2} \sigma_{j2} \leq \text{dom}(\bigwedge_{j \in J_1} \tau_{j1})
\]
\[
\left\{ \begin{array}{l}
\Delta \vdash \pi \vdash (e_1[\sigma_{j1}]_{j \in J_1})e_2[\sigma_{j2}]_{j \in J_2} : (\bigwedge_{j \in J_1} \tau_{j1}) \cdot (\bigwedge_{j \in J_2} \sigma_{j2})
\end{array} \right.
\]
Instantiation may be needed to bridge the gap between the (domain of the) function type and its argument (e.g., to apply \(\lambda^\alpha \rightarrow \beta. e\) to \(e_2\)). The side conditions imply that \(\sigma_{j1} \vdash_\pi \vdash t \equiv_\Delta 0 \rightarrow 1\) and \(s \equiv_\Delta \text{dom}(\bigwedge_{j \in J_1} \tau_{j1})\). Therefore, given an implicitly-typed application \(a_1a_2\) where \(a_1\) and \(a_2\) are typed with \(t\) and \(s\) respectively, we have to find two sets of substitutions \(\sigma_{j1}\) and \(\sigma_{j2}\) verifying the above preconditions to be able to type the application. If such sets of substitutions exist, then we can type the application with \((\bigwedge_{j \in J_1} \tau_{j1}) \cdot (\bigwedge_{j \in J_2} \sigma_{j2})\). Let \(t \cdot_\Delta s\) denote the set of such result types, that is,
\[
t \cdot_\Delta s = \left\{ u \mid \left[ \begin{array}{l}
\sigma_{j1} \vdash t \equiv_\Delta 0 \rightarrow 1 \\
s \equiv_\Delta \text{dom}(\bigwedge_{j \in J_1} \tau_{j1})
\end{array} \right. \bigwedge_{i \in I} \left( \sigma_{j1} \cdot \bigwedge_{j \in J_1} \tau_{j1} \right)
\right\}
\]
This set is closed under intersection (see Lemma B.8). Formally, we get the following inference rule for applications
\[
\Delta \vdash \pi \vdash a_1 : t \quad \Delta \vdash \pi \vdash a_2 : s \quad u \in t \cdot_\Delta s
\]
\[
\Delta \vdash \pi \vdash a_1a_2 : u
\]
\[
\text{Lemma B.8. Let } t, s \text{ be two types and } \Delta \text{ a set of type variables. If } u_1 \in t \cdot_\Delta s \text{ and } u_2 \in t \cdot_\Delta s, \text{ then } \exists u_0 \in t \cdot_\Delta s, u_0 \leq u_1 \land u_2.
\]
\[
\text{Proof. Let } u_k = (\bigwedge_{i \in I_k} \tau_{i k}) \cdot (\bigwedge_{j \in J_k} \sigma_{j k}) \text{ for } k = 1, 2. \text{ According to Lemma C.18 in the companion paper [3], we have } (\bigwedge_{i \in I_1 \cup I_2} \tau_{i}) \cdot (\bigwedge_{j \in J_1 \cup J_2} \sigma_{j}) \leq \bigwedge_{k=1,2} (\bigwedge_{i \in I_k} \tau_{i k}) \cdot (\bigwedge_{j \in J_k} \sigma_{j k}) \Rightarrow u_1 \land u_2.
\]
\[
\square
\]
For type cases, we distinguish the four possible behaviours: (i) no branch is selected, (ii) the first branch is selected, (iii) the second branch is selected, and (iv) both branches are selected. In all these cases, we
assume that the premises end with (ALG-INST). In case (i), we have the following derivation:

\[
\begin{align*}
\Delta_1 \Gamma \vdash \sigma : e \quad \forall j \in J, \sigma_j \not\in \Delta \\
\Delta_1 \Gamma \vdash \sigma[\sigma_j] : \bigwedge_{j \in J} \sigma_j \\
\end{align*}
\]

\[
\frac{\Delta_1 \Gamma \vdash \sigma_j \not\in \Delta}{\Delta_1 \vdash \Gamma \vdash (e[\sigma_j]) : \sigma_j} \quad \text{and all other cases of \(\Delta_1 \Gamma \vdash \sigma_j \not\in \Delta\)}
\]

Clearly, the side conditions implies \(t' \not\subseteq \Delta\). The type inference rule for implicitly-typed expressions corresponding to this case is then

\[
\begin{align*}
\Delta_1 \Gamma \vdash a : t' & \quad t' \not\subseteq \Delta \\
\Delta_1 \vdash \Gamma \vdash (a[t ] : a_2) : 0
\end{align*}
\]

For case (ii), consider the following derivation:

\[
\begin{align*}
\Delta_1 \Gamma \vdash \sigma_j \not\in \Delta \\
\Delta_1 \Gamma \vdash \sigma[\sigma_j] : \bigwedge_{j \in J} \sigma_j \\
\end{align*}
\]

\[
\frac{\Delta_1 \Gamma \vdash \sigma_j \not\in \Delta}{\Delta_1 \vdash \Gamma \vdash (e[\sigma_j]) : \sigma_j} \quad \text{and all other cases of \(\Delta_1 \Gamma \vdash \sigma_j \not\in \Delta\)}
\]

First, such a derivation can be rewritten as

\[
\begin{align*}
\Delta_1 \Gamma \vdash \sigma : e \quad \forall j \in J, \sigma_j \not\in \Delta \\
\Delta_1 \Gamma \vdash \sigma[\sigma_j] : \bigwedge_{j \in J} \sigma_j \\
\end{align*}
\]

\[
\frac{\Delta_1 \Gamma \vdash \sigma_j \not\in \Delta}{\Delta_1 \vdash \Gamma \vdash (e[\sigma_j]) : \sigma_j} \quad \text{and all other cases of \(\Delta_1 \Gamma \vdash \sigma_j \not\in \Delta\)}
\]

This indicates that it is equivalent to apply the substitutions \([\sigma_j]_{j \in J} \) to \(e\) or to the whole type case expression. Looking at the derivation for \(e\), for the first branch to be selected, we must have \(t' \not\subseteq \Delta\) \(t\). Note that if \(t' \subseteq \Delta\), we would have \(t' \not\subseteq \Delta\) by Lemma B.4, and no branch would be selected. Consequently, the type inference rule for a type case where the first branch is selected is as follows.

\[
\begin{align*}
\Delta_1 \Gamma \vdash a : t' & \quad t' \not\subseteq \Delta \\
\Delta_1 \vdash \Gamma \vdash a[t ] : a_1 \quad a_1 : t' \\
\end{align*}
\]

Case (iii) is similar to case (ii) where \(t\) is replaced by \(\neg t\).

At last, consider a derivation of Case (iv):

\[
\begin{align*}
\Delta_1 \Gamma \vdash \sigma_j \not\in \Delta \\
\Delta_1 \Gamma \vdash \sigma[\sigma_j] : \bigwedge_{j \in J} \sigma_j \\
\end{align*}
\]

\[
\frac{\Delta_1 \Gamma \vdash \sigma_j \not\in \Delta}{\Delta_1 \vdash \Gamma \vdash (e[\sigma_j]) : \sigma_j} \quad \text{and all other cases of \(\Delta_1 \Gamma \vdash \sigma_j \not\in \Delta\)}
\]

Using \(\alpha\)-conversion if necessary, we can assume that the polymorphic type variables of \(e_1\) and \(e_2\) are distinct, and therefore we have \(\text{var}(s_1) \cap \Delta \cap \text{var}(s_2) \cap \Delta = \emptyset\). According to Lemma B.5, we get \(s_1 \not\subseteq \Delta \land s_1 \not\subseteq \Delta \land s_2 \not\subseteq \Delta \land s_2 \not\subseteq \Delta \). Let \(s_1 s_2 \not\subseteq \Delta \land s_1 s_2 \not\subseteq \Delta \land s_1 s_2 \not\subseteq \Delta \land s_1 s_2 \not\subseteq \Delta \). We can rewrite this derivation as

\[
\begin{align*}
\Delta_1 \Gamma \vdash \sigma_j \not\in \Delta \\
\Delta_1 \Gamma \vdash \sigma[\sigma_j] : \bigwedge_{j \in J} \sigma_j \\
\end{align*}
\]

\[
\frac{\Delta_1 \Gamma \vdash \sigma_j \not\in \Delta}{\Delta_1 \vdash \Gamma \vdash (e[\sigma_j]) : \sigma_j} \quad \text{and all other cases of \(\Delta_1 \Gamma \vdash \sigma_j \not\in \Delta\)}
\]
\[ t' \not\subseteq_{\Delta} \neg t \text{ in general. If } t' \subseteq_{\Delta} t \text{ and/or } t' \not\subseteq_{\Delta} \neg t \text{ hold, then we are in one of the previous cases } (i) \text{ -- } (iii) \text{ (i.e., we type-check at most one branch), and the inferred result type for the whole type case belongs to } 0, s_1 \text{ or } s_2. \text{ We can then use subsumption to type the whole type-case expression with } s_1 \lor s_2. \text{ Otherwise, both branches are type-checked, and we deduce the corresponding inference rule as follows.}

\[
\begin{align*}
\Delta \vdash \Gamma \vdash a : t & \quad \text{if } t' \not\subseteq_{\Delta} \neg t \\
\Delta \vdash \Gamma \vdash a_1 : s_1 \\
\Delta \vdash \Gamma \vdash a_2 : s_2 \\
\Delta \vdash \Gamma \vdash (a t ? a_1 : a_2) : s_1 \lor s_2
\end{align*}
\]

From the study above, we deduce the type-substitution inference rules for implicitly-typed expressions given in Figure 5, which are the same as those in Section 3 except for the rules for products.

\[
\begin{align*}
\Delta \vdash \Gamma \vdash a : t & \quad \text{(INF-CONST)} \\
\Delta \vdash \Gamma \vdash a_1 : t_1 \\
\Delta \vdash \Gamma \vdash a_2 : t_2 \\
\Delta \vdash \Gamma \vdash (a_1, a_2) : t_1 \times t_2 & \quad \text{(INF-PAIR)} \\
\Delta \vdash \Gamma \vdash a_1 : t \\
\Delta \vdash \Gamma \vdash a_2 : s \\
\Delta \vdash \Gamma \vdash a_1 a_2 : u & \quad \text{(INF-APPL)} \\
\forall i \in I. \quad \{ \Delta \cup \operatorname{var} \left( \bigwedge_{i \in I} t_i \rightarrow s_i \right); \Gamma; (x : t_i) \vdash a : s_i' \\
\quad s_i' \subseteq_{\Delta; \varphi_{t_i \rightarrow s_i}} s_i \\
\Delta \vdash \Gamma \vdash \lambda^{i \in I} t_i \rightarrow s_i. a : \bigwedge_{i \in I} t_i \rightarrow s_i & \quad \text{(INF-ABST)} \\
\Delta \vdash \Gamma \vdash a : t' & \quad t' \not\subseteq_{\Delta} 0 \\
\Delta \vdash \Gamma \vdash (a t ? a_1 : a_2) : 0 & \quad \text{(INF-CASE-NONE)} \\
\Delta \vdash \Gamma \vdash a : t' & \quad t' \subseteq_{\Delta} t \\
\Delta \vdash \Gamma \vdash \neg t' \not\subseteq_{\Delta} \neg t & \quad \Delta \vdash \Gamma \vdash a_1 : s \\
\Delta \vdash \Gamma \vdash (a t ? a_1 : a_2) : s & \quad \text{(INF-CASE-FST)} \\
\Delta \vdash \Gamma \vdash a : t' & \quad t' \subseteq_{\Delta} t \\
\Delta \vdash \Gamma \vdash \neg t' \not\subseteq_{\Delta} t & \quad \Delta \vdash \Gamma \vdash a_2 : s \\
\Delta \vdash \Gamma \vdash (a t ? a_1 : a_2) : s & \quad \text{(INF-CASE-SND)} \\
\Delta \vdash \Gamma \vdash a : t' & \quad \{ t' \not\subseteq_{\Delta} \neg t \text{ and } \Delta \vdash \Gamma \vdash a_1 : s_1 \\
\quad \{ t' \not\subseteq_{\Delta} t \text{ and } \Delta \vdash \Gamma \vdash a_2 : s_2 \\
\Delta \vdash \Gamma \vdash (a t ? a_1 : a_2) : s_1 \lor s_2 & \quad \text{(INF-CASE-BOTH)}
\end{align*}
\]

Figure 5. Type-substitution inference rules

B.2 Soundness and Completeness

We now prove that the inference rules of the implicitly-typed calculus given in Figure 5 are sound and complete with respect to the type system of the explicitly-typed calculus (i.e., Figure 1 extended with the standard rules for products).

To construct an explicitly-typed expression from an implicitly-typed one \( a \), we have to insert sets of substitutions \( a \) each time a preorder check is performed in the rules of Figure 5. For an abstraction \( \lambda^{i \in I} t_i \rightarrow s_i. x.a \), different sets of substitutions may be constructed when type checking the body under the different hypotheses \( x : t_i \). For example, let \( a = \lambda^{(\operatorname{Int} \rightarrow \operatorname{Int}) \rightarrow (\operatorname{Bool} \rightarrow \operatorname{Bool})}. x. (\lambda^{\alpha \rightarrow \gamma} y).y \). When \( a \) is type-checked against \( \operatorname{Int} \rightarrow \operatorname{Int} \), that is, \( x \) is assumed to have type \( \operatorname{Int} \), we infer the type substitution \( \{ \operatorname{Int}/(a) \} \) for \( (\lambda^{\alpha \rightarrow \gamma} y).y \). Similarly, we infer \( \{ \operatorname{Bool}/(a) \} \) for \( (\lambda^{\alpha \rightarrow \gamma} y).y \), when \( a \) is type-checked against \( \operatorname{Bool} \rightarrow \operatorname{Bool} \). We have to collect these two different substitutions when constructing the explicitly-typed expression \( e \) which corresponds to \( a \). To this end, we introduce an intersection operator \( e \cap e' \) of expressions which is defined only for pair of expressions that have similar structure but different type substitutions. For example, the intersection of \( (\lambda^{\alpha \rightarrow \gamma} y).y[[\operatorname{Int}/(a)]]x \) and \( (\lambda^{\alpha \rightarrow \gamma} y).y[[\operatorname{Bool}/(a)]]x \) will be \( (\lambda^{\alpha \rightarrow \gamma} y).y[[\operatorname{Int}/(a)], [\operatorname{Bool}/(a)]]x \).
Definition B.9. Let $e, e' \in \delta_0$ be two expressions. Their intersection $e \cap e'$ is defined by induction as:

\[
c \cap e = c
\]
\[
x \cap x = x
\]
\[
(e_1, e_2) \cap (e'_1, e'_2) = ((e_1 \cap e'_1), (e_2 \cap e'_2))
\]
\[
\pi(e) \cap \pi(e') = \pi(e \cap e')
\]
\[
e_1 \cap e_2 \cap (e'_1, e'_2) = (e_1 \cap e'_1)(e_2 \cap e'_2)
\]
\[
\lambda^{\wedge 0_i} e \cap x.e = \lambda^{\wedge 0_i} e \cap x.e
\]
\[
(e_0 \in \varepsilon \? e_1 : e_2) \cap (e'_0 \in \varepsilon ? e'_1 : e'_2) = e_0 \cap e'_0 \in \varepsilon \? e_1 \cap e'_1 : e_2 \cap e'_2
\]
\[
(e_1[\sigma_j]_{i,j}) \cap (e'_1[\sigma_j]_{j'}) = (e_1 \cap e'_1)[\sigma_j]_{i,j'j'}
\]
\[
e \cap (e'_1[\sigma_j]_{j'}) = (e[\sigma_i]) \cap (e'_1[\sigma_j]_{j'})
\]
\[
\pi_i(e) \cap e \cap e' = (e[\sigma_i]) \cap (e' \cap e')
\]

where $\sigma_{id}$ is the identity type substitution and is undefined otherwise.

The intersection of the same constant or the same variable is the constant or the variable itself. If $e$ and $e'$ have the same form, then their intersection is defined if the intersections of their corresponding sub-expressions are defined. In particular when $e$ is of the form $e_1[\sigma_j]_{j \in J}$ and $e'$ is of the form $e'_1[\sigma_j]_{j' \in J'}$, we merge the sets of substitutions $\{\sigma_j \in J\}$ and $\{\sigma_j \in J'\}$ into one set $\{\sigma_j \in (J \cup J')\}$. Otherwise, $e$ and $e'$ have different forms. The only possible case where their intersection is well-defined is when they have similar structures but one with instantiations and the other without (i.e., $e = e_1[\sigma_j]_{j \in J}$, $e' \neq e'_1[\sigma_j]_{j' \in J'}$ or $e \neq e_1[\sigma_j]_{j \in J}$, $e' = e'_1[\sigma_j]_{j' \in J'}$). In order not to lose any inferred information and be able to reuse the cases defined above, we add the identity substitution $\sigma_{id}$ to the expression without substitutions (i.e., $e[\sigma_{id}]$ or $e'[\sigma_{id}]$).

Let us infer the substitutions for the abstraction $\lambda^{t_1 \rightarrow t_2}(x.e)$ Assume that we have inferred some substitutions for the body $e$ under $t_1 \rightarrow s_1$ and $t_2 \rightarrow s_2$ respectively, yielding two explicitly-typed expressions $e_1$ and $e_2[\sigma_j]_{j \in J}$. If we did not add the identity substitution $\sigma_{id}$ for the intersection of $e_1$ and $e_2[\sigma_j]_{j \in J}$, that is, $e_1[\sigma_j]_{j \in J}$ were $(e_1 \cap e_2)[\sigma_j]_{j \in J}$ rather than $(e_1 \cap e_2)[\sigma_{id}] [\sigma_j]_{j \in J}$, then the substitutions we inferred under $t_1 \rightarrow s_1$ would be lost since they may be modified by $[\sigma_j]_{j \in J}$.

Lemma B.10. Let $e, e' \in \delta_0$ be two expressions. If $erase(e) = erase(e')$, then $e \cap e'$ exists and $erase(e \cap e') = erase(e) = erase(e')$.

Proof. By induction on the structures of $e$ and $e'$. Because $erase(e) = erase(e')$, the two expressions have the same structure up to their sets of type substitutions.

\[c \cap c\] straightforward.
\[x \cap x\] straightforward.
\[(e_1, e_2) \cap (e'_1, e'_2)\]: we have $erase(e_i) = erase(e'_i)$.

\[
\pi(e) \cap \pi(e') = \pi(e \cap e')
\]

Similarly, we also have $erase((e_1, e_2) \cap (e'_1, e'_2)) = erase((e'_1, e'_2))$.
\[
\pi_i(e) \cap \pi_i(e') = \pi_i(e \cap e')
\]

Similarly, we also have $erase((e_1, e_2) \cap (e'_1, e'_2)) = erase((e'_1, e'_2))$.
\[
\pi_i(e) \cap \pi_i(e') = \pi_i(e \cap e')
\]

Similarly, we also have $erase((e_1, e_2) \cap (e'_1, e'_2)) = erase((e'_1, e'_2))$.
\[
\lambda^{\wedge 0_i} e \cap x.e = \lambda^{\wedge 0_i} e \cap x.e
\]
\[
(e_0 \in \varepsilon ? e_1 : e_2) \cap (e'_0 \in \varepsilon ? e'_1 : e'_2) = e_0 \cap e'_0 \varepsilon ? e_1 \cap e'_1 : e_2 \cap e'_2
\]
\[
(e_1[\sigma_j]_{i,j}) \cap (e'_1[\sigma_j]_{j'}) = (e_1 \cap e'_1)[\sigma_j]_{i,j'j'}
\]
\[
e \cap (e'_1[\sigma_j]_{j'}) = (e[\sigma_i]) \cap (e'_1[\sigma_j]_{j'})
\]
\[
\pi_i(e) \cap (e \cap e') = (e[\sigma_i]) \cap (e' \cap e')
\]

Similarly, we also have $erase((e_1, e_2) \cap (e'_1, e'_2)) = erase((e'_1, e'_2))$.
Similarly, we also have
\[
\text{erase}(\lambda^x \in t \mapsto s : x.e) \cap (\lambda^x \in t' \mapsto s' : x.e') = \text{erase}(\lambda^x \in t' \mapsto s' : x.e')
\]
\[e_0 \not\in t \mapsto e_1 : e_2, e'_0 \not\in t \mapsto e'_1 : e'_2 :\text{ we have } \text{erase}(e_1) = \text{erase}(e'_1) .\]
By induction, \(e_0 \not\in t \mapsto e_1 : e_2\) exists and \(\text{erase}(e_1 \mapsto e'_1)\). Therefore \((e_0 \not\in t \mapsto e_1 : e_2) \cap (e'_0 \not\in t \mapsto e'_1 : e'_2)\) exists and
\[
\text{erase}((e_0 \not\in t \mapsto e_1 : e_2) \cap (e'_0 \not\in t \mapsto e'_1 : e'_2)) = \text{erase}((e_0 \cap e'_0) \not\in t \mapsto (e_1 \cap e'_1) : (e_2 \cap e'_2)) = \text{erase}(e_0 \cap e'_0) \not\in t \mapsto \text{erase}(e_1 \cap e'_1) : (e_2 \cap e'_2) = \text{erase}(e_0 \not\in t \mapsto \text{erase}(e_1) : e_2) = \text{erase}(e_0 \not\in t \mapsto e_1 : e_2)
\]

Similarly, we also have
\[
\text{erase}((e_0 \not\in t \mapsto e_1 : e_2) \cap (e'_0 \not\in t \mapsto e'_1 : e'_2)) = \text{erase}(e_0 \not\in t \mapsto e'_1 : e'_2)
\]
\[e[\sigma_j]_{j \in J}, e'[\sigma_j]_{j \in J'} : \text{ we have } \text{erase}(e) = \text{erase}(e').\]
By induction, \(e \not\in e'\) exists and \(\text{erase}(e \mapsto e') = \text{erase}(e) = \text{erase}(e').\)
Therefore \((e \not\in e' \cap e')\) exists and
\[
\text{erase}((e \not\in e' \cap e') \cap (e'[\sigma_j]_{j \in J} \cap (e'[\sigma_j]_{j \in J'})) = \text{erase}((e \not\in e') \not\in e_j \mapsto (e'[\sigma_j]_{j \in J} \cap (e'[\sigma_j]_{j \in J'})) = \text{erase}(e \not\in e') = \text{erase}(e') = \text{erase}(e[\sigma_j]_{j \in J})
\]
\[e[\sigma_j]_{j \in J}, e'[\sigma_j]_{j \in J'} : \text{ a special case of } e[\sigma_j]_{j \in J} \text{ and } e'[\sigma_j]_{j \in J'} \text{ where } [\sigma_j]_{j \in J} = [\sigma_d].
\]

\[
\text{Lemma B.11. } \text{Let } e, e' \in \mathcal{E}_0 \text{ be two expressions. If } \text{erase}(e) = \text{erase}(e'), \Delta; \Gamma \vdash e : t, \Delta' \Gamma' \vdash e' : t', e \not\in \Delta' \text{ and } e' \not\Delta, \text{ then } \Delta; \Gamma \vdash e \cap e' : t \text{ and } \Delta' \Gamma' \vdash e \cap e' : t'.
\]

\begin{proof}
According to Lemma B.10, \(e \not\in e'\) and \(\text{erase}(e \mapsto e') = \text{erase}(e) = \text{erase}(e').\) We only prove \(\Delta; \Gamma \vdash e \cap e' : t\) as the other case is similar. For simplicity, we just consider one set of type substitutions.
For several sets of type substitutions, we can either compose them or apply (\text{instinctor}) several times. The proof proceeds by induction on \(\Delta; \Gamma \vdash e : t\).

\text{(const): } \Delta; \Gamma \vdash c : b_c.\text{ As } \text{erase}(e') = c, e' \text{ is either } c \text{ or } c[\sigma_j]_{j \in J}.\text{ If } e' = c, \text{ then } e \cap e' = c, \text{ and the result follows straightforwardly. Otherwise, we have } e \cap e' = c[\sigma_d, \sigma_j]_{j \in J}.\text{ Since } e' \not\Delta, \text{ we have } \sigma_j \not\Delta.\text{ By (instinctor), we have } \Delta; \Gamma \vdash c[\sigma_d, \sigma_j]_{j \in J} : b_c \land \bigwedge_{j \in J} b_c \sigma_j, \text{ that is, } \Delta; \Gamma \vdash c[\sigma_d, \sigma_j]_{j \in J} : b_c.\)

\text{(var): } \Gamma \vdash x : \Gamma(x).\text{ As } \text{erase}(e') = x, e' \text{ is either } x \text{ or } x[\sigma_j]_{j \in J}.\text{ If } e' = x, \text{ then } e \cap e' = x, \text{ and the result follows straightforwardly. Otherwise, we have } e \cap e' = x[\sigma_d, \sigma_j]_{j \in J}.\text{ Since } e' \not\Delta, \text{ we have } \sigma_j \not\Delta.\text{ By (instinctor), we have } \Delta; \Gamma \vdash x[\sigma_d, \sigma_j]_{j \in J} : \Gamma(x) \land \bigwedge_{j \in J} \Gamma(x) \sigma_j, \text{ that is, } \Delta; \Gamma \vdash x[\sigma_d, \sigma_j]_{j \in J} : \Gamma(x).\)

\text{(pair): consider the following derivation:}

\[
\Delta; \Gamma \vdash e_1 : t_1 \quad \Delta; \Gamma \vdash e_2 : t_2
\]
\[\Delta; \Gamma \vdash (e_1, e_2) : t_1 \times t_2 \quad \text{(pair)}
\]
As \(\text{erase}(e') = (\text{erase}(e_1), \text{erase}(e_2))\), \(e'\) is either \((e'_1, e'_2)\) or \((e'_1, e'_2)[\sigma_j]_{j \in J}\) such that \(\text{erase}(e'_1) = \text{erase}(e_1)\). By induction, we have \(\Delta; \Gamma \vdash e_1 \cap e'_1 : t_1.\) Then by (pair), we have \(\Delta; \Gamma \vdash (e_1 \cap e'_1, e_2 \cap e'_2) : (t_1 \times t_2).\) If \(e' = (e'_1, e'_2)\), then \(e \cap e' = (e_1 \cap e'_1, e_2 \cap e'_2).\) So the result follows.

\text{(proj): consider the following derivation:}

\[
\Delta; \Gamma \vdash e_0 : t_1 \times t_2
\]
\[\Delta; \Gamma \vdash \pi_t(e_0) : t_1 \quad \text{(proj)}
\]
As \(\text{erase}(e') = \pi_t(\text{erase}(e_0))\), \(e'\) is either \(\pi_t(e'_0)\) or \(\pi_t(e'_0)[\sigma_j]_{j \in J}\) such that \(\text{erase}(e'_0) = \text{erase}(e_0)\). By induction, we have \(\Delta; \Gamma \vdash e_0 \cap e'_0 : (t_1 \times t_2).\) Then by (proj), we have \(\Delta; \Gamma \vdash \pi_t(e_0 \cap e'_0) : t_1.\) If \(e' = \pi_t(e'_0)\), then \(e \cap e' = (e_0 \cap e'_0).\) So the result follows.

\text{(app): consider the following derivation:}

\[
\Delta; \Gamma \vdash e_1 : t \to s \quad \Delta; \Gamma \vdash e_2 : t
\]
\[\Delta; \Gamma \vdash e_1 ; e_2 : s \quad \text{(pair)}
\]
As erase($e'$) = erase($e_1$) erase($e_2$), $e'$ is either $e'_1 e'_2$ or $(e'_1 e'_2)[σ_j]_{j ∈ J}$ such that erase($e'_i$) = erase($e_i$).
By induction, we have $Δ_3 Γ ⊢ e_1 ⊓ e'_1 : t → s$ and $Δ_3 Γ ⊢ e_2 ⊓ e'_2 : t$. Then by (app1), we have $Δ_3 Γ ⊢ (e_1 ⊓ e'_1)(e_2 ⊓ e'_2) : s$. If $e' = e'_1 e'_2$, then $e ⊓ e' = (e_1 ⊓ e'_1)(e_2 ⊓ e'_2)$. So the result follows.
Otherwise, $e ⊓ e' = ((e_1 ⊓ e'_1)(e_2 ⊓ e'_2))[σ_{id, σ_j}]_{j ∈ J}$. Since $e' ⊓ Δ$, we have $σ_j ⊢ Δ$. By (inst1), we have $Δ_3 Γ ⊢ (e_1 ⊓ e'_1)(e_2 ⊓ e'_2)[σ_{id, σ_j}]_{j ∈ J} : s ∧ Δ_j e_j, σ_j$. Finally, by (subsum), we get $Δ_3 Γ ⊢ [(e_1 ⊓ e'_1)(e_2 ⊓ e'_2)[σ_{id, σ_j}]_{j ∈ J}] : s$.

(abstr): consider the following derivation:

$$\forall t ∈ I. Δ'' Γ, (x : t_i) ⊢ e_0 : s_i,$$
$$Δ'' = Δ ∪ \text{var}(\bigwedge_{i ∈ I} t_i → s_i) \quad \text{(abstr)}$$

As erase($e'$) = $λ_{i < i_1} ⊓ s_1.x.\text{erase}(e_0)$, $e'$ is either $λ_{i < i_1} ⊓ s_1.x.e'_0$ or $(λ_{i < i_1} ⊓ s_1.x.e'_0)[σ_{id, σ_j}]_{j ∈ J}$ such that erase($e'_0$) = erase($e_0$). As $λ_{i < i_1} ⊓ s_1.x.e'_0$ is well-typed under $Δ'$ and $Γ'$, $e'_0 ⊢ Δ' ∪ \text{var}(\bigwedge_{i ∈ I} t_i → s_i)$. By induction, we have $Δ'' Γ, (x : t_i) ⊢ e_0 ⊓ e'_0 : s_j$. Then by (abstr), we have $Δ'' Γ ⊢ (λ_{i < i_1} ⊓ s_1.x.e'_0) : \bigwedge_{i ∈ I} t_i → s_i$. If $e' = λ_{i < i_1} ⊓ s_1.x.e'_0$, then $e ⊓ e' = λ_{i < i_1} ⊓ s_1.x.e'_0$. So the result follows.

Otherwise, $e ⊓ e' = (λ_{i < i_1} ⊓ s_1.x.e_0 ⊓ e'_0)[σ_{id, σ_j}]_{j ∈ J}$. Since $e' ⊓ Δ$, we have $σ_j ⊢ Δ$. By (inst2), we have $Δ_3 Γ ⊢ (λ_{i < i_1} ⊓ s_1.x.e_0 ⊓ e'_0)[σ_{id, σ_j}]_{j ∈ J} : (\bigwedge_{i ∈ I} t_i → s_i) ∧ Δ_j e_j, σ_j$. Finally, by (subsum), we get $Δ_3 Γ ⊢ [(λ_{i < i_1} ⊓ s_1.x.e_0 ⊓ e'_0)[σ_{id, σ_j}]_{j ∈ J}] : \bigwedge_{i ∈ I} t_i → s_i$.

(case): consider the following derivation:

$$Δ_3 Γ ⊢ e_0 : t' \quad \left\{ \begin{array}{l}
t' \not\subseteq -t \quad \Rightarrow \quad Δ_3 Γ ⊢ e_1 : s \\
t' \subseteq -t \quad \Rightarrow \quad Δ_3 Γ ⊢ e_2 : s \end{array} \right. \quad \text{(case)}$$

As erase($e'$) = erase($e_0$) ∈ $t′$? erase($e_1$): erase($e_2$), $e'$ is either $e_0 ∈ t′$? $e'_1$? $e'_2$ or $(e_0 ∈ t′$? $e'_1$? $e'_2)[σ_{id, σ_j}]_{j ∈ J}$ such that erase($e'_i$) = erase($e_i$). By induction, we have $Δ_3 Γ ⊢ e_0 ⊓ e'_0 : t'$ and $Δ_3 Γ ⊢ e_1 ⊓ e'_1 : s$. Then by (case), we have $Δ_3 Γ ⊢ (e_0 ⊓ e'_0) ∈ t′? (e_1 ⊓ e'_1) : (e_2 ⊓ e'_2)[σ_{id, σ_j}]_{j ∈ J} : s$. If $e' = e_0 ⊓ e'_0 ∈ t′? e'_1$, then $e ⊓ e' = (e_0 ⊓ e'_0) ⊓ (e_1 ⊓ e'_1) : (e_2 ⊓ e'_2)[σ_{id, σ_j}]_{j ∈ J}$. So the result follows.

Otherwise, $e ⊓ e' = ((e_0 ⊓ e'_0) ∈ t′? (e_1 ⊓ e'_1) : (e_2 ⊓ e'_2))[σ_{id, σ_j}]_{j ∈ J}$. Since $e' ⊓ Δ$, we have $σ_j ⊢ Δ$. By (inst2), we have $Δ_3 Γ ⊢ (e_0 ⊓ e'_0) ∈ t′? (e_1 ⊓ e'_1) : (e_2 ⊓ e'_2)[σ_{id, σ_j}]_{j ∈ J} : s ∧ Δ_j e_j, σ_j$. Finally, by (subsum), we get $Δ_3 Γ ⊢ [(e_0 ⊓ e'_0) ∈ t′? (e_1 ⊓ e'_1) : (e_2 ⊓ e'_2)[σ_{id, σ_j}]_{j ∈ J}] : s$.

(inst2): consider the following derivation:

$$Δ_3 Γ ⊢ e_0 : t \quad σ_j ⊢ Δ \quad \text{(inst2)}$$

As erase($e'$) = erase($e_0$), $e'$ is either $e_0$ or $[σ_{j}]_{j ∈ J′}$ such that erase($e'_0$) = erase($e_0$). By induction, we have $Δ_3 Γ ⊢ e_0 ⊓ e'_0 : t$. If $e' = e_0$, then $e ⊓ e' = (e_0 ⊓ e'_0)[σ_{id, σ_j}]_{j ∈ J}$. By (inst2), we have $Δ_3 Γ ⊢ (e_0 ⊓ e'_0)[σ_{id, σ_j}]_{j ∈ J} : Δ_j e_j [σ_{j}]_{j ∈ J′}$ and $t$. Finally, by (subsum), we get $Δ_3 Γ ⊢ (e_0 ⊓ e'_0)[σ_{id, σ_j}]_{j ∈ J} : Δ_j e_j [σ_{j}]_{j ∈ J′}$. Otherwise, $e ⊓ e' = (e_0 ⊓ e'_0)[σ_{id, σ_j}]_{j ∈ J′}$. Since $e' ⊓ Δ$, we have $σ_j ⊢ Δ$ for all $j ∈ J′$. By (inst2), we have $Δ_3 Γ ⊢ (e_0 ⊓ e'_0)[σ_{id, σ_j}]_{j ∈ J′} : Δ_j e_j [σ_{j}]_{j ∈ J′}$. Finally, by (subsum), we get $Δ_3 Γ ⊢ (e_0 ⊓ e'_0)[σ_{id, σ_j}]_{j ∈ J′} : Δ_j e_j [σ_{j}]_{j ∈ J′}$.

(subsum): there exists a type $s$ such that

$$Δ_3 Γ ⊢ e : s \quad s ≤ t \quad \text{(subsum)}$$

By induction, we have $Δ_3 Γ ⊢ e ⊓ e' : s$. Then the rule (subsum) gives us $Δ_3 Γ ⊢ e ⊓ e' : t$.

Corollary B.12. Let $e, e′ ∈ e_0$ be two expressions. If erase($e$) = erase($e'$), $Δ_3 Γ ⊢ e : t$, $Δ'_3 Γ ⊢ e' : t$, $e' ⊓ Δ'$, and $e'' ⊓ Δ''$, then
1. there exists $s$ such that $Δ_3 Γ ⊢ e ⊓ e' : s$ and $s ≤ t$.
2. there exists $s'$ such that $Δ'_3 Γ ⊢ e ⊓ e' : s'$ and $s' ≤ t'$.

Proof. Immediate consequence of Lemma B.11 and Theorems C.22 and C.23 in the companion paper [3].

These type-substitution inference rules are sound and complete with respect to the typing algorithm in Section C.2 in the companion paper [3], modulo the restriction that all the decorations in the λ-abstractions are empty.
Theorem B.13 (Soundness). If \( \Delta \triangleright \Gamma \vdash \alpha : t \), then there exists an explicitly-typed expression \( e \in \mathcal{E}_0 \) such that \( \text{erase}(e) = \alpha \) and \( \Delta \triangleright \Gamma \vdash \alpha e : t \).

Proof. By induction on the derivation of \( \Delta \triangleright \Gamma \vdash \alpha : t \). We proceed by a case analysis of the last rule used in the derivation.

\textbf{(INF-CONST):} straightforward (take \( e \) as \( c \)).

\textbf{(INF-VAR):} straightforward (take \( e \) as \( x \)).

\textbf{(INF-PAIR):} consider the derivation

\[
\frac{\Delta \triangleright \Gamma \vdash \alpha_1 : t_1 \quad \Delta \triangleright \Gamma \vdash \alpha_2 : t_2}{\Delta \triangleright \Gamma \vdash (\alpha_1, \alpha_2) : t_1 \times t_2}
\]

Applying the induction hypothesis, there exists an expression \( e_i \) such that \( \text{erase}(e_i) = \alpha_i \) and \( \Delta \triangleright \Gamma \vdash \alpha_i e_i : t_i \). Then by (ALG-PAIR), we have \( \Delta \triangleright \Gamma \vdash (e_1, e_2) : t_1 \times t_2 \). Moreover, according to Definition B.2, we have \( \text{erase}(e_1, e_2) = (\text{erase}(e_1), \text{erase}(e_2)) = (\alpha_1, \alpha_2) \).

\textbf{(INF-PROJ):} consider the derivation

\[
\frac{\Delta \triangleright \Gamma \vdash \alpha : t \quad u \in \Pi_\Delta(t)}{\Delta \triangleright \Gamma \vdash \pi_i(\alpha) : u}
\]

By induction, there exists an expression \( e \) such that \( \text{erase}(e) = \alpha \) and \( \Delta \triangleright \Gamma \vdash \alpha e : t \). Let \( u = \pi_i(\lambda_{i \in I} \sigma_i) \cdot (\lambda_{i \in J} s_{\sigma_j}) \). As \( \sigma_i \not\in \Delta \), by (ALG-INST), we have \( \Delta \triangleright \Gamma \vdash e[s_{\sigma_j}]_{i \in J} : \lambda_{i \in J} s_{\sigma_j} \). Moreover, since \( \lambda_{i \in J} t_{\sigma_j} \leq 1 \times \mathcal{E}_0 \), by (ALG-PROJ), we get \( \Delta \triangleright \Gamma \vdash \sigma_i e[s_{\sigma_j}]_{i \in J} : \lambda_{i \in J} s_{\sigma_j} \). Finally, according to Definition B.2, we have \( \text{erase}(\sigma_i e[s_{\sigma_j}]_{i \in J}) = \pi_i(\text{erase}(e[s_{\sigma_j}]_{i \in J})) = \pi_i(\text{erase}(e)) = \pi_i(\alpha) \).

\textbf{(INF-APPL):} consider the derivation

\[
\frac{\Delta \triangleright \Gamma \vdash \alpha_1 : \mathcal{I} \quad \Delta \triangleright \Gamma \vdash \alpha_2 : \mathcal{s} \quad u \in t \triangleleft s}{\Delta \triangleright \Gamma \vdash \alpha_1 \alpha_2 : u}
\]

By induction, we have that (i) there exists an expression \( e_1 \) such that \( \text{erase}(e_1) = \alpha_1 \) and \( \Delta \triangleright \Gamma \vdash e_1 : t \) and (ii) there exists an expression \( e_2 \) such that \( \text{erase}(e_2) = \alpha_2 \) and \( \Delta \triangleright \Gamma \vdash e_2 : s \). Let \( u = (\lambda_{i \in I} t_i) \cdot (\lambda_{i \in J} s_{\sigma_j}) \). As \( \sigma_i \not\in \Delta \) for \( h \in \mathcal{I} \cup \mathcal{J} \), applying (ALG-INST), we get \( \Delta \triangleright \Gamma \vdash e_1[s_{\sigma_j}]_{i \in J} : \lambda_{i \in I} t_i \sigma_i \) and \( \Delta \triangleright \Gamma \vdash e_2[s_{\sigma_j}]_{i \in J} : \lambda_{i \in J} s_{\sigma_j} \). Then by (ALG-APPL), we have \( \Delta \triangleright \Gamma \vdash (e_1[s_{\sigma_j}]_{i \in J})(e_2[s_{\sigma_j}]_{i \in J}) : (\lambda_{i \in I} t_i) \cdot (\lambda_{i \in J} s_{\sigma_j}) \). Furthermore, according to Definition B.2, we have \( \text{erase}(e_1[s_{\sigma_j}]_{i \in J})(e_2[s_{\sigma_j}]_{i \in J}) = \text{erase}(e_1) \text{erase}(e_2) = \alpha_1 \alpha_2 \).

\textbf{(INF-ABST):} consider the derivation

\[
\forall i \in \mathcal{I}, \frac{\Delta \cup \text{var}(\lambda_{i \in I} t_i \rightarrow s_i) \triangleright \Gamma, (x : t_i) \vdash \alpha : s_i \quad s_i' \subseteq \Delta \cup \text{var}(\lambda_{i \in I} t_i \rightarrow s_i) \quad s_i}{\Delta \triangleright \Gamma \vdash \lambda^{\text{erase}(t_i) \rightarrow \text{erase}(s_i)} x. a : \lambda_{i \in I} t_i \rightarrow s_i}
\]

Let \( \Delta' = \Delta \cup \text{var}(\lambda_{i \in I} t_i \rightarrow s_i) \) and \( e[s_{\sigma_j}]_{j \in J} \mid \sigma_j \not\in \Delta' \) \( s_j' \subseteq \Delta' \). By induction, there exists an expression \( e_i \) such that \( \text{erase}(e_i) = \alpha_i \) and \( \Delta \triangleright \Gamma \vdash e_i : t_i \). Since \( \sigma_j \not\in \Delta' \), by (ALG-INST), we have \( \Delta \triangleright \Gamma \vdash e_i[s_{\sigma_j}]_{j \in J} : \lambda_{j \in J} s_j' \). Clearly, \( e[s_{\sigma_j}]_{i \in I}, s_j \not\in \Delta' \) and \( \text{erase}(e[s_{\sigma_j}]_{j \in J}) = \text{erase}(e_i) \). Then by Lemma B.10, the intersection \( \lambda_{i \in I} e_i[s_{\sigma_j}]_{j \in J} \) exists and we have \( \text{erase}(\bigcap_{i \in \mathcal{I}} e_i[s_{\sigma_j}]_{j \in J}) = a \) for any non-empty \( \mathcal{I}' \subseteq \mathcal{I} \). Let \( e = \bigcap_{i \in \mathcal{I}} e_i[s_{\sigma_j}]_{j \in J} \). According to Corollary B.12, there exists a type \( t_i' \) such that \( \Delta' \triangleright \Gamma, (x : t_i') \vdash \sigma_j e_i[s_{\sigma_j}]_{j \in J} : \lambda_{j \in J} s_j' \). Moreover, \( t_i' \subseteq \bigcap_{j \in J} s_j' \). Finally, according to Definition B.2, we have \( \text{erase}(\lambda^{\text{erase}(t_i) \rightarrow \text{erase}(s_j)} x. e) = \lambda^{\text{erase}(t_i) \rightarrow \text{erase}(s_j)} x. a \).

\textbf{(INF-CASE-NONE):} consider the derivation

\[
\frac{\Delta \triangleright \Gamma \vdash \alpha : t' \subseteq \Delta \quad \alpha \in \mathcal{E}_0}{\Delta \triangleright \Gamma \vdash (a e \sim a : a) : \mathcal{E}_0}
\]

By induction, there exists an expression \( e \) such that \( \text{erase}(e) = \alpha \) and \( \Delta \triangleright \Gamma \vdash e : t' \). Let \( [\sigma_i]_{i \in I} \mid \sigma_i \not\in \Delta \). Since \( \sigma_i \not\in \Delta \), by (ALG-INST), we have \( \Delta \triangleright \Gamma \vdash [\sigma_i]_{i \in I} : \lambda_{i \in I} t_i' \sigma_i \). Let \( e_1 \) and \( e_2 \) be two expressions such that \( \text{erase}(e_1) = \alpha_1 \) and \( \text{erase}(e_2) = \alpha_2 \). Then we have \( \text{erase}([\sigma_i]_{i \in I} e) \in \mathcal{E}_0 \Leftrightarrow [\sigma_i]_{i \in I} e_1 : e_2 \).

Moreover, since \( \bigcap_{i \in I} t_i' \sigma_i \leq 0 \), by (ALG-CASE-NONE), we have \( \Delta \triangleright \Gamma \vdash (e[s_{\sigma_j}]_{i \in I}) : e \in : e_2 : 0 \).
The proof of the soundness property constructs along the derivation for a some expression $e$ that satisfies the statement of the theorem. We denote by $\text{erase}^{-1}(a)$ the set of expressions $e$ that satisfy the statement.

**Theorem B.14 (Completeness).** Let $e \in \mathcal{E}_0$ be an explicitly-typed expression. If $\Delta ; \Gamma \vdash_{a} e : t$, then there exists a type $t'$ such that $\Delta ; \Gamma \vdash_{a} \text{erase}(e) : t'$ and $t' \subseteq \Delta ; t$.

**Proof.** By induction on the typing derivation of $\Delta ; \Gamma \vdash_{a} e : t$. We proceed by a case analysis on the last rule used in the derivation.

**Case (ALG-CONST):** take $t'$ as $b_{e}$.

**Case (ALG-VAR):** take $t'$ as $\Gamma(x)$.

**Case (ALG-PAIR):** consider the derivation

$$
\Delta ; \Gamma \vdash_{a} e_1 : t_1 \quad \Delta ; \Gamma \vdash_{a} e_2 : t_2
$$

Applying the induction hypothesis twice, we have

$$
\exists t'_1. \Delta ; \Gamma \vdash_{a} \text{erase}(e_1) : t'_1 \quad \text{and} \quad t'_1 \subseteq \Delta ; t_1,
$$

$$
\exists t'_2. \Delta ; \Gamma \vdash_{a} \text{erase}(e_2) : t'_2 \quad \text{and} \quad t'_2 \subseteq \Delta ; t_2.
$$

Then by (INF-PAIR), we have $\Delta ; \Gamma \vdash_{a} \text{erase}(e_1, e_2) : t'_1 \times t'_2$, that is, $\Delta ; \Gamma \vdash_{a} \text{erase}((e_1, e_2)) : t'_1 \times t'_2$. Finally, Applying Lemma B.4, we have $(t'_1 \times t'_2) \subseteq \Delta (t_1 \times t_2)$.

**Case (ALG-PRO):** consider the derivation

$$
\Delta ; \Gamma \vdash_{a} e : t \quad t \leq 1 \times 1
$$

By induction, we have

$$
\exists t'. [\sigma_k]_{k \in K}. \Delta ; \Gamma \vdash_{a} \text{erase}(e) : t' \quad \text{and} \quad [\sigma_k]_{k \in K} \vdash t' \subseteq \Delta ; t.
$$

It is clear that $\bigwedge_{k \in K} t' \sigma_k \leq 1 \times 1$. So $\pi_{t}(\bigwedge_{k \in K} t' \sigma_k) \in \Pi_{\Delta}(t')$. Then by (INF-PROJ), we have $\Delta ; \Gamma \vdash_{a} \pi_{t}(\text{erase}(e)) : \pi_{t}(\bigwedge_{k \in K} t' \sigma_k)$, that is, $\Delta ; \Gamma \vdash_{a} \text{erase}(\pi_{t}(e)) : \pi_{t}(\bigwedge_{k \in K} t' \sigma_k)$. According to Lemma C.5 in the companion paper [3], $t \leq \Pi(t_{1}(t), t_{2}(t))$. Then $\bigwedge_{k \in K} t' \sigma_k \leq (\Pi_{1}(t), \Pi_{2}(t))$. Finally, applying Lemma C.5 again, we get $\pi_{t}(\bigwedge_{k \in K} t' \sigma_k) \leq \pi_{t}(t)$ and $a \text{fortiori } \pi_{t}(\bigwedge_{k \in K} t' \sigma_k) \subseteq \Delta \pi_{t}(t)$.

**Case (ALG-APPL):** consider the derivation

$$
\Delta ; \Gamma \vdash_{a} e_1 : t \quad \Delta ; \Gamma \vdash_{a} e_2 : s \quad t \leq 0 \to 1 \quad s \leq \text{dom}(t)
$$

By induction, we have

$$
\exists t', [\sigma_k]_{k \in K}. \Delta ; \Gamma \vdash_{a} \text{erase}(e) : t' \quad \text{and} \quad [\sigma_k]_{k \in K} \vdash t' \subseteq \Delta ; t.
$$

Finally, applying Lemma C.5 again, we get $\pi_{t}(\bigwedge_{k \in K} t' \sigma_k) \leq \pi_{t}(t)$ and $a \text{fortiori } \pi_{t}(\bigwedge_{k \in K} t' \sigma_k) \subseteq \Delta \pi_{t}(t)$. 

\[\square\]
Applying the induction hypothesis twice, we have
\[ \exists t_1', \sigma_1^k \mid k \in K_1, \Delta \vdash_{\Delta} t_1' : \Delta t, \exists t_2', \sigma_1^k \mid k \in K_2, \Delta \vdash_{\Delta} t_2' \sqsubseteq \Delta s. \]
It is clear that \( \Lambda \in K_1, t_1'^k \sqsubseteq 0 \rightarrow 0 \), that is, \( \Lambda \in K_1, t_1'^k \) is a function type. So we get \( \text{dom}(t) \leq \text{dom}(\Lambda \in K_1, t_1'^k) \). Then we have \( \Lambda \in K_2, t_2'^k \sqsubseteq s \leq \text{dom}(t) \leq \text{dom}(\Lambda \in K_2, t_2'^k) \). Therefore, \( (\Lambda \in K_1, t_1'^k) \cdot (\Lambda \in K_2, t_2'^k) \in \Delta \cdot \Delta t' \). Then applying (INF-APPL), we have
\[ \Delta \vdash_{\Delta} \text{erase}(e_1) \text{erase}(e_2) : (\bigwedge_{k \in K_1} t_1'^k) \cdot (\bigwedge_{k \in K_2} t_2'^k), \]
that is, \( \Delta \vdash_{\Delta} \text{erase}(e_1) : (\bigwedge_{k \in K_1} t_1'^k) \cdot (\bigwedge_{k \in K_2} t_2'^k) \). Moreover, as \( \Lambda \in K_2, t_2'^k \sqsubseteq \text{dom}(t) \). t \cdot (\Lambda \in K_2, t_2'^k) \sqsubseteq t \cdot (\bigwedge_{k \in K_2} t_2'^k) \sqsubseteq t \cdot s.

Thus, \( (\Lambda \in K_1, t_1'^k) \cdot (\Lambda \in K_2, t_2'^k) \sqsubseteq t \cdot s. \)

(ALG-ABST0): consider the derivation
\[
\forall i \in I. \Delta \cup \var\left((\Lambda \in I, t_i \rightarrow s_i) \mid \Gamma, (x : t_i) \vdash e : s_i \right) \text{ and } s_i \leq s_i
\]

Let \( \Delta' = \Delta \cup \var\left((\Lambda \in I, t_i \rightarrow s_i) \mid \Gamma, (x : t_i) \vdash e : s_i \right) \). By induction, for each \( i \in I \), we have \( \exists t_i', \Delta' \vdash \text{erase}(e) : t_i' \) and \( t_i' \sqsubseteq \Delta' \cdot s_i \).

Clearly, we have \( t_i' \subseteq \Delta' \cdot s_i \). By (INF-ABSTR), we have
\[ \Delta \vdash_{\Delta} \lambda \lambda \cdot t_i \rightarrow s_i \cdot e. \text{erase}(e) : \bigwedge_{i \in I} t_i \rightarrow s_i, \]
that is, \( \Delta \vdash_{\Delta} \text{erase}(\lambda \lambda \cdot t_i \rightarrow s_i \cdot e) : \bigwedge_{i \in I} t_i \rightarrow s_i. \)

(ALG-CASE-NONE): consider the derivation
\[
\forall i \in I. \Delta \cup \var\left((\Lambda \in I, t_i \rightarrow s_i) \mid \Gamma, (x : t_i) \vdash e : s_i \right) \text{ and } s_i \leq s_i
\]

By induction, we have \( \exists t_0', \Delta \vdash_{\Delta} \text{erase}(e) : t_0' \) and \( t_0' \sqsubseteq \Delta \cdot 0. \)

By (INF-CASE-NONE), we have \( \Delta \vdash_{\Delta} (\text{erase}(e) \text{ ? } e_1) : (\text{erase}(e_2)) \) \( : 0 \), that is, \( \Delta \vdash_{\Delta} \text{erase}(e) \text{ ? } e_1 : e_2 \) \( : 0 \).

(ALG-CASE-FST): consider the derivation
\[
\forall i \in I. \Delta \cup \var\left((\Lambda \in I, t_i \rightarrow s_i) \mid \Gamma, (x : t_i) \vdash e : s_i \right) \text{ and } s_i \leq s_i
\]

Applying the induction hypothesis twice, we have
\[ \exists t_0', \Delta \vdash_{\Delta} \text{erase}(e) : t_0' \) and \( t_0' \sqsubseteq \Delta' \).

\[ \exists t_1', \Delta \vdash_{\Delta} \text{erase}(e_1) : t_1' \) and \( t_1' \sqsubseteq \Delta' \).

Clearly, we have \( t_0' \subseteq \Delta \cdot t \). If \( t_0' \subseteq \Delta' \cdot t' \), then by Lemma B.4, we have \( t_0' \subseteq \Delta' \cdot t. \). By (INF-CASE-NONE), we get
\[ \Delta \vdash_{\Delta} \text{erase}(e) \text{ ? } e_1 : e_2 \) \( : 0 \), that is, \( \Delta \vdash_{\Delta} \text{erase}(e) \text{ ? } e_1 : e_2 \) \( : 0 \). Clearly, we have \( 0 \subseteq s_1 \).

Otherwise, by (INF-CASE-FST), we have
\[ \Delta \vdash_{\Delta} \text{erase}(e) \text{ ? } e_1 : e_2 \) \( : t_1'. \) The result follows as well.

(ALG-CASE-SND): similar to the case of (ALG-CASE-FST).

(ALG-CASE-BOTH): consider the derivation
\[
\forall i \in I. \Delta \cup \var\left((\Lambda \in I, t_i \rightarrow s_i) \mid \Gamma, (x : t_i) \vdash e : s_i \right) \text{ and } s_i \leq s_i
\]

By induction, we have
\[ \exists t_0', \Delta \vdash_{\Delta} \text{erase}(e) : t_0' \) and \( t_0' \sqsubseteq \Delta' \).

\[ \exists t_1', \Delta \vdash_{\Delta} \text{erase}(e_1) : t_1' \) and \( t_1' \sqsubseteq \Delta' \).

\[ \exists t_2', \Delta \vdash_{\Delta} \text{erase}(e_2) : t_2' \) and \( t_2' \sqsubseteq \Delta' \).

By induction, we have
\[ \exists t_0', \Delta \vdash_{\Delta} \text{erase}(e) : t_0' \) and \( t_0' \sqsubseteq \Delta' \).

\[ \exists t_1', \Delta \vdash_{\Delta} \text{erase}(e_1) : t_1' \) and \( t_1' \sqsubseteq \Delta' \).

\[ \exists t_2', \Delta \vdash_{\Delta} \text{erase}(e_2) : t_2' \) and \( t_2' \sqsubseteq \Delta' \).
If \( t_0 \subseteq \Delta 0 \), then by (INF-CASE-NONE), we get
\[
\Delta \therefore \Gamma \vdash (\text{erase}(e) \in \sigma \text{?} \text{erase}(e_1) : \text{erase}(e_2)) : 0,
\]
that is, \( \Delta \Gamma \vdash \text{erase}(e) \in \sigma \text{?} e_1 : e_2 : 0 \). Clearly, we have \( 0 \subseteq \Delta s_1 \lor s_2 \).
If \( t_0 \subseteq \Delta t \), then by (INF-CASE-FST), we get
\[
\Delta \therefore \Gamma \vdash (\text{erase}(e) \in \sigma \text{?} \text{erase}(e_1) : \text{erase}(e_2)) : t_1,
\]
that is, \( \Delta \Gamma \vdash \text{erase}(e) \in \sigma \text{?} e_1 : e_2 : t_1 \). Moreover, it is clear that \( t_1 \subseteq \Delta s_1 \lor s_2 \), the result follows as well. Similarly for \( t_0 \subseteq \Delta \neg t \).
Otherwise, by (INF-CASE-BOTH), we have
\[
\Delta \therefore \Gamma \vdash (\text{erase}(e) \in \sigma \text{?} \text{erase}(e_1) : \text{erase}(e_2)) : t_1 \lor t_2,
\]
that is, \( \Delta \Gamma \vdash \text{erase}(e) \in \sigma \text{?} e_1 : e_2 : t_1 \lor t_2 \). Using \( \alpha \)-conversion, we can assume that the polymorphic type variables of \( t_1 \) and \( t_2 \) (and of \( e_1 \) and \( e_2 \)) are distinct, i.e., \( (\text{var}(t_1) \setminus \Delta) \cap (\text{var}(t_2) \setminus \Delta) = \emptyset \). Then applying Lemma B.5, we have \( t_1 \lor t_2 \subseteq \Delta t_1 \lor t_2 \).

(ALG-INST): consider the derivation
\[
\Delta \therefore \Gamma \vdash e : t \quad \forall j \in J, \sigma_j \not\in \Delta \quad |J| > 0
\]
\[
\Delta \therefore \Gamma \vdash e[\sigma_j]_{j \in J} : \bigwedge_{j \in J} \tau_j
\]
By induction, we have
\[
\exists t', [\sigma_k]_{k \in K}, \Delta \therefore \Gamma \vdash \text{erase}(e) : t' \text{ and } [\sigma_k]_{k \in K} \vdash \Gamma \subseteq \Delta t.
\]
Since \( \text{erase}(e[\sigma_j]_{j \in J}) = \text{erase}(e) \), we have \( \Delta \therefore \Gamma \vdash \text{erase}(e[\sigma_j]_{j \in J}) : t' \). As \( \bigwedge_{k \in K} t' \sigma_k \leq t \), we have \( \bigwedge_{j \in J} / \bigwedge_{k \in K} \sigma_j \sigma_k \leq \bigwedge_{j \in J} \tau_j \), that is \( \bigwedge_{k \in K} \bigwedge_{j \in J} t' \sigma_j o \sigma_k \leq \bigwedge_{j \in J} \tau_j \). Moreover, it is clear that \( \sigma_j o \sigma_k \not\in \Delta \). Therefore, we get \( t' \subseteq \bigwedge_{j \in J} \tau_j \).

The inference system is syntax directed and describes an algorithm that is parametric in the decision procedures for \( \subseteq \Delta \), \( \Pi\Delta(t) \) and \( t \circ s \). The problem of deciding them is tackled in Section C.2.

Finally, notice that we did not give any reduction semantics for the implicitly-typed calculus. The reason is that its semantics is defined in terms of the semantics of the explicitly-typed calculus: the relabeling at run-time is an essential feature —independently from the fact that we started from an explicitly-typed expression or not—and we cannot avoid it. The (big-step) semantics for \( a \) is then given in expressions of \( \text{erase}^{-1}(a) \): if an expression in \( \text{erase}^{-1}(a) \) reduces to \( v \), so does \( a \). As we see the result of computing an implicitly-typed expression is a value of the explicitly typed calculus (so \( \lambda \)-abstractions may contain non-empty decorations) and this is unavoidable since it may be the result of a partial application. Also notice that the semantics is not deterministic since different expressions in \( \text{erase}^{-1}(a) \) may yield different results. However this may happen only in one particular case, namely, when an occurrence of a polymorphic function flows into a type-case and its type is tested. For instance the application \( \lambda x. (\text{Int} \rightarrow \text{Int}) \rightarrow (\text{Bool} \rightarrow (\text{Int} \rightarrow \text{Int})) \cdot f \cdot (\text{Bool} \rightarrow (\text{Int} \rightarrow \text{Int})) \rightarrow (\text{Int} \rightarrow \text{Int}) \rightarrow (\text{Int} \rightarrow \text{Int}) \) results into \text{true} or \text{false} according to whether the polymorphic identity at the argument is instantiated by \( [(\text{Int})/a] \) or by \( [(\text{Int})/a], [(\text{Bool})/b] \).

Once more this is unavoidable in a calculus that can dynamically test the types of polymorphic functions that admit several sound instantiations.

### B.3 A More Tractable Type Inference System

With the rules of Figure 5, when type-checking an implicitly-typed expression, we have to compute sets of type substitutions for projections, applications, abstractions and type cases. Because type substitutions inference is a costly operation, we would like to perform it as less as possible. To this end, we give in this section a restricted version of the inference system, which is not complete but still sound and powerful enough to be used in practice.

First, we want to simplify the type inference rule for projections:
\[
\Delta \therefore \Gamma \vdash a : t \quad u \in \Pi\Delta(t)
\]
\[
\Delta \therefore \Gamma \vdash a \circ u : a
\]
where \( \Pi\Delta(t) = \{ u \mid [\sigma_j]_{j \in J} \vdash t \subseteq \Delta 1 \times 1, u = \pi_i(\bigwedge_{j \in J} \tau_j) \} \). Instead of picking any type in \( \Pi\Delta(t) \), we would like to simply project \( t \), i.e., assign the type \( \pi_i(t) \) to \( \pi_i(a) \). By doing so, we lose completeness on pair types that contain top-level variables. For example, if \( t = (\text{Int} \times \text{Int}) \land \alpha \), then \( \pi_i(t) \) is not a pair type, but can be instantiated in a pair type. For example, the type of \( \lambda x. (x \lor (\beta \land x)) \cdot \beta \cdot (\text{Int} \rightarrow \text{Int}) \cdot x \cdot x \cdot x \cdot x \cdot x \cdot x \cdot x \cdot x \cdot x \cdot x \) is \( (\text{Int} \times \text{Int}) \lor (\beta \to \beta) \land (\text{Int} \to \text{Int}) \), which is not a pair type, but can be instantiated in \( (\text{Int} \times \text{Int}) \) by taking \( \beta = \text{Int} \). We believe these kinds of types will not be written by programmers, and it is safe to use the following projection rule in practice.
\[
\Delta \therefore \Gamma \vdash a : t \quad t \leq 1 \times 1
\]
\[
\Delta \therefore \Gamma \vdash a \circ u : \pi_i(t)
\]
We now look at the type inference rules for the type case \( a \in t ? a_1 : a_2 \). The four different rules consider the different possible instantiations that make the type \( t' \) inferred for a fit \( t \) or not. For the sake of simplicity, we decide not to infer type substitutions for polymorphic arguments of type cases. Indeed, in the expression \((\lambda^{x:a} \cdot x) \in t \rightarrow t \top \text{true} : \text{false}\), we assume the programmer wants to do a type case on the polymorphic identity, and not on one of its instance (otherwise, he would have written the instantiated interface directly), so we do not try to instantiate it. And in any case there is no real reason for which the inference system should choose to instantiate the identity by \( t_\top \rightarrow t \top \) (and thus make the test succeed) rather than \( \text{Bool} \rightarrow \text{Bool} \) (and thus make the test fail). If we decide not to infer types for polymorphic arguments of type-case expression, then since \( \alpha \rightarrow \alpha \) is not a subtype of \( t \rightarrow t \top \) (we have \( \alpha \rightarrow \alpha \not\subseteq t \rightarrow t \top \)) the expression evaluates to \text{false}. With this choice, we can merge the different inference rules into the following one.

\[
\frac{\Delta ; \Gamma \vdash a : t' \quad t_1 = t' \wedge t \quad t_2 = t' \wedge \neg t}{\Delta ; \Gamma \vdash a : s_i}
\]

Finally, consider the inference rule for abstractions:

\[
\frac{\forall i \in I. \ \Delta \cup \text{var} \left( \bigwedge_{i \in I} t_i \rightarrow s_i \right) \Gamma, (x : t_i) \vdash \sigma a : s_i'}{\Delta ; \Gamma \vdash \lambda^{i \in I} t_i \rightarrow s_i x : a : \bigwedge_{i \in I} t_i \rightarrow s_i}
\]

We verify that the abstraction can be typed with each arrow type \( t_i \rightarrow s_i \) in the interface. Meanwhile, we also infer a set of type substitutions to tally the type \( s_i' \) we infer for the body expression with \( s_i \). In practice, similarly, we expect that the abstraction is well-typed only if the type \( s_i' \) we infer for the body expression is a subtype of \( s_i \). For example, the expression

\[
\lambda^{\text{Bool} \rightarrow \text{Int} \times \text{Int}} x.x \in \text{true} ? (\lambda^{\alpha \rightarrow \alpha} y. y, (\lambda^{\alpha \rightarrow \alpha} z. z) y)
\]

is not well-typed while

\[
\lambda^{\text{Bool} \rightarrow (\alpha \rightarrow \alpha) \times \text{Int} \times \text{Int}} x.x \in \text{true} ? (\lambda^{\alpha \rightarrow \alpha} y. y, (\lambda^{\alpha \rightarrow \alpha} z. z) y)
\]

is well-typed. So we use the following restricted rule for abstractions instead:

\[
\frac{\forall i \in I. \ \Delta \cup \text{var} \left( \bigwedge_{i \in I} t_i \rightarrow s_i \right) \Gamma, (x : t_i) \vdash \sigma a : s_i' \text{ and } s_i' \subseteq s_i}{\Delta ; \Gamma \vdash \lambda^{i \in I} t_i \rightarrow s_i x : a : \bigwedge_{i \in I} t_i \rightarrow s_i}
\]

In conclusion, we restrict the inference of type substitutions to applications. We give in Figure 6 the inference rules of the system which respects the above restrictions. With these new rules, the system remains sound, but it is not complete.

**Theorem B.15.** If \( \Gamma \vdash \sigma a : t \), then there exists an expression \( e \in \mathcal{E}_0 \) such that \( \text{erase}(e) = a \) and \( \Gamma \vdash \sigma e : t \).

*Proof.* Similar to the proof of Theorem B.13.

\[\square\]

## C. Type Tallying

Given two types \( t \) and \( s \), the goal of this section is to find pairs of sets of type-substitutions \([\sigma_i]_{i \in I} \) and \([\sigma_j]_{j \in J} \) such that \( \bigwedge_{i \in I} s \sigma_i \subseteq \bigvee_{i \in I} t \sigma_i \). Assuming that the cardinalities of \( I \) and \( J \) are known, then this problem can be reduced to a type tallying problem, that we define and solve first. We then explain how we can reduce the original problem to the type tallying problem, and provide a semi-algorithm for the original problem. Finally, we give some heuristics to establish upper bounds (which depend on \( t \) and \( s \)) for the cardinalities of \( I \) and \( J \).

### C.1 Type Tallying Problem

Given a finite set \( C \) of pairs of types and a finite set \( \Delta \) of type variables, the tallying problem for \( C \) and \( \Delta \) consists in verifying whether there exists a substitution \( \sigma \) such that \( \sigma \not\subseteq \Delta \) and for all \( (s, t) \in C \), \( s \sigma \not\subseteq t \sigma \) holds. In this section we denote constraints as triples. The notation is different from the one used in Section 3 in that it also specifies the symbol of the relation. So a pair of types \( (s, t) \in C \) corresponds to the constraint \((s, \leq, t)\):

**Definition C.1 (Constraints).** A constraint \((t, c, s)\) is a triple belonging to \( \mathcal{T} \times \{\leq, \geq\} \times \mathcal{T} \). Let \( \mathcal{C} \) denote the set of all constraints. Given a constraint-set \( C \subseteq \mathcal{C} \), the set of type variables occurring in \( C \) is defined as

\[
\text{var}(C) = \bigcup_{(t, c, s) \in C} \text{var}(t) \cup \text{var}(s)
\]
**Definition C.2 (Normalized constraint).** A constraint \((t, c, s)\) is said to be normalized if \(t\) is a type variable. A constraint-set \(C \subseteq \mathcal{C}\) is said to be normalized if every constraint \((t, c, s) \in C\) is normalized. Given a normalized constraint-set \(C\), its domain is defined as \(\text{dom}(C) = \{\alpha \mid \exists c, s. (\alpha, c, s) \in C\}\).

**Definition C.3 (Constraint solution).** Let \(C \subseteq \mathcal{C}\) be a constraint-set. A solution to \(C\) is a substitution \(\sigma\) such that
\[
\forall (t, \leq, s) \in C . \quad \sigma \times \leq \times s \quad \text{holds} \quad \text{and} \quad \forall (t, \geq, s) \in C . \quad \sigma \times \geq \times s \quad \text{holds}.
\]
If \(\sigma\) is a solution to \(C\), we write \(\sigma \vdash C\).

**Definition C.4.** Given two sets of constraint-sets \(\mathcal{S}_1, \mathcal{S}_2 \subseteq \mathcal{P}(\mathcal{C})\), we define their union as
\[
\mathcal{S}_1 \cup \mathcal{S}_2 = \{C_1 \cup C_2 \mid C_1 \in \mathcal{S}_1, C_2 \in \mathcal{S}_2\}
\]
and their intersection as
\[
\mathcal{S}_1 \cap \mathcal{S}_2 = \{C_1 \cap C_2 \mid C_1 \in \mathcal{S}_1, C_2 \in \mathcal{S}_2\}
\]
Given a constraint-set \(C\), the constraint solving algorithm produces the set of all the solutions of \(C\) by following the algorithm given in Section 3.2.1. Let us examine each step of the algorithm on some examples.

**Step 1:** constraint normalization.

Because normalized constraints are easier to solve than regular ones, we first turn each constraint into an equivalent set of normalized constraint-sets according to the decomposition rules in [4]. For example, the constraint \(C_1 = \{\alpha \times \alpha \leq ((\text{Int} \times \text{Int}) \times (\text{Int} \times \text{Int}))\}\) can be normalized into the set \(\mathcal{S}_1 = \{\{\alpha, \leq, 0\}; \{\alpha, \leq, (\text{Int} \times \text{Int})\}\}\). Another example is the constraint \(C_2 = \{((\beta \times \beta) \rightarrow (\text{Int} \times \text{Int}); \leq, \alpha \rightarrow \alpha\}\) which is equivalent to the following set of normalized constraint-sets \(\mathcal{S}_2 = \{\{\alpha, \leq, 0\}; \{\alpha, \leq, (\beta \times \beta)\}; \{\alpha, \leq, (\text{Int} \times \text{Int})\}\}\). Then we join all the sets of constraint-sets by (constraint-set) intersections, yielding the normalization of the original constraint-set. For instance, the normalization \(\mathcal{S}\) of \(\{C_1, C_2\}\) is \(\mathcal{S}_1 \cap \mathcal{S}_2\). It is easy to see that the constraint-set \(C_1 = \{\{\alpha, \leq, (\text{Int} \times \text{Int})\}; \{\alpha, \leq, (\beta \times \beta)\}; \{\alpha, \geq, (\text{Int} \times \text{Int})\}\}\) is in \(\mathcal{S}\) (see Definition C.4).

**Step 2:** constraint merging.

**Step 2.1:** merge the constraints with a same type variable.

In each constraint-set of the normalization of the original constraint-set, there may be several constraints of the form \((\alpha, \geq, s)\) (resp. \((\alpha, \leq, s)\)), which give different lower bounds (resp. upper bounds) for \(\alpha\). We merge all these constraints into one using unions (resp. intersections). For example, the constraint-set \(C_1\) of the previous step can be merged as \(C_2 = \{\{\alpha, \leq, (\text{Int} \times \text{Int})\}; \{\alpha, \leq, (\beta \times \beta)\}; \{\alpha, \geq, (\text{Int} \times \text{Int})\}\}\), which is equivalent to \(\{\alpha, \leq, (\text{Int} \times \beta \times \text{Int} \land \beta)\}; \{\alpha, \geq, (\text{Int} \times \text{Int})\}\) (see Definition C.4).

**Step 2.2:** saturate the lower and upper bounds of a same type variable.

If a type variable has both a lower bound \(s\) and an upper bound \(t\) in a constraint-set, then the solutions we are looking for must satisfy the constraint \((s, \leq, t)\) as well. Therefore, we have to saturate the
constraint-set with \((s, \leq, t)\), which has to be normalized, merged, and saturated itself first. Take \(C_2\) for example. We have to saturate \(C_2\) with \((\{(\text{Int} \times \text{Int}), \leq, (\text{Int} \land \beta \times \text{Int} \land \beta)\})\), whose normalization is \(\{((\beta, \geq, \text{Int}))\}\). Thus, the saturation of \(C_2\) is \(\{C_2\} \cap \{((\beta, \geq, \text{Int}))\}\), which contains only one constraint-set \(C_3 = \{(\alpha, \leq, (\text{Int} \land \beta \times \text{Int} \land \beta)), (\alpha, \geq, (\text{Int} \times \text{Int})), \beta, \geq, \text{Int}\}\).

Step 3: constraint solving.

Step 3.1: transform each constraint-set into an equation system.

To transform constraints into equations, we use the property that some set of constraints is satisfied for all assignments of \(\alpha\) included between \(s\) and \(t\) if and only if the same set in which we replace \(\alpha\) by \((s \lor \alpha') \land \langle t\rangle\) is satisfied for all possible assignments of \(\alpha'\) (with \(\alpha'\) fresh). Of course such a transformation works only if \(s \leq t\), but remember that we “checked” that this holds at the moment of the saturation. By performing this replacement for each variable we obtain a system of equations. For example, the constraint set \(C_3\) is equivalent to the following equation system \(E\):

\[
\begin{align*}
\alpha &= ((\text{Int} \times \text{Int}) \lor \alpha') \land (\text{Int} \land \beta \times \text{Int} \land \beta) \\
\beta &= \text{Int} \lor \beta'
\end{align*}
\]

where \(\alpha', \beta'\) are fresh type variables.

Step 3.2: extract a substitution from each equation system.

Finally, using the Courcelle’s work on infinite trees [7], we solve each equation system, which gives us a substitution which is a solution of the original constraint-set. For example, we can solve the equation system \(E\), yielding the type-substitution \([(\text{Int} \times \text{Int})/\alpha, \text{Int} \lor \beta'/\beta]\), which is a solution of \(C_3\) and thus of \(\{c_1, c_2\}\).

In the following subsections we study in details each step of the algorithm.

C.1.1 Constraint Normalization

The type typing problem is quite similar to the subtyping problem presented in [4]. We therefore reuse most of the technology developed in [4] such as, for example, the transformation of the subtyping problem into an emptiness decision problem, the elimination of top-level constructors, and so on. One of the main differences is that we do not want to eliminate top-level type variables from constraints, but, rather, we want to isolate them to build sets of normalized constraints (from which we then construct sets of substitutions).

In general, normalizing a constraint generates a set of constraints. For example, \((\alpha \lor \beta, \geq, 0)\) holds if and only if \((\alpha, \geq, 0)\) or \((\beta, \geq, 0)\) holds; therefore the constraint \((\alpha \lor \beta, \geq, 0)\) is equivalent to the normalized constraint-set \(\{(\alpha, \geq, 0), (\beta, \geq, 0)\}\). Consequently, the normalization of a constraint-set \(C\) yields a set \(\mathcal{F}\) of normalized constraint-sets.

Several normalized sets may be suitable replacements for a given constraint; for example, \(\{\alpha, \leq \beta \lor t_1), (\beta, \leq \alpha \lor t_1)\}\) and \(\{\alpha, \leq, \beta \lor t_1), (\alpha, \geq, \beta \land t_2)\}\) are clearly equivalent normalized sets. However, the equation systems generated by the algorithm for these two sets are completely different, and different equation systems yield different substitutions (see Section C.1.3 for more details). Concretely, \(\{\alpha, \leq, \beta \lor t_1), (\beta, \leq, \alpha \lor t_2)\}\) generates the equation system \(\{\alpha = \alpha' \land (\beta \lor t_1), \beta = \beta' \land (\alpha \lor t_2)\}\), which in turn gives the substitution \(\sigma_1\) such that

\[
\begin{align*}
\sigma_1(\alpha) &= \mu x.((\alpha' \land \beta' \land x) \lor (\alpha' \land \beta' \land t_2)) \lor (\alpha' \land t_1)) \\
\sigma_1(\beta) &= \mu x.((\beta' \land \alpha' \land x) \lor (\beta' \land \alpha' \land t_1) \lor (\beta' \land t_2))
\end{align*}
\]

where \(\alpha'\) and \(\beta'\) are fresh type variables and we used the \(\mu\) notation to denote regular recursive types. These recursive types are not valid in our calculs, because \(\mu\) does not occur under a type constructor (this means that the unfolding of the type does not satisfy the property that every infinite branch contains infinitely many occurrences of type constructors). In contrast, the equation system built from \(\{\alpha, \leq, (\beta \lor t_1), (\alpha, \geq, \beta \land t_2)\}\) is \(\alpha = ((\beta \land t_2) \lor \alpha') \land (\beta \lor t_1), \) and the corresponding substitution is \(\sigma_2 = \{(\beta \land t_2) \lor \alpha', (\beta \lor t_1)/\alpha\}\), which is valid since it maps the type variable \(\alpha\) into a well-formed type. Ill-formed recursive types are generated when there exists a chain \(\alpha_0 = \alpha_1 B_1 t_1, \ldots, \alpha_i = \alpha_{i+1} B_{i+1} t_{i+1}, \ldots, \alpha_n = \alpha_0 B_{n+1} t_{n+1}\) (where \(B_i \in \{\land, \lor\} \) for all \(i\) and \(n \geq 0\)) in the equation system built from the normalized constraint-set. This chain implies the equation \(\alpha_0 = \alpha_0 B I, t_1, t_1, \ldots, t_n\) for some \(B \in \{\land, \lor\} \) and \(t_1, \ldots, t_n\), and the corresponding solution for \(\alpha_0\) will be an ill-formed recursive type. To avoid this issue, we give an arbitrary ordering on type variables occurring in the constraint-set \(C\) such that different type variables have different orders. Then we always select the normalized constraint \((\alpha, c, t)\) such that the order of \(\alpha\) is smaller than all the orders of the top-level type variables in \(t\). As a result, the transformed equation system does not contain any problematic chain like the one above.

Definition C.5 (Ordering). Let \(V\) be a set of type variables. An ordering \(O\) on \(V\) is an injective map from \(V\) to \(\mathbb{N}\).

We formalize normalization as a judgement \(\Sigma \vdash \gamma C \Rightarrow \mathcal{F}\), which states that under the environment \(\Sigma\) (which, informally, contains the types that have already been processed at this point), \(C\) is normalized to \(\mathcal{F}\). The judgement is derived according the rules of Figure 7. These rules describe the same algorithm

\[\text{Or by } s \lor \alpha' \land t\].
as the function norm given in Figure 3 (i.e., $\Sigma \vdash_{\mathcal{F}} \{(t, \leq, 0)\} \rightsquigarrow \text{norm}(t, \Sigma)$ is provable in the system of Figure 7) but extended to handle also product types. We just switched to a deduction systems since it eases the formal treatment.

The following rules handle constraints of the form $\{\tau, \leq, 0\}$ where $\tau$ is disjunctive normal form: the first rule reverses $(t', \geq, t)$ into $(t, \leq, t')$, the second rule moves the type $t'$ from the right of $\leq$ to the left, yielding $(t \land \neg t', \leq, 0)$, and finally the last rule puts $t \land \neg t'$ in disjunctive normal form. Such a type $\tau$ is the type to be normalized. If $\tau$ is a union of single normal forms, the rule (NUNION) splits the union of single normal forms into constraints featuring each of the single normal forms. Then the results of each constraint normalization are joined by the rule (NJOIN).

The following rules handle constraints of the form $\{\tau, \leq, 0\}$, where $\tau$ is a single normal form. If there are some top-level type variables, the rule (NTLV) generates a normalized constraint for the top-level type variable whose order is the smallest. Otherwise, there are no top-level type variables. If $\tau$ has already been normalized (i.e., it belongs to $\Sigma$), then it is not processed again (rule (NHYP)). Otherwise, we memoize it and then process it using the predicate for single normal forms $\Sigma \vdash_{\mathcal{F}} C \rightsquigarrow \mathcal{F}$ (rule (NASSUM)). Note that switching from $\Sigma \vdash_{\mathcal{F}} C \rightsquigarrow \mathcal{F}$ to $\Sigma \vdash_{\mathcal{F}} C \rightsquigarrow \mathcal{F}$ prevents the incorrect use of (NHYP) just after (NASSUM), which would wrongly say that any type is normalized without doing any computation.

**Figure 7.** Normalization rules
Finally, the last four rules state how to normalize constraints of the form $(\tau, \leq, \emptyset)$ where $\tau$ is a single normal form and contains no top-level type variables. Thereby $\tau$ should be an intersection of atoms with the same constructor. If $\tau$ is an intersection of basic types, normalizing is equivalent to checking whether $\tau$ is empty or not: if it is (rule (NBasic-T)), we return the singleton containing the empty set (any substitution is a solution), otherwise there is no solution and we return the empty set (rule (NBasic-F)). When $\tau$ is an intersection of products, the rule (NProd) decomposes $\tau$ into several candidate types (following Lemma 3.11 in [4]). Which case $\tau$ is, the result follows by Lemma 3.11 in [4], which are to be further normalized. The case when $\tau$ is an intersection of arrows (rule (Narrow)) is treated similarly. Note that, in the last two rules, we switch from $\tau$ to $\tau'$ in the premises to ensure termination.

If $\emptyset \vdash C \rightsquigarrow \cal F$, then $\cal F$ is the result of the normalization of $C$. We now prove soundness, completeness, and termination of the constraint normalization algorithm.

To prove soundness, we use a family of subtyping relations $\leq n$ that layer $\leq^{11}$ (i.e., such that $\bigcup_{n\in \mathbb{N}} \leq n = \leq$) and a family of satisfaction predicates $\vdash_n$ that layer $\vdash^{11}$ (i.e., such that $\bigcup_{n\in \mathbb{N}} \vdash_n = \vdash$), which are defined as follows.

**Definition C.6.** Let $\leq$ be the subtyping relation induced by a well-founded convex model with infinite support $([.]_n, \emptyset)$. We define the family $(\leq_n)_{n\in \mathbb{N}}$ of subtyping relations as

$$t \leq_n s \overset{\text{def}}{\iff} \forall \eta. \llbracket t \rrbracket_n \eta \subseteq \llbracket s \rrbracket_n \eta$$

where $[.]_n$ is the rank $n$ interpretation of a type, defined as

$$\llbracket t \rrbracket_n \eta = \{ d \in [t]_\eta \mid \text{height}(d) \leq n \}$$

and height($d$) is the height of an element $d$ in $\mathcal{D}$, defined as

$$\text{height}(c) = 1$$
$$\text{height}((d, d')) = \max(\text{height}(d), \text{height}(d')) + 1$$
$$\text{height}((\ldots, (d_1, d'_1), \ldots, (d_n, d'_n))) = \begin{cases} 1 & n = 0 \\ \max(\text{height}(d_i), \text{height}(d'_i), \ldots) + 1 & n > 0 \end{cases}$$

**Lemma C.7.** Let $\leq$ be the subtyping relation induced by a well-founded convex model with infinite support. Then

1. $t \leq_0 s$ for all $t, s \in \mathcal{D}$.
2. $t \leq s \iff \forall n. t \leq_n s$.
3. $\bigwedge_{i \in I} (t_i \times s_i) \leq_{n+1} \bigvee_{j \in J} (t_j \times s_j) \iff \forall J' \subseteq J . \bigwedge_{i \in I} t_i \leq_n \bigvee_{j \in J \setminus J'} t_j$
4. $\bigwedge_{i \in I} (t_i \rightarrow s_i) \leq_{n+1} \bigvee_{j \in J} (t_j \rightarrow s_j) \iff \exists j_0 \in J . \forall I' \subseteq I . \bigwedge_{i \in I \setminus I'} t_i \leq_n s_j \leq_n s_{j_0}$

**Proof:** (1) straightforward.
(2) straightforward.
(3) the result follows by Lemma 3.11 in [4] and Definition C.6.
(4) the result follows by Lemma 3.12 in [4] and Definition C.6.

**Definition C.8.** Given a constraint-set $C$ and a type substitution $\sigma$, we define the rank $n$ satisfaction predicate $\vdash_n$ as

$$\sigma \vdash_n C \overset{\text{def}}{=} \forall (t, \leq, s) \in C. t \leq_n s \text{ and } \forall (t, \geq, s) \in C. t \leq_n s$$

**Lemma C.9.** Let $\leq$ be the subtyping relation induced by a well-founded convex model with infinite support. Then

1. $\sigma \vdash_0 C$ for all $\sigma$ and $C$.
2. $\sigma \vdash C \iff \forall n. \sigma \vdash_n C$.

**Proof.** Consequence of Lemma C.7.

---

11 See [4] for the definitions of the notions of models, interpretations, and assignments.
Lemma C.10 (Soundness). Let $C$ be a constraint-set. If $\emptyset \vdash_{\mathcal{X}} C \rightarrow \mathcal{S}$, then for all normalized constraint-set $C' \subseteq \mathcal{S}$ and all substitution $\sigma$, we have $\sigma \vdash C' \Rightarrow \sigma \vdash C$.

Proof. We prove the following stronger statements.

1. Assume $\Sigma \vdash_{\mathcal{X}} C \rightarrow \mathcal{S}$. For all $C' \subseteq \mathcal{S}$, $\sigma$ and $n$, if $\sigma \vdash_n C(\Sigma)$ and $\sigma \vdash_n C'$, then $\sigma \vdash_n C$.
2. Assume $\Sigma \vdash_{\mathcal{X}} C \rightarrow \mathcal{S}$. For all $C' \subseteq \mathcal{S}$, $\sigma$ and $n$, if $\sigma \vdash_n C(\Sigma)$ and $\sigma \vdash_n C'$, then $\sigma \vdash_{n+1} C$.

Before proving these statements, we explain how the first property implies the lemma. Suppose $\emptyset \vdash_{\mathcal{X}} C \rightarrow \mathcal{S}$ and $\Sigma \vdash_{\mathcal{X}} C \rightarrow \mathcal{S}$. It is easy to check that $\sigma \vdash_n C(\emptyset)$ holds for all $n$. From $\sigma \vdash C'$, we deduce $\sigma \vdash_n C'$ for all $n$ (by Lemma C.9). By Property (1), we have $\sigma \vdash_n C$ for all $n$, and we have then the required result by Lemma C.9.

We prove these two properties simultaneously by induction on the derivations of $\Sigma \vdash_{\mathcal{X}} C \rightarrow \mathcal{S}$ and $\Sigma \vdash_{\mathcal{X}} C \rightarrow \mathcal{S}$.

(NEMPY): straightforward.

(NJOIN): according to Definition C.4, if there exists $C_i \in \mathcal{S}$ such that $C_i = \emptyset$, then $\prod_{i \in I} \mathcal{S}_i = \emptyset$, and the result follows immediately. Otherwise, we have $C' = \bigcup_{i \in I} C_i$, where $C_i \in \mathcal{S}_i$. As $\sigma \vdash_n C'$, then clearly $\sigma \vdash_n C_i$. By induction, we have $\sigma \vdash_n \{ \{t_i, c_i, t'_i\} \mid i \in I\}$. Therefore, we get $\sigma \vdash_n \{ \{t, c, t' \} \mid i \in I\}$. (NSYM): by induction, we have $\sigma \vdash_n \{ \{\{t \leq t'\} \mid i \in I\}$. Then clearly $\sigma \vdash_n \{ \{t \leq t'\} \}$.

(NZER): by induction, we have $\sigma \vdash_n \{ \{\{\emptyset \leq \emptyset\} \mid i \in I\}$. According to set-theory, we have $\sigma \vdash_n \{ \{\emptyset \leq \emptyset\} \}$.

(NDNF): similar to the case of (NZER).

(NUN): similar to the case of (NZER).

(NTYL): assume $\alpha$ has the smallest order in $P \cup N$. If $\alpha' \in P$, then we have $C' = (\alpha', \leq, -\alpha')$. From $\sigma \vdash_n C'$, we deduce $\sigma(\alpha') \leq -\alpha' \sigma$. Intersecting both sides of the inequality by the same type, we obtain $\sigma(\alpha') \leq -\alpha' \sigma \leq 0$, that is, $\sigma \vdash_n \{ \{\emptyset \leq \emptyset\} \}$.

(NHY): since we have $\tau_0 \in \Sigma$ and $\sigma \vdash_n C(\Sigma)$, then $\sigma \vdash_n \{ \{\emptyset \leq \emptyset\} \}$.

(NASS): it is easy to prove that $\sigma \vdash_k C(\Sigma)$ and $\sigma \vdash_k C'$, it is easy to prove that $\sigma \vdash_k C(\Sigma)$ and $\sigma \vdash_k C'$, it is easy to prove that $\sigma \vdash_k C(\Sigma)$ and $\sigma \vdash_k C'$, it is easy to prove that $\sigma \vdash_k C(\Sigma)$ and $\sigma \vdash_k C'$, it is easy to prove that $\sigma \vdash_k C(\Sigma)$ and $\sigma \vdash_k C'$.

(NJT): it is easy to prove that $\sigma \vdash_k C(\Sigma)$ and $\sigma \vdash_k C'$.

(NBASIC): straightforward.

(NPROD): if $\prod_{i \in N'} C_i$ is $\emptyset$, then the result follows straightforwardly. We have $C' = \prod_{i \in N'} C_i$, where $C_i \in \mathcal{S}_i$. Since $\sigma \vdash_n C'$, we have $\sigma \vdash_n C_i$ for all subset $N' \subseteq N$. Moreover, following Definition C.4, either $C_i \in \mathcal{S}_i$ and $C_i \in \mathcal{S}_i$. By induction, we have $\sigma \vdash_n \{ \{\emptyset \leq \emptyset\} \} \Rightarrow \sigma \vdash_n \{ \{\emptyset \leq \emptyset\} \}$.

(NARROW): similar to the case of (NPROD).

Given a normalized constraint-set $C$ and a set $X$ of type variables, we define the restriction $C|_X$ of $C$ by $X$ to be $\{ \{\alpha, c, t\} \in C \mid \alpha \in X \}$.

Lemma C.11. Let $t$ be a type and $\emptyset \vdash_{\mathcal{X}} \{ \{t, \leq, 0\} \rightarrow \mathcal{S}$. Then for all normalized constraint-set $C \subseteq \mathcal{S}$, all substitution $\sigma$ and all $n$, if $\sigma \vdash_n C|_{\sigma(t)}$ and $\sigma \vdash_{n+1} C \setminus \sigma|_{\sigma(t)}$, then $\sigma \vdash_n \{ \{t, \leq, 0\} \}$.

Proof. By applying the rules (NDNF) and (NUN), the constraint-set $\{ \{t, \leq, 0\} \}$ is normalized into a new constraint-set $C'$, consisting of the constraints of the form $(\tau, \leq, 0)$, where $\tau$ is a single normal form. That is, $\emptyset \vdash_{\mathcal{X}} \{ \{t, \leq, 0\} \rightarrow \{C'\}$. Let $C_1 = \{ \{\tau, \leq, 0\} \in C' \mid \sigma(t) \neq 0 \}$ and $C_2 = C \setminus \{C_1\}$. It is easy to deduce that all the constraints in $C \setminus \sigma|_{\sigma(t)}$ are generated from $C_2$ and must pass at least one instance of $\vdash_{\mathcal{X}}$ (i.e., being decomposed at least once). Since $\sigma \vdash_{n+1} C \setminus \sigma|_{\sigma(t)}$ and according to the statement (2) in the proof of Lemma C.10, we have $\sigma \vdash_n C_2$. Moreover, from $\sigma \vdash_n C_2$, we have $\sigma \vdash_n C'_1$ and $\sigma \vdash_{n+1} \{ \{t, \leq, 0\} \}$. 

\qed
Lemma C.12 (Completeness). Let \( C \) be a constraint-set such that \( \emptyset \vdash_C C \rightarrow \mathcal{J} \). For all substitution \( \sigma \), if \( \sigma \models C \), then there exists \( C' \in \mathcal{J} \) such that \( \sigma \models C' \).

Proof. We prove the following stronger statements.

1. Assume \( \Sigma \vdash_C C \rightarrow \mathcal{J} \). For all \( \sigma \), if \( \sigma \models C(\Sigma) \) and \( \sigma \models C \), then there exists \( C' \in \mathcal{J} \) such that \( \sigma \models C' \).
2. Assume \( \Sigma \vdash^* \mathcal{J} \). For all \( \sigma \), if \( \sigma \models C(\Sigma) \) and \( \sigma \models C \), then there exists \( C' \in \mathcal{J} \) such that \( \sigma \models C' \).

The result is then a direct consequence of the first item (indeed, we have \( \sigma \models C(\emptyset) \) for all \( \sigma \)). We prove the two items simultaneously by induction on the derivations of \( \Sigma \vdash_C C \rightarrow \mathcal{J} \) and \( \Sigma \vdash^* \mathcal{J} \).

(NEMPTY): straightforward.
(NJOIN): as \( \sigma \models \{ t_i, c_i, t'_i \} \mid i \in I \), we have in particular \( \sigma \models \{ t_i, c_i, t'_i \} \) for all \( i \). By induction, there exists \( C_i \in \mathcal{J} \) such that \( \sigma \models C_i \). So \( \sigma \models \bigcup_{i \in I} C_i \). Moreover, according to Definition C.4, \( \bigcup_{i \in I} C_i \) must be in \( \bigcap_{i \in I} \mathcal{J}_i \). Therefore, the result follows.
(NSYM): if \( \sigma \models \{ t' \geq t \} \), then \( \sigma \models \{ t \leq t' \} \). By induction, the result follows.
(NZERO): since \( \sigma \models \{ t \leq t' \} \), we can subtract \( t' \) from both sides obtain \( \sigma \models \{ (t \land t' \leq 0) \} \). By induction, the result follows.
(NZF): similar to the case of (NZERO).
(NUNION): similar to the case of (NZERO).
(NTLV): assume \( \alpha' \) has the smallest order in \( P \cup N \). If \( \alpha' \in P \), then according to set-theory, we have \( \alpha' \sigma \models \{ (t \land t' \leq 0) \} \). Otherwise, we have \( \alpha' \in N \) and the result follows as well.
(NHYP): it is clear that \( \sigma \models \emptyset \).
(NASSUM): as \( \sigma \models C(\Sigma) \) and \( \sigma \models \{ \tau_0 \leq 0 \} \), we have \( \sigma \models C(\Sigma \cup \{ \tau_0 \}) \). By induction, the result follows.
(NBASIC): straightforward.
(NPROD): as
\[ \sigma \models \{ \bigwedge_{i \in P} (t_i \land t'_i) \land \bigwedge_{j \in N} (t_j \land t'_j) \leq 0 \} \]
we have
\[ \bigwedge_{i \in P} t_i \sigma \land \bigwedge_{j \in N} t_j \sigma \leq 0 \]
Applying Lemma 3.11 in [4], for all subset \( N' \subseteq N \), we have
\[ \bigwedge_{i \in P} t_i \sigma \land \bigwedge_{j \in N \setminus N'} t_j \sigma \leq 0 \text{ or } \bigwedge_{i \in P} t_i \sigma \land \bigwedge_{j \in N \setminus N'} t_j \sigma \leq 0 \]
that is,
\[ \sigma \models \{ \bigwedge_{i \in P} (t_i \land \bigwedge_{j \in N \setminus N'} (t_j \sigma \leq 0)) \} \text{ or } \sigma \models \{ \bigwedge_{i \in P} (t_i \land \bigwedge_{j \in N \setminus N'} t_j \sigma \leq 0) \} \]
By induction, either there exists \( C'_N \in \mathcal{J}'_N \) such that \( \sigma \models C'_N \), or there exists \( C''_N \in \mathcal{J}''_N \); such that \( \sigma \models C''_N \). According to Definition C.4, we have \( C'_N, C''_N \in \mathcal{J}'_N \cup \mathcal{J}''_N \). Thus there exists \( C'_N \in \mathcal{J}'_N \cup \mathcal{J}''_N \) such that \( \sigma \models C'_N \). Therefore \( \sigma \models \bigcup_{N' \subseteq N} C'_N \). Moreover, according to Definition C.4 again, \( \bigcup_{N' \subseteq N} C'_N \in \prod_{N' \subseteq N} (\mathcal{J}'_N \cup \mathcal{J}''_N) \). Hence, the result follows.
(NARROW): similar to the case (NPROD) except we use Lemma 3.12 in [4].

We now prove termination of the algorithm.

Definition C.13 (Plinth). A plinth \( \mathfrak{D} \subseteq \mathcal{J} \) is a set of types with the following properties:
- \( \mathfrak{D} \) is finite;
- \( \mathfrak{D} \) contains \( \mathbb{1}, \emptyset \) and is closed under Boolean connectives \((\land, \lor, \lnot)\);
- for all types \( t_1 \times t_2 \) or \( t_1 \rightarrow t_2 \) in \( \mathfrak{D} \), we have \( t_1 \in \mathfrak{D} \) and \( t_2 \in \mathfrak{D} \).

As stated in [11], every finite set of types is included in a plinth. Indeed, we already know that for a regular type \( t \) the set of its subtrees \( S \) is finite. The definition of the plinth ensures that the closure of \( S \) under Boolean connective is also finite. Moreover, if \( t \) belongs to a plinth \( \mathfrak{D} \), then the set of its subtrees is contained in \( \mathfrak{D} \). This is used to show the termination of algorithms working on types.

Lemma C.14 (Termination). Let \( C \) be a finite constraint-set. Then the normalization of \( C \) terminates.
Proof. Let $T$ be the set of type occurring in $C$. As $C$ is finite, $T$ is finite as well. Let $\mathcal{B}$ be a plinth such that $T \subseteq \mathcal{B}$. Then when we normalize a constraint $(t \leq 0)$ during the process of $\emptyset \vdash_{\mathcal{B}} C$, $t$ would belong to $\mathcal{B}$. We prove the lemma by induction on $(|\mathcal{B} \setminus \Sigma|, U, |C|)$ lexicographically ordered, where $\Sigma$ is the set of types we have normalized, $U$ is the number of unions $\lor$ occurring in the constraint-set $C$ plus the number of constraints $(t, \geq, s)$ and the number of constraint $(t, \leq, s)$ where $s \neq 0$ or $t$ is not in disjunctive normal form, and $C$ is the constraint-set to be normalized.

(NEMPTY): it terminates immediately.
(NJOIN): $|C|$ decreases, and neither $|\mathcal{B} \setminus \Sigma|$ nor $U$ increase.
(NSYM): $U$ decreases and $\Sigma$ is unchanged
(NZERO): $U$ decreases and $\Sigma$ is unchanged.
(NDNF): $U$ decreases and $\Sigma$ is unchanged.
(NUNION): although $|C|$ increases, $U$ decreases and $\Sigma$ is unchanged
(NTLV): it terminates immediately.
(NHYP): it terminates immediately.
(NASSUM): as $\tau_{0} \in \mathcal{B}$ and $\tau_{0} \notin \Sigma$, the number $|\mathcal{B} \setminus \Sigma|$ decreases.
(NBASIC): it terminates immediately.
(NPROD): although $(|\mathcal{B} \setminus \Sigma|, U, |C|)$ may not change, the next rule to apply must be one of (NEMPTY), (NJOIN), (NSYM), (NZERO), (NDNF), (NUNION), (NTLV), (NHYP) or (NASSUM). Therefore, either the normalization terminates or the triple decreases in the next step.
(NARROW): similar to Case (NPROD).

Lemma C.15 (Finiteness). Let $C$ be a constraint-set and $\emptyset \vdash_{\mathcal{B}} C \rightsquigarrow \mathcal{I}$. Then $\mathcal{I}$ is finite.

Proof. It is easy to prove that each normalizing rule generates a finite set of finite sets of normalized constraints.

Definition C.16. Let $C$ be a normalized constraint-set and $O$ an ordering on $\var(C)$. We say $C$ is well-ordered if for all normalized constraint $(\alpha, c, t_{a}) \in C$ and for all $\beta \in \text{tv}(t_{a})$, $O(\alpha) < O(\beta)$ holds.

Lemma C.17. Let $C$ be a constraint-set and $\emptyset \vdash_{\mathcal{B}} C \rightsquigarrow \mathcal{I}$. Then for all normalized constraint-set $C' \subseteq \mathcal{I}$, $C'$ is well-ordered.

Proof. The only way to generate normalized constraints is Rule (NTLV), where we have selected the normalized constraint for the type variable $\alpha$ whose order is minimum as the representative one, that is, $\forall \beta \in \text{tv}(t_{a}) . O(\alpha) < O(\beta)$. Therefore, the result follows.

Definition C.18. A general renaming $\rho$ is a special type substitution that maps each type variable to another (fresh) type variable.

Lemma C.19. Let $t$, $s$ be two types and $[\rho_{i}]_{i \in I}$, $[\rho'_{j}]_{j \in J}$ two sets of general renamings. Then if $\emptyset \vdash_{\mathcal{B}} \{(s \land t, \leq, 0)\} \rightsquigarrow \emptyset$, then $\emptyset \vdash_{\mathcal{B}} \{(\bigwedge_{j \in J} \rho_{j}) \land (\bigwedge_{i \in I} \rho'_{i}), \leq, 0\} \rightsquigarrow \emptyset$.

Proof. By induction on the number of (NPROD) and (NARROW) used in the derivation of $\emptyset \vdash_{\mathcal{B}} \{(s \land t, \leq, 0)\}$ and by cases on the disjunctive normal form $\tau$ of $s \land \neg t$. The failure of the normalization of $(s \land t, \leq, 0)$ is essentially due to (NBASIC-F), (NPROD) and (NARROW), where there are no top-level type variables to make the type empty.

The case of arrows is a little complicated, as we need to consider more than two types: one type for the negative parts and two types for the positive parts from $t$ and $s$ respectively. Indeed, what we prove is the following stronger statement:

$$\emptyset \vdash_{\mathcal{B}} \{\bigwedge_{k \in K} t_{k}, \leq, 0\} \rightsquigarrow \emptyset \implies \emptyset \vdash_{\mathcal{B}} \{\bigwedge_{k \in K} (\bigwedge_{i \in I} t_{k}, \rho_{i}), \leq, 0\} \rightsquigarrow \emptyset$$

where $|K| \geq 2$ and $\rho_{i}$’s are general renamings. For simplicity, we only consider $|K| = 2$, as it is easy to extend to the case of $|K| > 2$.

Case 1: $\tau = \tau_{0a} \land \tau_{0b}$ and $\tau \neq 0$, where $\tau_{0a}$, $\tau_{0b}$ (resp.) is an intersection of basic types from $s$ ($t$ resp.). Then the expansion of $\tau$ is

$$(\bigwedge_{j \in J} \tau_{0a}, \rho_{j}) \land (\bigwedge_{i \in I} \tau_{0b}, \rho_{i}) \simeq \tau_{0a} \land \tau_{0b} \neq 0$$

So $\emptyset \vdash_{\mathcal{B}} \{((\bigwedge_{j \in J} \tau_{0a}, \rho_{j}) \land (\bigwedge_{i \in I} \tau_{0b}, \rho_{i}), \leq, 0)\} \rightsquigarrow \emptyset$. 

Case 2: \( \tau = \bigwedge_{p_s \in P_s} (w_{p_s} \times v_{p_s}) \land \bigwedge_{n_s \in N_s} - (w_{n_s} \times v_{n_s}) \land \bigwedge_{p_t \in P_t} (w_{p_t} \times v_{p_t}) \land \bigwedge_{n_t \in N_t} - (w_{n_t} \times v_{n_t}) \), where \( P_s, N_s \) are from \( s \) and \( P_t, N_t \) are from \( t \). Since \( \emptyset \vdash \{ \tau, \leq, 0 \} \sim \emptyset \), by the rule (NPRODUCT), there exist two sets \( N_s' \subseteq N_s \) and \( N_t' \subseteq N_t \) such that

\[
\begin{align*}
\emptyset & \vdash \{ \bigwedge_{p_r \in P_r} \bigwedge_{n_r \in N_r'} \neg w_{n_r} \land \bigwedge_{p_r \in P_r} \bigwedge_{n_r \in N_r'} \neg w_{n_r}, \leq, 0 \} \sim \emptyset \\
\emptyset & \vdash \{ \bigwedge_{p_r \in P_r} \bigwedge_{n_r \in N_r \setminus N_r'} \neg w_{n_r} \land \bigwedge_{p_r \in P_r} \bigwedge_{n_r \in N_r \setminus N_r'} \neg w_{n_r}, \leq, 0 \} \sim \emptyset
\end{align*}
\]

By induction, we have

\[
\emptyset \vdash \{ \bigwedge_{p_s \in P_s} \bigwedge_{n_s \in N_s} \neg w_{n_s} \land \bigwedge_{p_t \in P_t} \bigwedge_{n_t \in N_t} \neg w_{n_t} \} \sim \emptyset
\]

Then by the rule (NPRODUCT) again, we get

\[
\emptyset \vdash \{ \bigwedge_{j \in J} (\tau_s) \land \bigwedge_{i \in I} (\tau_i) \} \sim \emptyset
\]

where \( \tau_s = \bigwedge_{p_s \in P_s} (w_{p_s} \times v_{p_s}) \land \bigwedge_{n_s \in N_s} - (w_{n_s} \times v_{n_s}) \) and \( \tau_t = \bigwedge_{p_t \in P_t} (w_{p_t} \times v_{p_t}) \land \bigwedge_{n_t \in N_t} - (w_{n_t} \times v_{n_t}) \).

Case 3: \( \tau = \bigwedge_{p_s \in P_s} (w_{p_s} \rightarrow v_{p_s}) \land \bigwedge_{n_s \in N_s} - (w_{n_s} \rightarrow v_{n_s}) \land \bigwedge_{p_t \in P_t} (w_{p_t} \rightarrow v_{p_t}) \land \bigwedge_{n_t \in N_t} - (w_{n_t} \rightarrow v_{n_t}) \), where \( P_s, N_s \) are from \( s \) and \( P_t, N_t \) are from \( t \). Since \( \emptyset \vdash \{ \tau, \leq, 0 \} \sim \emptyset \), by the rule (NARROW), for all \( v \rightarrow w \in N \cup N' \), there exist a set \( P'_s \subseteq P_s \) and a set \( P'_t \subseteq P_t \) such that

\[
\begin{align*}
\emptyset & \vdash \{ \bigwedge_{p_r \in P'_s} \bigwedge_{n_r \in N_r} \neg w_{n_r} \land \bigwedge_{p_r \in P'_t} \bigwedge_{n_r \in N_r} \neg w_{n_r}, \leq, 0 \} \sim \emptyset \\
P'_s = P_s \land P'_t = P_t
\end{align*}
\]

By induction, for all \( \rho \in [ \rho_j ]_{j \in J} \cup [ \rho_j ]_{j \in J} \), we have

\[
\emptyset \vdash \{ \bigwedge_{j \in J} (\tau_s) \bigwedge_{i \in I} (\tau_i) \} \sim \emptyset
\]

where \( \tau_s = \bigwedge_{p_s \in P_s} (w_{p_s} \rightarrow v_{p_s}) \land \bigwedge_{n_s \in N_s} - (w_{n_s} \rightarrow v_{n_s}) \) and \( \tau_t = \bigwedge_{p_t \in P_t} (w_{p_t} \rightarrow v_{p_t}) \land \bigwedge_{n_t \in N_t} - (w_{n_t} \rightarrow v_{n_t}) \).

Case 4: \( \tau = (\forall k_s \in K_s \tau_k_s) \land (\forall k_t \in K_t \tau_k_t) \), where \( \tau_k_s \) and \( \tau_k_t \) are single normal forms. As \( \emptyset \vdash \{ \tau, \leq, 0 \} \sim \emptyset \), there must exist at least one \( k_s \in K_s \) and at least one \( k_t \in K_t \) such that \( \emptyset \vdash \{ \tau_k_s \land \tau_k_t, \leq, 0 \} \sim \emptyset \). By Cases (1) – (3), the result follows.

\[\square\]

The type tallying problem is parameterized with a set \( \Delta \) of type variables that cannot be instantiated, but so far, we have not considered these monomorphic variables in the normalization procedure. Taking \( \Delta \) into account affects only the (NTLV) rule, where a normalized constraint is built by singling out a variable \( \alpha \). Since the type substitution \( \sigma \) we want to construct must not touch the type variables in \( \Delta \) (i.e., \( \sigma \notin \Delta \)), we cannot choose a variable \( \alpha \) in \( \Delta \). To avoid this, we order the variables in \( C \) so that those belonging to \( \Delta \) are always greater than those not in \( \Delta \). If, by choosing the minimum top-level variable \( \alpha \), we obtain \( \alpha \in \Delta \), it means that all the top-level type variables are contained in \( \Delta \). According to Lemmas C.3 and C.11 in the companion paper [3], we can then safely eliminate these type variables. So taking \( \Delta \) into account, we amend the (NTLV) rule as follows.

\[
\text{tlv}(\tau_0) = \emptyset \quad \alpha' \lor_0 P \cup N \quad \mathcal{F} = \left\{ \begin{array}{ll}
\{ \{ \alpha', \leq, \neg t_{\alpha'} \} \} & \alpha' \in P \setminus \Delta \\
\{ \{ \alpha', \geq, t_{\alpha'} \} \} & \alpha' \in N \setminus \Delta \\
\Sigma \vdash \{ \tau_0 \leq 0 \} & \alpha' \in \Delta
\end{array} \right.
\]

\[
\Sigma \vdash \{ \bigwedge_{\alpha \in P} \bigwedge_{\alpha \in N} \neg \alpha \land \tau_0 \leq 0 \} \sim \mathcal{F} \quad \text{-(NTLV)}
\]
Furthermore, it is easy to prove the soundness, completeness, and termination of the algorithm extended with \( \Delta \).

### C.1.2 Constraint merging

A normalized constraint-set may contain several constraints for a same type variable, which can eventually be merged together. For instance, the constraints \( \alpha \geq t_1 \) and \( \alpha \geq t_2 \) can be replaced by \( \alpha \geq t_1 \lor t_2 \), and the constraints \( \alpha \leq t_1 \) and \( \alpha \leq t_2 \) can be replaced by \( \alpha \leq t_1 \land t_2 \). That is to say, we can merge all the lower bounds (resp. upper bounds) of a type variable into only one by unions (resp. intersections).

\[
\forall i \in I. \ (\alpha \geq t_i) \in C \quad |i| \geq 2 \quad \vdash \text{MUB}
\]

\[
\forall i \in I. \ (\alpha \leq t_i) \in C \quad |i| \geq 2 \quad \vdash \text{MLB}
\]

**Figure 8.** Merging rules

After repeated uses of the merging rules, a set \( C \) contains at most one lower bound constraint and at most one upper bound constraint for each type variable. If both lower and upper bounds exist for a given \( \alpha \), that is, \( \alpha \geq t_1 \) and \( \alpha \leq t_2 \) belong to \( C \), then the substitution we want to construct from \( C \) must satisfy the constraint \( (t_1, \leq, t_2) \) as well. For that, we first normalize the constraint \( (t_1, \leq, t_2) \), yielding a set of constraint-sets \( \mathcal{F} \), and then saturate \( C \) with any normalized constraint-set \( C' \in \mathcal{F} \). Formally, we describe the saturation process as the saturation rule \( \Sigma_p, C_\Sigma \vdash \mathcal{F} \), where \( \Sigma_p \) is a set of type pairs (if \( (t_1, t_2) \in \Sigma_p \), then the constraint \( t_1 \leq t_2 \) has already been treated at this point), \( C_\Sigma \) is a normalized constraint-set (which collects the treated original constraints, like \( (\alpha \geq t_1) \) and \( (\alpha \leq t_2) \), that generate the additional constraints), \( C \) is the normalized constraint-set we want to saturate, and \( \mathcal{F} \) is a set of sets of normalized constraints (the result of the saturation of \( C \) joined with \( C_\Sigma \)). The saturation rules are given in Figure 9, which describe the same algorithm as Step 2 of the function merge given in Subsection 3.2.1.

\[
\Sigma_p, C_\Sigma \cup \{ (\alpha \geq t_1), (\alpha \leq t_2) \} \vdash \mathcal{F} \quad (t_1, t_2) \in \Sigma_p \quad C \vdash \mathcal{F} \ni C \ni \mathcal{F} (\text{SHYP})
\]

\[
\forall \alpha, t_1, t_2 \notin \Sigma_p \quad \emptyset \vdash \{ (t_1 \leq t_2) \} \ni \mathcal{F} \quad \mathcal{F} = \{ (\alpha \geq t_1), (\alpha \leq t_2) \} \cup C \cup C_\Sigma \ni \mathcal{F} \quad \forall C' \in \mathcal{F}, \Sigma_p \cup \{ (t_1, t_2) \}, \emptyset \vdash \mathcal{F} \ni C' \ni \mathcal{F} (\text{SASSUM})
\]

\[
\forall \alpha, t_1, t_2 \notin \Sigma_p \quad \text{\#}(\alpha \geq t_1), (\alpha \leq t_2) \ni C \quad \Sigma_p, C_\Sigma \vdash \mathcal{F} \ni C \ni \mathcal{F} \ni \mathcal{F} (\text{SDONE})
\]

where \( \Sigma_p, C_\Sigma \vdash \mathcal{F} \ni \mathcal{F} \) means that there exists \( C' \) such that \( \vdash \mathcal{F} \ni C' \) and \( \Sigma_p, C_\Sigma \vdash \mathcal{F} \ni C' \ni \mathcal{F} \).

**Figure 9.** Saturation rules

If \( \alpha \geq t_1 \) and \( \alpha \leq t_2 \) belongs to the constraint-set \( C \) that is being saturated, and \( t_1 \leq t_2 \) has already been processed (i.e., \( (t_1, t_2) \in \Sigma_p \)), then the rule (SHYP) simply extends \( C_\Sigma \) (the result of the saturation so far) with \( \{ \alpha \geq t_1, \alpha \leq t_2 \} \). Otherwise, the rule (SASSUM) first normalizes the fresh constraint \( (t_1, \leq, t_2) \), yielding a set of normalized constraint-sets \( \mathcal{F} \). It then saturates (joins) \( C \) and \( C_\Sigma \) with each constraint-set \( C_\mathcal{F} \in \mathcal{F} \), the union of which gives a new set \( \mathcal{F}' \) of normalized constrain-sets. Each \( C' \) in \( \mathcal{F}' \) may contain several constraints for the same type variable, so they have to be merged and saturated themselves. Finally, if \( C \) does not contain any couple \( \alpha \geq t_1 \) and \( \alpha \leq t_2 \) for a given \( \alpha \), the process is over and the rule (SDONE) simply returns \( C \cup C_\Sigma \).

If \( \emptyset, \emptyset \vdash \mathcal{F} \ni \mathcal{F} \), then the result of the merging of \( C \) is \( \mathcal{F} \).
Lemma C.20 (Soundness). Let $C$ be a normalized constraint-set. If $\emptyset, \emptyset \vdash_C C \Rightarrow \mathcal{F}$, then for all normalized constraint-sets $C' \in \mathcal{F}$ and all substitution $\sigma$, we have $\sigma \vdash_C C'$.

Proof. We prove the following statements.

- Assume $\vdash_C C \Rightarrow C'$. For all $\sigma$, if $\sigma \vdash_C C'$, then $\sigma \vdash C$.
- Assume $\Sigma_p, C_0 \vdash_C C \Rightarrow \mathcal{F}$. For all $\sigma$ and $C_0 \in \mathcal{F}$, if $\sigma \vdash_C C_0$, then $\sigma \vdash C \cup C_0$.

Clearly, these two statements imply the lemma. The first statement is straightforward. The proof of the second statement proceeds by induction of the derivation of $\Sigma_p, C_0 \vdash_C C \Rightarrow \mathcal{F}$.

\section{SHYP:}
by induction, we have $\sigma \vdash (C_0 \cup \{(\alpha \geq t_1), (\alpha \leq t_2)\}) \cup C$, that is $\sigma \vdash C_0 \cup \{(\alpha \geq t_1), (\alpha \leq t_2)\} \cup C$.

\section{SASSUM:}
according to Definition C.4, $C_0 \in \mathcal{F}_C$ for some $C' \in \mathcal{F}$. By induction on the premise $\Sigma_p \cup \{(t_1, t_2)\}, \emptyset \vdash_{\mathcal{F}}, C' \Rightarrow \mathcal{F}'$, we have $\sigma \vdash C'$. Moreover, the equation $\mathcal{F}' = \{(\alpha \geq t_1), (\alpha \leq t_2)\} \cup C \cup \mathcal{F}_C \subseteq C'$.

\section{SDONE:}
then we have $\sigma \vdash C_0 \cup \{(\alpha \geq t_1), (\alpha \leq t_2)\} \cup C$.

\section{SHYP:}
the result follows by induction.

\section{SASSUM:}
as $\sigma \vdash C_0 \subseteq \{(\alpha \geq t_1), (\alpha \leq t_2)\} \cup C$, we have $\sigma \vdash \{(t_1 \leq t_2)\} \cup C$.

\section{SDONE:}
then we have $\sigma \vdash C_0$.

\section{(SHYP):}
|C| decreases.

\section{(SASSUM):}
as $(t_1, t_2) \notin \Sigma_p$ and $t_1, t_2 \notin \mathcal{D}$, $|\mathcal{D} \cup \mathcal{D}| = |\Sigma_p|$ decreases.

\section{(SDone):}
it terminates immediately.

Definition C.23 (Sub-constraint). Let $C_1, C_2 \subseteq \mathcal{G}$ be two normalized constraint-sets. We say $C_1$ is a sub-constraint of $C_2$, denoted as $C_1 \subseteq C_2$, if for all $(\alpha, c, t) \in C_1$, there exists $(\alpha, c, t') \in C_2$ such that $t' \in C$.

Lemma C.24. Let $C_1, C_2 \subseteq \mathcal{G}$ be two normalized constraint-sets and $C_1 \subseteq C_2$. Then for all substitution $\sigma$, if $\sigma \vdash_C C_1$, then $\sigma \vdash_C C_2$.

Proof. Considering any constraint $(\alpha, c, t) \in C_1$, there exists $(\alpha, c, t') \in C_2$ such that $t' \in t$.

Definition C.25. Let $C \subseteq \mathcal{G}$ be a normalized constraint-set. We say $C$ is saturated if for each type variable $\alpha \in \text{dom}(C)$,

1. there exists at most one form $(\alpha \geq t_1) \in C$. 

there exists at most one form \( (\alpha \leq t_2) \in C \).

(3) if \( (\alpha \geq t_1), (\alpha \leq t_2) \in C \), then \( \emptyset \vdash C \{ (t_1 \leq t_2) \} \leadsto \mathcal{I} \) and there exists \( C' \in \mathcal{I} \) such that \( C' \) is a sub-constraint of \( C \) (i.e., \( C' \subseteq C \)).

**Lemma C.26.** Let \( C \) be a finite normalized constraint-set and \( \emptyset, \emptyset \vdash C \leadsto \mathcal{I} \). Then for all normalized constraint set \( C' \in \mathcal{I}, C' \) is saturated.

**Proof.** We prove a stronger statement: assume \( \Sigma_p, C \vdash \mathcal{I} \). If

(i) for all \( (t_1, t_2) \in \Sigma_p \), there exists \( C' \in (\emptyset \vdash C \{ (t_1 \leq t_2) \}) \) such that \( C' \subseteq C \cup C \) and

(ii) for all \( (\alpha \geq t_1), (\alpha \leq t_2) \subseteq C \), the pair \((t_1, t_2)\) is in \( \Sigma_p \),

then \( C_0 \) is saturated for all \( C_0 \in \mathcal{I} \).

The proof of conditions (1) and (2) for a saturated constraint-set is straightforward for all \( C_0 \in \mathcal{I} \). The proof of the condition (3) proceeds by induction on the derivation \( \Sigma_p, C \vdash \mathcal{I} \) and a case analysis on the last rule used in the derivation.

(\textsc{shyp}): as \((t_1, t_2) \in \Sigma_p \), the conditions (i) and (ii) hold for the premise. By induction, the result follows.

(\textsc{asume}): take any premise \( \Sigma_p \cup \{ (t_1, t_2) \}, \emptyset \vdash C'' \leadsto \mathcal{I}' \), where \( C'' \in \mathcal{I}' \) and \( \vdash \mathcal{I} \leadsto C'' \ leadsto \mathcal{I}'' \). For any \((s_1, s_2) \in \Sigma_p \), the condition (i) gives us that there exists \( C_0 \in (\emptyset \vdash (s_1 \leq s_2)) \) such that \( C_0 \subseteq C \cup (s_1 \leq s_2) \cup C \). Since \( \mathcal{I}' = C \cup (s_1 \leq s_2) \cap \mathcal{I} \), we have \( C_0 \subseteq C'' \subseteq C'' \). Moreover, consider \((t_1, t_2) \). As \( \emptyset \vdash (t_1 \leq t_2) \leadsto \mathcal{I} \), there exists \( C_0 \in \mathcal{I} \) such that \( C_0 \subseteq C'' \). Thus the condition (i) holds for the premise. Moreover, the condition (ii) holds straightforwardly for premise. By induction, the result follows.

(\textsc{sdone}): the result follows by the conditions (i) and (ii).

**Lemma C.27 (Finiteness).** Let \( C \) be a constraint-set and \( \emptyset, \emptyset \vdash \mathcal{I} \). Then \( \mathcal{I} \) is finite.

**Proof.** It follows by Lemma C.15.

**Lemma C.28.** Let \( C \) be a well-ordered normalized constraint-set and \( \emptyset, \emptyset \vdash \mathcal{I} \). Then for all normalized constraint-set \( C' \in \mathcal{I}, C' \) is well-ordered.

**Proof.** The merging of the lower bounds (or the upper bounds) of a same type variable preserves the orders. The result of saturation is well-ordered by Lemma C.17.

Normalization and merging may produce redundant constraint-sets. For example, consider the constraint-set \( \{ (\alpha \times \beta), \leq, (\text{Int} \times \text{Bool}) \} \). Applying the rule (\textsc{nprod}), the normalization of this set is

\[
\{ (\alpha \leq 0), (\beta \leq 0), (\alpha \leq 0, \beta \leq 0), (\alpha \leq \text{Int}, \beta \leq \text{Bool}) \}.
\]

Clearly each constraint-set is a saturated one. Note that \( \{ (\alpha \leq 0), (\beta \leq 0) \} \) is redundant, since any solution of this constraint-set is a solution of \( \{ (\alpha \leq 0) \} \) and \( (\beta \leq 0) \}. Therefore it is safe to eliminate it. Generally, for any two different normalized constraint sets \( C_1, C_2 \in \mathcal{I} \), if \( C_1 < C_2 \), then according to Lemma C.24, any solution of \( C_2 \) is a solution of \( C_1 \). Therefore, \( C_2 \) can be eliminated from \( \mathcal{I} \).

**Definition C.29.** Let \( \mathcal{I} \) be a set of normalized constraint-sets. We say that \( \mathcal{I} \) is minimal if for any two different normalized constraint-sets \( C_1, C_2 \in \mathcal{I} \), neither \( C_1 < C_2 \) nor \( C_2 < C_1 \). Moreover, we say \( \mathcal{I} \) is a set of \( \mathcal{I} \). Then there exists a minimal set \( \mathcal{I}_0 \) such that \( \mathcal{I}_0 \leq \mathcal{I} \).

**Lemma C.30.** Let \( C \) be a well-ordered normalized constraint-set and \( \emptyset, \emptyset \vdash \mathcal{I} \). Then for all normalized constraint-set \( C' \in \mathcal{I}, C' \) is well-ordered.

**Proof.** By eliminating the redundant constraint-sets in \( \mathcal{I} \).

**C.1.3 Constraint solving**

**From constraints to equations.** Given a well-ordered saturated constraint-set, we transform it into an equivalent equation system. This shows that the type tallying problem is essentially a unification problem.

**Definition C.31 (Equation system).** An equation system \( E \) is a set of equations of the form \( \alpha = t \) such that there exists at most one equation in \( E \) for every type variable \( \alpha \). We define the domain of \( E \), written \( \text{dom}(E) \), as the set \( \{ \alpha \mid \exists t . \alpha = t \in E \} \).

**Definition C.32 (Equation system solution).** Let \( E \) be an equation system. A solution to \( E \) is a substitution \( \sigma \) such that

\[
\forall \alpha = t \in E . \sigma(\alpha) \simeq t \sigma \text{ holds}
\]

If \( \sigma \) is a solution to \( E \), we write \( \sigma \models E \).
From a normalized constraint-set $C$, we obtain some explicit conditions for the substitution $\sigma$ we want to construct from $C$. For instance, from the constraint $\alpha \leq t$ (resp. $\alpha \geq t$), we know that the type substituted for $\alpha$ must be a subtype of $t$ (resp. a super type of $t$).

We assume that each type variable $\alpha \in \text{dom}(C)$ has a lower bound $t_1$ and an upper bound $t_2$, using, if necessary, the fact that $0 \leq \alpha \leq \beta$. Formally, we rewrite $C$ as follows:

$$
\begin{align*}
\{ t_1 \leq \alpha \leq 1 & \text{ if } \alpha \geq t_1 \in C \text{ and } \# t. \alpha \leq t \in C \\
0 \leq \alpha \leq t_2 & \text{ if } \alpha \leq t_2 \in C \text{ and } \# t. \alpha \geq t \in C \\
t_1 \leq \alpha \leq t_2 & \text{ if } \alpha \geq t_1, \alpha \leq t_2 \in C
\end{align*}
$$

We then transform each constraint $t_1 \leq \alpha \leq t_2$ in $C$ into an equation $\alpha = (t_1 \lor \alpha') \land t_2'$, where $\alpha'$ is a fresh type variable. The type $(t_1 \lor \alpha') \land t_2$ ranges from $t_1$ to $t_2$, so the equation $\alpha = (t_1 \lor \alpha') \land t_2$ expresses the constraint that $t_1 \leq \alpha \leq t_2$, as wished. We prove the soundness and completeness of this transformation.

To prove soundness, we define the rank $n$ satisfaction predicate $\models_n$ for equation systems, which is similar to the one for constraint-sets.

**Lemma C.33 (Soundness).** Let $C \subseteq \mathcal{C}$ be a well-ordered saturated normalized constraint-set and $E$ its transformed equation system. Then for all substitution $\sigma$, if $\sigma \vdash E$ then $\sigma \models C$.

**Proof.** Without loss of generality, we assume that each type variable $\alpha \in \text{dom}(C)$ has a lower bound and an upper bound, that is $t_1 \leq \alpha \leq t_2 \in C$. We write $O(C_1) < O(C_2)$ if $O(\alpha) < O(\beta)$ for all $\alpha \in \text{dom}(C_1)$ and all $\beta \in \text{dom}(C_2)$. We first prove a stronger statement:

(*) for all $\sigma$, $n$ and $C \subseteq C$, if $\sigma \models_n E$, $\sigma \models_n C_2$, $\sigma \models_{n-1} C \setminus C_2$, and $O(C \setminus C_2) < O(C_2)$, then $\sigma \models_n C \setminus C_2$.

Here $C_2$ denotes the set of constraints that have been checked. The proof proceeds by induction on $|C| \setminus C_2|.

$C \setminus C_2 = \emptyset$: straightforward.

$C \setminus C_2 \neq \emptyset$: take the constraint $(t_1 \leq \alpha \leq t_2) \in C \setminus C_2$ such that $O(\alpha)$ is the maximum in $\text{dom}(C \setminus C_2)$.

Clearly, there exists a corresponding equation $\alpha = (t_1 \lor \alpha') \land t_2 \in E$. As $\sigma \models_n E$, we have $\sigma(\alpha) \models_n ((t_1 \lor \alpha') \land t_2)\sigma$.

Then, $\sigma(\alpha) \land \lnot t_2 \sigma \models_n ((t_1 \lor \alpha') \land t_2)\sigma \land \lnot t_2 \sigma \models_n 0$.

Therefore, $\sigma(\alpha) \leq_n t_2 \sigma$.

Consider the constraint $(t_1, \leq, \alpha)$. We have $t_1 \sigma \land \lnot \sigma(\alpha) \models_n t_1 \sigma \land \lnot ((t_1 \lor \alpha') \land t_2)\sigma \models_n t_1 \sigma \land \lnot t_2 \sigma$.

What remains to do is to check the subtyping relation $t_3 \sigma \land \lnot t_2 \sigma \leq_n 0$, that is, to check that the judgement $\sigma \models_n \{(t_1 \leq t_2)\}$ holds. Since the whole constraint-set $C$ is saturated, according to Definition C.25, we have $\emptyset \vdash_{\mathcal{C'}} \{(t_1 \leq t_2)\} \rightarrow \mathcal{J}$ and there exists $C' \in \mathcal{J}$ such that $C' \subseteq C$, that is $C' \noteq C \cup C \setminus C_2$. Moreover, as $C$ is well-ordered, $O(\{\alpha\}) < O(\text{tv}(t_1) \cup \text{tv}(t_2))$ and thus $O(C \setminus C_2) < O(\text{tv}(t_1) \cup \text{tv}(t_2))$. Therefore, we can deduce that $C' \setminus \text{tv}(t_1) \cup \text{tv}(t_2) < C_2$ and $C' \setminus \text{tv}(t_1) \cup \text{tv}(t_2) < C \setminus C_2$. From the premise and Lemma C.24, we have $\sigma \models_n C' \setminus \text{tv}(t_1) \cup \text{tv}(t_2)$ and $\sigma \models_{n-1} C' \setminus \text{tv}(t_1) \cup \text{tv}(t_2)$. Then, by Lemma C.11, we get $\sigma \models_n \{(t_1 \leq t_2)\}$.

Finally, consider the constraint-set $C \setminus (C_2 \cup \{(t_1 \leq \alpha \leq t_2)\})$. By induction, we have $\sigma \models_n C \setminus (C_2 \cup \{(t_1 \leq \alpha \leq t_2)\})$. Thus the result follows.

Finally, we explain how to prove the lemma with the statement (*). Take $C_2 = \emptyset$. Since $\sigma \models E$, we have $\sigma \models_n E$ for all $n$. Trivially, we have $\sigma \models_0 C$. This can be used to prove $\sigma \models_1 C$. Since $\sigma \models_1 E$, by (*), we get $\sigma \models_1 C$, which will be used to prove $\sigma \models_2 C$. Consequently, we can get $\sigma \models_n C$ for all $n$, which clearly implies the lemma.

**Lemma C.34 (Completeness).** Let $C \subseteq \mathcal{C}$ be a saturated normalized constraint-set and $E$ its transformed equation system. Then for all substitution $\sigma$, if $\sigma \models C$ then there exists $\sigma'$ such that $\sigma' \leq \sigma$ and $\sigma \cup \sigma' \models E$.

**Proof.** Let $\sigma' = \{\sigma(\alpha)/\alpha' \mid \alpha \in \text{dom}(C)\}$. Consider each equation $\alpha = (t_1 \lor \alpha') \land t_2 \in E$. Correspondingly, there exist $\alpha \geq t_1 \in C$ and $\alpha \leq t_2 \in C$. As $\sigma \models C$, then $t_1 \sigma \leq \alpha(\alpha)$ and $\sigma(\alpha) \leq t_2 \sigma$. Thus

$$(t_1 \lor \alpha') \land t_2 \sigma = (t_1 \sigma \lor \alpha(\alpha') \land t_2 \sigma) \models (t_1 \sigma \lor \alpha(\alpha) \land t_2 \sigma) \models (\sigma(\alpha) \land t_2 \sigma) \models (\sigma(\alpha) \land t_2 \sigma) \models (\sigma \cup \sigma')(\alpha).$$

$\sigma'$.

Or, equivalently, $\alpha = t_1 \lor (\alpha' \land t_2)$. Besides, in practice, if only $\alpha \geq t_1, \alpha \leq t_2$ resp.) and all the occurrences of $\alpha$ in the co-domain of the function type are positive (negative resp.), we can use $\alpha = t_1 (\alpha \equiv t_2$ resp.) instead, and the completeness is ensured by subsumption.
Definition C.35. Let $E$ be an equation system and $O$ an ordering on $\text{dom}(E)$. We say that $E$ is well ordered if for all $\alpha = t_\alpha \in E$, we have $O(\alpha) < O(\beta)$ for all $\beta \in \text{tlv}(t_\alpha) \cap \text{dom}(E)$.

Lemma C.36. Let $C$ be a well-ordered saturated normalized constraint-set and $E$ its transformed equation system. Then $E$ is well ordered.

Proof. Clearly, $\text{dom}(E) = \text{dom}(C)$. Consider an equation $\alpha = (t_1 \lor \alpha') \land t_2$. Correspondingly, there exist $\alpha \geq t_1 \in C$ and $\alpha \leq t_2 \in C$. By Definition C.16, for all $\beta \in (\text{tlv}(t_1) \cup \text{tlv}(t_2)) \cap \text{dom}(C)$, $O(\alpha) < O(\beta)$. Moreover, $\alpha'$ is a fresh type variable in $C$, that is $\alpha' \notin \text{dom}(C)$. And then $\alpha' \notin \text{dom}(E)$. Therefore, $\text{tlv}((t_1 \lor \alpha') \land t_2) \cap \text{dom}(E) = (\text{tlv}(t_1) \cup \text{tlv}(t_2)) \cap \text{dom}(C)$. Thus the result follows. □

Solution of Equation Systems. We now extract a solution (i.e., a substitution) from the equation system we build from $C$. In an equation $\alpha = t_\alpha$, $\alpha$ may also appear in the type $t_\alpha$; such an equality reminds the definition of a recursive type. As a first step, we introduce a recursion operator $\mu$ in all the equations of the system, transforming $\alpha = t_\alpha$ into $\alpha = \mu x_\alpha.\ t_\alpha\{x_\alpha/\alpha\}$. This ensures that type variables do not appear in the right-hand side of the equalities, making the whole solving process easier. If some recursion operators are in fact not needed in the solution (i.e., we have $\alpha = \mu x_\alpha.\ t_\alpha$ with $x_\alpha \notin \text{fv}(t_\alpha)$), then we can simply eliminate them.

If the equation system contains only one equation, then this equation is immediately a substitution. Otherwise, consider the equation system $\{\alpha = \mu x_\alpha.\ t_\alpha\} \cup E$, where $E$ contains only equations closed with the recursion operator $\mu$ as explained above. The next step is to substitute the content expression $\mu x_\alpha.\ t_\alpha$ for all the occurrences of $\alpha$ in equations in $E$. In detail, let $\beta = \mu x_\beta.\ t_\beta \in E$. Since $t_\alpha$ may contain some occurrences of $\beta$ and these occurrences are clearly bounded by $\mu x_\beta$, we in fact replace the equation $\beta = \mu x_\beta.\ t_\beta$ with $\beta = \mu x_\beta.\ t_\beta\{\mu x_\beta.\ t_\beta/\beta\}\{x_\beta/\beta\}$, yielding a new equation system $E'$. Finally, assume that the equation system $E'$ (which has fewer equations) has a solution $\sigma'$. Then the substitution $\{\mu x_\alpha.\ t_\alpha/\alpha\} \odot \sigma'$ is a solution to the original equation system $\{\alpha = \mu x_\alpha.\ t_\alpha\} \cup E$. The solving algorithm $\text{Unify}(\cdot)$ is given in Figure 10.

**Figure 10. Equation system solving algorithm Unify(·)**

Require: an equation system $E$
Ensure: a substitution $\sigma$
1. let $e2mu(\alpha, t_\alpha) = (\alpha, \mu x_\alpha.\ t_\alpha\{x_\alpha/\alpha\})$ in
2. let subst(\alpha, t_\alpha) (\beta, t_\beta) = (\beta, t_\beta\{t_\alpha/\alpha\}\{x_\beta/\beta\}) in
3. let rec $mu2sub E =$
4. match $E$ with
5. | [] -> []
6. | (\alpha, t_\alpha) :: $E' ->$
7. let $E'' = \text{List.map subst(\alpha, t_\alpha) E'}$ in
8. let $\sigma' = mu2sub E''$ in \{t_\alpha/\alpha\} $\odot \sigma'$
9. in
10. let $e2sub E =$
11. let $E' = \text{List.map e2mu E}$ in
12. $mu2sub E'$

Definition C.37 (General solution). Let $E$ be an equation system. A general solution to $E$ is a substitution $\sigma$ from $\text{dom}(E)$ to $\mathcal{F}$ such that

$$\forall \alpha \in \text{dom}(\sigma) . \text{var}(\sigma(\alpha)) \cap \text{dom}(\sigma) = \emptyset$$

and

$$\forall \alpha = t \in E . \sigma(\alpha) \simeq t \sigma$$

Lemma C.38. Let $E$ be an equation system. If $\sigma = \text{Unify}(\cdot)$, then $\forall \alpha \in \text{dom}(\cdot), \text{var}(\sigma(\alpha)) \cap \text{dom}(\sigma) = \emptyset$ and $\text{dom}(\cdot) = \text{dom}(E)$.

Proof. The algorithm $\text{Unify}(\cdot)$ consists of two steps: (i) transform types into recursive types and (ii) extract the substitution. After the first step, for each equation $\alpha = t_\alpha \in E$, we have $\alpha \notin \text{var}(t_\alpha)$. Consider the second step. Let $\text{var}(E) = \bigcup_{(\alpha = t_\alpha) \in E} \text{var}(t_\alpha)$ and $S = \mathcal{V} \setminus S$, where $S$ is a set of type variables. We prove a stronger statement:

$$\forall \alpha \in \text{dom}(\sigma), \text{var}(\sigma(\alpha)) \cap (\text{dom}(\sigma) \cup \text{var}(E)) = \emptyset$$

and $\text{dom}(\sigma) = \text{dom}(E)$.

The proof proceeds by induction on $E$:
Proof. By induction on $E$.

$E = \emptyset$: straightforward.
$E = \{ (\alpha = t_\alpha) \} \cup E'$: let $E'' = \{ (\beta = t_\beta \{ t_\alpha / \alpha \} \{ x_\beta / \beta \} ) \mid (\beta = t_\beta) \in E' \}$. Then there exists a substitution $\sigma''$ such that $\sigma'' = \text{Unify}(E'')$ and $\sigma = \{ t_\alpha \sigma''/\alpha \} \oplus \sigma''$. By induction, we have $\forall \beta \in \text{dom}(\sigma'')$, $\text{var}(\sigma''(\beta)) \cap (\text{dom}(\sigma'') \cup \text{var}(E'')) = \emptyset$ and $\text{dom}(\sigma'') = \text{dom}(E'')$. As $\alpha \notin \text{dom}(E'')$, we have $\alpha \notin \text{dom}(\sigma'')$ and then $\text{dom}(\sigma) = \text{dom}(\sigma'') \cup \{ \alpha \} = \text{dom}(E)$.

Moreover, $\alpha \notin \text{var}(E'')$, then $\text{dom}(\sigma) \subseteq \text{dom}(\sigma'') \cup \text{var}(E'')$. Thus, for all $\beta \in \text{dom}(\sigma'')$, we have $\text{var}(\sigma''(\beta)) \cap \text{dom}(\sigma) = \emptyset$. Consider $t_\alpha \sigma''$. It is clear that $\text{var}(t_\alpha \sigma'') \cap \text{dom}(\sigma) = \emptyset$. Besides, the algorithm does not introduce any fresh variable, then for all $\beta \in \text{dom}(\sigma)$, we have $\text{var}(t_\beta) \cap \text{var}(E) = \emptyset$. Therefore, the result follows.

\[ \square \]

**Lemma C.39 (Soundness).** Let $E$ be an equation system. If $\sigma = \text{Unify}(E)$, then $\sigma \vDash E$.

Proof. By induction on $E$.

$E = \emptyset$: straightforward.
$E = \{ (\alpha = t_\alpha) \} \cup E'$: let $E'' = \{ (\beta = t_\beta \{ t_\alpha / \alpha \} \{ x_\beta / \beta \} ) \mid (\beta = t_\beta) \in E' \}$. Then there exists a substitution $\sigma''$ such that $\sigma'' = \text{Unify}(E'')$ and $\sigma = \{ t_\alpha \sigma''/\alpha \} \oplus \sigma''$. By induction, we have $\sigma'' \vDash E''$. According to Lemma C.38, we have $\text{dom}(\sigma'') = \text{dom}(E'')$. So $\text{dom}(\sigma) = \text{dom}(\sigma'') \cup \{ \alpha \}$.

Considering any equation $(\beta = t_\beta) \in E$ where $\beta \in \text{dom}(\sigma'')$. Then

$$
\sigma(\beta) = \sigma''(\beta) \quad \text{(apply $\sigma$)}
$$

$$
\simeq t_\beta \{ t_\alpha \sigma'' / \alpha \} \{ x_\beta / \beta \} \sigma'' \quad \text{(as $\sigma'' \vDash E''$)}
$$

$$
= t_\beta \{ t_\alpha \sigma'' / \alpha \} \{ x_\beta \sigma'' / \beta \} \oplus \sigma''
$$

$$
= t_\beta \{ t_\alpha \sigma'' / \alpha \} \{ x_\beta \sigma'' / \beta \} \oplus \sigma''
$$

$$
\simeq t_\beta \{ t_\alpha \sigma'' / \alpha \} \{ x_\beta \sigma'' / \beta \} \oplus \sigma'' \quad \text{(as $\sigma'' \vDash E''$)}
$$

Finally, consider the equation $(\alpha = t_\alpha)$. As

$$
\sigma(\alpha) = t_\alpha \sigma'' \quad \text{(apply $\sigma$)}
$$

$$
= t_\alpha \{ \beta \sigma'' / \beta \mid \beta \in \text{dom}(\sigma'') \} \quad \text{(expand $\sigma''$)}
$$

$$
= t_\alpha \{ \beta \sigma'' / \beta \mid \beta \in \text{dom}(\sigma'') \} \quad \text{(as $\beta \sigma = \beta \sigma''$)}
$$

$$
= t_\alpha \{ \beta \sigma'' / \beta \mid \beta \in \text{dom}(\sigma) \cup \{ \alpha \} \} \quad \text{(as $\alpha \notin \text{var}(t_\alpha)$)}
$$

$$
= t_\alpha \sigma \quad \text{(as $\text{dom}(\sigma) = \text{dom}(\sigma'') \cup \{ \alpha \}$)}
$$

Thus, the result follows.

\[ \square \]

**Lemma C.40.** Let $E$ be an equation system. If $\sigma = \text{Unify}(E)$, then $\sigma$ is a general solution to $E$.

Clearly, given an equation system $E$, the algorithm Unify($E$) terminates with a substitution $\sigma$.

**Lemma C.41 (Termination).** Given an equation system $E$, the algorithm Unify($E$) terminates.

Proof. By induction on the number of equations in $E$.

**Definition C.42.** Let $\sigma, \sigma'$ be two substitutions. We say $\sigma \simeq \sigma'$ if and only if $\forall \alpha. \sigma(\alpha) \simeq \sigma'(\alpha)$.

**Lemma C.43 (Completeness).** Let $E$ be an equation system. For all substitution $\sigma$, if $\sigma \vDash E$, then there exist $\sigma_0$ and $\sigma'$ such that $\sigma_0 = \text{Unify}(E)$ and $\sigma \simeq \sigma' \circ \sigma_0$.

Proof. According to Lemma C.41, there exists $\sigma_0$ such that $\sigma_0 = \text{Unify}(E)$. For any $\alpha \notin \text{dom}(\sigma_0)$, clearly we have $\alpha \sigma_0 \sigma = \alpha \sigma$ and then $\alpha \sigma_0 \sigma \simeq \sigma \alpha$. What remains to prove is that if $\sigma \vDash E$ and $\sigma_0 = \text{Unify}(E)$ then $\forall \alpha \in \text{dom}(\sigma_0). \alpha \sigma_0 \sigma \simeq \alpha \sigma$. The proof proceeds by induction on $E$:

$E = \emptyset$: straightforward.
\[ E = \{ (\alpha = t_\omega) \} \cup E' \; \text{let } E'' = \{ (\beta = t_\beta\{t_\alpha/\alpha\}\{x/\beta\}) \mid (\beta = t_\beta) \in E' \}. \] Then there exists a substitution \( \sigma'' \) such that \( \sigma'' = \text{Unify}(E'') \) and \( \sigma_0 = \{ t_\alpha\sigma''/\alpha \} + \sigma'' \). Considering each equation \( (\beta = t_\beta\{t_\alpha/\alpha\}\{x/\beta\}) \in E'' \), we have

\[
t_x^{\{t_\alpha/\alpha\}\{x/\beta\}} \sigma = t_\beta\{t_\alpha\{x/\beta\}/\alpha, x/x_\beta\} \sigma + t_\beta\{t_\alpha\{x/\beta\}\sigma/\alpha, x/x_\beta\} \sigma \quad (\text{expand } x_\beta)
\]

Therefore, \( \sigma \models E'' \). By induction on \( E'' \), we have \( \forall \beta \in \dom(\sigma'') \), \( \beta\sigma''/\sigma \simeq \beta \sigma \). According to Lemma C.38, \( \dom(\sigma'') = \dom(E'') \). As \( \alpha \notin \dom(E'') \), then \( \dom(\sigma_0) = \dom(\sigma'') \cup \{ \alpha \} \). Therefore for any \( \beta \in \dom(\sigma'') \cap \dom(\sigma_0), \beta\sigma_0/\sigma \simeq \beta\sigma''/\sigma \simeq \beta \sigma \). Finally, considering \( \alpha \), we have

\[
\alpha\sigma_0/\sigma = t_\alpha\{x/\beta\}/\alpha \sigma = t_\alpha\{x/\beta\\beta/\sigma/\beta \sigma/\beta\} \sigma \quad (\text{apply } \sigma_0)
\]

Therefore, the result follows.

\[ \square \]

In our calculus, a type is well-formed if and only if the recursion traverses a constructor. In other words, the recursive variable should not appear at the top level of the recursive content. For example, the type \( \mu x. x \forall t \) is not well-formed. To make the substitutions usable, we should avoid these substitutions with ill-formed types. Fortunately, this can be done by giving an ordering on the domain of an equation system to make sure that the equation system is well-ordered.

**Lemma C.44.** Let \( E \) be a well-ordered equation system. If \( \sigma = \text{Unify}(E) \), then for all \( \alpha \in \dom(\sigma), \sigma(\alpha) \) is well-formed.

**Proof.** Assume that there exists an ill-formed \( \sigma(\alpha) = \mu x. t \) where \( x \) occurs at the top level of \( t \). According to the algorithm Unify(), there exists a sequence of equations \( (\alpha =) \alpha_0 = t_{\alpha_0}, \alpha_1 = t_{\alpha_1}, \ldots, \alpha_n = t_{\alpha_n} \) such that \( \alpha_i \in \text{tv}(t_{\alpha_{i-1}}) \) and \( \alpha_0 \in \text{tv}(t_{\alpha_n}) \) where \( i \in \{1, \ldots, n\} \) and \( n \geq 0 \). According to Definition C.35, \( O(\alpha_{n-1}) < O(\alpha_1) \) and \( O(\alpha_n) < O(\alpha_0) \). Therefore, we have \( O(\alpha_0) < O(\alpha_1) < \ldots < O(\alpha_n) < O(\alpha_0) \), which is impossible. Thus the result follows.

\[ \square \]

As mentioned above, there may be some useless recursion constructor \( \mu \). They can be eliminated by checking whether the recursive variable appears in the content expression or not. Moreover, if a recursive type is empty (which can be checked with the subtyping algorithm), then it can be replaced by \( 0 \).

### C.1.4 The complete algorithm

To conclude, we now describe the solving procedure \( \text{Sol}_\Delta(C) \) for the type tallying problem \( C \). We first normalize \( C \) into a finite set \( \mathcal{J} \) of well-ordered normalized constraint-sets (Step 1). If \( \mathcal{J} \) is empty, then there are no solutions to \( C \). Otherwise, each constraint-set \( C_i \in \mathcal{J} \) is merged and saturated into a finite set \( \mathcal{J}_C \) of well-order saturated normalized constraint-sets (Step 2). Then all these sets are collected into another set \( \mathcal{J}' \) (i.e. \( \mathcal{J}' = \bigcup_{C_i \in \mathcal{J}_C} \mathcal{J}_C \)). If \( \mathcal{J}' \) is empty, then there are no solutions to \( C \). Otherwise, for each constraint-set \( C'_i \in \mathcal{J}' \), we transform \( C'_i \) into an equation system \( E_i \) and then construct a general solution \( \sigma_i \) from \( E_i \) (Step 3). Finally, we collect all the solutions \( \sigma_i \), yielding a set \( \Theta \) of solutions to \( C \). We write \( \text{Sol}_\Delta(C) \sim \Theta \) if \( \text{Sol}_\Delta(C) \) terminates with \( \Theta \), and we call \( \Theta \) the solution of the type tallying problem \( C \).

**Theorem C.45 (Soundness).** Let \( C \) be a constraint-set. If \( \text{Sol}_\Delta(C) \sim \Theta \), then for all \( \sigma \in \Theta, \sigma \models C \).

**Theorem C.46 (Completeness).** Let \( C \) be a constraint-set and \( \text{Sol}_\Delta(C) \sim \Theta \). Then for all substitution \( \sigma \), if \( \sigma \models C \), then there exists \( \sigma' \in \Theta \) and \( \sigma'' \) such that \( \sigma \approx \sigma' \circ \sigma'' \).

**Proof.** Consequence of Lemmas C.12, C.21, C.34 and C.43.

**Theorem C.47 (Termination).** Let \( C \) be a constraint-set. Then \( \text{Sol}_\Delta(C) \) terminates.
Lemma C.48. Let $C$ be a constraint-set and $\text{Sol}_\Delta(C) \leadsto \Theta$. Then

1. $\Theta$ is finite.
2. for all $\sigma \in \Theta$ and for all $\alpha \in \text{dom}(\sigma)$, $\sigma(\alpha)$ is well-formed.

C.2 Type-Substitution Inference Algorithm

In Section B, we presented a sound and complete inference system, which is parametric in the decision procedures for $\Box_\Delta$, $\Pi_\Delta(\cdot)$, and $\bullet_\Delta$. In this section we tackle the problem of computing these operators. We focus on the application problem $\bullet_\Delta$ since the other two can be solved similarly. Recall that to compute $t \bullet_\Delta s$, we have to find two sets of substitutions $\{\sigma_i\}_{i \in I}$ and $\{\sigma_j\}_{j \in J}$ such that $\forall h \in I \cup J. \sigma_h \notin \Delta$ and

$$\bigwedge_{i \in I} \sigma_i \leq 0 \rightarrow 1$$  \hspace{1cm} \hspace{1cm} \hspace{1cm} \hspace{1cm} \hspace{1cm} (18)

$$\bigwedge_{j \in J} \sigma_j \leq \text{dom}(\bigwedge_{i \in I} \sigma_i)$$  \hspace{1cm} \hspace{1cm} \hspace{1cm} \hspace{1cm} \hspace{1cm} (19)

This problem is more general than the other two problems. If we are able to decide inequation (19), it means that we are able to decide $s' \subseteq_\Delta t'$ for any $s'$ and $t'$, just by considering $t'$ ground. Therefore we can decide $\Box_\Delta$. We can also decide $|\sigma_i| \vdash s \subseteq_\Delta \bot \times 1$ for all $s$, and therefore compute $\Pi_\Delta(s)$.

Let the cardinalities of $I$ and $J$ be $p$ and $q$ respectively. We first show that for fixed $p$ and $q$, we can reduce the application problem to a type tallying problem. Note that if we increase $p$, the type on the right of Inequality (19) is larger, and if we increase $q$ the type on the left is smaller. Namely, the larger $p$ and $q$ are, the higher the chances that the inequality holds. Therefore, we can search for cardinalities that make the inequality hold by starting from $p = q = 1$, and then by increasing $p$ and $q$ in a dove-tail order until we get a solution. This gives us a semi-decision procedure for the general application problem. In order to ensure termination, we give some heuristics based on the shapes of $s$ and $t$ to set upper bounds for $p$ and $q$.

C.2.1 Application problem with fixed cardinalities

We explain how to reduce the application problem with fixed cardinalities for $I$ and $J$ to a type tallying problem. Without loss of generality, we can split each substitution $\sigma_k$ ($k \in I \cup J$) into two substitutions: a renaming substitution $\rho_k$ that maps each variable in the domain of $\sigma_k$ into a fresh variable and a second substitution $\sigma'_k$ such that $\sigma_k = \sigma'_k \circ \rho_k$. The two inequalities then can be rewritten as

$$\bigwedge_{i \in I} (t\rho_i)\sigma'_i \leq 0 \rightarrow 1$$

$$\bigwedge_{j \in J} (s\rho_j)\sigma'_j \leq \text{dom}(\bigwedge_{i \in I} (t\rho_i)\sigma'_i)$$

The domains of the substitutions $\sigma'_k$ are pairwise distinct, since they are composed by fresh type variables. We can therefore merge the $\sigma'_k$ into one substitution $\sigma = \bigcup_{k \in I \cup J} \sigma'_k$. We can then further rewrite the two inequalities as

$$(\bigwedge_{i \in I} (t\rho_i))\sigma \leq 0 \rightarrow 1$$

$$(\bigwedge_{j \in J} (s\rho_j))\sigma \leq \text{dom}(\bigwedge_{i \in I} (t\rho_i))\sigma$$

which are equivalent to

$$t' \sigma \leq 0 \rightarrow 1$$

$$s' \sigma \leq \text{dom}(t' \sigma)$$

where $t' = (\bigwedge_{i \in I} t\rho_i)$ and $s' = (\bigwedge_{j \in J} s\rho_j)$. As $t' \sigma \leq 0 \rightarrow 1$, then $t' \sigma$ must be a function type. Then according to Lemmas C.12 and C.13 in the companion paper [3], we can reduce these two inequalities to the constraint set\(^{13}\):

$$C = \{(t', \leq, 0 \rightarrow 1), (t', \leq, s' \rightarrow \gamma)\}$$

where $\gamma$ is a fresh type variable. We have reduced the original application problem $t \bullet_\Delta s$ to solving $C$, which can be explained as explained in Section C.1. We write $\text{AppFix}_\Delta(t, s)$ for the algorithm of the application problem with fixed cardinalities $t \bullet_\Delta s$ and $\text{AppFix}_\Delta(t, s) \leadsto \Theta$ if $\text{AppFix}_\Delta(t, s)$ terminates with $\Theta$.

Lemma C.49. Let $t, s$ be two types and $\gamma$ a type variable such that $\gamma \notin \text{var}(t) \cup \text{var}(s)$. Then for all substitution $\sigma$, if $t \sigma \leq \sigma \rightarrow \gamma \sigma$, then $s \sigma \leq \text{dom}(t \sigma)$ and $\sigma(\gamma) \geq t \sigma \cdot s \sigma$.

\(^{13}\) The first constraint $(t', \leq, 0 \rightarrow 1)$ can be eliminated since it is implied by the second one.
Proof. Consider any substitution $\sigma$. As $t\sigma \leq s\sigma \to \gamma\sigma$, by Lemma C.12 in the companion paper [3], we have $s\sigma \leq \text{dom}(t\sigma)$. Then by Lemma C.13 in the companion paper [3], we get $\sigma(\gamma) \geq t\sigma \cdot s\sigma$. \qed

Lemma C.50. Let $t, s$ be two types and $\gamma$ a type variable such that $\gamma \notin \text{var}(t) \cup \text{var}(s)$. Then for all substitution $\sigma$, if $s\sigma \leq \text{dom}(t\sigma)$ and $\gamma \notin \text{dom}(\sigma)$, then there exists $\sigma'$ such that $\sigma' \cdot \sigma$ and $t(\sigma \cup \sigma') \leq (s \rightarrow \gamma)(\sigma \cup \sigma')$.

Proof. Consider any substitution $\sigma$. As $s\sigma \leq \text{dom}(t\sigma)$, by Lemma C.13 in the companion paper [3], the type $(t\sigma) \cdot (s\sigma)$ exists and $t\sigma \leq s\sigma \rightarrow ((t\sigma) \cdot (s\sigma))$. Let $\sigma' = \{(t\sigma) \cdot (s\sigma)/\gamma\}$. Then

\[
t(\sigma \cup \sigma') = t\sigma \leq s\sigma \rightarrow ((t\sigma) \cdot (s\sigma)) \\
\equiv \sigma \rightarrow \gamma\sigma' \\
= (s \rightarrow \gamma)(\sigma \cup \sigma')
\]

Note that the solution of the $\gamma$ introduced in the constraint $(t, \leq, s \to \gamma)$ represents a result type for the application of $t$ to $s$. In particular, completeness for the tallying problem ensures that each solution will assign to $\gamma$ (which occurs in a covariant position) the minimum type for that solution. So the minimum solutions for $\gamma$ are in $t \bullet s$ (see the substitution $\sigma'(\gamma) = (t\sigma) \cdot (s\sigma)$ in the proof of Lemma C.50).

Theorem C.51 (Soundness). Let $t$ and $s$ be two types. If $\text{AppFix}_\Delta(t, s) \sim \Theta$, then for all $\sigma \in \Theta$, we have $t\sigma \leq 0 \to 1$ and $s\sigma \leq \text{dom}(t\sigma)$.

Proof. Consequence of Lemmas C.49 and C.45. \qed

Theorem C.52 (Completeness). Let $t$ and $s$ be two types and $\text{AppFix}_\Delta(t, s) \sim \Theta$. For all substitution $\sigma$, if $t\sigma \leq 0 \to 1$ and $s\sigma \leq \text{dom}(t\sigma)$, then there exists $\sigma' \in \Theta$ and $\sigma''$ such that $\sigma \simeq \sigma'' \cdot \sigma'$.

Proof. Consequence of Lemmas C.50 and C.46. \qed

C.2.2 General application problem

Now we take the cardinalities of $I$ and $J$ into account to solve the general application problem. We start with $I$ and $J$ both of cardinality 1 and explore all the possible combinations of the cardinalities of $I$ and $J$ by, say, a dove-tail order until we get a solution. More precisely, the algorithm consists of two steps:

Step A: we generate a constraint set as explained in Section C.2.1 and apply the tallying solving algorithm described in Section C.1, yielding either a solution or a failure.

Step B: if all attempts to solve the constraint sets have failed at Step 1 of the tallying solving algorithm given at the beginning of Section C.1.1, then fail (the expression is not typable). If they all failed but at least one did not fail in Step 1, then increment the cardinalities $I$ and $J$ to their successor in the dove-tail order and start from Step A again. Otherwise all substitutions found by the algorithm are solutions of the application problem.

Notice that the algorithm returns a failure only if the solving of the constraint-set fails at Step 1 of the algorithm for the tallying problem. The reason is that up to Step 1 all the constraints at issue are on distinct occurrences of type variables: if they fail there is no possible expansion that can make the constraint-set satisfiable (see Lemma C.53). For example, the function $\text{map}$ can not be applied to any integer, as the normalization of $\{(\text{Int}, \leq, \alpha \rightarrow \beta)\}$ is empty (and even for any expansion of $\alpha \rightarrow \beta$). In Step 2 instead constraints of different occurrences of a same variable are merged. Thus even if the constraints fail it may be the case that they will be satisfied by expanding different occurrences of a same variable into different variables. Therefore an expansion is tried. For example, consider the application of a function of type $((\text{Int} \rightarrow \text{Int}) \land (\text{Bool} \rightarrow \text{Bool})) \rightarrow t$ to an argument of type $\alpha \rightarrow \alpha$. We start with the constraint $\{(\alpha \to \alpha, \leq, (\text{Int} \rightarrow \text{Int}) \land (\text{Bool} \rightarrow \text{Bool})\}$.

The tallying algorithm first normalizes it into the set

\[
\{(\alpha, \leq, \text{Int}), (\alpha, \geq, \text{Int}), (\alpha, \leq, \text{Bool}), (\alpha, \geq, \text{Bool})\}\} \ (\text{Step 1}).
\]

But it fails at Step 2 as neither Int $\leq$ Bool nor Bool $\leq$ Int hold. However, if we expand $\alpha \rightarrow \alpha$, the constraint to be solved becomes

\[
((\alpha_1 \rightarrow \alpha_1) \land (\alpha_2 \rightarrow \alpha_2), \leq, (\text{Int} \rightarrow \text{Int}) \land (\text{Bool} \rightarrow \text{Bool}))
\]

and one of the constraint-set of its normalization is

\[
\{(\alpha_1, \leq, \text{Int}), (\alpha_1, \geq, \text{Int}), (\alpha_2, \leq, \text{Bool}), (\alpha_2, \geq, \text{Bool})\}
\]

The conflict between Int and Bool disappears and we can find a solution to the expanded constraint.

Note that we keep trying expansion without giving any bound on the cardinalities $I$ and $J$, so the procedure may not terminate, which makes it only a semi-algorithm. The following lemma justifies why we do not try to expand if normalization (i.e., Step 1 of the tallying algorithm) fails.
Lemma C.53. Let $t, s$ be two types, $\gamma$ a fresh type variable and $[p_i]_{i \in I}, [p_j]_{j \in J}$ two sets of general renamings. If $\emptyset \vdash \{(t, s \rightarrow \gamma)\}, \emptyset \vdash \emptyset$, then $\emptyset \vdash ((\bigwedge_{i \in I} t p_i, \leq, 0 \rightarrow \emptyset), (\bigwedge_{i \in I} t p_i, \leq, (\bigwedge_{j \in J} s p_j) \rightarrow \gamma)) \leadsto \emptyset$.

Proof. As $\emptyset \vdash \{(t, s \rightarrow \gamma)\}, \emptyset \vdash \emptyset$, then either $\emptyset \vdash \emptyset$ or $\emptyset \vdash \emptyset$. If the first one holds, then according to Lemma C.19, we have $\emptyset \vdash \emptyset$ and a fortiori $\emptyset \vdash \emptyset$.

Assume that $\emptyset \vdash \emptyset$. Without loss of generality, we consider the disjunctive normal form $\tau$ of $t$:

$$\tau = \bigvee_{k_b \in K_b} \tau_{k_b} \lor \bigvee_{k_p \in K_p} \tau_{k_p} \lor \bigvee_{k_a \in K_a} \tau_{k_a}$$

where $\tau_{k_b}$, $\tau_{k_p}$ and $\tau_{k_a}$ (resp.) is an intersection of basic types (products and arrows resp.) and type variables. Then there must exist $k \in K_b \cup K_p \cup K_a$ such that $\emptyset \vdash \emptyset$ is equivalent to $\emptyset$. If $k \in K_b \cup K_p$, then the constraint $\tau_k$ is equivalent to $\emptyset$. By Lemma C.19, we get $\emptyset \vdash \emptyset$. Otherwise, $\emptyset \vdash \emptyset$ does not hold. Applying Lemma C.19 again, we get $\emptyset \vdash \emptyset$. Moreover, following the rule (NARROW), there exists a set $P' \subseteq P$ such that

$$\begin{aligned}
\emptyset \vdash \emptyset \quad \text{and} \quad P' = P \lor \emptyset \vdash \emptyset
\end{aligned}$$

Applying C.19, we get

$$\begin{aligned}
\emptyset \vdash \emptyset \quad \text{and} \quad P' = P \lor \emptyset \vdash \emptyset
\end{aligned}$$

By the rule (NARROW), we have

$$\emptyset \vdash \emptyset \quad \text{and} \quad P' = P \lor \emptyset \vdash \emptyset$$

Therefore, we have $\emptyset \vdash \emptyset$. So the result follows. \hfill \square

Let $\text{App}_{\Delta}(t, s)$ denote the semi-algorithm for the general application problem.

Theorem C.54. Let $t, s$ be two types and $\gamma$ the special fresh type variable introduced in $(\bigwedge_{i \in I} t \sigma_i, \leq, (\bigwedge_{j \in J} s \sigma_j) \rightarrow \gamma)$. If $\text{App}_{\Delta}(t, s)$ terminates with $\Theta$, then

1. (Soundness) if $\Theta \neq \emptyset$, then for each $\sigma \in \Theta$, $\sigma(\gamma) \in t \bullet_{\Delta} s$.
2. (Weak completeness) if $\Theta = \emptyset$, then $t \bullet_{\Delta} s = \emptyset$.

(2): consequence of Lemma C.53. \hfill \square

Consider the application map even, whose types are

- map : $\text{map} : (\alpha \rightarrow \beta) \rightarrow [\alpha] \rightarrow [\beta]
- even : (\text{Int} \rightarrow \text{Bool}) \land ((\alpha \setminus \text{Int}) \rightarrow (\alpha \setminus \text{Int}))$

We start with the constraint-set

$$C_1 = \{(\alpha_1 \rightarrow \beta_1) \rightarrow [\alpha_1] \rightarrow [\beta_1] \leq ((\text{Int} \rightarrow \text{Bool}) \land ((\alpha \setminus \text{Int}) \rightarrow (\alpha \setminus \text{Int}))) \rightarrow \gamma\}$$
where $\gamma$ is a fresh type variable (and where we $\alpha$-converted the type of \texttt{map}). Then the algorithm \texttt{Sol}_{\Delta}(C_1)\text{ }generates\text{ }a\text{ }set\text{ }of\text{ }eight\text{ }constraint-sets\text{ }at\text{ }Step\text{ }2:\n\{\gamma \geq \alpha_1 \rightarrow \beta_1, \alpha_1 \leq 0\}\n\{\gamma \geq \alpha_1 \rightarrow \beta_1, \alpha_1 \leq 0, \beta_1 \geq \textbf{Bool}\}\n\{\gamma \geq \alpha_1 \rightarrow \beta_1, \alpha_1 \leq 0, \beta_1 \geq \textbf{Int}\}\n\{\gamma \geq \alpha_1 \rightarrow \beta_1, \alpha_1 \leq 0, \beta_1 \geq \textbf{Bool} \lor (\alpha \land \textbf{Int})\}\n\{\gamma \geq \alpha_1 \rightarrow \beta_1, \alpha_1 \leq 0, \beta_1 \geq \textbf{Bool} \land (\alpha \land \textbf{Int})\}\n\{\gamma \geq \alpha_1 \rightarrow \beta_1, \alpha_1 \leq 0, \beta_1 \geq \textbf{Int}, \beta_1 \geq \textbf{Bool}\}\n\{\gamma \geq \alpha_1 \rightarrow \beta_1, \alpha_1 \leq 0, \beta_1 \geq \textbf{Int} \lor (\alpha \land \textbf{Int})\}\nClearly, the solutions to the 2nd-5th constraint-sets are included in those to the first constraint-set. For the other four constraint-sets, by minimum instantiation, we can get four solutions for $\gamma$ (i.e., the result types of \texttt{map even}: $[\ ] \rightarrow [\ ]$, or \texttt{Int} $\rightarrow \textbf{Bool}$, or $[\alpha \land \textbf{Int}] \rightarrow [\alpha \land \textbf{Int}]$, or $[\textbf{Int} \land \alpha] \rightarrow [\textbf{Bool} \lor (\alpha \land \textbf{Int})]$). Of these solutions only the last two are minimal (the first type is an instance of the third one and the second is an instance of the fourth one) and since both are valid we can take their intersection, yielding the (minimum) solution
\[ ([\alpha \land \textbf{Int}] \rightarrow [\alpha \land \textbf{Int}]) \land ([\textbf{Int} \lor \alpha] \rightarrow [\textbf{Bool} \lor (\alpha \land \textbf{Int})]) \] (20)

Alternatively, we can duly follow the algorithm, perform an iteration, expand the type of the function, yielding the constraint-set
\[\{(\alpha_1 \rightarrow \beta_1) \rightarrow (\alpha_1 \rightarrow \beta_1) \land ((\alpha_2 \rightarrow \beta_2) \rightarrow (\alpha_2 \rightarrow \beta_2)) \leq ((\textbf{Int} \rightarrow \textbf{Bool}) \land ((\alpha \land \textbf{Int}) \rightarrow (\alpha \land \textbf{Int}))) \rightarrow \gamma\}\]

from which we get the type (20) directly.

As stated in Section C.1, we chose an arbitrary ordering on type variables, which affects the generated substitutions and then the resulting types. Assume that $\sigma_1$ and $\sigma_2$ are two type substitutions generated by different orders. Thanks to the completeness of the tallying problem, there exist $\sigma_1$ and $\sigma_2$ such that $\sigma_1 \equiv \sigma_1 \circ \sigma_1$ and $\sigma_1 \equiv \sigma_2 \circ \sigma_2$. Therefore, the result types corresponding to $\sigma_1$ and $\sigma_2$ are equivalent under $\equiv_\Delta$, that is $\sigma_1(\gamma) \equiv_\Delta \sigma_2(\gamma)$ and $\sigma_2(\gamma) \equiv_\Delta \sigma_1(\gamma)$. However, this does not imply that $\sigma_1(\gamma) \equiv \sigma_2(\gamma)$. For example, $\alpha \equiv_\Delta \textbf{Int}$ and $0 \equiv_\Delta \alpha$, but $\alpha \not\equiv_\Delta 0$. Moreover, some result types are easier to understand or more precise than some others. Which one is better is a language design and implementation problem. For example, consider the \texttt{map even} again. The type (20) is obtained under the ordering $o(\alpha) < o(\beta_1) < o(\alpha)$. While under the ordering $o(\alpha) < o(\beta_1) < o(\alpha)$, we would instead get
\[([\beta \land \textbf{Int}] \rightarrow [\beta]) \land ([\textbf{Int} \lor \textbf{Bool} \lor \beta] \rightarrow [\textbf{Bool} \lor \beta]) \] (21)

It is clear that (20) $\equiv_\emptyset$ (21) and (21) $\equiv_\emptyset$ (20). However, compared with (20), (21) is less precise and less comprehensible, if we look at the type $[\textbf{Int} \lor \textbf{Bool} \lor \beta] \rightarrow [\textbf{Bool} \lor \beta]$ where there is a \textbf{Bool} in the domain which is useless here and (2) we know that \textbf{Int} cannot appear in the returned list, but this is not expressed in the type.

There is a final word on completeness, which states that for every solution of the application problem, our algorithm finds a solution that is more general. However this solution is not necessarily the first one found by the algorithm: even if we find a solution, continuing with a further expansion may yield a more general solution. We have just seen that, in the case of \texttt{map even}, the good solution is the second one, although this solution could have already been deduced by intersecting the first minimal solutions we found. Another simple example is the case of the application of a function of type $\alpha \times \beta \rightarrow (\beta \times \alpha)$ to an argument of type $[\textbf{Int} \lor \textbf{Bool}] \lor (\textbf{Bool} \lor \textbf{Int})$. For this application our algorithm returns after one iteration the type $([\textbf{Int} \lor \textbf{Bool}] \times ([\textbf{Int} \lor \textbf{Bool}] \lor (\textbf{Bool} \lor \textbf{Int})$ (since it unifies $\alpha$ with $\beta$) while one further iteration allows the system to deduce the more precise type $\textbf{Int} \lor (\textbf{Int} \lor \textbf{Bool}) \lor (\textbf{Bool} \lor \textbf{Int})$. Of course this raises the problem of the existence of principal types: may an infinite sequence of increasingly general solutions exist? This is a problem we did not tackle in this work, but if the answer to the previous question were negative then it would be easy to prove the existence of a principal type: since at each iteration there are only finitely many solutions, then the principal type would be one of the minimal solutions of the last iteration (how to decide that an iteration is the last one is yet another problem).

C.2.3 Heuristics to stop type-substitution inference

We only have a semi-algorithm for $t \bullet_\Delta s$ because, as long as we do not find a solution, we may increase the cardinalities of $I$ and $J$ (where $I$ and $J$ are defined as in the previous sections) indefinitely. In this section, we propose two heuristic numbers $p$ and $q$ for the cardinalities of $I$ and $J$ that are established according to the form of $s$ and $t$. These heuristic numbers set the upper limit for the procedure: if no solution is found when the cardinalities of $I$ and $J$ have reached these heuristic numbers, then the procedure stops returning failure. This yields a terminating algorithm for $t \bullet_\Delta s$ which is clearly sound but, in our case, not complete. Whether it is possible to define these boundaries so that they ensure termination and completeness is still an open issue.

\footnote{In the current implementation we assume that the type variables in the function type always have smaller orders than those in the argument type.}
Through some examples, we first analyze the reasons why one needs to expand the function type $t$ and/or the argument type $s$: the intuition is that type connectives are what makes the expansions necessary. Then based on this analysis, we give some heuristic numbers for the copies of types that are needed by the expansions. These heuristics follow some simple (but, we believe, reasonable) guidelines. First, when the substitutions found for a given $p$ and $q$ yield a useless type (e.g., “$0 \to 0$” the type of a function that cannot be applied to any value), it seems sensible to expand the types (i.e., increase $p$ or $q$), in order to find more informative substitutions. Second, if iterating the process does not give a more precise type (in the sense of $\sqsubseteq$), then it seems sensible to stop. Last, when the process continuously yields more and more precise types, we choose to stop when the type is “good enough” for the programmer. In particular we choose to avoid to introduce too many new fresh variables that make the type arbitrarily more precise but at the same time less “programmer friendly”. We illustrate these behaviours for three strategies: increasing $p$ (that is, expanding the domain of the function), increasing $q$ (that is, expanding the type of the argument) or lastly increasing both $p$ and $q$ at the same time.

**Expansion of $t$.** A simple reason to expand $t$ is the presence of (top-level) unions in $s$. Generally, it is better to have as many copies of $t$ as there are disjunctions in $s$. Consider the example,

$t = (\alpha \to \alpha) \to (\alpha \to \alpha)$
$s = (\text{Int} \to \text{Int}) \lor (\text{Bool} \to \text{Bool})$  \hspace{1cm} (22)

If we do not expand $t$ (i.e., if $p$ is 1), then the result type computed for the application of $t$ to $s$ is $0 \to 0$. However, this result type cannot be applied hereafter, since its domain is 0, and is therefore useless (more precisely, it can be applied only to expressions that are provably diverging). When $p$ is 2, we get an extra result type, $(\text{Int} \to \text{Int}) \lor (\text{Bool} \to \text{Bool})$, which is obtained by instantiating $t$ twice, by $\text{Int}$ and $\text{Bool}$ respectively. Carrying on expanding $t$ does not give more precise result types, as we always select only two copies of $t$ to match the two summands in $s$, according to the decomposition rule for arrows [4].

A different example that shows that the cardinality of the summands in the union type of the argument is a good heuristic choice for $p$ is the following one:

$t = (\alpha \times \beta) \to (\beta \times \alpha)$
$s = (\text{Int} \times \text{Bool}) \lor (\text{Bool} \times \text{Int})$  \hspace{1cm} (23)

Without expansion, the result type is $((\text{Int} \lor \text{Bool}) \times (\text{Bool} \lor \text{Int}))$ (with unification $\text{Int}$ and $\text{Bool}$). If we expand $t$, there exists a more precise result type $(\text{Int} \times \text{Bool}) \lor (\text{Bool} \times \text{Int})$, each summand of which corresponds to a different summand in $s$. Besides, due to the decomposition rule for product types [4], there also exist some other result types which involve type variables, like $((\text{Int} \lor \text{Bool}) \times \alpha) \lor ((\text{Int} \lor \text{Bool}) \times (\text{Int} \lor \text{Bool}) \setminus \alpha)$. Further expanding $t$ makes more product decompositions possible, which may in turn generate new result types. However, the type $(\text{Int} \times \text{Bool}) \lor (\text{Bool} \times \text{Int})$ is informative enough, and so we set the heuristic number to 2, that is, the number of summands in $s$.

We may have to expand $t$ also because of intersection. First, suppose $s$ is an intersection of basic types; it can be viewed as a single basic type. Consider the example

$t = \alpha \to (\alpha \times \alpha) \land s = \text{Int}$  \hspace{1cm} (24)

Without expansion, the result type is $\gamma_1 = (\text{Int} \times \text{Int})$. With two copies of $t$, besides $\gamma_1$, we get another result type $\gamma_2 = (\beta \times \beta) \lor (\text{Int} \setminus \beta \times \text{Int} \lor \beta)$, which is more general than $\gamma_1$ (e.g., $\gamma_1 = \gamma_2(\emptyset/\beta)$). Generally, with $k$ copies, we get $k$ result types of the form

$\gamma_k = (\beta_1 \times \beta_1) \lor \ldots \lor (\beta_{k-1} \times \beta_{k-1}) \lor (\text{Int} \setminus (\bigvee_{i=1}^{k-1} \beta_i) \times \text{Int} \setminus (\bigvee_{i=1}^{k-1} \beta_i))$

It is clear that $\gamma_{k+1} \supseteq \gamma_k \supseteq \ldots$ for $k \geq 2$. Therefore, $\gamma_2$ is the minimum (with respect to $\sqsubseteq$) of $\gamma_k$ ($k \geq 1$), so expanding $t$ more than once is useless (we do not get a type more precise than $\gamma_2$). However, we think the programmer expects $(\text{Int} \times \text{Int})$ as a result type instead of $\gamma_2$. So we take the heuristic number here as 1.

An intersection of product types is equivalent to $\bigvee_{i \in I} (s_i^1 \times s_i^2)$, so we consider just a single product type (and then use union for the general case). For instance,

$t = ((\alpha \to \alpha) \times (\beta \to \beta)) \to ((\beta \to \beta) \times (\alpha \to \alpha))$
$s = (((\text{Even} \to \text{Even}) \lor (\text{Odd} \to \text{Odd})) \times (\text{Bool} \to \text{Bool}))$  \hspace{1cm} (25)

For the application to succeed, we have a constraint generated for each component of the product type, namely $(\alpha \to \alpha \geq (\text{Even} \to \text{Even}) \lor (\text{Odd} \to \text{Odd}))$ and $(\beta \to \beta \geq (\text{Bool} \to \text{Bool}))$. As with Example (22), it is better to expand $\alpha \to \alpha$ once for the first constraint, while there is no need to expand $\beta \to \beta$ for the second one. As a result, we expand the whole type $t$ once, and get the result type $((\text{Bool} \to \text{Bool}) \times ((\text{Even} \to \text{Even}) \lor (\text{Odd} \to \text{Odd})))$ as expected. Generally, if the heuristic numbers of the components of a product type are respectively $p_1$ and $p_2$, we take $p_1 + p_2$ as the heuristic number for the whole product.

Finally, suppose $s$ is an intersection of arrows, like for example map even.

$t = (\alpha \to \beta) \to [\alpha] \to [\beta]$
$s = (\text{Int} \to \text{Bool}) \land ((\gamma \setminus \text{Int}) \to (\gamma \setminus \text{Int}))$  \hspace{1cm} (26)

When $p = 1$, the constraint to solve is $(\alpha \to \beta \geq s)$. As stated in Subsection C.2.2, we get four possible result types: $[\gamma \to [\gamma], [\text{Int}] \to [\text{Bool}], [\alpha \setminus \text{Int}] \to [\alpha \setminus \text{Int}], \text{or} [\text{Int} \lor \alpha] \to [\text{Bool} \lor (\alpha \lor \text{Int})], and
we can build the minimum one by taking the intersection of them. If we continue expanding \( t \), any result type we obtain is an intersection of some of the result types we have deduced for \( p = 1 \). Indeed, assume we expand \( t \) so that we get \( p \) copies of it. Then we would have to solve either \( \bigvee_{i=1,p} \alpha_i \rightarrow \beta_i \geq s \) or \( \bigwedge_{i=1,p} \alpha_i \rightarrow \beta_i \geq s \). For the first constraint to hold, by the decomposition rule of arrows, there exists \( i_0 \) such that \( s \leq \alpha_{i_0} \rightarrow \beta_{i_0} \), which is the same constraint as for \( p = 1 \). The second constraint implies \( s \leq \alpha_i \rightarrow \beta_i \) for all \( i \); we recognize again the same constraint as for \( p = 1 \) (except that we intersect \( p \) copies of it). Consequently, expanding does not give us more information, and it is enough to take \( p = 1 \) as the heuristic number for this case.

Following the discussion above, we propose in Table 1 a heuristic number \( H_p(s) \), according to the shape of \( s \), sets an upper bound to the number of copies of \( t \). We assume that \( s \) is in normal form. This definition can be easily extended to recursive types by memoization.

The next example shows that performing the expansion of \( t \) with \( H_p(s) \) copies may not be enough to get a result type, confirming that this number is a heuristic that does not ensure completeness. Let

\[
\begin{align*}
t &= ((\text{true} \times (\text{Int} \rightarrow \alpha)) \rightarrow t_1) \land ((\text{false} \times (\alpha \rightarrow \text{Bool})) \rightarrow t_2) \\
s &= (\text{Bool} \times (\text{Int} \rightarrow \text{Bool}))
\end{align*}
\]

Table 1. Heuristic number \( H_p(s) \) for the copies of \( t \)

<table>
<thead>
<tr>
<th>Shape of ( s )</th>

</tr>
</tbody>
</table>

where \( (s_1' \times s_2''') = (\bigwedge_{i \in P} s_i' \land \bigwedge_{i \in N} \neg s_i' \times \bigwedge_{i \in P} s_i'' \land \bigwedge_{i \in N, \neg \alpha_i} \neg s_i''') \).

For the application to succeed, we need to expand \( \text{Int} \rightarrow (\alpha \rightarrow \alpha) \) with two copies (so that we can make two distinct instantiations \( \alpha = \text{Bool} \) and \( \alpha = \text{Int} \)) and \( \text{Bool} \rightarrow (\beta \rightarrow \beta) \) with three copies (for three instantiations \( \beta = \text{Bool}, \beta = \text{Int}, \) and \( \beta = \text{Real} \)), corresponding to the first and the second summand in \( \text{dom}(t) \) respectively. Since the expansion distributes the union over the intersections, we need to get six copies of \( s \). In detail, we need the following six substitutions: \( \{ \alpha = \text{Bool}, \beta = \text{Bool} \}, \{ \alpha = \text{ BOOL}, \beta = \text{Int} \}, \{ \alpha = \text{Bool}, \beta = \text{Real} \}, \{ \alpha = \text{Int}, \beta = \text{Bool} \}, \{ \alpha = \text{Int}, \beta = \text{Int} \}, \) and \( \{ \alpha = \text{Int}, \beta = \text{Real} \} \), which are the Cartesian products of the substitutions for \( \alpha \) and \( \beta \).

If \( \text{dom}(t) \) is an intersection of basic types, we use 1 for the heuristic number. If it is an intersection of product types, we can rewrite it as a union of products and we only need to consider the case of just a single product type. For instance,

\[
\begin{align*}
\text{dom}(t) &= \left( (\text{Int} \rightarrow \text{Int}) \times (\text{Bool} \rightarrow \text{Bool}) \right) \\
s &= \left( (\alpha \rightarrow \alpha) \times (\alpha \rightarrow \alpha) \right)
\end{align*}
\]

It is easy to infer that the substitution required by the left component needs \( \alpha \) to be \( \text{Int} \), while the one required by the right component needs \( \alpha \) to be \( \text{Bool} \). Thus, we need to expand \( s \) at least once. Assume that \( \alpha = (s_1 \times s_2) \) and we need \( q_1 \) copies of \( s_1 \), with the type substitutions: \( \sigma_1^1, \ldots, \sigma_1^{q_1} \). Generally, we can expand the whole product type so that we get \( s_1 \times s_2 \) copies as follows:

\[
\begin{align*}
\bigwedge_{j=1..q_1} (s_1 \times s_2)_{\sigma_1^j} & \land \bigwedge_{j=1..q_2} (s_1 \times s_2)_{\sigma_2^j} \\
&= \left( \bigwedge_{j=1..q_1} s_1 \sigma_1^j \land \bigwedge_{j=1..q_2} s_1 \sigma_2^j \right) \times \left( \bigwedge_{j=1..q_1} s_2 \sigma_1^j \land \bigwedge_{j=1..q_2} s_2 \sigma_2^j \right)
\end{align*}
\]

Clearly, this expansion type is a subtype of \( \bigwedge_{j=1..q_1} s_1 \sigma_1^j \times \bigwedge_{j=1..q_2} s_2 \sigma_2^j \) and so the type tallying succeeds.

Next, consider the case where \( \text{dom}(t) \) is an intersection of arrows:

\[
\begin{align*}
\text{dom}(t) &= \left( \text{Int} \rightarrow \text{Int} \right) \land (\text{Bool} \rightarrow \text{Bool}) \\
s &= \alpha \rightarrow \alpha
\end{align*}
\]
This is the main reason why we fail to prove the decidability of the application problem (that is, deciding another type tallying between $\alpha$. As in Example (30), this is impossible. Thus, we have to expand $s$ once, for the two conjunctions in $\text{dom}(t^2)$.

Without expansion, we need $(\alpha \rightarrow \alpha) \leq (\text{Int} \rightarrow \text{Int})$ and $(\alpha \rightarrow \alpha) \leq (\text{Bool} \rightarrow \text{Bool})$, which reduce to $\alpha = \text{Int}$ and $\alpha = \text{Bool}$; this is impossible. Thus, we have to expand $s$ once, for the two conjunctions in $\text{dom}(t)$.

Note that we may also have to expand $s$ because of unions or intersections occurring under arrows. For example,

$$\text{dom}(t) = t' \rightarrow ((\text{Int} \rightarrow \text{Int}) \land (\text{Bool} \rightarrow \text{Bool}))$$

$$\text{dom}(s) = t' \rightarrow (\alpha \rightarrow \alpha) \tag{31}$$

As in Example (30), expanding once the type $\alpha \rightarrow \alpha$ (which is under an arrow in $s$) makes type tallying succeed. Because $(t' \rightarrow s_1) \land (t' \rightarrow s_2) \equiv t' \rightarrow (s_1 \land s_2)$, we can in fact perform the expansion of $s$ and then use subsumption to obtain the desired result. Likewise, we may have to expand $t$ if $\text{dom}(t)$ is an arrow type and contains an union in its domain. Therefore, we have to look into $\text{dom}(t)$ and $\text{dom}(s)$ deeply if they contain both arrow types.

Following these intuitions, we define in Table 2 a heuristic number $H_q(\text{dom}(t))$ that, according to the sharp of $\text{dom}(t)$, sets an upper bound to the number of copies of $s$.

<table>
<thead>
<tr>
<th>Shape of $\text{dom}(t)$</th>
<th>Number $H_q(\text{dom}(t))$</th>
</tr>
</thead>
<tbody>
<tr>
<td>$\bigwedge_{i \in P} t_i$</td>
<td>$\prod_{i \in I} H_q(t_i)$</td>
</tr>
<tr>
<td>$\bigwedge_{i \in P} (t_i \times t_i') \land \bigwedge_{i \in N} \neg (t_i \times t_i') \land \bigwedge_{i \in N} \neg (t_i \times t_i') \land (t_i \times t_2)$</td>
<td>$H_q(t_1) + H_q(t_2)$</td>
</tr>
<tr>
<td>$\bigwedge_{i \in P} (t_i \times t_i') \land \bigwedge_{i \in N} \neg (t_i \times t_i') \land (t_i \times t_i')$</td>
<td>$</td>
</tr>
</tbody>
</table>

where $(t_i \times t'_i) = (\bigwedge_{i \in P} t_i \times \bigwedge_{i \in N} \neg t_i \times \bigwedge_{i \in P} t_i' \times \bigwedge_{i \in N} \neg t_i')$.

To illustrate this phenomenon, consider the following example:

$$\text{dom}(t) = ((\text{Bool} \rightarrow \text{Bool}) \rightarrow (\text{Int} \rightarrow \text{Int})) \lor ((\text{Bool} \rightarrow \text{Bool}) \lor (\text{Int} \rightarrow \text{Int})) \lor (\beta \rightarrow \beta) \lor (\text{Bool} \rightarrow \text{Bool})$$

$$\text{dom}(s) = (\alpha \rightarrow (\text{Int} \rightarrow \text{Int})) \lor ((\text{Bool} \rightarrow \text{Bool}) \lor \alpha) \lor (\text{Bool} \lor \text{Int}) \tag{32}$$

Let us consider each summand in $s$ respectively. A solution for the first summand is $\alpha \geq \text{Bool} \lor \text{Bool}$, which corresponds to the first summand in $\text{dom}(t)$. The second one requires $\alpha \leq \text{Int} \rightarrow \text{Int}$ and the third one $\beta \geq \text{Bool}$. Since $(\text{Bool} \lor \text{Bool})$ is not a subtype of $(\text{Int} \rightarrow \text{Int})$, we need to expand $s$ once, that is,

$$s' = s((\text{Bool} \lor \text{Bool}) \lor \alpha) \land s((\text{Int} \rightarrow \text{Int}))$$

Almost all the summands of $s'$ are contained in $\text{dom}(t)$ except the extra type

$$((\text{Bool} \lor \text{Bool}) \lor (\text{Bool} \lor \text{Bool})) \land ((\text{Int} \rightarrow \text{Int}) \rightarrow (\text{Int} \rightarrow \text{Int}))$$

where $(\text{ Bool} \lor \text{Bool}) = (\bigwedge_{i \in P} \text{Bool} \lor \bigwedge_{i \in N} \neg \text{Bool})$.

Table 2. Heuristic number $H_q(\text{dom}(t))$ for the copies of $s$
Therefore, we need to consider another type tallying involving this extra type and \( \text{dom}(t) \). By doing so, we obtain \( \beta = \text{Int} \); however we have inferred before that \( \beta \) should be a supertype of \( \text{Bool} \). Consequently, we need to expand \( \text{dom}(t) \); the expansion of \( \text{dom}(t) \) with \( \{ \text{Bool} \}_{/\beta} \) and \( \{ \text{Int} \}_{/\beta} \) makes the type tallying succeed.

In day-to-day examples, the extra type brought by the expansion of \( s \) is always a subtype of (the expansion type of) \( \text{dom}(t) \), and we do not have to expand \( \text{dom}(t) \) or \( s \) again. The heuristic numbers we gave seem to be enough in practice.

### D. Type reconstruction

We define an implicit calculus without interfaces, for which we define a reconstruction system.

**Definition D.1.** An implicit expression \( m \) is an expression without any interfaces (or type substitutions). It is inductively generated by the following grammar:

\[
m ::= c \mid x \mid (m, m) \mid \pi_i(m) \mid m \text{ } \lambda x. m \mid m \in t \text{ } m : m
\]

The type reconstruction for expressions has the form \( \Gamma \vdash e : t \rightarrow \mathcal{J} \), which states that under the typing environment \( \Gamma \), \( e \) has type \( t \) if there exists at least one constraint-set \( C \) in the set of constraint-sets \( \mathcal{J} \) such that \( C \) are satisfied. The type reconstruction rules are given in Figure 11.

**Figure 11.** Type reconstruction rules

Most of the rules, except the rules for type cases, are standard but differ from most of the type inference of other work in that they generate a set of constraint-sets rather than a single constraint-set. This is due to the type inference for type-cases. There are four possible cases for type-cases (\( \text{RECON-CASE} \)): (i) if no branch is selected, then the type \( t_0 \) inferred for the argument \( m_0 \) should be \( \emptyset \) (and the result type can be any type); (ii) if the first branch is selected, then the type \( t_0 \) should be a subtype of \( t \) and the result type \( \alpha \) for the whole type-case should be a super-type of the type \( t_1 \) inferred for the first branch \( m_1 \); (iii) if the second branch is selected, then the type \( t_0 \) should be a subtype of \( \neg t \) and the result type \( \alpha \) should be a super-type.
of the type $t_2$ inferred for the second branch $m_2$; and (iv) both branches are selected, then the result type
alpha should be a supertyp of the union of $t_1$ and $t_2$ (note that the condition for $t_0$ is the one that does not
satisfy (i), (ii) and (iii)). Therefore, there are four possible solutions for type-cases and thus four possible
constraint-sets. Finally, the rule (RECON-CASE-VAR) deals with the type inference for the special binding
type-case introduced in Appendix E in the companion paper [3].

Let $m$ be an implicit expression such that $\Gamma \vdash m : t \leadsto \mathcal{S}$. By inserting into $m$ those types form
of $\alpha \rightarrow \beta$ introduced by the derivation of $\Gamma \vdash m : t \leadsto \mathcal{S}$ for the $\lambda$-abstractions in $m$ correspondingly, we
obtain an explicit expression $e$ for $m$, denoted as $\text{insert}(m)$. In particular, for $\lambda$-abstraction $\lambda x. m$, we have

$$\text{insert}(\lambda x. m) = \lambda x. \text{insert}(m)$$

where $\alpha \rightarrow \beta$ is a fresh type introduced for $\lambda x. m$.

**Theorem D.2 (Soundness).** Let $m$ be an implicit expression such that $\Gamma \vdash m : t \leadsto \mathcal{S}$. Then for all
$C \in \mathcal{S}$ and for all $\sigma$, if $\sigma \vdash C$, then $\text{eval} 1 \Gamma \sigma \vdash \text{insert}(m) \otimes [\sigma] : t \sigma$.

**Proof.** By induction on the derivation of $\Gamma \vdash m : t \leadsto \mathcal{S}$. We proceed by a case analysis of the last rule
used in the derivation.

(3) **RECON-CONST**: straightforward.

(2) **RECON-VAR**: straightforward.

(1) **RECON-PAIR**: consider the following derivation:

$$\begin{align*}
\Gamma \vdash m_1 : t_1 & \leadsto \mathcal{S}_1 & \Gamma \vdash m_2 : t_2 & \leadsto \mathcal{S}_2 \\
\Gamma \vdash (m_1, m_2) : t_1 \times t_2 & \leadsto \mathcal{S}_1 \cap \mathcal{S}_2
\end{align*}$$

Since $C \in \mathcal{S}_1 \cap \mathcal{S}_2$, according to Definition C.4, there exists $C_1 \in \mathcal{S}_1$ and $C_2 \in \mathcal{S}_2$ such that $C = C_1 \cup C_2$. Thus, we have $\sigma \vdash C_1$ and $\sigma \vdash C_2$. By induction, we have $\text{eval} 1 \Gamma \sigma \vdash \text{insert}(m_1) \otimes [\sigma] : t_1 \sigma$ and $\text{eval} 1 \Gamma \sigma \vdash \text{insert}(m_2) \otimes [\sigma] : t_2 \sigma$. By (pair), we get $\text{eval} 1 \Gamma \sigma \vdash (\text{insert}(m_1) \otimes [\sigma], \text{insert}(m_2) \otimes [\sigma]) : (t_1 \sigma \times t_2 \sigma)$, that is $\text{eval} 1 \Gamma \sigma \vdash \text{insert}((m_1, m_2), \otimes [\sigma]) : (t_1 \times t_2) \sigma$.

(2) **RECON-PROJ**: consider the following derivation:

$$\begin{align*}
\Gamma \vdash m' : t' & \leadsto \mathcal{S}' \\
\Gamma \vdash \pi_1(m') : \alpha_1 & \leadsto \mathcal{S}' \cap \{(t', \leq, \alpha \times \alpha_2)\}
\end{align*}$$

According to Definition C.4, there exists $C' \in \mathcal{S}'$ such that $C = C' \cup \{(t', \leq, \alpha \times \alpha_2)\}$. Thus, we have $\sigma \vdash C'$ and $t' \sigma \leq (\alpha \sigma \times \alpha \sigma_2)$. By induction, we have $\text{eval} 1 \Gamma \sigma \vdash \text{insert}(m') \otimes [\sigma] : t' \sigma$. By substitution, we have $\text{eval} 1 \Gamma \sigma \vdash \text{insert}(\pi_1(m')) \otimes [\sigma] : (\alpha \sigma \times \alpha \sigma_2)$. Then by (prod), we get $\text{eval} 1 \Gamma \sigma \vdash (\pi_1(\text{insert}(m')) \otimes [\sigma]) : \alpha \sigma$, that is $\text{eval} 1 \Gamma \sigma \vdash \text{insert}(\pi_1(m')) \otimes [\sigma] : \alpha \sigma$.

(3) **RECON-APPL**: consider the following derivation:

$$\begin{align*}
\Gamma \vdash m_1 : t_1 & \leadsto \mathcal{S}_1 & \Gamma \vdash m_2 : t_2 & \leadsto \mathcal{S}_2 \\
\Gamma \vdash (m_1, m_2) : \alpha \leadsto \mathcal{S}_1 \cap \mathcal{S}_2 \cap \{(t_1, \leq, t_2 \rightarrow \alpha)\}
\end{align*}$$

According to Definition C.4, there exists $C_1 \in \mathcal{S}_1$ and $C_2 \in \mathcal{S}_2$ such that $C = C_1 \cup C_2 \cup \{(t_1, \leq, t_2 \rightarrow \alpha)\}$. Thus, we have $\sigma \vdash C_1$, $\sigma \vdash C_2$ and $t_1 \sigma \leq t_2 \sigma \rightarrow \alpha \sigma$. By induction, we have $\text{eval} 1 \Gamma \sigma \vdash \text{insert}(m_1) \otimes [\sigma] : t_1 \sigma$ and $\text{eval} 1 \Gamma \sigma \vdash \text{insert}(m_2) \otimes [\sigma] : t_2 \sigma$. By substitution, we can get $\text{eval} 1 \Gamma \sigma \vdash \text{insert}(m_1) \otimes [\sigma] : t_1 \sigma \rightarrow \alpha \sigma$. Then by (appl), we get $\text{eval} 1 \Gamma \sigma \vdash (\text{insert}(m_1) \otimes [\sigma], \text{insert}(m_2) \otimes [\sigma]) : \alpha \sigma$, that is $\text{eval} 1 \Gamma \sigma \vdash \text{insert}((m_1, m_2), \otimes [\sigma]) : \alpha \sigma$.

(4) **RECON-ABSTR**: consider the following derivation:

$$\begin{align*}
\Gamma, (x : \alpha) \vdash m' & \leadsto \mathcal{S}' \\
\Gamma \vdash \lambda x.m : \alpha & \rightarrow \beta \leadsto \mathcal{S}' \cap \{(t', \leq, \beta)\}
\end{align*}$$

According to Definition C.4, there exists $C' \in \mathcal{S}'$ such that $C = C' \cup \{(t', \leq, \beta)\}$. Thus, we have $\sigma \vdash C'$ and $t' \sigma \leq \beta \sigma$. By induction, we have $\text{eval} 1 \Gamma \sigma, (x : \alpha \sigma) \vdash \text{insert}(m') \otimes [\sigma] : t' \sigma$. By substitution, we can get $\text{eval} 1 \Gamma \sigma, (x : \alpha \sigma) \vdash \text{insert}(m') \otimes [\sigma] : \beta \sigma$. It is clear that there are no subterms of $e[\sigma_1] e_2$ in $\text{insert}(m') \otimes [\sigma]$, so $\text{insert}(m') \otimes [\sigma] \notin \text{var}(\alpha \sigma \rightarrow \beta \sigma)$. Then according to weakening (i.e., Lemma B.8 in the companion paper [3]), we have $\text{var}(\alpha \sigma \rightarrow \beta \sigma) \vdash \Gamma, (x : \alpha \sigma) \vdash \text{insert}(m') \otimes [\sigma] : \beta \sigma$. Finally, by (abstr), we get $\text{eval} 1 \Gamma \sigma \vdash (\lambda x. m') : \alpha \sigma \rightarrow \beta \sigma$, that is $\text{eval} 1 \Gamma \sigma \vdash \text{insert}(\lambda x.m') \otimes [\sigma] : \alpha \sigma \rightarrow \beta \sigma$.

(5) **RECON-CASE**: consider the following derivation:

$$\begin{align*}
\Gamma \vdash m_0 : t_0 & \leadsto \mathcal{S}_0 & (m_0 \notin \mathcal{S}) \\
\Gamma \vdash m_1 : t_1 & \leadsto \mathcal{S}_1 \\
\Gamma \vdash m_2 : t_2 & \leadsto \mathcal{S}_2 \\
\mathcal{S} = & \{(\mathcal{S}_0 \cap \{(t_0, \leq, 0), (0, \leq, \alpha)\}) \}
\cup \{(\mathcal{S}_0 \cap \mathcal{S}_1 \cap \{(t_0, \leq, t'), (t_1, \leq, \alpha)\}) \}
\cup \{(\mathcal{S}_0 \cap \mathcal{S}_2 \cap \{(t_0, \leq, t'), (t_2, \leq, \alpha)\}) \}
\cup \{(\mathcal{S}_0 \cap \mathcal{S}_1 \cap \mathcal{S}_2 \cap \{(t_0, \leq, 0), (t_1 \lor t_2, \leq, \alpha)\}) \}
\end{align*}$$

$$\Gamma \vdash \mathcal{S} : m_0 \in l' \ ? m_1 : m_2 : \alpha \leadsto \mathcal{S}$$
Since $C \in \mathcal{S}$, according to Definition C.4, there are four possible cases for $C$: (i) $C \in \mathcal{S}_0 \cap \{\{(t_0, \leq 0), (0, \leq \alpha)\}\}$, (ii) $C \in \mathcal{S}_0 \cap \mathcal{S}_1 \cap \{\{(t_0, \leq t'), (t_1, \leq \alpha)\}\}$, (iii) $C \in \mathcal{S}_0 \cap \mathcal{S}_2 \cap \{\{(t_0, \leq \alpha), (t_1 \land t_2, \leq \alpha)\}\}$, and (iv) $C \in \mathcal{S}_0 \cap \mathcal{S}_1 \cap \mathcal{S}_2 \cap \{\{(t_0, \leq \alpha), (t_1 \lor t_2, \leq \alpha)\}\}$.

**Case (i):** there exists $C_0 \in \mathcal{S}_0$ such that $\sigma \vdash C_0, t_0 \sigma \leq 0$ and $0 \leq \alpha \sigma$. By induction, we have $\emptyset_1 \Gamma \vdash \text{insert}(m_0)@[\sigma] : t_0 \sigma$. Since $t_0 \sigma \leq 0$, we have $t_0 \sigma \leq -t'$ and $t_0 \sigma \leq -t''$. Then applying the rule (case), we have $\emptyset_1 \Gamma \vdash \text{insert}(m_0)@[\sigma] \in t' ? \text{insert}(m_1)@[\sigma] : \text{insert}(m_2)@[\sigma] : 0$, that is, $\emptyset_1 \Gamma \vdash \text{insert}(m'@[\sigma] \in t' ? \text{insert}(m_1)@[\sigma] : \text{insert}(m_2)@[\sigma] : t_1 \sigma$. Finally, by subsumption, the result follows.

**Case (ii):** there exists $C_0 \in \mathcal{S}_0$ and $C_1 \in \mathcal{S}_2$ such that $\sigma \vdash C_0, C_1 : t_0 \sigma \leq 0 \leq \alpha \sigma$. By induction, we have $\emptyset_1 \Gamma \vdash \text{insert}(m_0)@[\sigma] : t_0 \sigma$ and $\emptyset_1 \Gamma \vdash \text{insert}(m_1)@[\sigma] : t_1 \sigma$. If $t_0 \sigma \leq -t'$, then $t_0 \sigma \leq t' \land (t'' \land (t'' \land t_1 \sigma \land t_2 \sigma) \leq 0$, and thus the result follows by subsumption. Otherwise, we have $t_0 \sigma \leq -t''$. Then applying the rule (case), we have $\emptyset_1 \Gamma \vdash \text{insert}(m'@[\sigma] \in t' ? \text{insert}(m_1)@[\sigma] : \text{insert}(m_2)@[\sigma] : t_1 \sigma$. Finally, by subsumption, the result follows.

**Case (iii):** similar to Case (ii).

**Case (iv):** there exists $C_0 \in \mathcal{S}_0, C_1 \in \mathcal{S}_1$ and $C_2 \in \mathcal{S}_2$ such that $\sigma \vdash C_0, C_1, C_2 : t_0 \sigma \land t_1 \sigma \lor t_2 \sigma \leq \alpha \sigma$. By induction, we have $\emptyset_1 \Gamma \vdash \text{insert}(m_0)@[\sigma] : t_0 \sigma, \emptyset_1 \Gamma \vdash \text{insert}(m_1)@[\sigma] : t_1 \sigma$, and $\emptyset_1 \Gamma \vdash \text{insert}(m_2)@[\sigma] : t_2 \sigma$. By subsumption, we have $\emptyset_1 \Gamma \vdash \text{insert}(m_0)@[\sigma] : t_1 \sigma \land t_2 \sigma$. If $t_0 \sigma \leq t'' \land t_0 \sigma \leq -t''$, then we are in Case (i) – (iii), thus the result follows by subsumption. Otherwise, applying the rule (case), we have $\emptyset_1 \Gamma \vdash \text{insert}(m'@[\sigma] \in t' ? \text{insert}(m_1)@[\sigma] : \text{insert}(m_2)@[\sigma] : t_1 \sigma \land t_2 \sigma$.

(Recon-case-var): similar to (Recon-case).

Consider the implicit version of map, which can be defined as:

$$\mu m \lambda f . \lambda \ell . \ell \in \text{nil} \?
\text{nil} : (f(\pi_1 \ell), m(f(\pi_2 \ell)))$$

The type inferred for map by the type reconstruction system is $\alpha_1 \to \alpha_2$ and the generated set $\mathcal{S}$ of constraint-sets is:

\[
\begin{align*}
\{ & \alpha_2 \to \alpha_4 \leq \alpha_2, \alpha_5 \leq \alpha_4, \alpha_3 \leq \alpha_4, \alpha_3 \leq 0, 0 \leq \alpha_3, \\
& \alpha_2 \to \alpha_3 \leq \alpha_2, \alpha_5 \leq \alpha_4, \alpha_3 \leq \alpha_4, \alpha_3 \leq \text{nil}, \text{nil} \leq \alpha_5, \\
& \alpha_2 \to \alpha_4 \leq \alpha_2, \alpha_5 \leq \alpha_4, \alpha_3 \leq \alpha_4, \alpha_3 \leq \text{nil}, \text{nil} \leq \alpha_5, \leq \alpha_5 \leq \alpha_5 \} \cup C, \\
& \alpha_2 \to \alpha_3 \leq \alpha_2, \alpha_5 \leq \alpha_4, \alpha_3 \leq \alpha_4, \alpha_3 \leq 0, \alpha_5 \leq \alpha_5 \} \cup C
\end{align*}
\]

where $C$ is $\{ \alpha_1 \leq \alpha_7 \to \alpha_6, \alpha_3 \\\text{nil} \leq \alpha_1 \to \alpha_6 \land (f(\pi_1 \ell), m(f(\pi_2 \ell)))$.

Then applying the tainting algorithm to the sets, we get the following types for map:

\[
\begin{align*}
\alpha_1 \to (0 \to \alpha_5) \\
\alpha_1 \to (\text{nil} \to \text{nil}) \\
0 \to ((\alpha_7 \land \alpha_{11} \land \alpha_8 \land (\alpha_7 \land \alpha_{12} \to (\alpha_6 \alpha_9)) \\
(\alpha_7 \to \alpha_9) \to (0 \to (\alpha_9 \alpha_9)) \\
(\alpha_7 \to \alpha_9) \to (0 \to (\alpha_9 \alpha_9)) \\
0 \to ((\text{nil} \vee (\alpha_7 \land \alpha_{11} \land \alpha_8 \land (\alpha_7 \land \alpha_{12} \to (\alpha_6 \alpha_9))) \\
(\alpha_7 \to \alpha_9) \to (\text{nil} \to (\text{nil} \vee (\alpha_9 \alpha_9))) \\
(\alpha_7 \to \alpha_9) \to (\mu x . \text{nil} \land (\alpha_7 \land \alpha_{11} \land \alpha_8 \land (\alpha_7 \land \alpha_{12} \to (\alpha_6 \alpha_9))) \\
\end{align*}
\]

By replacing type variables that only occur positively by $0$ and those only occurring negatively by $1$, we obtain

\[
\begin{align*}
1 \to (0 \to 0) \\
1 \to (\text{nil} \to \text{nil}) \\
0 \to ((1 \times 1) \to 0) \\
(0 \to 1) \to (0 \to 0) \\
(1 \to \beta) \to (0 \to \beta) \\
0 \to ((\text{nil} \vee (1 \times 1)) \to \text{nil}) \\
(0 \to 1) \to (\text{nil} \to \text{nil}) \\
(\alpha \to \beta) \to (\alpha \to \beta)
\end{align*}
\]

All the types, except the last two, are useless $^{15}$, as they provide no further information. Thus we deduce the following type for map:

$$((\alpha \to \beta) \rightarrow ((\alpha \to \beta)) \land ((0 \rightarrow 1) \rightarrow (\text{nil} \rightarrow \text{nil}))$$

$^{15}$These useless types are generated from the fact that $0 \rightarrow t$ contains all the functions, or the fact that $(0 \times t) \lor (t \times 0)$ is a subtype of any type, or the fact that Case (i) in type-cases is useless in practice.
which is more precise than \((\alpha \to \beta) \to ([\alpha] \to [\beta])\) since it states that the application of \(map\) to any
function and the empty list returns the empty list.

E. Application to CDuce

We give a rough overview of the modifications that are necessary in order to transpose the algorithms and the
results of this work to the implementation of the polymorphic extension of CDuce. In particular, we
show how to generalize the static and dynamic semantics of explicit type-case expressions of this work to
CDuce’s pattern matching expressions. Details about the syntax and semantics of CDuce can be found in [2]
or, better, in the online documentation available at www.cduce.org.

E.1 Intermediate language

The CDuce compiler includes three different languages (source, typed, and lambda) that are refined one into
the other in different passes of the compiler. The first language corresponds to parsed CDuce expressions
the last is closer to CDuce bytecode.

The source language is defined in the module ast.ml of the CDuce’s source distribution. It is the
representation of the source code.

\[
a \ ::= \ c \mid x \mid aa \mid (a, a) \mid \lambda^p.a \ \text{match} \ a \ with \ p \to a \ | \ p \to a
\]  

(33)

The source language is composed of variables, constants, tuples, application of two expressions, lambda abstractions where \(p\) is a pattern, and match expressions. Patterns are defined as follows

\[
p \ ::= \ t \mid (p, p) \mid pkp \mid \Sigma \mid \{x \ ::= e\} \mid x
\]

with types, tuples of patterns, intersection, union, constants, and capture variables (plus recursive patterns
here omitted).

The typed language is the result of the type inference performed on the source language and it is defined
in the module typed.ml in the source distribution of CDuce.

\[
e \ ::= \ c \mid x \mid \Sigma \mid ee \mid (e, e) \mid \lambda^p.e \ \text{match} \ e \ with \ p_1 : \Sigma_1 \to e_1 \ | \ p_2 : \Sigma_2 \to e_2
\]  

(34)

The typed language is similar to the source language. The notable differences are the presence of poly-
morphic variables \(\Sigma\) (cf. Part 1,§5.3 [3]), the application of substitutions to expressions \(\sigma_1\) and the \(\Sigma\)’s
associated to patterns in the match expressions. Each \(\Sigma\) is a mapping from the capture variables of the
pattern \(p_1\) to sets of type variable and will be used to compile away \(\lambda\)-polymorphic expression variables
(compiling a source expression variable into a monomorphic variable is much less expensive in terms of
run-time performance). Also since this language is the target of type-inference and we do not infer the
decorations of lambdas, then \(\lambda^p.e\) stands for \(\lambda^pa.e\).

The typed language is transformed in the intermediate language as result of the compilation step. The
evaluation language is defined in the module lambda.ml

\[
e \ ::= \ c \mid x \mid \Sigma \mid ee \mid (e, e) \mid \lambda^p.e \ \text{match} \ e \ with \ p_1 : \Sigma_1 \to e_1 \ | \ p_2 : \Sigma_2 \to e_2
\]  

(35)

In the intermediate (or compiled) language, (lazy) type-substitutions “\(\Sigma\)” are now associated to polymorphic
variables and to polymorphic lambda expressions. The \(\Sigma\) annotations present in the patterns of the match
expressions are now removed since they were used to determine whether a variable \(x\) has to be compiled
as \(x\); or just as \(x\). The symbol \(\lambda\) is a compiler optimization that is explained at the end of Section 5.3
in Part I [3]. Notice that we added in lambda abstractions an explicit variable to capture the argument
of the function. This is used to compile lambda-expressions with lazy type-substitutions (in particular
\(sel(x, t, \Sigma)\) defined right below); in the actual implementation these variables are nameless and compiled
by reserving a special slot in the type-environment of closures. \(\Sigma\) ranges over expressions that denote sets
of type substitutions.

\[
\Sigma ::= \sigma_1 \mid \text{comp}(\Sigma, \Sigma') \mid \text{sel}(x, t, \Sigma)
\]

we use \(\hat{s}\) to denote the identity of these expressions that is the empty set of type substitutions. We use
\(\text{dom}(\Sigma)\) to denote the domain \(\Sigma\). It is inductively defined as follows:

\[
\text{dom}(\sigma_1)_{\hat{s}} = \bigcup_{\sigma \in \hat{s}} \text{dom}(\sigma)
\]

\[
\text{dom}(\text{comp}(\Sigma, \Sigma')) = \text{dom}(\Sigma) \cup \text{dom}(\Sigma') \quad \text{(note: this is a rough approximation)}
\]

\[
\text{dom}(\text{sel}(x, t, \Sigma)) = \text{dom}(\Sigma)
\]

Note that \(\text{dom}(\hat{s}) = \emptyset\). We use \(\text{var}(t)\) to denote the set of all type variables occurring in the type \(t\).

We use two containment relations. The first \(s \subseteq t\) is the semantic subtyping relation that states that for
all substitutions \(s\) is a subtype of \(t\). The second \(s \subseteq_{\Delta} t\) specifies that there exists a substitution for the
variables not in \(\Delta\) (\(\Delta\) is a set containing all monomorphic variables) such that \(s \subseteq t\). We denote the set of
all polymorphic variables as \(\Delta\).

E.2 Type-directed translation

The CDuce compiler translates one internal language into another.
The translation from the language in (33) to the language in (34) is given contextually to the typing relation. In particular we extend the typing rules in order to prove judgments of the form $\Delta, \Gamma \vdash a : t \triangleright e$ where $a$ is a term of the source language (33) and $e$ its translation in the intermediate language (34).

The type inference rules that perform the translation from (33) to the language in (34) are specified in Figure 12. The rules (INF-VAR-Mono) translate variables into polymorphic or monomorphic ones according to whether their type contains polymorphic type variables or not. The rule for application (INF-MATCH) uses the standard relation. In particular we extend the typing rules in order to prove judgments of the form $\Delta, \Gamma \vdash a : t \triangleright e$.

</tr>
</tbody>
</table>

where the pairwise union of mappings assumes that the domains are distinct

$$(\Gamma_1 \cup \Gamma_2)(x) = \begin{cases} \Gamma_1(x) & \text{if } x \in \text{dom}(\Gamma_1) \\ \Gamma_2(x) & \text{if } x \in \text{dom}(\Gamma_2) \end{cases}$$
Finally, the compilation of the explicitly-typed language (34) into the intermediate language (35) is given by the following rules:

\[
[x]_{\Sigma, \Xi} = x \\
[\Xi]_{\Sigma, \Xi} = \begin{cases} x & \text{if } \Xi(x) \cap \text{dom}(\Sigma) = \emptyset^{16} \\ x_\Sigma & \text{otherwise} \end{cases} \\
[\lambda \cdot p.e]_{\Sigma, \Xi} = \begin{cases} \lambda^{2}_{x:p.e} & \text{if } \text{var}(t) \cap \text{dom}(\Sigma) = \emptyset^{16} (x \text{ fresh}) \\ \lambda^{2}_{x:p.e} & \text{otherwise} \end{cases} \\
[[e_1, e_2]]_{\Sigma, \Xi} = ([e_1]_{\Xi, \Xi} \cdot [e_2]_{\Xi, \Xi}) \\
[e_1 e_2]_{\Sigma, \Xi} = [e_1]_{\Xi, \Xi} [e_2]_{\Xi, \Xi} \\
[e_{\sigma}]_{\Sigma, \Xi} = [e]_{\text{comp}(\Sigma, \sigma), \Xi} \\
\text{match } e \text{ with } p_1 : \Xi_1 \rightarrow e_1 | p_2 : \Xi_2 \rightarrow e_2 ]_{\Sigma, \Xi} = \text{match } [e]_{\Sigma, \Xi} \text{ with } p_1 \rightarrow [e_1]_{\Xi_1 \cup (\Xi_1 \cup \Xi_2)} | p_2 \rightarrow [e_2]_{\Xi_2 \cup (\Xi_1 \cup \Xi_2)}
\]

These rules are mostly straightforward except that we try to compile into monomorphic expression variables as many capture variables as possible. In particular, we compile as monomorphic also those polymorphic expression variables for which we can statically determine that type substitutions will have no effect at run-time (i.e., every variable \( x \) for which \( \Xi(x) \cap \text{dom}(\Sigma) = \emptyset \) holds).

### E.3 Evaluation Rules

The evaluation procedure transforms the evaluation language into values of the following form:

\[ v ::= c | (v, v)_{\Sigma} | (\lambda^{2}_{p.e} x, x') \]

Notice that closures now include a slot for a variable. This slot stores the fresh variables that were introduced in the translations of lambdas and it is used at the application (rule (OE-APPLY)).

The operational semantics must be modified to take into account new constructions and to lazily propagate type substitutions for all constructed values.

\[
\begin{align*}
\text{(OE-CONST)} & \quad \delta \vdash_o c \Downarrow c \\
\text{(OE-CLOSURE)} & \quad \delta \vdash_o \lambda^{2}_{x:p.e} \Downarrow (\lambda^{2}_{x:p.e} x, x') \\
\text{(OE-PAIRVALUE)} & \quad \delta \vdash_o (v_1, v_2) \Downarrow (v_1, v_2) \\
\text{(OE-VAR)} & \quad \delta \vdash_o x \Downarrow \delta(x) \\
\text{(OE-PVAR-C)} & \quad \delta \vdash_o x \Downarrow c \\
\text{(OE-PAIR)} & \quad \delta \vdash_o e_1 \Downarrow v_1 \\
\text{(OE-PVAR-F)} & \quad \delta \vdash_o x \Downarrow (\lambda_{\text{comp}(\Sigma, \Sigma')}^{2} p.e, x', \delta') \\
\text{(OE-PAIR-F)} & \quad \delta \vdash_o e_1 \Downarrow v_0 \\
\text{(OE-MATCH 1)} & \quad \delta \vdash_o e \Downarrow v' \\
\text{(OE-APPLY)} & \quad \delta \vdash_o e \Downarrow e_1 \\
\text{(OE-MATCH 2)} & \quad \delta \vdash_o e \Downarrow v' \\
\end{align*}
\]

Pattern matching is defined as follows:

\[
\begin{align*}
\Theta / x & = \{ x \mapsto v \} \\
\Theta / t & = \{ \{ \} & \text{if } v \in_o t \\
& \Omega & \text{otherwise} \\
(v_1, v_2)/(p_1, p_2) & = v_1/p_1 \oplus v_2/p_2 \\
(v_1, v_2)/(\Sigma, \Sigma)/(p_1, p_2) & = v_1/\Sigma/p_1 \oplus v_2/\Sigma/p_2 \\
\Sigma/v_1 & = v_1/p_1 \oplus v_2/p_2 \\
\Sigma / v_1 & = v_1/p_1 \oplus v_2/p_2 \\
\Sigma / (x := c) & = \{ x \mapsto c \}
\end{align*}
\]

\(^{16}\) or \( \Sigma = \emptyset \) which is a special case of the condition (since \( \text{dom}(1) = \emptyset \)) that can be checked more easily.
where the ⊕ operator has the following definition (γ ranges over value substitutions, i.e., mappings from expression variables to values):

$$(\gamma_1 \oplus \gamma_2)(x) = \begin{cases} 
\gamma_1(x) & \text{if } x \in \text{dom}(\gamma_1) \setminus \text{dom}(\gamma_2) \\
\gamma_2(x) & \text{if } x \in \text{dom}(\gamma_2) \setminus \text{dom}(\gamma_1) \\
(\gamma_1(x), \gamma_2(x)) & \text{if } x \in \text{dom}(\gamma_1) \cap \text{dom}(\gamma_2)
\end{cases}$$

Notice that in the fourth rule of the definition of pattern matching when we deconstruct a pair that is annotated by a lazy type-substitution we do not immediately propagate the substitution to the sub-components. Instead we delay it until this substitution is needed. This is implemented by the “delay substitution” operation “$\gamma@\Sigma$” defined as

$$(v@\Sigma) = \begin{cases} 
c \in_0 t & \iff b_c \leq t \\
(\lambda c'\Sigma.p.e, x, e')@\Sigma = (\lambda_{\text{comp}(\Sigma, \Sigma')}p.e, x, e') \\
(v_1, v_2)@\Sigma = (v_1, v_2)\circ \Sigma \\
(v_1, v_2)@\Sigma = (v_1, v_2)\circ \Sigma' \quad (v_1, v_2)\circ \Sigma' = (v_1, v_2)\circ \Sigma \\
\end{cases}$$

This requires a modification of the rules used to check the type of a value:

$$\begin{align*}
(c@\Sigma) & \in_0 t & \iff b_c \leq t \\
(\lambda c'\Sigma.p.e, x, e') & \in_0 t & \iff s \leq t \\
(v_1, v_2) & \in_0 t & \iff v_i \in_0 \pi_i(t), i \in 1, 2 \\
(v_1, v_2)\circ \Sigma & \in_0 t & \iff v_i@\Sigma \in_0 \pi_i(t), i \in 1, 2 \\
\end{align*}$$

where, we recall, the evaluation of the symbolic set of type-substitutions is inductively defined as

$$\begin{align*}
eval(\epsilon, \sigma_1) & = \sigma_1 \\
eval(\epsilon', \text{comp}(\Sigma, \Sigma')) & = \text{eval}(\epsilon', \Sigma) \circ \text{eval}(\epsilon', \Sigma') \\
eval(\epsilon, \text{sel}(x, \bigwedge_{i \in I} \lambda t_i \rightarrow s_i, \Sigma)) & = [ \sigma_j \in \text{eval}(\epsilon', \Sigma) | \exists i \in I : \epsilon'(x) \in_0 t_i, \sigma_j ]
\end{align*}$$

F. Experiments

To gauge the practicality of our local type inference algorithm, we performed extensive experiments, applying higher-order polymorphic function. To that end, we automatically generated function applications from the List module of the OCaml standard distribution. More specifically we considered the following functions:

```plaintext
val length : 'a list -> int
val hd : 'a list -> 'a
val tl : 'a list -> 'a list
val nth : 'a list -> int -> 'a
val rev : 'a list -> 'a list
val append : 'a list -> 'a list -> 'a list
val map : ('a -> 'b) -> 'a list -> 'b list
val fold_right : ('a -> 'b -> 'c) -> 'a list -> 'c
val fold_left : ('a -> 'b -> 'c) -> 'a list -> 'c
val mapi : (int -> 'a -> 'b) -> 'a list -> 'b list
val for_all : ('a -> bool) -> 'a list -> bool
val for_all2 : ('a -> 'b -> bool) -> 'a list -> bool
val for_all3 : ('a -> 'b -> 'c -> bool) -> 'a list -> bool
val for_all4 : ('a -> 'b -> 'c -> 'd -> bool) -> 'a list -> bool
val mem : 'a -> 'a list -> bool
val memq : 'a -> 'a list -> bool
val mem_assoc : 'a -> ('a * 'b) list -> bool
```
We then devised a series of tests as follows. First, we generated all the applications that were well typed in OCaml from one function against all the others. This gave, for instance, applications such as `map length` or `map hd`, that is performing local type inference for the applications 

\((\alpha \to \beta) \to [\alpha] \to [\beta] \cdot \alpha \to \text{Int}\)

and

\((\alpha \to \beta) \to [\alpha] \to [\beta] \cdot [\alpha] \to \alpha\)

Then, for each function \(f\) of type \(t\) and \(f_1, \ldots, f_n\) of type \(t_1, \ldots, t_n\) such that all the applications “\(ff_1\)”, “\(ff_2\)” are well-typed, we performed the local type inference on

\[ t \cdot t_1 \land \ldots \land t_k \quad \text{for all} \quad k \leq n \]

Remark that these applications are well typed since a function of type \(t_1 \land \ldots \land t_n\) has also type \(t_i\) \((i = 1, \ldots, n)\), and any of these type is in the domain of \(t\) (since each individual application \(t_i\) is well-typed. Notice also that intersection of arrow types are never empty (all arrow types contain the type \(1 \rightarrow 0\). Conversely, for all triple of functions \(f, f_1, f_2\) such as “\(f_1f\)” and “\(f_2f\)” are well-typed, we also typed performed local type inference for \(t_1 \lor t_2\). Lastly, we added to our test suite some ill-typed applications (such as \((\alpha \to \beta) \to [\alpha] \to [\beta] \cdot \text{Int}\)) to ensure our implementation indeed detects these as invalid applications. Our test machine is an average laptop with 64bit Intel Core i3-2367M, 1.4Ghz, 4 cores and 8GB of RAM.

The results of our experiments are summarized in the following table:

<table>
<thead>
<tr>
<th># of tests</th>
<th>Total Time</th>
<th>Average Time</th>
<th>Median Time</th>
<th>Min. Time</th>
<th>Max. Time</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 859</td>
<td>27s</td>
<td>14ms</td>
<td>2.1ms</td>
<td>0.1ms</td>
<td>2.090s</td>
</tr>
</tbody>
</table>

The worst time (2.09s) is the one for the local type inference of

\[ \text{map} \ \text{(length \& hd \& tl \& nth \& rev \& append \& rev_append \& concat \& flatten \& iter \& iteri \& map \& mapi \& rev_map \& fold_left) }\]

As expected, the behavior of our algorithm is exponential (subtyping is already EXPTIME-complete, although our implementation performs very well even for large types). We illustrate the general behavior of our algorithm on two kinds of application. First, given a function of type \(t \rightarrow s\) where \(t\) does not contain any arrows (but may contain products, sequences and so forth), local type inference scales linearly with the sum of the size of types \(t \rightarrow s\) and \(u\), when computing \((t \rightarrow s) \cdot u\).

However (and as expected) if we consider types \(t \rightarrow s\) where \(t\) contains one, two, or more arrows, then local type inference becomes exponential with respect to the size of the argument \(u\).
While these tests already represent cases that are unlikely to happen in practice (the worst time case features more than 45 connectives/constructors, namely 15 intersections and 30 arrows), we conjecture that standard optimization techniques (hash-consing, memoization, laziness) will make our semi-naïve implementation even more tractable. During the experiment, memory usage was negligible (few megabytes).

Finally we also tested the type inference for applications of curried functions to several arguments. We added (by hand) to our test suite a set of functions that accept up to $n$ arguments. More precisely for each arity $n$ we added functions with the following types

\[
\begin{align*}
\alpha_1 & \to \cdots \to \alpha_n \to \text{Int} \\
\alpha_1 & \to \cdots \to \alpha_n \to \alpha_1 \\
\alpha_1 & \to \cdots \to \alpha_n \to (\alpha_1 \times \ldots \times \alpha_n) \\
(\beta_1 \to \alpha_1) & \to \cdots \to (\beta_n \to \alpha_n) \to \text{Int} \\
(\beta_1 \to \alpha_1) & \to \cdots \to (\beta_n \to \alpha_n) \to \alpha_1 \\
(\beta_1 \to \alpha_1) & \to \cdots \to (\beta_n \to \alpha_n) \to (\alpha_1 \times \ldots \times \alpha_n)
\end{align*}
\]

each of these functions, if its arity is $k$, was then applied to $k$ other randomly selected functions of this set. The test showed that our implementation can smoothly handle inference for the application of up to 20 arguments (for $n = 20$ the 120 tests take less than one second of cpu on a desktop workstation), then the exponential blowup becomes too important (in particular because of the memory footprint). The following table reports a sample of the cpu times for different $n$'s

<table>
<thead>
<tr>
<th>arity $n$</th>
<th># of tests</th>
<th>Total Time for all the tests</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>60</td>
<td>0m0.033s</td>
</tr>
<tr>
<td>15</td>
<td>90</td>
<td>0m0.272s</td>
</tr>
<tr>
<td>20</td>
<td>120</td>
<td>0m0.768s</td>
</tr>
<tr>
<td>25</td>
<td>150</td>
<td>2m39.689s</td>
</tr>
</tbody>
</table>

Consider that in the standard library of OCaml export all functions have at most 5 arguments, and that there is margin for important improvement since we did not simplify the types of partial applications (whose intersection types are in general quite redundant).

Our implementation is already included in the development branch of the the C.Duce distribution which can be retrieved at https://www.cduce.org/redmine/projects/cduce. It currently is in alpha-testing therefore we recommend the user to check the bug-tracker for open issues.

Also available is a prototype which implements the work described in both papers: type inference/reconstruction for implicitly-typed expressions, constraint solving with basic simplification algorithms, evaluation. The implementation is naive, not optimized, and implements very naive simplification heuristics, but it permits a smoother and friendlier evaluation and testing of our system since it is stable, includes an interactive toplevel and contains, a different test suite based on the examples used in both papers.

It is available at http://www.pps.univ-paris-diderot.fr/~gc/misc/polyduce.tar.gz
