HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L’archive ouverte pluridisciplinaire HAL, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d’enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.
Growth of weaner steers grazing Tagasaste 
(*Chamaecytisus palmensis*) over summer/autumn with and without cereal grain supplements

Tagasaste (*Chamaecytisus palmensis*), from the barren volcanic hills in the Canary islands, is a hardy, perennial leguminous shrub reaching 3 to 5 m in height with very leafy stems and branches. It grows well in the medium rainfall zone (~450 mm) in the southwest region of Western Australia where there are an estimated 700,000 ha of leached deep sands. The variation in the protein (14 - 25 %) and energy (65 - 80 % *in vitro* dry matter digestibility) of tagasaste through the year suggests high rates of growth in cattle should be possible. Growth rates > 1.3 kg/d have been recorded in spring but growth in autumn is poor. Cereal grain supplements in autumn could complement the protein of the green leafy material to produce a well balanced production diet.

One hundred and four weaner cross-bred steers were stratified on initial liveweight of 238 ± 28.4 kg (± SD) and allocated at random into 3 treatments each with 3 replicates: control (n = 31; no supplements), low grain (n = 34; supplement fed at 0.75 % of liveweight) and high grain (n = 39; 1.5 % of liveweight). The animals grazed the tagasaste and were supplemented for 120 days. Different stocking pressure was used to equalise availability of energy from tagasaste and grain supplements, between treatments. Cereal barley grain (11.0 MJ ME/kg DM and 9.3 % crude protein) was cracked and mixed with virginiamycin® (SmithKline Beecham Animal Health) at 40 g/t to control acidosis (Rowe and Zorrilla-Rios, 1993, *Rec Adv Anim Nutr Aust*, 89-96.). The animals were weighed every 2 weeks and supplemented animals were fed weekly. At the end of the experiment 30 animals (10 from each treatment) were bled by jugular puncture and plasma was analysed for metabolic profile including plasma urea and creatinine. The data were analysed by ANOVA.

The average ME and crude protein of the tagasaste was 9.4 MJ/kg DM and 13.7 %, respectively. Animals with no grain supplement only maintained weight and the increase in liveweight gain in the grain supplemented animals reflected grain consumption. The barley supplement substituted for, and did not stimulate tagasaste intake. Plasma urea and creatinine levels suggest the lack of growth is due to a protein deficiency caused by inability of the animals to utilise the protein from the tagasaste. This may be due to the phenolic and flavinol compounds which increase in concentration in summer and autumn, and have been shown to decrease fermentation of protein in the rumen (Waghorn, 1990, *Proc Aust Soc Anim Prod*, 18, 412-415).
