A flexible and tractable class of one-factor copulas

Gildas Mazo, Stéphane Girard and Florence Forbes

MISTIS, Inria - Laboratoire Jean Kuntzmann, France

Abstract

Copulas are a useful tool to model multivariate distributions. While there exist various families of bivariate copulas, the construction of flexible and yet tractable copulas suitable for high-dimensional applications is much more challenging. This is even more true if one is concerned with the analysis of extreme values. In this paper, we construct a class of one-factor copulas and a family of extreme-value copulas well suited for high-dimensional applications and exhibiting a good balance between tractability and flexibility. The inference for these copulas is performed by using a least-squares estimator based on dependence coefficients. The modeling capabilities of the copulas are illustrated on simulated and real datasets.

Keywords: tractable, flexible, extreme-value copula, factor copula, multivariate, high-dimension, copula.

1 Introduction

The modelling of random multivariate events (i.e., of dimension strictly greater than 2) is a central problem in various scientific domains and the construction of multivariate distributions able to properly model the variables at play is challenging. The challenge is even more difficult if the data provide evidence of tail dependencies or non Gaussian behaviors. To address this problem, the concept of copulas is a useful tool as it permits to impose a dependence structure on pre-determined marginal distributions. Standard books covering this subject include [19,26]. See also [16] for an introduction to this topic. The most common copula models used in high dimensional applications are discussed below.

The popular Archimedean copulas are tractable and allow to model a different behavior in the lower and upper tails. For instance, the Gumbel copula is upper, but no lower, tail dependent; the opposite holds for the Clayton copula. Nevertheless, the dependence structure of Archimedean copulas is severely restricted because they are exchangeable, implying that all the pairs of variables have the same distribution. More details about these copulas can be found in the above mentioned books.

Nested Archimedean copulas are a class of hierarchical copulas generalizing the class of Archimedean copulas. They allow to introduce asymmetry in the dependence structure but only between groups of variables. This hierarchical structure is not desirable when no prior knowledge of the random phenomenon under consideration is available. Furthermore, constraints on the parameters

restrict the tractability of these copulas. These copulas first appeared in [19] Section 4.2.

The class of elliptical copulas arises from the class of elliptical distributions. These copulas are interesting in many respect but they are tail symmetric, meaning that the lower tail dependence coefficient is equal to the upper tail dependence coefficient (these coefficients are defined in Section 2.2). This may not be the case in applications. See, e.g., [25] Section 5 or [14] for an introduction to these copulas.

Pair copula constructions and Vines are flexible copula models based on the decomposition of the density as a product of conditional bivariate copulas. However, these models are difficult to handle. Furthermore, the conditional bivariate copulas are typically assumed not to depend on the conditioning variables. This so called *simplifying assumption* can be misleading, as remarked in [2]. Pair-copula constructions first appeared in [19] Section 4.5. See also [4, 5, 22] for theoretical developments and [1] for a practical introduction to modelling with Vines.

As shown above, most copula models are either tractable or flexible, but rarely both. In this paper, we propose a tractable and yet flexible class of one-factor copulas well suited for high-dimensional applications. This class is nonparametric, and, therefore, encompasses many distributions with different features. Unlike elliptical copulas, the members of this class allow for tail asymmetry. Furthermore, we have derived the associated extreme-value copulas, and, therefore, the analysis of extreme values can be carried out with the presented models. Finally, we show how to perform theoretically well-grounded, and practically fast and accurate, inference of these copulas, thanks to the ability of calculating explicitly the dependence coefficients.

The remaining of this paper is as follows. Section 2 presents the proposed class of one-factor copulas, Section 3 deals with inference, and, in Section 4, the proposed copulas are applied to simulated and real datasets. The proofs are postponed to the Appendix.

2 A tractable and flexible class of one-factor copulas

The class of copulas proposed in this paper, referred to as the FDG class (see Section 2.2 for an explanation of this acronym), can be embedded in the framework of one-factor models. We therefore introduce the later in Section 2.1. The construction and properties of FDG copulas are given in Section 2.2. Parametric examples are proposed in Section 2.3. The extreme-value copulas associated to the FDG class are derived in Section 2.4.

2.1 One-factor copulas

By definition, the coordinates of a random vector distributed according to a one-factor copula [21] are independent given a latent factor. More precisely, let U_0, U_1, \dots, U_d be standard uniform random variables such that the coordinates of (U_1, \dots, U_d) are conditionally independent given U_0 . The variable U_0 plays the role of a latent, or unobserved, factor. Let us write C_{0i} the distribution of (U_0, U_i) and $C_{i|0}(\cdot|u_0)$ the conditional distribution of U_i given $U_0 = u_0$ for

$i = 1, \dots, d$. It is easy to see that the distribution of (U_1, \dots, U_d) , called a one-factor copula, is given by

$$C(u_1, \dots, u_d) = \int_0^1 C_{1|0}(u_1|u_0) \dots C_{d|0}(u_d|u_0) du_0. \quad (1)$$

The copulas C_{0i} are called the *linking copulas* because they link the factor U_0 to the variables of interest U_i . The one-factor model has many advantages to address high dimensional problems. We recall and briefly discuss them below.

Nonexchangeability. The one-factor model is nonexchangeable. Recall that a copula C is said to be *exchangeable* if $C(u_1, \dots, u_d) = C(u_{\pi(1)}, \dots, u_{\pi(d)})$ for any permutation π of $(1, \dots, d)$. This means in particular that all the bivariate marginal distributions are equal to each other. For example, Archimedean copulas are exchangeable copulas. Needless to say, this assumption may be too strong in practice.

Parsimony. The one-factor model is parsimonious. Indeed, only d linking copulas are involved in the construction of the one-factor model, and since they are typically governed by one parameter, the number of parameters in total is no more than d , which increases only linearly with the dimension. Parsimony is more and more desirable as the dimension increases.

Random generation. The conditional independence property of the one factor model allows to easily generate data (U_1, \dots, U_d) from this copula.

- 1 Generate U_0, V_1, \dots, V_d independent standard uniform random variables.
- 2 For $i = 1, \dots, d$, put $U_i = C_{i|0}^{-1}(V_i|U_0)$ where $V \mapsto C_{i|0}^{-1}(V|U_0)$ denotes the inverse of $V \mapsto C_{i|0}(V|U_0)$.

Dependence properties of the one-factor model have been studied in [21]. The authors investigated how positive dependence properties of the linking copulas extend to the bivariate margins

$$C_{ij}(u_i, u_j) := C(1, \dots, 1, u_i, 1, \dots, 1, u_j, 1, \dots, 1).$$

These properties included positive quadrant dependence, increasing in the concordance ordering, stochastic increasing, and tail dependence. For details about these dependence concepts, see [19] Section 2. The copulas proposed in this paper, presented in Section 2.2 and Section 2.4, possess simple expressions and therefore the properties mentioned above can be made more precise.

2.2 Construction and properties of FDG copulas

The class of FDG copulas is constructed by choosing appropriate linking copulas for the one-factor copula model (1). The class of linking copulas which served to build the FDG copulas is referred to as the *Durante* class [9] of bivariate copulas, which can also be viewed as part of the framework of [3]. The Durante class consists of the copulas C of the form

$$C(u, v) = \min(u, v)f(\max(u, v)), \quad (2)$$

where $f : [0, 1] \rightarrow [0, 1]$, called the *generator* of C , is a differentiable and increasing function such that $f(1) = 1$ and $t \mapsto f(t)/t$ is decreasing. Hence the choice of the acronym, FDG, which stands for “one-Factor copula with Durante Generators”. The advantages of taking Durante linking copulas are twofold: the integral (1) can be calculated and the resulting multivariate copula is non-parametric.

Theorem 1. *Let C be defined by (1) and assume that C_{0i} belongs to the Durante class (2) with given generator f_i . Then*

$$C(u_1, \dots, u_d) = u_{(1)} \left[\left(\prod_{j=2}^d u_{(j)} \right) \int_{u_{(d)}}^1 \prod_{j=1}^d f'_j(x) dx + f_{(1)}(u_{(2)}) \left(\prod_{j=2}^d f_{(j)}(u_{(j)}) \right) \right. \\ \left. + \sum_{k=3}^d \left(\prod_{j=2}^{k-1} u_{(j)} \right) \left(\prod_{j=k}^d f_{(j)}(u_{(j)}) \right) \int_{u_{(k-1)}}^{u_{(k)}} \prod_{j=1}^{k-1} f'_{(j)}(x) dx \right], \quad (3)$$

where $u_{(i)} := u_{\sigma(i)}$, $f_{(i)} := f_{\sigma(i)}$ and σ is the permutation of $(1, \dots, d)$ such that $u_{\sigma(1)} \leq \dots \leq u_{\sigma(d)}$.

The particularity of the copula expression (3) is that it depends on the generators through their reordering underlain by the permutation σ . For instance, with $d = 3$ and $u_1 < u_3 < u_2$ we have $u_{(1)} = u_1$, $u_{(2)} = u_3$, $u_{(3)} = u_2$, $\sigma = \{1, 3, 2\}$ and $f_{(1)} = f_{\sigma(1)} = f_1$, $f_{(2)} = f_{\sigma(2)} = f_3$, $f_{(3)} = f_{\sigma(3)} = f_2$. This feature gives its flexibility to the model. Observe also that $C(u_1, \dots, u_d)$ writes as $u_{(1)}$ multiplied by a functional of $u_{(2)}, \dots, u_{(d)}$, form that is similar to (2). Although the expression of a FDG copula has the merit to be explicit, it is rather cumbersome. Hence, we shall continue its analysis through the prism of its bivariate margins.

Proposition 1. *Let C_{ij} be a bivariate margin of the FDG copula (3). Then C_{ij} belongs to the Durante class (2) with generator*

$$f_{ij}(t) = f_i(t)f_j(t) + t \int_t^1 f'_i(x)f'_j(x)dx.$$

In other words,

$$C_{ij}(u_i, u_j) = C_{f_{ij}}(u_i, u_j) = \min(u_i, u_j) f_{ij}(\max(u_i, u_j)).$$

In view of Proposition 1, the FDG copula can be regarded as a multivariate generalization of the Durante class of bivariate copulas. In fact, such a generalization was already proposed in the literature [11]:

$$C_f(u_1, \dots, u_d) = u_{(1)} \prod_{i=2}^d f(u_{(i)}),$$

where f is a generator in the usual sense of the Durante class of bivariate copulas. Nonetheless, since there is only one generator to determine the whole copula in arbitrary dimension, this generalization lacks flexibility to be used in applications. This issue is overcome by the FDG copula. To illustrate this

further, its pairwise dependence coefficients are given next. (Note that, since the bivariate margins of the FDG copula belong to the Durante class of bivariate copulas, a more detailed account of their properties can be found in the original paper [9]). Recall that the Spearman's rho ρ , the Kendall's tau τ , the lower $\lambda^{(L)}$ and upper $\lambda^{(U)}$ tail dependence coefficients of a general bivariate copula C are respectively given by

$$\rho = 12 \int_{[0,1]^2} C(u,v) dudv - 3, \quad \tau = 4 \int_{[0,1]^2} C(u,v) dC(u,v) - 1, \quad (4)$$

$$\lambda^{(L)} = \lim_{u \downarrow 0} \frac{C(u,u)}{u}, \quad \text{and} \quad \lambda^{(U)} = \lim_{u \uparrow 1} \frac{1 - 2u + C(u,u)}{1 - u}.$$

In the case where C belongs to the Durante class with generator f , these coefficients are respectively given by

$$\rho = 12 \int_0^1 x^2 f(x) dx - 3, \quad \tau = 4 \int_0^1 x f(x)^2 dx - 1,$$

$$\lambda^{(L)} = f(0), \quad \text{and} \quad \lambda^{(U)} = 1 - f'(1). \quad (5)$$

Hence, to get the dependence coefficients of the FDG bivariate margins, it is enough to apply the above formulas and Proposition 1. The obtained coefficient expressions are given in Proposition 2 below.

Proposition 2. *The Spearman's rho, the Kendall's tau, the lower and upper tail dependence coefficients of the FDG bivariate margins C_{ij} are respectively given by*

$$\rho_{ij} = 12 \int_0^1 x^2 f_i(x) f_j(x) dx + 3 \int_0^1 x^4 f_i'(x) f_j'(x) dx - 3,$$

$$\tau_{ij} = 4 \int_0^1 x \left(f_i(x) f_j(x) + x \int_x^1 f_i'(t) f_j'(t) dt \right)^2 dx - 1,$$

$$\lambda_{ij}^{(L)} = \lambda_i^{(L)} \lambda_j^{(L)} \quad \text{and}$$

$$\lambda_{ij}^{(U)} = \lambda_i^{(U)} \lambda_j^{(U)},$$

where $\lambda_i^{(L)} := f_i(0)$, $\lambda_i^{(U)} := 1 - f_i'(1)$, $i = 1, \dots, d$ are the lower and upper tail dependence coefficients of the bivariate linking copulas respectively.

2.3 Examples of parametric families

Four examples of families indexed by a real parameter for the generators f_1, \dots, f_d are given below.

Example 1 (Cuadras-Augé generators). In (3), let

$$f_i(t) = t^{1-\theta_i}, \quad \theta_i \in [0, 1]. \quad (6)$$

A copula belonging to the Durante class with generator (6) gives rise to the well known Cuadras-Augé copula with parameter θ_i [7]. By Proposition 1, the generator for the bivariate margin C_{ij} of the FDG copula is given by

$$f_{ij}(t) = \begin{cases} t^{2-\theta_i-\theta_j} \left(1 - \frac{(1-\theta_i)(1-\theta_j)}{1-\theta_i-\theta_j} \right) + t \frac{(1-\theta_i)(1-\theta_j)}{1-\theta_i-\theta_j} & \text{if } \theta_i + \theta_j \neq 1 \\ t(1 - (1-\theta)\theta \log t) & \text{if } \theta = \theta_j = 1 - \theta_i. \end{cases}$$

The Spearman's rho, the lower and upper tail dependence coefficients are respectively given by

$$\rho_{ij} = \frac{3\theta_i\theta_j}{5 - \theta_i - \theta_j}, \lambda_{ij}^{(L)} = 0 \text{ and } \lambda_{ij}^{(U)} = \theta_i\theta_j.$$

The Kendall's tau is given by

$$\tau_{ij} = \begin{cases} \frac{\theta_i\theta_j(\theta_i\theta_j+6-2(\theta_i+\theta_j))}{(\theta_i+\theta_j)^2-8(\theta_i+\theta_j)+15} & \text{if } \theta_i + \theta_j \neq 1 \\ \frac{\theta(\theta-1)(\theta^2-\theta-4)}{8} & \text{if } \theta = \theta_i = 1 - \theta_j. \end{cases}$$

Example 2 (Fréchet generators). In (3), let

$$f_i(t) = (1 - \theta_i)t + \theta_i, \quad \theta_i \in [0, 1]. \quad (7)$$

A copula belonging to the Durante class with generator (7) gives rise to the well known Fréchet copula with parameter θ_i [15]. By Proposition 1, the generator for the bivariate margin C_{ij} of the FDG copula is given by

$$f_{ij}(t) = (1 - \theta_i\theta_j)t + \theta_i\theta_j.$$

By noting that f_{ij} is of the form (7) with parameter $\theta_i\theta_j$, one can see that the bivariate margins of the FDG copula based on Fréchet generators are still Fréchet copulas. The Spearman's rho, the lower and upper tail dependence coefficients are respectively given by

$$\rho_{ij} = \lambda_{ij}^{(L)} = \lambda_{ij}^{(U)} = \theta_i\theta_j,$$

the Kendall's tau is given by

$$\tau_{ij} = \frac{\theta_i\theta_j(\theta_i\theta_j + 2)}{3}.$$

Example 3 (Durante-sinus generators). In (3), let

$$f_i(t) = \frac{\sin(\theta_i t)}{\sin(\theta_i)}, \quad \theta_i \in (0, \pi/2]. \quad (8)$$

This generator was proposed in [9]. By Proposition 1, the generator for the bivariate margin C_{ij} of the FDG copula is given by

$$\begin{aligned} f_{ij}(t) &= \frac{\sin(\theta_i t) \sin(\theta_j t)}{\sin(\theta_i) \sin(\theta_j)} + \frac{t\theta_i\theta_j}{2(\theta_j^2 - \theta_i^2) \sin(\theta_i) \sin(\theta_j)} \times \\ &\left\{ (\theta_i + \theta_j) [\sin((\theta_i - \theta_j)t) + \sin(\theta_j - \theta_i)] \right. \\ &\left. + (\theta_j - \theta_i) [\sin(\theta_i + \theta_j) - \sin((\theta_i + \theta_j)t)] \right\} \text{ if } \theta_i \neq \theta_j, \text{ and} \\ f_{ij}(t) &= \frac{4 \sin(t\theta)^2 + t\theta (2(1-t)\theta + \sin(2\theta) - \sin(2t\theta))}{4 \sin(\theta)^2} \text{ if } \theta_i = \theta_j = \theta. \end{aligned}$$

The Spearman's rho, the lower and upper tail dependence coefficients are respectively given by

$$\rho_{ij} = 12(\sin \theta_i \sin \theta_j)^{-1} \int_0^1 x^2 \sin(\theta_i x) \sin(\theta_j x) + \frac{1}{4} \theta_i \theta_j x^4 \cos(\theta_i x) \cos(\theta_j x) dx - 3, \quad (9)$$

$$\lambda_{ij}^{(L)} = 0 \text{ and } \lambda_{ij}^{(U)} = \left(1 - \frac{\theta_i}{\tan(\theta_i)}\right) \left(1 - \frac{\theta_j}{\tan(\theta_j)}\right). \quad (10)$$

Example 4 (Durante-exponential generators). In (3), let

$$f_i(t) = \exp\left(\frac{t^{\theta_i} - 1}{\theta_i}\right), \quad \theta_i > 0 \quad (11)$$

This generator was proposed in [9]. By Proposition 1, the generator for the bivariate margin C_{ij} of the FDG copula is given by

$$f_{ij}(t) = \exp\left(\frac{t^{\theta_i} - 1}{\theta_i} + \frac{t^{\theta_j} - 1}{\theta_j}\right) + t \int_t^1 \exp\left(\frac{x^{\theta_i} - 1}{\theta_i} + \frac{x^{\theta_j} - 1}{\theta_j}\right) x^{\theta_i + \theta_j - 2} dx.$$

The Spearman's rho, the lower and upper tail dependence coefficients are respectively given by

$$\rho_{ij} = 12 \int_0^1 \exp\left(\frac{x^{\theta_i} - 1}{\theta_i} + \frac{x^{\theta_j} - 1}{\theta_j}\right) \left(x^2 + \frac{1}{4} x^{2 + \theta_i + \theta_j}\right) dx - 3,$$

$$\lambda_{ij}^{(L)} = \exp\left(-\frac{1}{\theta_i} - \frac{1}{\theta_j}\right), \text{ and } \lambda_{ij}^{(U)} = 0.$$

Remark 1. The calculation of the integral in (9) with $\theta_i = \theta_j = \pi/2$ shows that for the FDG copula with Durante-sinus generators, the Spearman's rho is such that

$$0 \leq \rho_{ij} \leq \frac{3\pi^4 - 100\pi^2 + 840}{40\pi^2} \simeq 0.37.$$

The Spearman's rho values for all the other models in the examples above spread the entire interval $[0, 1]$.

The four examples above allow to get all possible types of tail dependencies, as shown in Table 1. The Cuadras-Augé and Durante-sinus families allow for upper but no lower tail dependence, the Durante-exponential family allows for lower but no upper tail dependence, and the Fréchet family allows for both. In the Fréchet case, furthermore, the lower and upper tail dependence coefficients are equal: this is called tail symmetry, a property of elliptical copulas.

2.4 Extreme-value attractors associated to FDG copulas

Extreme-value copulas are theoretically well-grounded copulas to perform a statistical analysis of extreme values such as maxima of random samples. Recall that a copula $C_{\#}$ is an extreme-value copula if there exists a copula \tilde{C} such that

$$C_{\#}(u_1, \dots, u_d) = \lim_{n \uparrow \infty} \tilde{C}^n(u_1^{1/n}, \dots, u_d^{1/n}), \quad (u_1, \dots, u_d) \in [0, 1]^d, \quad (12)$$

family of generators	$\lambda_{ij}^{(L)}$	$\lambda_{ij}^{(U)}$
Cuadras-Augé	0	$\theta_i \theta_j$
Fréchet	$\theta_i \theta_j$	$\theta_i \theta_j$
Durante-sinus	0	$(1 - \frac{\theta_i}{\tan \theta_i})(1 - \frac{\theta_j}{\tan \theta_j})$
Durante-exponential	$\exp(-\frac{1}{\theta_i} - \frac{1}{\theta_j})$	0

Table 1: Lower $\lambda_{ij}^{(L)}$ and upper $\lambda_{ij}^{(U)}$ tail dependence coefficients for the four families presented in Section 2.3.

see, e.g. [17]. The extreme-value copula $C_{\#}$ is called the *attractor* of \tilde{C} and \tilde{C} is said to belong to the *domain of attraction* of $C_{\#}$. The class of extreme-value copulas corresponds exactly to the class of max-stable copulas, that is, the copulas $C_{\#}$ such that

$$C_{\#}^n(u_1^{1/n}, \dots, u_d^{1/n}) = C_{\#}(u_1, \dots, u_d), \quad n \geq 1, (u_1, \dots, u_d) \in [0, 1]^d.$$

The upper tail dependence coefficient of a (bivariate) extreme-value copula $C_{\#}$ has the particular form

$$\lambda^{(U)} = 2 + \log C_{\#}(e^{-1}, e^{-1}). \quad (13)$$

This coefficient is a natural dependence coefficient for extreme-value copulas because of the following representation on the diagonal of the unit square:

$$C_{\#}(u, u) = u^{2-\lambda}, \quad (14)$$

where $\lambda := \lambda^{(U)}$. If $\lambda = 0$ then $C_{\#}(u, u) = \Pi(u, u) = u^2$, where Π stands for the independence copula. If $\lambda = 1$ then $C_{\#}(u, u) = M(u, u) = \min(u, u) = u$, where M stands for the Fréchet-Hoeffding upper bound for copulas, that is, the case of perfect dependence. In the case of extreme-value copulas, this interpolation between Π and M allows to interpret λ as a coefficient that measures general dependence, not only dependence in the tails. In order to emphasize this interpretation, λ will be referred to as the *extremal dependence coefficient* of an extreme-value copula. See [6] for more about extreme-value statistics, and, see, e.g. [17] for an account about extreme-value copulas.

In the case of FDG copulas, the limit (12) can be calculated. This leads to a new family of extreme-value copulas, referred to as the family EV-FDG. The bivariate margins $C_{\#,ij}$ of this new family are Cuadras-Augé copulas. These results are precised in Theorem 2 and Proposition 3, given next.

Theorem 2. *Assume that the generators f_i of the FDG copula are twice continuously differentiable on $[0, 1]$. Then, the attractor $C_{\#}$ of the FDG copula exists and is given by*

$$C_{\#}(u_1, \dots, u_d) = \prod_{i=1}^d u_{(i)}^{\chi_i}, \quad (15)$$

where

$$\chi_i = \left(\prod_{j=1}^{i-1} (1 - \lambda_{(j)}) \right) \lambda_{(i)} + 1 - \lambda_{(i)},$$

with the convention that $\prod_{j=1}^0 (1 - \lambda_{(j)}) = 1$ and where $\lambda_i = 1 - f'_i(1)$. As in (3), $u_{(i)} = u_{\sigma(i)}$ and $f'_{(i)}(1) = f'_{\sigma(i)}(1)$ where σ is the permutation of $(1, \dots, d)$ such that $u_{(1)} \leq \dots \leq u_{(d)}$.

Proposition 3. Let $C_{\#,ij}$ be a bivariate margin of an EV-FDG copula (15). Then $C_{\#,ij}$ is a Cuadras-Augé copula with parameter (and therefore extremal dependence coefficient) $\lambda_i \lambda_j$. In other words,

$$C_{\#,ij}(u_i, u_j) = \min(u_i, u_j) \max(u_i, u_j)^{1 - \lambda_i \lambda_j}. \quad (16)$$

Remark 2. In view of Table 1, the FDG copulas with Cuadras-Augé and Fréchet generators both lead to the same EV-FDG copula.

Multivariate generalizations of the bivariate Cuadras-Augé copula were already proposed in the literature [12,23], but they are less flexible than EV-FDG. Thus, let

$$A(u_1, \dots, u_d) = u_{(1)} \prod_{i=2}^d u_{(i)}^{a_i},$$

where $(a_1 = 1, a_2, a_3, \dots, a_d)$ is a d -monotone sequence of real numbers, that is, a sequence which satisfies $\nabla^{j-1} a_k \geq 0$, $k = 1, \dots, d$, $j = 1, \dots, d - k + 1$ where $\nabla^j a_k = \sum_{i=0}^j (-1)^i \binom{j}{i} a_{k+i}$, $j, k \geq 1$ and $\nabla^0 a_k = a_k$. This exchangeable copula was proposed in [23]. In particular, the bivariate margins are Cuadras-Augé copulas

$$A_{ij}(u_i, u_j) = \min(u_i, u_j) \max(u_i, u_j)^{a_2}$$

with the same parameter $1 - a_2$. This means that all of them exhibit the same statistical behavior. For instance, all the upper tail dependence coefficients are equal and are given by $1 - a_2$. This is far too restrictive for most applications. Now let

$$B(u_1, \dots, u_d) = \prod_{i=1}^d u_i^{1 - \sum_{j=1, j \neq i}^d \lambda_{ij}} \prod_{i < j} \min(u_i, u_j)^{\lambda_{ij}},$$

where $\lambda_{ij} \in [0, 1]$, $\lambda_{ij} = \lambda_{ji}$ and

$$\sum_{j=1, \dots, d; j \neq i} \lambda_{ij} \leq 1, \quad i = 1, \dots, d. \quad (17)$$

This copula was proposed in [12]. The bivariate margins B_{ij} are Cuadras-Augé copulas

$$B_{ij}(u_i, u_j) = \min(u_i, u_j) \max(u_i, u_j)^{1 - \lambda_{ij}}$$

with parameters λ_{ij} . Unlike the copula A , the tail dependence coefficients can take distinct values from each other. Unfortunately, the constraints (17) are quite restrictive, as it was already stressed by the original authors in [12]. To summarize, the class EV-FDG achieves greater flexibility than its competitors. In particular, one can obtain different bivariate marginal distributions with *no* conditions on the parameters.

3 Parametric inference

Let (X_1, \dots, X_d) be a random vector following a distribution F with continuous margins F_1, \dots, F_d . Suppose that its copula, C , is a FDG copula defined by (3). Denote by

$$(X_1^{(k)}, \dots, X_d^{(k)}), k = 1, \dots, n,$$

independent and identically distributed observations obtained from F . Suppose that all the generators f_i of the FDG copula belong to the same parametric family $\{f_\theta, \theta \in \Theta \subset \mathbb{R}\}$, that is, there exists $\theta_0 = (\theta_{01}, \dots, \theta_{0d}) \in \Theta^d$ such that $f_{\theta_{0i}} = f_i$. The generators f_i are regarded as functions defined over the product space $[0, 1] \times \Theta$ and we write $f_i(t) = f(t, \theta_i)$ for all t in $[0, 1]$. The nonparametric inference problem has turned into a parametric one where the parameter vector $\theta_0 \in \Theta^d$ has to be estimated.

In order to estimate the parameters of the FDG and EV-FDG copulas, we consider a least-squares estimator based on dependence coefficients. Its construction is given below. Choose a type of dependence coefficient (Spearman's rho, Kendall's tau, tail dependence coefficient, etc) and denote by $r(\theta_i, \theta_j)$ the chosen dependence coefficient between the variables X_i and X_j . Suppose that the map r is continuous and symmetric in its arguments. Let $p = d(d-1)/2$ be the number of variable pairs (X_i, X_j) , $i < j$. Denote by \mathbf{r} be the p -variate map defined on Θ^d such that $\mathbf{r}(\theta_1, \dots, \theta_d) = (r(\theta_1, \theta_2), \dots, r(\theta_{d-1}, \theta_d))$. The least-squares estimator based on dependence coefficients is defined as

$$\hat{\theta} = \arg \min_{\theta \in \Theta^d} \|\hat{\mathbf{r}} - \mathbf{r}(\theta)\|^2, \quad (18)$$

where the quantity $\hat{\mathbf{r}} = (\hat{r}_{1,2}, \dots, \hat{r}_{d-1,d})$ is an empirical estimator of $\mathbf{r}(\theta_0)$. The empirical coefficient $\hat{\mathbf{r}}$ has to be chosen such that, as $n \rightarrow \infty$,

$$\hat{\mathbf{r}} \xrightarrow{P} \mathbf{r}(\theta_0) \text{ and } \sqrt{n}(\hat{\mathbf{r}} - \mathbf{r}(\theta_0)) \xrightarrow{d} N(\mathbf{0}, \Sigma), \quad (19)$$

for some symmetric and positive definite matrix Σ . For example, the convergences (19) hold for the Spearman's rho and the Kendall's tau dependence coefficients, see [18].

Example 5 (Spearman's rho). Let $r(\theta_i, \theta_j)$ be the Spearman's rho (4) of (X_i, X_j) . Let $\hat{U}_i^{(k)} = \sum_{l=1}^n \mathbf{1}(X_i^{(l)} \leq X_i^{(k)}) / (n+1)$ and put

$$\hat{r}_{i,j} = \frac{\sum_{k=1}^n (\hat{U}_i^{(k)} - \bar{\hat{U}}_i) (\hat{U}_j^{(k)} - \bar{\hat{U}}_j)}{\left[\sum_{k=1}^n (\hat{U}_i^{(k)} - \bar{\hat{U}}_i)^2 \sum_{k=1}^n (\hat{U}_j^{(k)} - \bar{\hat{U}}_j)^2 \right]^{1/2}},$$

where $\bar{\hat{U}}_i = \sum_{k=1}^n \hat{U}_i^{(k)} / n$. Then (19) holds.

Example 6 (Kendall's tau). Let $r(\theta_i, \theta_j)$ be the Kendall's tau (4) of (X_i, X_j) and put

$$\hat{r}_{i,j} = \binom{n}{2}^{-1} \sum_{k < l} \text{sign} \left((X_i^{(k)} - X_i^{(l)})(X_j^{(k)} - X_j^{(l)}) \right),$$

where $\text{sign}(x) = 1$ if $x > 0$, -1 if $x < 0$ and 0 if $x = 0$. Then (19) holds.

The relationship (14) suggests that the extremal dependence coefficient can be used to estimate the parameters of an extreme-value copula. If the margins F_i are known, (19) holds with various empirical estimators of the extremal dependence coefficient, see [24]. In the following example, an estimator proposed in [13] is used.

Example 7 (extremal dependence coefficient). *Assume that C is an extreme-value copulas and put $U_i^{(k)} = F_i(X_i^{(k)})$. Let $r(\theta_i, \theta_j)$ be the extremal dependence coefficient (4) of (X_i, X_j) . Put*

$$\hat{r}_{i,j} = 3 - \frac{1}{1 - \sum_{k=1}^n \max(U_i^{(k)}, U_j^{(k)})/n}.$$

Then (19) holds.

The least-squares estimator is unique with probability tending to one, consistent, and asymptotically normal under mild assumptions that are stated in the following proposition, due to [24].

Proposition 4. *Suppose that (19) and the following assumptions hold.*

(A1) *The map \mathbf{r} is a twice continuously differentiable homeomorphism from Θ^d to its image $\mathbf{r}(\Theta^d)$.*

(A2) *The Jacobian matrix of the map \mathbf{r} at $\boldsymbol{\theta}_0$, that is,*

$$\mathbf{J} := \begin{pmatrix} \left. \frac{\partial r(\boldsymbol{\theta})}{\partial \theta_1} \right|_{\boldsymbol{\theta}=\boldsymbol{\theta}_0} & \left. \frac{\partial r(\boldsymbol{\theta})}{\partial \theta_2} \right|_{\boldsymbol{\theta}=\boldsymbol{\theta}_0} & \cdots & \left. \frac{\partial r(\boldsymbol{\theta})}{\partial \theta_d} \right|_{\boldsymbol{\theta}=\boldsymbol{\theta}_0} \\ \vdots & \vdots & \ddots & \vdots \\ \left. \frac{\partial r(\boldsymbol{\theta})}{\partial \theta_1} \right|_{\boldsymbol{\theta}=\boldsymbol{\theta}_0} & \left. \frac{\partial r(\boldsymbol{\theta})}{\partial \theta_2} \right|_{\boldsymbol{\theta}=\boldsymbol{\theta}_0} & \cdots & \left. \frac{\partial r(\boldsymbol{\theta})}{\partial \theta_d} \right|_{\boldsymbol{\theta}=\boldsymbol{\theta}_0} \end{pmatrix},$$

is of full rank.

Then, as $n \rightarrow \infty$, the estimator $\hat{\boldsymbol{\theta}}$ defined in (18) is unique with probability tending to one, consistent for $\boldsymbol{\theta}_0$, and asymptotically normal

$$\sqrt{n}(\hat{\boldsymbol{\theta}} - \boldsymbol{\theta}_0) \xrightarrow{d} N(\mathbf{0}, \boldsymbol{\Xi}), \quad \text{where } \boldsymbol{\Xi} = (\mathbf{J}^T \mathbf{J})^{-1} \mathbf{J}^T \boldsymbol{\Sigma} \mathbf{J} (\mathbf{J}^T \mathbf{J})^{-1}.$$

Remark 3. *From the asymptotic normality of $\hat{\boldsymbol{\theta}}$, standard arguments in mathematical statistics yield, as $n \rightarrow \infty$,*

$$n(\hat{\boldsymbol{\theta}} - \boldsymbol{\theta}_0)^T \boldsymbol{\Xi}(\hat{\boldsymbol{\theta}})^{-1} (\hat{\boldsymbol{\theta}} - \boldsymbol{\theta}_0) \xrightarrow{d} \chi_d^2,$$

where χ_d^2 stands for a chi-square distribution with d degrees of freedom. This result will be useful in Section 4.1.1 to assess the accuracy of the inference.

The map \mathbf{r} of one-factor copula models possesses the property that all of its components involve the same bivariate function r . This allows to establish a lemma that gives sufficient conditions for the assumptions of Proposition 4 to hold.

Lemma 1. (i) Define the univariate function $r_{\theta_j}(\theta_i) := r(\theta_i, \theta_j)$ and assume that it is a twice continuously differentiable homeomorphism. Let $r_{1,2}, \dots, r_{d-1,d}$ be p elements of $\mathbf{r}(\Theta^d)$. Define $s_{i,j}(\theta) := r_{\theta}^{-1}(r_{i,j})$ for $\theta \in \Theta$. Then, the function $s_{1,3} \circ s_{1,2} \circ s_{2,3}$ has at least one fix point, that is, the equation

$$s_{1,3} \circ s_{1,2} \circ s_{2,3}(\theta) = \theta, \quad \theta \in \Theta \quad (20)$$

has at least one solution.

(ii) If, moreover, the function $s_{1,3} \circ s_{1,2} \circ s_{2,3}$ has exactly one fix point, that is, equation (20) has exactly one solution, then the assumptions (A1) and (A2) of Proposition 4 hold.

The fact that the extremal dependence coefficients of the EV-FDG bivariate margins write $\lambda_{i,j}(\boldsymbol{\theta}) = \lambda(\theta_i)\lambda(\theta_j)$, where

$$\lambda(\theta) = 1 - \left. \frac{\partial f(t, \theta)}{\partial t} \right|_{t=1}, \quad \theta \in \Theta,$$

allows to apply Lemma 1 and therefore to satisfy the assumptions of Proposition 4.

Corollary 1. Assume that (X_1, \dots, X_d) has EV-FDG (15) as copula and consider one of the following cases:

- The generators are Cuadras-Augé (6) and $\Theta = (0, 1)$.
- The generators are Fréchet (7) and $\Theta = (0, 1)$.
- The generators are Durante-sinus (8) and $\Theta = (0, \pi/2)$.

Then the assumptions (A1) and (A2) of Proposition 4 hold with $r(\theta_i, \theta_j)$ and $\hat{\mathbf{r}}$ being as in Example 7.

Remark 4. For the FDG copula with Fréchet generators presented in Example 2, the Spearman's rho dependence coefficient is equal to the extremal dependence coefficient, hence, one can also apply Lemma 1 to this copula. Therefore, also for this model, the assumptions (A1) and (A2) of Proposition 4 hold with $r(\theta_i, \theta_j)$ and $\hat{\mathbf{r}}$ being as in Example 5.

Except for the FDG copula with Fréchet generators (see Remark 4), the results of Corollary 1 could not be extended to general FDG copulas because the analytical forms of the Spearman's rho and Kendall's tau dependence coefficients are not as simple as the forms of the extremal dependence coefficients. Nonetheless, we shall provide empirical evidence by means of numerical experiments in Section 4.1 that the assumptions of Proposition 4 are likely to hold.

4 Applications to simulated and real datasets

The modeling of data with (EV-)FDG copulas is illustrated through numerical experiments in Section 4.1 and a real dataset application in Section 4.2. In the numerical experiments, we first provide empirical evidence to support the assumptions (A1) and (A2) of Proposition 4. We then illustrate, by fitting $d = 50$ variables, that the proposed FDG copulas are well suited for high-dimensional

applications. In the real dataset application, critical levels of potentially dangerous hydrological events are estimated. Throughout this section, the four copulas of Example 1–4, are respectively referred to as FDG-CA, FDG-F, FDG-sinus, and FDG-exponential.

The minimization of the loss function (18) was carried out with standard gradient descent algorithms whose implementations can be found in the function `optim` from the R software [27]. In principle, several runs with different starting points should be tested to ensure that the global minimizer is reached. However, we found that a single run was enough to find what appeared to be the global optimum. Thus, the loss functions one encounters when dealing with FDG copulas seem to be easy to minimize in practice.

4.1 Numerical experiments

4.1.1 Empirical evidence in favor of the assumptions of Proposition 4

The first step of this numerical experiment consists of generating 200 datasets of dimension $d = 4$ and size $n = 500$ for each of the copulas FDG-CA, FDG-F, FDG-sinus, and FDG-exponential. The true parameter vectors were respectively set to

$$(0.6, 0.7, 0.8, 0.9), (0.3, 0.5, 0.7, 0.9), (1, 1.2, 1.37, 1.55) \text{ and } (3, 8.7, 14.3, 20).$$

The second step consists of estimating the parameters of the models. To this end, the loss function (18) was used with the Spearman’s rho dependence coefficient as in Example 5. The amount of time required with a 8 GiB memory and 3.20 GHz processor computer to carry out the simulation of one dataset of size $n = 500$ and dimension $d = 4$ and perform the corresponding inference is given in Table 2 (columns $d = 4$). The computational costs for performing the inference of FDG-exponential and FDG-sinus are larger because their dependence coefficient expressions, given in Example 3 and 4, involve integrals which have to be computed numerically. The third step consists of defining and computing

Copula	Time (ms)			
	Simulation		Inference	
	$d = 4$	$d = 50$	$d = 4$	$d = 50$
FDG-CA	1.3	16	8	920
FDG-F	0.2	1	2	390
FDG-sinus	0.7	7	62	9700
FDG-exponential	2.2	25	228	82700

Table 2: Time required, in milliseconds, to simulate a dataset of size $n = 500$ and dimension d , and to perform the corresponding inference.

error criteria in order to assess the inference method accuracy. For each dataset and each model, the mean absolute error and the relative mean absolute error, respectively defined as

$$\text{MAE}_r = \frac{1}{p} \sum_{i < j} |r_{i,j} - r(\hat{\theta}_i, \hat{\theta}_j)| \text{ and } \text{RMAE} = \frac{1}{d} \sum_{i=1}^d \frac{|\hat{\theta}_i - \theta_{0i}|}{\theta_{0i}},$$

were computed and averaged over the replications. These criteria are reported in Table 3 (columns $d = 4$).

Copula	MAE _r		RMAE	
	$d = 4$	$d = 50$	$d = 4$	$d = 50$
FDG-CA	0.03	0.03	0.08	0.06
FDG-F	0.03	0.03	0.08	0.06
FDG-sinus	0.03	0.02	0.08	0.05
FDG-exponential	0.03	0.03	0.08	0.17

Table 3: (Relative) mean absolute errors averaged over the 200 dataset replications for the four FDG copula models.

All the models giving the same small errors, it seems that the method proposed in Section 3 to estimate the parameters of FDG copulas works well in practice. In order to check the validity of the estimator’s asymptotic distribution, and since this distribution is multivariate – hence, not straightforward to study –, we rely on the following argument. If the assumptions of Proposition 4 hold, then, by Remark 3, the values $n(\hat{\boldsymbol{\theta}}^{(k)} - \boldsymbol{\theta}_0)^T \boldsymbol{\Xi}(\hat{\boldsymbol{\theta}}^{(k)})^{-1}(\hat{\boldsymbol{\theta}}^{(k)} - \boldsymbol{\theta}_0)$, $k = 1, \dots, 200$, should be approximately χ_d^2 distributed, where $\hat{\boldsymbol{\theta}}^{(k)}$ denotes the parameter vector estimated on the k -th dataset replication. This approximation, shown in Figure 1, appears to be satisfactory. Therefore, the assumptions of Proposition 4 are more likely. Recall that these assumptions lead to the consistency and asymptotic normality of the parameter vector estimator for FDG copulas.

4.1.2 A high-dimensional illustration

The experiment carried out in Section 4.1.1 is repeated but the dimension is increased to $d = 50$. The coordinates of the parameter vector were chosen to be regularly spaced within $[0.3, 0.9]$, $[0.3, 0.9]$, $[1, 1.55]$ and $[3, 20]$ for FDG-CA, FDG-F, FDG-sinus, and FDG-exponential respectively. The amount of time required to simulate a dataset of size $n = 500, d = 50$ and to perform the corresponding inference is given in Table 2 (columns $d = 50$). Simulating all the models even in high dimension is instantaneous because of the conditional independence property seen in (1). Less than 2 minutes are necessary to fit all the models. In particular, simulating or fitting FDG-F is instantaneous. The MAEs/RMAEs computed in this high-dimensional context are reported in Table 3 (columns $d = 50$). The results are quite satisfying for FDG-CA, FDG-F and FDG-sinus: although the sample size n did not increase, the error values are similar to those found in Section 4.1.1. The inference for these models seems not to be sensitive to the dimension. FDG-exponential has a larger RMAE, but it is still below 17%, and its MAE_r is as good as the other models. To summarize, FDG copulas seem to scale up well.

4.2 Application to a hydrological dataset

4.2.1 Data and context

The dataset consists of $n = 32$ observations $(X_1^{(k)}, \dots, X_d^{(k)})$, $k = 1, \dots, n$, of annual maxima river flow rates located at $d = 9$ sites across south-east France

Figure 1: Histograms of $n(\hat{\boldsymbol{\theta}}^{(k)} - \boldsymbol{\theta}_0)^T \boldsymbol{\Xi}(\hat{\boldsymbol{\theta}}^{(k)})^{-1}(\hat{\boldsymbol{\theta}}^{(k)} - \boldsymbol{\theta}_0)$, $k = 1, \dots, 200$, together with the density of a χ_d^2 distribution. From left to right, top to bottom: FDG-CA, FDG-F, FDG-sinus, and FDG-exponential.

between 1969 and 2007 (some records are missing). Let us denote by F the distribution with continuous margins F_1, \dots, F_d of the random vector (X_1, \dots, X_d) whose realizations provide the observed dataset. The location of the sites are shown in Figure 2. The number of variable pairs is $p = 36$. Due to the heterogeneous dispersion of the sites, the span of positive dependence is almost maximum; for instance, the Spearman's rho dependence coefficients range from about 0 to 0.9.

In hydrology, it is of interest to get information about the statistical distribution of a potentially dangerous event, such as $\{F_1(X_1) > q, \dots, F_d(X_d) > q\}$, or, equivalently, $\{\min(F_1(X_1), \dots, F_d(X_d)) > q\}$, where q is the *critical level* associated to that event. The *return period* T is defined as

$$T = \frac{1}{1 - M(q)}, \quad \text{where } M(q) = P(\min(F_1(X_1), \dots, F_d(X_d)) \leq q). \quad (21)$$

For instance, a return period of $T = 30$ years and a critical level of $q = 0.7$ means that each X_i exceeds its quantile of order 70% once every 30 years in average. A common question in the study of extreme events is the following. Given a return period T , how dangerous is the corresponding event? In other words,

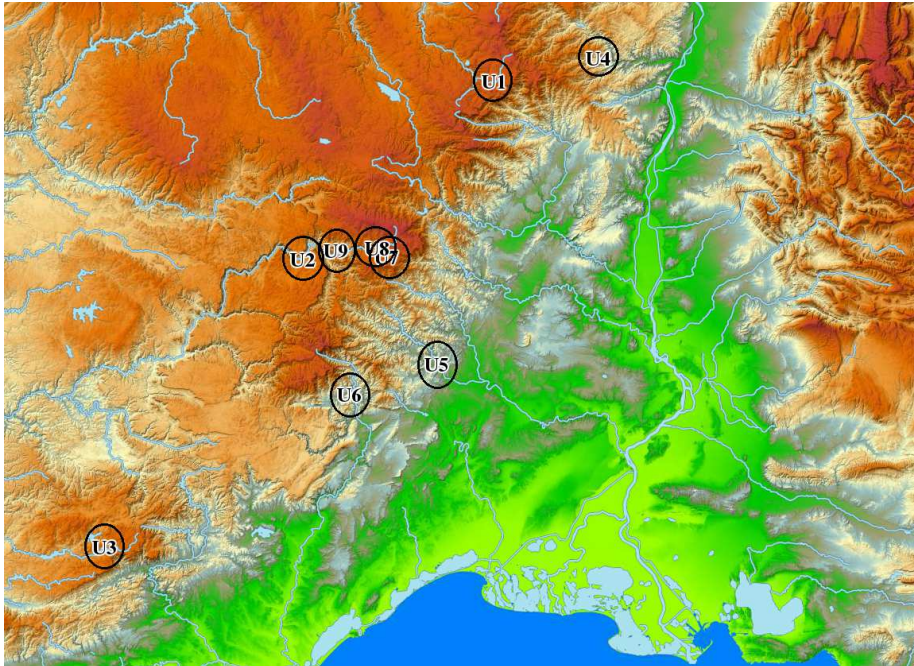

Figure 2: Location of the 9 sites for the flow rate dataset. The sea in dark blue at the bottom (south) is the Mediterranean sea. The rivers are shown in light blue. The river flowing from north to south in the green area is the Rhône. Green indicates low altitude, and orange high altitude. The map of this figure was drawn with Géoportail www.geoportail.gouv.fr.

what is the associated critical level q ? The answer is obtained by inverting (21)

$$q = M^{-1} \left(1 - \frac{1}{T} \right). \quad (22)$$

Thus, the answer q is the quantile of order $1 - 1/T$ of the distribution M . This quantile can be estimated empirically from the data and parametrically by fitting a model to the data.

Potentially dangerous events happen with the co-occurrence of extremely high flow rates at several locations. Thus, it is clear that the models to describe this dataset should be upper tail dependent. Hence, good candidates are the copulas of Example 1–3, referred to as FDG-CA, FDG-F, and FDG-sinus respectively, and all the extreme-value copulas. However, as it was shown in Remark 1, the Spearman’s rho of FDG-sinus cannot take values greater than 0.37. Hence, this copula is removed from the candidate models. So the considered models are FDG-CA, FDG-F, and their extreme-value attractor EV-FDG-CAF given in (15) (recall that FDG-CA and FDG-F lead to the same extreme-value copula). Two other popular copula models, the Gumbel and Student copulas, are also fitted to the data. The Gumbel copula is famous among hydrologists [29] and the Student copula is well known in risk management [25]. They serve as a benchmark for our models. A factor structure is assumed for the Student copula, that is, its (i, j) -th element ($i \neq j$) of its correlation matrix writes $\theta_i \theta_j$,

where $\theta_1, \dots, \theta_d$ belong to $[-1, 1]$. Recall that a Gumbel copula is an extreme-value copula. More details about the Gumbel and the Student copula can be found respectively in, e.g., [19, 26] and [8].

4.2.2 Method

A practically convenient approach dictated the estimation of the copula parameters. For each copula model, the dependence coefficients with the simplest mathematical forms were chosen to build the loss function (18). In other words, the parameters of FDG-F and FDG-CA were estimated with the Spearman's rho as in Example 5. The parameters of EV-FDG-CAF were estimated with the extremal dependence coefficient as in Example 7. The parameters of the Gumbel and Student copulas were estimated with the Kendall's tau as in Example 6. Finally, the degree of freedom of the Student copula was estimated by maximizing its likelihood but with all the parameters of the correlation matrix held fixed. This approach improves the speed, tractability, and chances of success of the minimization procedure.

To be valid, the asymptotic properties of the estimator based on the extremal dependence coefficients require the knowledge of the marginal distributions F_i . Assuming that the data come from an extreme-value distribution, the marginal distributions theoretically pertain to the family of the Generalized Extreme Value (GEV) distributions. The good results of the GEV fit to the data margins are depicted by the quantile-quantile plot in Figure 3. In addition to transform the data to have standard uniform margins, these fitted GEV distributions served to calculate the critical levels of (22) as well. This primary step, that of fitting a parametric model to the margins, is standard in extreme-value statistics; see, for instance, [6] Chapter 8 and [28]. Details for the GEV distribution are to be found, e.g., in [6] Chapter 3.

4.2.3 Results

The fit of the tested copulas was assessed by comparing the pairwise dependence coefficients and the critical levels.

Pairwise dependence coefficients. The mean absolute error (MAE), defined as

$$MAE_r = \frac{1}{p} \sum_{i < j} |\hat{r}_{i,j} - r(\hat{\theta}_i, \hat{\theta}_j)|$$

was computed for the Spearman's rho (MAE_ρ), the Kendall's tau (MAE_τ) and the extremal dependence coefficient (MAE_λ). They are reported in Table 4. MAE_λ was computed only for EV-FDG-CAF and the Gumbel copula because, with this dependence coefficient, (19) holds only for extreme-value copulas, see Example 7. The Gumbel copula has the largest errors (more than 0.17) and does not seem to fit the data well. This was expected, because this model has only one parameter to account for a $d = 9$ dimensional phenomenon. All the remaining errors (but MAE_ρ for EV-FDG-CAF) are smaller and of the same magnitude. Thus, according to these criteria, the Gumbel copula is not appropriate.

Figure 3: Quantile-Quantile plots with confidence intervals for the GEV fit of the data margins.

	FDG-F	FDG-CA	EV-FDG-CAF	Gumbel	Student
MAE_ρ	0.12	0.12	0.17	0.22	0.12
MAE_τ	0.12	0.11	0.12	0.17	0.10
MAE_λ			0.11	0.45	

Table 4: Mean absolute error for the Spearman's rho (MAE_ρ), Kendall's tau (MAE_τ) and extremal (MAE_λ) dependence coefficient of the models.

Critical levels. The critical levels obtained from the empirical data and the models were calculated by making use of (22). In statistical terms, this amounts to compare the quantiles of the distribution M under the empirical data and under the different models. The results are presented in Figure 4, where the independence copula $C(u_1, \dots, u_d) = u_1 \dots u_d$ was added to emphasize the need for a joint model on such a dataset. The Gumbel model is confirmed to perform poorly. FDG-F, FDG-CA and EV-FDG-CAF seem to fit the data quite well. In particular, FDG-F and FDG-CA are as close as the Student copula to the

empirical curve.

Figure 4: Critical level q as a function of the return period T . “empirical” stands for the empirical critical levels, and “independence” for the independence copula $C(u_1, \dots, u_d) = \prod_{i=1}^d u_i$.

With such a small sample size $n = 32$, one must be extremely careful when looking at empirical data, because one is likely to observe a large deviation from the true underlying statistical distribution. In view of this remark, one should select a statistical model based not only on empirical data, but also on the model properties. The class of FDG copulas is very interesting in this respect. Indeed, the practitioner has with this class three models that fit well the data and with different features: FDG-F is upper, lower, and symmetric tail dependent, FDG-CA is upper tail dependent but no lower tail dependent, and EV-FDG-CAF is an extreme-value copula. The user is then free to choose the model that most suits his expert knowledge about the underlying phenomenon at play. The test of extreme-value dependence [20] gave a p-value of 0.21, which means that one does not reject extreme-value copulas at the 5% level. Of course, as before, one must be extremely careful when looking at the p-value because of the small data sample size. However, no other statistical tests are available in such a situation.

5 Discussion

In this article, we have constructed a new class of copulas by combining one-factor copulas, that is, a conditional independent property, together with a class of bivariate copulas called the Durante class of bivariate copulas. This combination led to many advantageous properties. The copulas within the proposed class, referred to as FDG copulas, are tractable, flexible, and cover all types of tail dependencies. The theoretically well grounded least-squares inference estimator is particularly well suited for FDG copulas because their dependence coefficients are easy to compute, if not in closed form. This allows to perform fast and reliable inference in the parametric case. We have demonstrated, furthermore, that FDG copulas work well in practice and are able to model both high-dimensional and real datasets. Finally, we have derived the extreme-value copulas (EV-FDG) associated to FDG copulas, yielding a new extreme-value copula, which can be viewed as a generalisation of the well known Cuadras-Augé copula. This copula benefits from almost all the many advantageous properties of FDG copulas, and therefore opens the door for statistical analyses of extreme data in high dimension.

One may argue that a model with a singular component, as a FDG copula, is not natural nor realistic to model hydrological data. While this may be true in the bivariate case, this argument becomes weaker when the dimension increases. Indeed, in high-dimensional applications, the focus is less on the distribution itself than on a feature of interest of the data, such as, for instance, the critical levels defined in (22). If alleged “unrealistic” models are able to better estimate these features than “realistic” models – compare the fit of the Gumbel copula to the fit of FDG copulas in Section 4.2 – then one should consider using them.

This work raises several research questions. First, how to estimate the generators nonparametrically? The generator of a bivariate Durante copula was estimated nonparametrically in [10], but the matter is more complicated in our case because this bivariate relationship occurs between the variable of interest and the unobserved latent factor. Second, one may add more factors when building an FDG copula. Nonetheless, the model might not be as tractable as it is and therefore it may be less appealing in practice. Finally, FDG copulas possess the conditional independence property, but the extreme-value EV-FDG copulas were not shown to do so. If this property held, this would be of great interest for the simulation of datasets from this model.

A Appendix

Proof of Theorem 1

Let $C_{j|0}(\cdot|u_0)$ be the conditional distribution of U_j given $U_0 = u_0$. The U_j 's are conditionally independent given U_0 , hence,

$$\begin{aligned}
C(u) &= \int_0^1 \prod_{j=1}^d C_{j|0}(u_j|u_0) du_0 & (23) \\
&= \int_0^1 \prod_{j=1}^d \frac{\partial C_{0j}(u_0, u_j)}{\partial u_0} du_0 \\
&= \int_0^1 \prod_{j=1}^d \frac{\partial C_{0(j)}(u_0, u_{(j)})}{\partial u_0} du_0 \\
&= \int_0^{u_{(1)}} \prod_{j=1}^d \frac{\partial C_{0(j)}(u_0, u_{(j)})}{\partial u_0} du_0 \\
&\quad + \sum_{k=2}^d \int_{u_{(k-1)}}^{u_{(k)}} \prod_{j=1}^{k-1} \frac{\partial C_{0(j)}(u_0, u_{(j)})}{\partial u_0} \prod_{j=k}^d \frac{\partial C_{0(j)}(u_0, u_{(j)})}{\partial u_0} \\
&\quad + \int_{u_{(d)}}^1 \prod_{j=1}^d \frac{\partial C_{0(j)}(u_0, u_{(j)})}{\partial u_0} du_0.
\end{aligned}$$

Since

$$\frac{\partial C_{0j}(u_0, u_j)}{\partial u_0} = \begin{cases} f_j(u_j) & \text{if } u_0 < u_j \\ u_j f'_j(u_0) & \text{if } u_0 > u_j, \end{cases}$$

(23) yields

$$\begin{aligned}
C(u) &= u_{(1)} \prod_{j=1}^d f_j(u_j) + \sum_{k=2}^d \prod_{j=k}^d f_j(u_{(j)}) \int_{u_{(k-1)}}^{u_{(k)}} \prod_{j=1}^{k-1} u_{(j)} f'_j(u_0) du_0 \\
&\quad + \prod_{j=1}^d u_j \int_{u_{(d)}}^1 f'_j(u_0) du_0.
\end{aligned}$$

Putting $u_{(1)}$ in factor and noting that $\int_{u_{(1)}}^{u_{(2)}} f'_1(x) dx = f_1(u_{(2)}) - f_1(u_{(1)})$ finishes the proof.

Proof of Proposition 1

It suffices to set all u_k equal to one but u_i and u_j in the formula (3).

Proof of Proposition 2

It suffices to apply the formulas (5) with f_{ij} given in Proposition 1. To compute the Spearman's rho, note that

$$\int_0^1 x^2 f_{ij}(x) dx = \int_0^1 x^2 f_i(x) f_j(x) dx + \int_0^1 x^3 \int_x^1 f'_i(z) f'_j(z) dz dx.$$

An integration by parts yields $\int_0^1 x^3 \int_x^1 f'_i(z) f'_j(z) dz dx = (1/4) \int_0^1 x^4 f'_i(x) f'_j(x) dx$ and the result follows.

Proof of Theorem 2

Fix $(u_1, \dots, u_d) \in [0, 1]^d$ and let $n \geq 1$ be an integer. Put

$$\begin{aligned}\alpha_n &:= u_{(1)}^{1/n} \prod_{j=1}^d \frac{f_j(u_j^{1/n})}{u_j^{1/n}}, \\ \beta_n &:= \int_{u_{(d)}^{1/n}}^1 \prod_{j=1}^d f'_j(u_0) du_0, \\ \gamma_n &:= \prod_{j=k}^d \frac{f_{(j)}(u_{(j)}^{1/n})}{u_{(j)}^{1/n}}, \\ \delta_{n,k} &:= \int_{u_{(k-1)}^{1/n}}^{u_{(k)}^{1/n}} \prod_{j=1}^{k-1} f'_{(j)}(u_0) du_0,\end{aligned}$$

and define

$$A_n := \alpha_n + \beta_n + \sum_{k=2}^d \gamma_{n,k} \delta_{n,k}.$$

We are going to derive asymptotic equivalent sequences for $\alpha_n, \beta_n, \gamma_n$ and δ_n . Let \sim denote the equivalent symbol at infinity (i.e., $a_n \sim b_n$ means $a_n/b_n \rightarrow 1$ as $n \rightarrow \infty$). By using the well known formulas $e^x \sim 1 + x$ (when $x \rightarrow 0$), $\log x \sim x - 1$ (when $x \rightarrow 1$) and $f_j(x) \sim 1 + (x - 1)f'_j(1)$ (when $x \rightarrow 1$) we get

$$\begin{aligned}\alpha_n &\sim \left(1 + \frac{1}{n} \log u_{(1)}\right) \left(1 - \frac{1}{n} \log(u_1 \dots u_d)\right) \left(1 + \frac{1}{n} \sum_{j=1}^d \log u_{(j)} f'_{(j)}(1)\right) \text{ and} \\ \gamma_{n,k} &\sim \left(1 - \frac{1}{n} \sum_{j=k}^d \log u_{(j)}\right) \left(1 + \frac{1}{n} \sum_{j=k}^d \log u_{(j)} f'_{(j)}(1)\right).\end{aligned}$$

For β_n the equivalence is obtained as follows. Let $F(x)$ be a primitive of $\prod_{j=1}^d f'_j(x)$. It follows that $\beta_n = F(1) - F(u_{(d)}^{1/n})$. A Taylor expansion yields

$$F(u_{(d)}^{1/n}) = F(1) + (u_{(d)}^{1/n} - 1)F'(1) + \frac{(u_{(d)}^{1/n} - 1)^2}{2} F''(x_n)$$

where x_n is between $u_{(d)}^{1/n}$ and 1. Since F'' is assumed to be continuous on $[0, 1]$, it is uniformly bounded on this set and therefore $(u_{(d)}^{1/n} - 1)^2 F''(x_n)/2 = o(1/n)$ where $o(1/n)$ is a quantity such that $no(1/n) \rightarrow 0$ as $n \rightarrow \infty$. Hence, since $u_{(d)}^{1/n} = \exp(\log(u_{(d)})/n) \sim 1 + \log(u_{(d)})/n$, we have as $n \rightarrow \infty$

$$F(1) - F(u_{(d)}^{1/n}) \sim -\frac{1}{n} \log(u_{(d)}) F'(1).$$

The same arguments apply to get

$$\begin{aligned}\beta_n &\sim -\frac{1}{n} \log u_{(d)} \prod_{j=1}^d f'_j(1) \\ \delta_{n,k} &\sim \frac{1}{n} \log \left(\frac{u_{(k)}}{u_{(k-1)}} \right) \prod_{j=1}^{k-1} f'_j(1).\end{aligned}$$

The quantity A_n is a polynomial with respect to n^{-1} of order at most three. In (24), the coefficients of order 0, 2, and 3 vanish at infinity. Only remain the terms of order 1, hence,

$$\begin{aligned}\lim_{n \uparrow \infty} n(A_n - 1) &= \log u_{(1)} - \log(u_1 \dots u_d) + \sum_{j=1}^d \log u_{(j)} f'_j(1) \\ &\quad - \log u_{(d)} \prod_{j=1}^d f'_j(1) + \sum_{k=2}^d \prod_{j=1}^{k-1} f'_j(1) \log \left(\frac{u_{(k)}}{u_{(k-1)}} \right).\end{aligned}\tag{24}$$

From Abel's identity, that is, $\sum_{i=1}^{d-1} a_i(b_{i+1} - b_i) = \sum_{i=1}^{d-1} b_i(a_{i+1} - a_i) + a_d b_d - a_1 b_1$ for two sequences (a_i) and (b_i) of real numbers, we can write

$$\lim_{n \uparrow \infty} n(A_n - 1) = \sum_{k=1}^d \left(\underbrace{\left(\prod_{j=1}^{k-1} f'_j(1) \right) (1 - f'_{(k)}(1)) + f'_{(k)}(1) - 1}_{=: \chi_k} \right) \log u_{(k)},$$

with the convention that $\prod_{j=1}^0 f'_j(1) = 1$. From (3) it follows that

$$\begin{aligned}C^n(u_1^{1/n}, \dots, u_d^{1/n}) &= u_1 \dots u_d \exp [n \log A_n] \\ &= u_1 \dots u_d \exp [n(A_n - 1)(1 + o(1))] \\ &\rightarrow \prod_{i=k}^d u_{(i)}^{\chi_k}\end{aligned}$$

as $n \rightarrow \infty$.

Proof of Lemma 1

(i) Since the p -uple $(r_{1,2}, \dots, r_{d-1,d})$ belongs to the image space $\mathbf{r}(\Theta^d)$, the system

$$\begin{aligned}r(\theta_1, \theta_2) &= r_{1,2} \\ &\vdots \\ r(\theta_{d-1}, \theta_d) &= r_{d-1,d}\end{aligned}$$

has at least one solution. In particular, there exists $(\theta_1, \theta_2, \theta_3)$ in Θ^3 such that

$$\begin{aligned}r(\theta_1, \theta_2) &= r_{1,2} \\ r(\theta_1, \theta_3) &= r_{1,3} \\ r(\theta_2, \theta_3) &= r_{2,3}.\end{aligned}\tag{25}$$

The system (25) rewrites

$$\begin{aligned} r_{\theta_2}(\theta_1) &= r_{1,2} \\ r_{\theta_3}(\theta_1) &= r_{1,3} \\ r_{\theta_3}(\theta_2) &= r_{2,3}, \end{aligned}$$

or equivalently,

$$\begin{aligned} \theta_1 &= s_{1,2}(\theta_2) \\ \theta_1 &= s_{1,3}(\theta_3) \\ \theta_2 &= s_{2,3}(\theta_3). \end{aligned}$$

This yields

$$s_{1,3}(\theta_3) = s_{1,2} \circ s_{2,3}(\theta_3). \quad (26)$$

Note that $s_{1,3}$ is involutive at θ_3 , that is, $s_{1,3} \circ s_{1,3}(\theta_3) = \theta_3$. Indeed, $r(\theta_1, \theta_3) = r_{\theta_3}(\theta_1) = r_{1,3}$ is equivalent to $\theta_1 = r_{\theta_3}^{-1}(r_{1,3}) = s_{1,3}(\theta_3)$. This implies $r(s_{1,3}(\theta_3), \theta_3) = r_{1,3}$, and, composing by $r_{s_{1,3}(\theta_3)}^{-1}$ in both sides, we get $r_{s_{1,3}(\theta_3)}^{-1}(r_{1,3}) = s_{1,3}(s_{1,3}(\theta_3)) = \theta_3$. Therefore, one can compose both sides of (26) by $s_{1,3}$ to get

$$\theta_3 = s_{1,3} \circ s_{1,2} \circ s_{2,3}(\theta_3).$$

Hence (20) has at least one solution.

(ii) If (20) admits exactly one solution θ_3 , then θ_2 and θ_1 are also unique. Furthermore, for all $j \geq 3$,

$$\theta_{j+1} = s_{j,j+1}(\theta_j)$$

which concludes the proof that assumption (A1) holds. It is now shown that assumption (A2) holds as well. Define $\partial_1 r$, respectively, $\partial_2 r$, the derivative of r with respect to the first, respectively, second, variable of r . Hence for all θ_i and θ_j in Θ , the quantities $\partial_1 r(\theta_i, \theta_j)$ and $r_{\theta_j}(\theta_i)$ only differ in the notation. The first step in the proof is to consider the case $d = 3$. The Jacobian matrix of \mathbf{r} at $\boldsymbol{\theta}_0$ is given by

$$\mathbf{J} = \begin{pmatrix} \partial_1 r(\theta_{01}, \theta_{02}) & \partial_2 r(\theta_{01}, \theta_{02}) & 0 \\ \partial_1 r(\theta_{01}, \theta_{03}) & 0 & \partial_2 r(\theta_{01}, \theta_{03}) \\ 0 & \partial_1 r(\theta_{02}, \theta_{03}) & \partial_2 r(\theta_{02}, \theta_{03}) \end{pmatrix}.$$

To show that \mathbf{J} has full rank, we show that its determinant

$$\partial_1 r(\theta_{01}, \theta_{02}) \partial_2 r(\theta_{01}, \theta_{03}) \partial_1 r(\theta_{02}, \theta_{03}) + \partial_2 r(\theta_{02}, \theta_{03}) \partial_1 r(\theta_{01}, \theta_{03}) \partial_2 r(\theta_{01}, \theta_{02})$$

is nonzero. Indeed, note that for all θ in Θ , the map $r_\theta : \Theta \rightarrow r_\theta(\Theta)$ is a twice continuously differentiable homeomorphism. Furthermore, by assumption, the true parameter vector $\boldsymbol{\theta}_0$ lies in the interior of Θ that is open. Finally, by symmetry, for all $i < j$,

$$\partial r_1(\theta_{0i}, \theta_{0j}) > 0 \quad (\text{respectively } \partial r_1(\theta_{0i}, \theta_{0j}) < 0)$$

is equivalent to

$$\partial r_2(\theta_{0j}, \theta_{0i}) > 0 \quad (\text{respectively } \partial r_2(\theta_{0j}, \theta_{0i}) < 0).$$

For the general case, we proceed by mathematical induction. When the dimension is d , write $\mathbf{J}(\boldsymbol{\theta}) = \mathbf{J}^{(d)}(\boldsymbol{\theta})$ to emphasize the dependence on the dimension. Notice that it was already shown above that $\mathbf{J}^{(3)}(\boldsymbol{\theta})$ has full rank. Now suppose that the kernel of $\mathbf{J}^{(d-1)}(\boldsymbol{\theta})$ is null when the dimension is $d-1$. Let $\mathbf{A} = \mathbf{J}^{(d)}(\boldsymbol{\theta})$. Each row of \mathbf{A} writes

$$(0, \dots, 0, \partial_1 r(\theta_i, \theta_j), 0, \dots, 0, \partial_2 r(\theta_i, \theta_j), 0, \dots, 0)$$

where $\partial_1 r(\theta_i, \theta_j)$ is at the i -th position and $\partial_2 r(\theta_i, \theta_j)$ at the j -th position. There are $d-1$ rows of A which depend on θ_d and $p-d+1$ which do not (recall $p = d(d-1)/2$ is the number of pairs). Since the kernel of a matrix is invariant by permutation, we can without loss of generality put all the rows which do not depend on θ_d on the top. More precisely, decompose \mathbf{A} as

$$\mathbf{A} = \begin{pmatrix} \mathbf{A}_{11} & \mathbf{A}_{12} \\ \mathbf{A}_{21} & \mathbf{A}_{22} \end{pmatrix}$$

such that \mathbf{A}_{11} is a $(p-d+1) \times (d-1)$ matrix containing all the rows which do not depend on θ_d and \mathbf{A}_{12} and \mathbf{A}_{22} are $(p-d+1) \times 1$ and $(d-1) \times 1$ matrices respectively. Note that \mathbf{A}_{12} is the null vector of size $p-d+1 \times 1$. Let $\mathbf{x} \in \mathbb{R}^d$, $\mathbf{x} = (\mathbf{x}_1^T, x_2)^T$ where $\mathbf{x}_1 \in \mathbb{R}^{d-1}$, $x_2 \in \mathbb{R}$. It follows that $\mathbf{A}\mathbf{x} = \mathbf{0}$ is equivalent to

$$\begin{cases} \mathbf{A}_{11}\mathbf{x}_1 + \mathbf{A}_{12}x_2 = \mathbf{0} \\ \mathbf{A}_{21}\mathbf{x}_1 + \mathbf{A}_{22}x_2 = 0. \end{cases}$$

But $\mathbf{A}_{12} = \mathbf{0}$ and since $\mathbf{A}_{11} = \mathbf{J}^{(d-1)}(\boldsymbol{\theta})$ whose kernel is null, $\mathbf{x}_1 = \mathbf{0}$. Then $\mathbf{A}_{22}x_2 = 0$ and the assumptions imply $x_2 = 0$, which concludes the proof.

Proof of Corollary 1

To prove Corollary 1, it suffices to apply Lemma 1. Since $r(\theta_i, \theta_j)$ denotes the extremal dependence coefficient of the \mathcal{E} copula bivariate marginal $C_{\#,ij}$ defined in (16), we have

$$r(\theta_i, \theta_j) = \lambda(\theta_i)\lambda(\theta_j), \text{ where} \\ \lambda(\theta) := 1 - \frac{\partial f(t, \theta)}{\partial t} \Big|_{t=1}. \quad (27)$$

In the Cuadras-Augé and the Fréchet cases, (27) is given by $\lambda(\theta) = \theta$, and in the sinus case, $\lambda(\theta) = 1 - \theta/\tan(\theta)$. In all these situations, it is easy to see that the map $r_{\theta_j}(\cdot)$ is a twice continuously differentiable homeomorphism. Therefore, Lemma 1 (i) applies.

To apply the second part of Lemma 1, note that equation (20) translates into

$$\lambda(\theta)^2 = \frac{r_{1,3}r_{2,3}}{r_{1,2}}.$$

Since it has a unique solution, Lemma 1 (ii) applies, and the result is proved.
