# Integral equations for three-dimensional problems 

A. LE VAN and J. ROYER<br>Laboratoire de Mécanique des Structures, Ecole Nationale Supérieure de Mécanique, $I$ Rue de la Noë, 44072 NANTES Cédex, France

#### Abstract

An integral equations method for a three-dimensional crack in a finite or infinite body is achieved by means of Kupradze potentials. Surface and through cracks can be studied according to this approach with only the assumption that the body has a linear, elastic, homogeneous and isotropic behavior. Both singular surface integrals and line integrals appear in the derived equations. For surface and through cracks, the line integral is taken on a part of the crack boundary. The use of our integral equations to the particular problem of an embedded plane crack leads to those formulated by Bui. Another application is devoted to a through crack in a circular cylinder.

## 1. Introduction

For plane problems, linear fracture mechanics permits predicting crack behavior from the knowledge of stress intensity factors. We expect these parameters are always relevant to three-dimensional cracks; unfortunately we cannot derive them for general cases. Complexity results, of course, from the three-dimensional feature of the problem, from the connexion with boundaries of the solid when it is finite and from the fact that stress intensity factors vary all along the crack front. Except for the particular case of the penny shaped crack studied by Sneddon [1] one does not know closed solutions to more general problems.

Present trends are turning towards the use of integral equations and, for many authors, Somigliana formula is considered as a starting point. This method enabled Cruse [2] to write integral equations for an uncracked body. The problem of a cracked body can be tackled with the help of Kupradze elastic potentials [3], also known as Bashelishvili potentials.

These elastic potentials were applied by Bui [4] in order to solve the problem of an arbitrarily shaped plane crack embedded in an infinite body. He obtained its solution by the help of the sum of two potentials: the first is a simple layer and the second is a double-layer of the second kind. The use of these potentials and symmetry considerations allowed Putot [5] to deal with the problem of a plane surface crack perpendicular to the free plane boundary of a semi-infinite body.

After transformation of Somigliana formula, V. and J. Sládek [6] achieved the derivation of the stress vector at any point of the body in terms of the displacement discontinuity resulting from a three-dimensional crack embedded in an infinite body. Properties of Kupradze potentials [7] enable them to pass to the limit and explain the stress value at any point of the crack surface; this is always given in terms of displacement discontinuities.

First, we defined the displacement field inside a cracked body by means of a double-layer Kupradze potential of the first kind, then we proved that stress vectors can be explained in terms of a density function defined on an open set including crack surface. The passing to the limit enables us to derive stress vector on crack surfaces.

Next we showed that only the partial derivatives of the unknown densities restriction on crack surfaces, with respect to suitable variables, are involved in the integral equation. This result confirms the idea that the problem is well formulated.

We provided another confirmation of our approach in solving the problem of a plane crack as dealt with by Bui. By means of a similar transformation to that formerly proposed by V. and J. Sládek we succeeded in dealing with embedded crack problems as well as transverse crack ones.

The last step of this work is devoted to an application of our results to the problem of a plane through crack lying in the cross section of a thick tube. This points out the contribution, in the integral equation, of the line integral that does not appear in the previous problems concerning embedded cracks.

Integral equations derived below can be applied to any finite or infinite body containing a three dimensional crack; it can be a surface or a through crack. Linear elastic behavior of the medium is the only assumption required.

## 2. Basic notations

The elastic body under consideration is denoted by D , characterized by either the Lamé constants $\lambda, \mu$ or the Young's modulus $E$ and the Poisson's ratio $\nu$. Its exterior boundary is denoted by $\partial D$.

The crack $S$ is considered as a geometric surface, and not as the union of its upper and lower faces $S^{+}$and $S^{-}$. It is assumed that $S$ is a Liapunov surface, i.e. it belongs to the class $V^{1, \alpha}, 0<\alpha \leqslant 1$. The boundary of the crack surface $S$ is denoted by $\partial S$, which is not included in $S$, so that the interior of $S$ is $S$ itself:

$$
\stackrel{\circ}{S}=S \backslash \partial S=S
$$

$\boldsymbol{e}_{i}(i=1,2,3)$ is a unit vector of a fixed Cartesian coordinates system in the Euclidean space $E_{3}$. A point of $E_{3}$ and the corresponding radius-vector are denoted by the same symbol. $\boldsymbol{n}_{x}, \boldsymbol{n}_{z}$ designate normals at any points $\boldsymbol{x}, \boldsymbol{z}$ of $D, \boldsymbol{y}$ is any point of $S$, and $\boldsymbol{x}_{0}$ is a particular one. The notations $\boldsymbol{n}(\boldsymbol{x}), \boldsymbol{n}(\boldsymbol{z})$ will not be used, since an infinite number of normals can be chosen at each point, the normal is not a function of this latter. Note, though, that for convenience reasons, one may encounter the $i$-component of $\boldsymbol{n}_{x}$ denoted by $n_{i}(\boldsymbol{x})$, instead of $n_{x i}$. Moreover, an orientation of $S$ being chosen once and for all, $\boldsymbol{n}_{y}$ or $\boldsymbol{n}_{x_{0}}$ will not refer to any normals of $S$ at the point $\boldsymbol{y}, \boldsymbol{x}_{0}$ respectively, but those orienting the surface $S$.

The displacement, which is a function of $\boldsymbol{x}$, is denoted by $\boldsymbol{u}(\boldsymbol{x})$. At any point $\boldsymbol{x}$ the stress tensor is $\overline{\bar{\Sigma}}(\boldsymbol{x})$ and the stress vector, with respect to the normal $\boldsymbol{n}_{x}$, is $\boldsymbol{t}\left(\boldsymbol{x}, \boldsymbol{n}_{x}\right)$. For a point $\boldsymbol{x}_{0} \in S, \boldsymbol{t}\left(\boldsymbol{x}_{0}, \boldsymbol{n}_{x_{0}}\right)$ is understood as a limit value: $\lim \boldsymbol{t}\left(\boldsymbol{x}, \boldsymbol{n}_{x}\right)$ as $\boldsymbol{x} \rightarrow \boldsymbol{x}_{0}, \boldsymbol{n}_{x} \rightarrow \boldsymbol{n}_{x_{0}}$, the normal $\boldsymbol{n}_{x_{0}}$ being well-defined by the orientation of $S$.

An implicit sum is implied on any repeated indices. Thus, let $f$ and $\psi$ be some differentiable functions in $D$, we have:

$$
\begin{aligned}
& \operatorname{grad} f=f_{, i} \cdot \boldsymbol{e}_{i} \\
& \operatorname{rot} \psi=-\epsilon_{i j k} \cdot \psi_{j, k} \cdot \boldsymbol{e}_{i} \\
& \frac{\mathrm{~d} \psi}{\mathrm{~d} n}=\psi_{i, j} n_{j} \boldsymbol{e}_{i}
\end{aligned}
$$

Defining the tensor product $\boldsymbol{a} \otimes \boldsymbol{b}$ by:

$$
\forall c, \quad(a \otimes b) . c=a .(b \cdot c)
$$

we have:

```
\(\operatorname{grad} \psi=\psi_{i, j} \boldsymbol{e}_{i} \otimes \boldsymbol{e}_{j}\)
```

$\overline{\bar{T}}^{T}$, the transposed tensor of $\overline{\bar{T}}$ is defined by:

$$
\forall i, j:\left(\overline{\bar{T}}^{T}\right)_{i j}=(\overline{\bar{T}})_{j i}
$$

$\overline{\bar{I}}$ denotes the unit tensor:

$$
\forall i, j:(\overline{\bar{I}})_{i j}=\delta_{i j},
$$

where:

$$
\delta_{i j}=\left\lvert\, \begin{array}{ll}
0 & \text { if } i \neq j \\
1 & \text { if } i=j
\end{array}\right. \text { and } \boldsymbol{\epsilon}_{i j k}=\left(\boldsymbol{e}_{i}, \boldsymbol{e}_{j}, \boldsymbol{e}_{k}\right)=\boldsymbol{e}_{i}\left(\boldsymbol{e}_{j} \Lambda \boldsymbol{e}_{k}\right)
$$

The symbols pv $\int$ or $\int^{*}$ indicate that the associated integral must be understood in the sense of the Cauchy principal value.

Let $f$ denote a function of two variables $\boldsymbol{x}, \boldsymbol{z}$. Unless stated otherwise, $f_{. \mathrm{i}}$ denotes the partial derivatives of $f$ with respect to $z_{i}$ :

$$
f_{. i} \equiv \frac{\partial f}{\partial z_{i}}
$$

and $f_{i}(y \in S)$ designates the value of the derivative of $f$, with respect to $z_{i}$, at a point $y \in S$ :

$$
\left.f_{. i}(\boldsymbol{y} \in S) \equiv \frac{\partial f(z)}{\partial z_{i}}\right|_{z=y \in S}
$$

When partial derivatives with respect to $x_{i}$ are involved, it will be explicitly mentioned.

## 3. Definition of the auxiliary problem

Let us consider an elastic body $D$ under arbitrary loading, containing a crack $S$ unloaded on its faces. Without this crack, the state of stress in the body would be $\bar{\Sigma}^{0}$, and the two faces of $S$ would remain in contact with one another under internal forces resulting from $\bar{\Sigma}^{0}: \boldsymbol{t}^{0}\left(\boldsymbol{x}_{0}, \boldsymbol{n}_{x_{0}}\right), \boldsymbol{x}_{0} \in S$. These internal forces are computed on the uncracked finite body subjected to the aforementioned loading.

In order to obtain unloaded crack faces, it is necessary to add on the crack the stresses $-\boldsymbol{t}^{0}\left(\boldsymbol{x}_{0}, \boldsymbol{n}_{x_{0}}\right)$, opposite to those resulting from the initial stress state $\overline{\bar{\Sigma}}^{0}$, whereas, the external loading applied on $\partial D$, is forced to zero. This loading on the crack faces will generate another state of stress in the body, denoted by $\bar{\Sigma}^{1}$.

Thus, the solution to the problem of a cracked body can be obtained by superposition of $\overline{\bar{\Sigma}}^{1}$ on $\overline{\bar{\Sigma}}^{0}$ :

$$
\overline{\bar{\Sigma}}(x)=\overline{\bar{\Sigma}}^{0}(x)+\overline{\bar{\Sigma}}^{1}(x)
$$

where $\overline{\bar{\Sigma}}^{0}(\boldsymbol{x})$ is a regular stress tensor and $\overline{\bar{\Sigma}}^{1}(\boldsymbol{x})$ is a singular one in the vicinity of the crack edge $\partial S$ (Fig. 1).

This leads us to consider what is called the auxiliary problem stated as the problem of a crack under arbitrary loadings. The boundary conditions are:

$$
\begin{align*}
& \forall x \in S: \lim _{x \rightarrow x_{0}^{ \pm}, n_{x}=\boldsymbol{n}_{x_{0}}} t\left(x, n_{x}\right)=-\boldsymbol{t}^{0}\left(\boldsymbol{x}_{0}, \boldsymbol{n}_{x_{0}}\right)  \tag{1}\\
& \forall x \in \partial D: \boldsymbol{t}\left(\boldsymbol{x}, \boldsymbol{n}_{x}\right)=\mathbf{0} \tag{2}
\end{align*}
$$

Figure 1. Analysis of the problem of a cracked body.

In fact, one begins to obtain a solution to the problem with the boundary conditions (1) and another one slightly different from (2):

$$
\begin{equation*}
\forall \boldsymbol{x},\|\boldsymbol{x}\| \rightarrow \infty: \boldsymbol{t}\left(\boldsymbol{x}, \boldsymbol{n}_{x}\right)=\mathbf{0} \tag{2bis}
\end{equation*}
$$

The corresponding solution is rather satisfactory in the case of a little crack embedded in a large body. Nevertheless, if the crack is not sufficiently far away from the boundary $\partial D$ of the body (especially in the case of surface and through cracks) use must be made of an appropriate method for satisfying the boundary condition (2). This method will be illustrated in the example at the end of this paper.

## 4. Integral equations for the auxiliary problem

## 1) Definition of the displacement field

Let us represent the displacement field by means of the double-layer potential of the first kind of Kupradze [7]:

$$
\begin{equation*}
\forall x \in E_{3}(\text { instead of } D): u(x)=\boldsymbol{W}_{I}(x)=\int_{S} \overline{\bar{T}}^{T}\left(\boldsymbol{y}-\boldsymbol{x}, \boldsymbol{n}_{y}\right) \psi(\boldsymbol{y}) \mathrm{d} S_{y} \tag{3}
\end{equation*}
$$

where the density $\psi$ is a vector function of three variables $z=\left(z_{1}, z_{2}, z_{3}\right)$ defined on an open set $\vartheta$ containing $S$. Its restriction on $S \psi_{\mid S}(z)=\psi(y \in S)$ satisfying the condition: $\psi_{\mid S} \in C^{1, \alpha}(S), 0<\alpha \leqslant 1$, is the unknown of the problem.

It is proved in [7] that $\boldsymbol{u}(\boldsymbol{x})$ thus defined satisfies the homogeneous static Navier's equation:

$$
\begin{equation*}
\mathscr{L} u \equiv \mu \Delta u+(\lambda+\mu) \operatorname{grad} \operatorname{div} \boldsymbol{u}=\mathbf{0}, \quad \forall x \in E_{3} \backslash S \tag{4}
\end{equation*}
$$

It must be stated that the stress state generated by this displacement field satisfies the boundary condition (1), the condition (2bis) being identically satisfied.

Following [1], we have a relation on limit behaviour of the displacement:

$$
\begin{equation*}
u\left(x_{0}^{ \pm}\right)= \pm \frac{1}{2} \psi\left(x_{0}\right)+p v \int_{S} \overline{\bar{T}}^{T}\left(y-x_{0}, n_{y}\right) \psi(y) \mathrm{d} S_{y}, \quad \forall x_{0} \in S \tag{5}
\end{equation*}
$$

where:

$$
\begin{align*}
\overline{\bar{T}}\left(z-\boldsymbol{x}, \boldsymbol{n}_{z}\right)= & \frac{2 \mu}{8 \pi(\lambda+2 \mu) r^{2}}\left[\boldsymbol{n}_{z} \otimes \boldsymbol{e}_{r}-\boldsymbol{e}_{r} \otimes \boldsymbol{n}_{z}-\left(\boldsymbol{e}_{r} \cdot \boldsymbol{n}_{z}\right) \overline{\bar{I}}\right] \\
& -\frac{6(\lambda+\mu)}{8 \pi(\lambda+2 \mu)} \cdot \frac{\boldsymbol{e}_{r} \cdot \boldsymbol{n}_{z}}{r^{2}} \boldsymbol{e}_{r} \otimes \boldsymbol{e}_{r} \tag{6}
\end{align*}
$$

$$
\begin{aligned}
& r=r(z-\boldsymbol{x}), \quad \boldsymbol{e}_{r}=\boldsymbol{e}_{r}(\boldsymbol{z}-\boldsymbol{x}), \\
& \overline{\bar{T}}\left(\boldsymbol{y}-\boldsymbol{x}, \boldsymbol{n}_{y}\right)=\left.\overline{\bar{T}}\left(\boldsymbol{z}-\boldsymbol{x}, \boldsymbol{n}_{z}\right)\right|_{z=\boldsymbol{y} \in S}
\end{aligned}
$$

Using (5), we obtain the displacement discontinuity on the crack:

$$
\begin{equation*}
\left[u\left(x_{0}\right)\right] \equiv u\left(x_{0}^{+}\right)-u\left(x_{0}^{-}\right)=\psi\left(x_{0}\right), \quad \forall x_{0} \in S \tag{7}
\end{equation*}
$$

This discontinuity is thus directly related to the unknown density $\psi(y \in S)$. Knowing $\psi(y \in S)$ will allow us to calculate, in particular, the stress intensity factors.

## 2) The state of stress

Since the boundary conditions are expressed in terms of stresses, we have to derive the expression of the stress from the displacement. According to (3), we have:

$$
\begin{equation*}
\forall x \in E_{3}: t\left(\boldsymbol{x}, \boldsymbol{n}_{x}\right)=\mathscr{T}\left(\partial_{x}, \boldsymbol{n}_{x}\right) \boldsymbol{u}(\boldsymbol{x})=\mathscr{T}\left(\partial_{x}, \boldsymbol{n}_{x}\right) \int_{S}^{\overline{\bar{T}}^{T}}\left(\boldsymbol{y}-\boldsymbol{x}, \boldsymbol{n}_{y}\right) \psi(\boldsymbol{y}) \mathrm{d} S_{y} \tag{8}
\end{equation*}
$$

where $\mathscr{T}\left(\partial_{\mathrm{x}}, \boldsymbol{n}_{\mathrm{x}}\right)$ is the stress operator:

$$
\begin{equation*}
\mathscr{T}\left(\partial_{x}, \boldsymbol{n}_{x}\right)=2 \mu \frac{\mathrm{~d}}{\mathrm{~d} n_{x}}+\mu \boldsymbol{n}_{x} \Lambda \operatorname{rot}+\lambda \boldsymbol{n}_{x} \operatorname{div}=c_{i j k l} \cdot n_{j}(\boldsymbol{x}) \cdot \frac{\partial}{\partial x_{l}} \tag{9}
\end{equation*}
$$

where:

$$
\begin{equation*}
c_{i j k l}=\lambda \delta_{i j} \cdot \delta_{k l}+\mu\left(\delta_{i k} \cdot \delta_{j l}+\delta_{i l} \cdot \delta_{k j}\right) \tag{10}
\end{equation*}
$$

Let the Green's tensor of the Navier's operator be $\overline{\bar{E}}(\boldsymbol{z}-\boldsymbol{x})$ (also identified as Kelvin-Somigliana tensor):

$$
\begin{equation*}
\overline{\bar{E}}(z-\boldsymbol{x})=\frac{1}{8 \pi \mu(\lambda+2 \mu)}\left[(\lambda+3 \mu) \overline{\bar{I}}+(\lambda+\mu) \boldsymbol{e}_{r} \otimes \boldsymbol{e}_{r}\right] \cdot \frac{1}{r} \tag{11}
\end{equation*}
$$

Where:

$$
\boldsymbol{e}_{r}=\boldsymbol{e}_{r}(\boldsymbol{z}-\boldsymbol{x}), \quad r=r(\boldsymbol{z}-\boldsymbol{x})
$$

By denoting:

$$
U\left(e_{i}, z-x\right)=\overline{\bar{E}}(z-x) \cdot e_{i}
$$

We have [7] (see notations of (4)):

$$
\begin{equation*}
\mathscr{L} \boldsymbol{U}\left(\boldsymbol{e}_{i}, z-\boldsymbol{x}\right)=-\delta_{R^{3}}(z-x) \cdot \boldsymbol{e}_{i} \tag{12}
\end{equation*}
$$

where $\delta_{R^{3}}(z-x)$ denotes the Dirac measure concentrated at the point $z$.
On account of the equality:

$$
\overline{\bar{T}}\left(z-\boldsymbol{x}, \boldsymbol{n}_{z}\right)=\mathscr{T}\left(\partial_{z}, \boldsymbol{n}_{z}\right) \overline{\bar{E}}(z-\boldsymbol{x})
$$

the stress vector at a point $\boldsymbol{x}$, with respect to the normal $\boldsymbol{n}_{x}$ can be rewritten in the form:

$$
\begin{equation*}
\boldsymbol{t}\left(\boldsymbol{x}, \boldsymbol{n}_{x}\right)=\left.\mathscr{T}\left(\partial_{x}, \boldsymbol{n}_{x}\right) \int_{S}\left[\mathscr{T}\left(\partial_{z}, \boldsymbol{n}_{z}\right) \overline{\bar{E}}(\boldsymbol{z}-\boldsymbol{x})\right]^{T}\right|_{z=y} . \psi(\boldsymbol{y}) \mathrm{d} S_{y} \tag{13}
\end{equation*}
$$

i.e., for the $l$-component, using:

$$
\begin{align*}
& \frac{\partial E_{i j}}{\partial x_{k}}(z-\boldsymbol{x})=-\frac{\partial E_{i j}}{\partial z_{k}}(z-\boldsymbol{x}) \\
& \begin{aligned}
t_{l}\left(\boldsymbol{x}, \boldsymbol{n}_{x}\right) & =\left.\mathscr{T}_{l j}\left(\partial_{x}, \boldsymbol{n}_{x}\right) \int_{S}\left[\mathscr{T}_{i k}\left(\partial_{z}, \boldsymbol{n}_{z}\right) E_{k j}(z-\boldsymbol{x})\right]\right|_{z=\boldsymbol{y}} \psi_{i}(\boldsymbol{y}) \mathrm{d} S_{y} \\
& =-c_{l p j r} c_{i s k t} \cdot n_{p}(\boldsymbol{x}) \int_{S} \frac{\partial}{\partial z_{r}} \frac{\partial E_{k j}}{\partial z_{t}}(\boldsymbol{y}-\boldsymbol{x}) \cdot n_{s}(\boldsymbol{y}) \cdot \psi_{i}(\boldsymbol{y}) \mathrm{d} S_{y}
\end{aligned}
\end{align*}
$$

where:

$$
\left.\frac{\partial}{\partial z_{r}} \frac{\partial E_{k j}}{\partial z_{t}}(\boldsymbol{y}-\boldsymbol{x}) \equiv \frac{\partial}{\partial z_{r}} \frac{\partial E_{k j}(z-\boldsymbol{x})}{\partial z_{t}}\right|_{z=\boldsymbol{y} \in S}
$$

Since $E_{k j}$ has a point singularity of the type $r^{-1}$, the kernel of integral (14) has a singularity of the type $r^{-3}$. This prevents us from applying the theorems on the limit behaviour of double-layer potentials. Therefore it is necessary to perform some additional transformations so as to obtain afterwards a kernel of the type $r^{-2}$. This will be achieved by using the Stokes theorem:

$$
\int_{S} \operatorname{rot}_{z} a(y) \cdot n_{y} \mathrm{~d} S_{y}=\int_{\partial S} a(y) \mathrm{d} \boldsymbol{l}_{y}
$$

where rot $_{z}$ implies that the derivatives must be performed with respect to the variable $z_{i}$ :

$$
\left.\operatorname{rot}_{z} a(y) \equiv \operatorname{rot}_{z} a(z)\right|_{z=y \in S}
$$

and $\mathrm{d} \boldsymbol{l}_{y}$ is the contour element vector:

$$
\mathrm{d} \boldsymbol{l}_{y}=\mathrm{d} y_{i} \cdot \boldsymbol{e}_{i}
$$

Setting:

$$
a(z)=f(z) \cdot a_{0}
$$

where $a_{0}$ is some arbitrary constant vector, we obtain:

$$
\int_{S} \operatorname{grad}_{z} f \Lambda \boldsymbol{n}_{y} \mathrm{~d} S_{y}=-\oint_{\partial S} f \mathrm{~d} l .
$$

i.e., for the $m$-component:

$$
\begin{equation*}
\int_{S} \epsilon_{m j k} f_{, j} \cdot n_{k}(\boldsymbol{y}) \mathrm{d} S_{y}=-\oint_{\partial S} f \mathrm{~d} y_{m} \tag{15}
\end{equation*}
$$

Multiplying both sides of (15) by $\epsilon_{\text {msr }}$, and taking into account:

$$
\epsilon_{m s r} \cdot \epsilon_{m j k}=\delta_{s j} \cdot \delta_{r k}-\delta_{s k} \cdot \delta_{r j}
$$

we arrive at the following relation:

$$
\begin{equation*}
\oint_{\partial S} \epsilon_{m s r} . f \mathrm{~d} y_{m}=\int_{S}\left(f_{, r} n_{s}-f_{, s} n_{r}\right) \mathrm{d} S \tag{16}
\end{equation*}
$$

Setting here:

$$
f(z)=\psi_{i}(z) \cdot E_{k j, t}(z-x),
$$

we obtain:

$$
\begin{equation*}
\int_{S} \psi_{i} n_{s} E_{k j, t r} \mathrm{~d} S=\int_{S} \kappa_{r s}^{i} \cdot E_{k j, t} \mathrm{~d} S+\int_{S} \psi_{i} n_{r} E_{k j, s t} \mathrm{~d} S+\oint_{\partial S} \epsilon_{m s r} \psi_{i} E_{k j, t} \mathrm{~d} y_{m} \tag{17}
\end{equation*}
$$

where $\kappa_{\mathrm{rs}}^{\mathrm{i}}$ is defined by:

$$
\begin{align*}
\kappa_{r s}^{i}(\boldsymbol{y}) & =n_{r}(\boldsymbol{y}) \psi_{i, s}(\boldsymbol{y})-n_{s}(\boldsymbol{y}) \psi_{i, r}(\boldsymbol{y}) \\
& \left.\equiv n_{r}(\boldsymbol{y}) \frac{\partial \psi_{i}(z)}{\partial z_{s}}\right|_{z=y \in S}-\left.n_{s}(\boldsymbol{y}) \frac{\partial \psi_{i}(z)}{\partial z_{r}}\right|_{z=\boldsymbol{y} \in S} \tag{18}
\end{align*}
$$

Substituting (17) in (14) gives:

$$
\begin{aligned}
t_{l}\left(\boldsymbol{x}, \boldsymbol{n}_{x}\right)= & -c_{l p j r} c_{i s k t} n_{p}(\boldsymbol{x}) \int_{S} \kappa_{r s}^{i} E_{k j, t}(\boldsymbol{y}-\boldsymbol{x}) \mathrm{d} S \\
& -c_{l p j r} c_{i s k t} n_{p}(\boldsymbol{x}) \int_{S} \psi_{i} n_{r} E_{k j, s t} \mathrm{~d} S \\
& -c_{l p j r} c_{i s k t} n_{p}(\boldsymbol{x}) \oint_{\partial S} \epsilon_{m s t} \psi_{i} E_{k j, t} \mathrm{~d} y_{m} .
\end{aligned}
$$

Now in virtue of (10) and (12):

$$
c_{i s k t} E_{k j, s t}=\mu E_{i j . s s}+(\lambda+\mu) E_{k j, i k}=\boldsymbol{e}_{j} \cdot \mathscr{L} \boldsymbol{U}\left(\boldsymbol{e}_{i}, \boldsymbol{y}-\boldsymbol{x}\right)=-\delta_{i j} . \delta_{R^{3}}(\boldsymbol{y}-\boldsymbol{x})=0
$$

since $\boldsymbol{x} \notin S$, we eventually obtain:

$$
\begin{aligned}
t_{l}\left(\boldsymbol{x}, \boldsymbol{n}_{x}\right)= & -c_{l p j r} c_{i s k t} n_{p}(\boldsymbol{x}) \int_{S} \kappa_{r s}^{i} \cdot \frac{\partial E_{k j}}{\partial z_{t}}(\boldsymbol{y}-\boldsymbol{x}) \mathrm{d} S_{y} \\
& +c_{l p j r} c_{i s k t} n_{p}(\boldsymbol{x}) \oint_{\partial S} \epsilon_{m r s} \psi_{i} E_{k j . t} \mathrm{~d} y_{m}
\end{aligned}
$$

which gives, after performing all summations:

$$
\begin{align*}
t_{l}\left(\boldsymbol{x}, \boldsymbol{n}_{x}\right)= & \frac{\mu n_{p}(\boldsymbol{x})}{8 \pi(1-\nu)} \int_{S} \frac{1}{r^{2}}\left\{4 \nu \delta_{l p} \kappa_{i k}^{i} r_{. k}\right. \\
& +(1-2 \nu)\left[\kappa_{i p}^{i} r_{. l}+\kappa_{i l}^{i} r_{. p}+r_{. k}\left(\kappa_{p k}^{l}+\kappa_{l k}^{p}\right)\right] \\
& \left.+3 r_{. i} r_{, k}\left(\kappa_{p k}^{i} r_{, l}+\kappa_{l k}^{i} r_{. p}\right)\right\} \mathrm{d} S_{y} \\
& -\frac{\mu n_{p}(\boldsymbol{x})}{8 \pi(1-\nu)} \oint_{\partial S} \frac{\psi_{i}}{r^{2}}\left\{4 \nu \delta_{l p} \epsilon_{m i k} r_{. k}+(1-2 \nu)\right. \\
& \times\left[\epsilon_{m i p} r_{. l}+\epsilon_{m i l} r_{. p}+r_{. k}\left(\epsilon_{m p k} \delta_{i l}+\epsilon_{m l k} \delta_{i p}\right)\right] \\
& \left.+3 r_{, i} r_{. k}\left(\epsilon_{m p k} r_{. l}+\epsilon_{m l k} r_{. p}\right)\right\} \mathrm{d} y_{m} \tag{19}
\end{align*}
$$

where:

$$
r=r(\boldsymbol{y}-\boldsymbol{x}),\left.\quad r_{. j} \equiv \frac{\partial r(\boldsymbol{z}-\boldsymbol{x})}{\partial z_{i}}\right|_{z=\boldsymbol{y} \in S}
$$

Thus, the stress vector is written as a sum of surface and line integrals, the kernel of surface integral is singular as $r^{-2}$. Next we will pass to the limit as $\boldsymbol{x} \rightarrow \boldsymbol{x}_{0}^{ \pm}$, the limit behaviour of double-layer potential being now available. On the other hand, when passing to the limit, there is no singularity in the line integral, since we have assumed the surface $S$ does not include its boundary $\partial S$ (see $\S 2$ - Basic notations), so that $r^{-2}$ in the line integral remains bounded when $x$ tends to $x_{0} \in S$. However, for $x_{0}$ close by the contour $\partial S$, numerical difficulties should be expected.

Starting from another point of view, V. Sladek and J. Sládek [6] obtained similar equations where the displacement discontinuity $[\boldsymbol{u}]$ was involved instead of $\psi$. Despite the equality (7), there are more difficulties in formulating surface or through crack problems in terms of $[\boldsymbol{u}]$. This will be well illustrated in the example by the end of this paper. For embedded crack problems, these two points of view are equivalent. Moreover, in [6], the crack $S$ is considered as a closed surface resulting from the union of its upper and lower faces $S^{+}$and $S^{-}$, so the line integral taken on the boundary $\partial S$ vanishes. On the contrary
$S$, herein considered, is regarded as a geometric surface through which the displacement field is subjected to a discontinuity.

For an embedded crack we have:

$$
[u(y)] \equiv u\left(y^{+}\right)-u\left(y^{-}\right) \equiv 0, \quad \forall y \in \partial S
$$

which is equivalent to, by virtue of (7):

$$
\psi(y)=0, \quad \forall y \in \partial S
$$

thus the line integral vanishes, and this result is consistent with Slàdek's equations. On the other hand, for a surface or through crack, we have:

$$
\exists y \in \partial S:[u(y)] \neq 0
$$

The line integral does not vanish on a portion $L$ included in $\partial S$ ( $L$ may be the union of separate arcs of $\partial S$ ), and it is reduced to a line integral taken along $L$. As mentioned before, the kernel of the line integral is not singular, we shall denote it for simplicity:

$$
\int_{L} \frac{\psi_{i}(\boldsymbol{y}) \cdot f_{l m p}^{i}(\boldsymbol{y}-\boldsymbol{x})}{r^{2}(\boldsymbol{y}-\boldsymbol{x})} \mathrm{d} y_{m}
$$

## 5. Integral equations

Formula (19) will allow us to express the boundary condition (1) in terms of stresses. For this purpose, the limit of the $l$-component of stress $t_{l}\left(\boldsymbol{x}, \boldsymbol{n}_{x}\right)$ as $\boldsymbol{x} \rightarrow \boldsymbol{x}_{0}^{ \pm}$and $\boldsymbol{n}_{x}=\boldsymbol{n}_{x_{0}}, \boldsymbol{x}_{0}$ $\in S$, is investigated (Fig. 2).

As was mentioned previously in $\S 2$ - Basic notations, $S$ is a Liapunov surface, i.e. belonging to the class $V^{1, \alpha}, 0<\alpha \leqslant 1$. Moreover, $\psi_{\mid S}$ was assumed to belong to the class

Figure 2. Case when $\boldsymbol{x} \rightarrow \boldsymbol{x}_{0}^{+}$and $\boldsymbol{n}_{\boldsymbol{x}}=\boldsymbol{n}_{x_{0}}$

$$
r=r(y-x), r_{0}=r\left(y-x_{0}\right)
$$

$C^{1, \alpha}(S) \subset C^{0, \alpha}(S)$. Then one can prove the following formulae, valid for any point $\boldsymbol{x}_{0} \in S$ :

$$
\begin{align*}
& \lim _{x \rightarrow \boldsymbol{x}_{0}^{ \pm}, \boldsymbol{n}_{x}=\boldsymbol{n}_{x_{0}}} \int_{S} \frac{\boldsymbol{e}_{r}(\boldsymbol{y}-\boldsymbol{x}) \otimes \boldsymbol{n}_{y}}{r^{2}(\boldsymbol{y}-\boldsymbol{x})} \psi(\boldsymbol{y}) \mathrm{d} S_{y} \\
= & \mp 2 \pi\left(\boldsymbol{n}_{x_{0}} \otimes \boldsymbol{n}_{x_{0}}\right) \psi\left(\boldsymbol{x}_{0}\right)+p v \int_{S} \frac{\boldsymbol{e}_{r}\left(\boldsymbol{y}-\boldsymbol{x}_{0}\right) \otimes \boldsymbol{n}_{y}}{r^{2}\left(\boldsymbol{y}-\boldsymbol{x}_{0}\right)} \cdot \psi(\boldsymbol{y}) \mathrm{d} S_{y}  \tag{20a}\\
& \lim _{\boldsymbol{x} \rightarrow \boldsymbol{x}_{0}^{ \pm}, \boldsymbol{n}_{x}=\boldsymbol{n}_{x_{0}}} \int_{S} \frac{\boldsymbol{e}_{r}(\boldsymbol{y}-\boldsymbol{x}) \cdot \boldsymbol{n}_{y}}{r^{2}(\boldsymbol{y}-\boldsymbol{x})} \psi(\boldsymbol{y}) \mathrm{d} S_{y} \\
= & \mp 2 \pi \psi\left(\boldsymbol{x}_{0}\right)+p v \int_{S} \frac{\boldsymbol{e}_{r}\left(\boldsymbol{y}-\boldsymbol{x}_{0}\right) \cdot \boldsymbol{n}_{y}}{r^{2}\left(\boldsymbol{y}-\boldsymbol{x}_{0}\right)} \cdot \psi(\boldsymbol{y}) \mathrm{d} S_{y}  \tag{20b}\\
= & \lim _{\boldsymbol{x} \rightarrow \boldsymbol{x}_{0}^{ \pm}, \boldsymbol{n}_{x}=\boldsymbol{n}_{x_{0}}} \int_{S} \frac{n_{r} r_{, p}}{r^{2}}\left(\boldsymbol{e}_{r} \otimes \boldsymbol{e}_{r}\right) \psi(\boldsymbol{y}) \mathrm{d} S_{y} \\
= & \frac{2 \pi}{3}\left[n_{l}\left(\boldsymbol{e}_{p} \otimes \boldsymbol{n}_{y}+\boldsymbol{n}_{y} \otimes \boldsymbol{e}_{p}\right)+n_{l} n_{p}\left(\overline{\bar{I}}-2 \boldsymbol{n}_{y} \otimes \boldsymbol{n}_{y}\right)\right] \psi\left(\boldsymbol{x}_{0}\right) \\
& +p v \int_{S} \frac{n_{l} r_{. p}}{r^{2}}\left(\boldsymbol{e}_{r} \otimes \boldsymbol{e}_{r}\right) \psi(\boldsymbol{y}) \mathrm{d} S_{y} \tag{20c}
\end{align*}
$$

It should be noticed that every function occuring in the left-hand sides of (20) is expressed in terms of $\boldsymbol{y}$ or $(\boldsymbol{y}-\boldsymbol{x})$, whereas that in the right-hand side in terms of $\boldsymbol{y}$ or $\left(\boldsymbol{y}-\boldsymbol{x}_{0}\right)$. One also remarks the discontinuity when passing to the limit as $\boldsymbol{x} \rightarrow \boldsymbol{x}_{0}^{ \pm}$.

From (20c), we obtain by changing the indices $l, p$, a symmetric equation:

$$
\begin{align*}
& \lim _{\boldsymbol{x} \rightarrow \boldsymbol{x}_{0}^{ \pm}, \boldsymbol{n}_{x}=\boldsymbol{n}_{x_{0}}} \int_{S} \frac{n_{l} r_{, p}+n_{p} r_{, l}}{r^{2}}\left(\boldsymbol{e}_{r} \otimes \boldsymbol{e}_{r}\right) \psi(\boldsymbol{y}) \mathrm{d} S_{y} \\
&= \mp \frac{2 \pi}{3}\left[\left(n_{l} \boldsymbol{e}_{p}+n_{p} \boldsymbol{e}_{l}\right) \otimes \boldsymbol{n}_{y}+\boldsymbol{n}_{y} \otimes\left(n_{l} \boldsymbol{e}_{p}+n_{p} \boldsymbol{e}_{l}\right)+2 n_{l} n_{p}\left(\overline{\bar{I}}-2 \boldsymbol{n}_{y} \otimes \boldsymbol{n}_{y}\right)\right] \psi\left(\boldsymbol{x}_{0}\right) \\
&+p v \int_{S} \frac{n_{l} \boldsymbol{r}_{, p}+n_{p} r_{, l}}{r^{2}}\left(\boldsymbol{e}_{r} \otimes \boldsymbol{e}_{r}\right) \psi(\boldsymbol{y}) \mathrm{d} S_{y} \tag{20d}
\end{align*}
$$

Moreover, setting $l=p$ in (20c), we have:

$$
\begin{align*}
& \lim _{\boldsymbol{x} \rightarrow \boldsymbol{x}_{0}^{ \pm}, \boldsymbol{n}_{x}=\boldsymbol{n}_{x_{0}}} \int_{S} \frac{\boldsymbol{e}_{r} \cdot \boldsymbol{n}_{y}}{r^{2}}\left(\boldsymbol{e}_{r} \otimes \boldsymbol{e}_{r}\right) \psi(\boldsymbol{y}) \mathrm{d} S_{y} \\
= & \mp \frac{2 \pi}{3} \psi\left(\boldsymbol{x}_{0}\right)+p v \int_{S} \frac{\boldsymbol{e}_{r} \cdot \boldsymbol{n}_{y}}{r^{2}}\left(\boldsymbol{e}_{r} \otimes \boldsymbol{e}_{r}\right) \psi(\boldsymbol{y}) \mathrm{d} S_{y} \tag{20e}
\end{align*}
$$

Using (20), we easily obtain:

$$
\begin{align*}
& n_{p}\left(x_{0}\right) \delta_{l p} \lim _{x \rightarrow x_{0}^{ \pm}, n_{x}=n_{x_{0}}} \int_{S} \frac{\kappa_{i k}^{i} r_{, k}}{r^{2}} \mathrm{~d} S_{y} \\
& \quad=\mp 2 \pi\left(n_{l} n_{i} n_{k} \psi_{i, k}-n_{l} \psi_{i, i}\right)+n_{l}\left(x_{0}\right) \cdot p v \int_{S} \frac{\kappa_{i k \cdot}^{i} \cdot r_{. k}}{r^{2}} \mathrm{~d} S_{y} \tag{21a}
\end{align*}
$$

$$
\begin{align*}
& n_{p}\left(x_{0}\right) \lim _{x \rightarrow x_{0}^{ \pm}, n_{x}=n_{x_{0}}} \int_{S} \frac{1}{r^{2}}\left[\kappa_{i p}^{i} r_{, l}+\kappa_{i l}^{i} r_{, p}+r_{, k}\left(\kappa_{p k}^{l}+\kappa_{l k}^{p}\right)\right] \mathrm{d} S_{y} \\
& = \\
& \mp 2 \pi\left(n_{l} n_{p} n_{i} \psi_{i, p}-n_{l} \psi_{i, l}\right)+n_{p}\left(x_{0}\right)  \tag{21b}\\
& \quad \times p v \int_{S} \frac{1}{r^{2}}\left[\kappa_{i p}^{i} r_{, l}+\kappa_{i l}^{i} r_{, p}+r_{. k}\left(\kappa_{p k}^{l}+\kappa_{l k}^{p}\right)\right] \mathrm{d} S_{y} \\
& n_{p}\left(x_{0}\right) \lim _{x \rightarrow x_{0}^{ \pm}, n_{x}=n_{x_{0}}} \int_{S} \frac{1}{r^{2}} r_{, i} r_{. k}\left(\kappa_{p k}^{i} r_{, l}+\kappa_{l k}^{i} r_{, p}\right) \mathrm{d} S_{y} \\
& =\mp \frac{2 \pi}{3}\left(-n_{p} \psi_{l, p}-n_{p} \psi_{p, l}-2 n_{l} n_{i} n_{p} \psi_{i, p}+n_{k} \psi_{l, k}+n_{i} \psi_{i, l}+2 n_{l,} \psi_{i, i}\right)  \tag{21c}\\
& \quad+n_{p}\left(x_{0}\right) \cdot p v \int_{S} \frac{1}{r^{2}} r_{, i, k} r_{, k}\left(\kappa_{p k}^{i} r_{, l}+\kappa_{l k}^{i} r_{, p}\right) \mathrm{d} S_{y}
\end{align*}
$$

We recall that functions in the left-hand side of (21c) are reckoned at $\boldsymbol{y}$ or $(\boldsymbol{y}-\boldsymbol{x})$, whereas those in the right-hand side at $\boldsymbol{y}$ or $\left(\boldsymbol{y}-\boldsymbol{x}_{0}\right)$. On account of (21), the limit of the stress vector $t_{l}\left(\boldsymbol{x}, \boldsymbol{n}_{x}\right)$ as $\boldsymbol{x} \rightarrow \boldsymbol{x}_{0}^{ \pm}, \boldsymbol{n}_{x}=\boldsymbol{n}_{x_{0}}$, can be written in the form:

$$
\begin{aligned}
& \lim _{x \rightarrow x_{0}^{ \pm}, n_{x}=n_{x_{0}}} t_{l}\left(x, n_{x}\right)=\mp[\ldots]+\frac{\mu n_{p}\left(x_{0}\right)}{8 \pi(1-\nu)} p v \int_{S}[\ldots] \mathrm{d} S_{y}-\frac{\mu n_{p}\left(x_{0}\right)}{8 \pi(1-\nu)} . \\
& \int_{L} \frac{\psi_{i}(\boldsymbol{y}) f_{l m p}^{i}\left(\boldsymbol{y}-\boldsymbol{x}_{0}\right)}{r^{2}\left(\boldsymbol{y}-\boldsymbol{x}_{0}\right)} \mathrm{d} y_{m}
\end{aligned}
$$

One can easily verify that the first bracket is identically zero, so that the limits as $\boldsymbol{x} \rightarrow \boldsymbol{x}_{0}^{+}$and $\boldsymbol{x} \rightarrow \boldsymbol{x}_{0}^{-}$coincide. This "continuity" is predicted by the Liapunov-Tauber theorem (see for instance [7] or [8] as well). It should be noticed that the line integral on $L$ is not singular. We eventually arrive at the following formula:

$$
\begin{align*}
t_{l}\left(x_{0}, n_{x_{0}}\right)= & \frac{\mu n_{p}\left(x_{0}\right)}{8 \pi(1-\nu)} p v \int_{S} \frac{1}{r^{2}}\left\{4 \nu \delta_{l p} \kappa_{i k}^{i} r_{, k}+(1-2 \nu)\right. \\
& \left.\times\left[\kappa_{i p}^{i} r_{, l}+\kappa_{i l}^{i} r_{, p}+r_{, k}\left(\kappa_{p k}^{\prime}+\kappa_{l k}^{p}\right)\right]+3 r_{, i} r_{, k}\left(\kappa_{p k}^{i} r_{, l}+\kappa_{l k}^{i} r_{, p}\right)\right\} \\
& \times \mathrm{d} S_{y}-\frac{\mu n_{p}\left(x_{0}\right)}{8 \pi(1-\nu)} \int_{L} \frac{\psi_{i}(\boldsymbol{y}) \cdot f_{l m p}^{i}\left(\boldsymbol{y}-\boldsymbol{x}_{0}\right)}{r^{2}\left(\boldsymbol{y}-\boldsymbol{x}_{0}\right)} \mathrm{d} y_{m} \tag{22}
\end{align*}
$$

where $t_{l}\left(\boldsymbol{x}_{0}, \boldsymbol{n}_{x_{0}}\right)$ is understood in the sense of a limit, and:

$$
\begin{aligned}
& \kappa_{j k}^{i}(\boldsymbol{y})=n_{j}(\boldsymbol{y}) \cdot \psi_{i, k}(\boldsymbol{y})-n_{k}(\boldsymbol{y}) \psi_{i j}(\boldsymbol{y}) \\
& r=r\left(\boldsymbol{y}-\boldsymbol{x}_{0}\right)=\left\|\boldsymbol{y}-\boldsymbol{x}_{0}\right\| \\
& \left.r_{, i} \equiv \frac{\partial r(\boldsymbol{z}-\boldsymbol{x})}{\partial z_{i}}\right|_{\substack{z=y \in S \\
\boldsymbol{x}=x_{0} \in S}}=\left.\frac{\partial r\left(\boldsymbol{z}-\boldsymbol{x}_{0}\right)}{\partial z_{i}}\right|_{z=\boldsymbol{y} \in S}
\end{aligned}
$$

For calculations in curvilinear coordinates (e.g. in cylindrical or spherical coordinates) it should be interesting to write (22) in the tensor form. Without more details, we give the
final result:

$$
\begin{align*}
\boldsymbol{t}\left(\boldsymbol{x}_{0}, \boldsymbol{n}_{x_{0}}\right)= & \frac{\mu}{8 \pi(1-\nu)} p v \int_{S} \frac{1}{r^{2}}\left\{4 \nu\left(\boldsymbol{n}_{y} \operatorname{grad} \psi \boldsymbol{e}_{r}-\left(\boldsymbol{n}_{y} \boldsymbol{e}_{r}\right) \operatorname{div} \psi\right) \boldsymbol{n}_{x_{0}}\right. \\
& +\left[(1-2 \nu)\left(\boldsymbol{n}_{y} \operatorname{grad} \psi \boldsymbol{n}_{x_{0}}-\left(\boldsymbol{n}_{y} \boldsymbol{n}_{x_{0}}\right) \operatorname{div} \psi\right)+3\left(\boldsymbol{n}_{y} \boldsymbol{n}_{x_{0}}\right) \boldsymbol{e}_{r} \operatorname{grad} \psi \boldsymbol{e}_{r}\right. \\
& \left.-3\left(\boldsymbol{n}_{y} \boldsymbol{e}_{r}\right)\left(\boldsymbol{e}_{r} \operatorname{grad} \psi \boldsymbol{n}_{x_{0}}\right)\right] \boldsymbol{e}_{r}+\left[(1-2 \nu)\left(\boldsymbol{n}_{x_{0}} \operatorname{grad} \psi \boldsymbol{e}_{r}-\left(\boldsymbol{n}_{x_{0}} \boldsymbol{e}_{r}\right) \operatorname{div} \psi\right)\right. \\
& \left.+3\left(\boldsymbol{n}_{x_{0}} \boldsymbol{e}_{r}\right) \boldsymbol{e}_{r} \operatorname{grad} \psi \boldsymbol{e}_{r}\right] \boldsymbol{n}_{y}+(1-2 \nu)\left[\left(\boldsymbol{n}_{x_{0}} \boldsymbol{e}_{r}\right) \operatorname{grad}^{T} \psi \boldsymbol{n}_{y}\right. \\
& \left.+\left(\boldsymbol{n}_{y} \boldsymbol{n}_{x_{0}}\right) \operatorname{grad} \psi \boldsymbol{e}_{r}-\left(\boldsymbol{n}_{y} \boldsymbol{e}_{r}\right) \operatorname{grad} \psi \boldsymbol{n}_{x_{0}}-\left(\boldsymbol{n}_{y} \boldsymbol{e}_{r}\right) \operatorname{grad}^{T} \psi \boldsymbol{n}_{x_{0}}\right] \\
& \left.-3\left(\boldsymbol{n}_{x_{0}} \boldsymbol{e}_{r}\right)\left(\boldsymbol{n}_{y} \boldsymbol{e}_{r}\right) \operatorname{grad}^{T} \psi \boldsymbol{e}_{r}\right\} \mathrm{d} S_{y} \\
& -\frac{\mu}{8 \pi(1-\boldsymbol{\nu})} \int_{L} \frac{1}{r^{2}}\left\{4 \nu\left[\psi\left(\boldsymbol{e}_{r} \Lambda \mathrm{~d} \boldsymbol{l}\right)\right] \boldsymbol{n}_{x_{0}}+\left\{(1-2 \nu)\left[\left(\psi \Lambda \boldsymbol{n}_{x_{0}}\right) \mathrm{d} \boldsymbol{l}\right]\right.\right. \\
& \left.+3\left[\boldsymbol{n}_{x_{0}}\left(\boldsymbol{e}_{r} \Lambda \mathrm{~d} \boldsymbol{l}\right)\right]\left(\boldsymbol{e}_{r} \psi\right)\right\} \boldsymbol{e}_{r}+(1-2 \nu)\left[\boldsymbol{n}_{x_{0}}\left(\boldsymbol{e}_{r} \Lambda \mathrm{~d} \boldsymbol{l}\right)\right] \psi \\
& +(1-2 \nu)\left(\boldsymbol{e}_{r} \boldsymbol{n}_{x_{0}}\right) \mathrm{d} \boldsymbol{l} \Lambda \psi+\left[(1-2 \nu)\left(\psi \boldsymbol{n}_{x_{0}}\right)+3\left(\boldsymbol{e}_{r} \psi\right)\left(\boldsymbol{e}_{r} \boldsymbol{n}_{x_{0}}\right)\right] \boldsymbol{e}_{r} \Lambda \mathrm{~d} \boldsymbol{l} \boldsymbol{l} \tag{22bis}
\end{align*}
$$

In the left-hand side of (22) and (22bis), the stress vector $\boldsymbol{t}\left(\boldsymbol{x}_{0}, \boldsymbol{n}_{x_{0}}\right)$ is known for each point $x_{0} \in S$. The derivatives $\psi_{i j}(\boldsymbol{y})$ appear in the right-hand side, these are the derivatives of the function $\psi$ with respect to three independent variables $z_{1}, z_{2}, z_{3}$, reckoned at a point $y \in S$. In fact, since the restriction of $\psi$ on $S$ is the unknown of the problem i.e. $\psi(\boldsymbol{y})$ for $\boldsymbol{y} \in S$, one must prove that these $\psi_{i j}$ are actually reduced to the derivatives of the restriction of $\psi$ on $S$, with respect to some suitable variables.

Let a parametric representation of $S$ be:

$$
(u, v) \in \Delta \mapsto y \in S=\boldsymbol{F}(u, v)=\left\lvert\, \begin{align*}
& F_{1}(u, v)  \tag{23}\\
& F_{2}(u, v) \\
& F_{3}(u, v)
\end{align*} \quad F \in C^{1, \alpha}(\Delta)\right.
$$

where $\Delta$ is a domain of $R^{2}$ and the components of $\boldsymbol{F}$ are given in Cartesian coordinates. The parameter $u$ must not be confused with the displacement. For a point $z$ of $E_{3}$ close to $S$, let us consider the coordinate transformation defined by:

$$
z \in E_{3}=\left\lvert\, \begin{align*}
& z_{1}  \tag{24}\\
& z_{2} \\
& z_{3}
\end{aligned}=\begin{aligned}
& F_{1}(u, v)+w \cdot n_{1}(u, v) \\
& F_{2}(u, v)+w \cdot n_{2}(u, v) \\
& F_{3}(u, v)+w \cdot n_{3}(u, v)
\end{align*}\right.
$$

where $\boldsymbol{n}_{y}\left(n_{1}, n_{2}, n_{3}\right)$ is the normal to $S$ at the point $\boldsymbol{y} \in S$ represented by the couple $(u, v)$. Since $S \in C^{1, \alpha}, 0<\alpha \leqslant 1$, every point of $S$ is a regular point, and $\boldsymbol{F}_{, u}$ and $\boldsymbol{F}_{. v}$ are linearly independent, so $\boldsymbol{n}_{y}$ is well defined:

$$
\boldsymbol{n}_{y}=\left\lvert\, \begin{align*}
& n_{1}(u, v)  \tag{25}\\
& n_{2}(u, v)=\boldsymbol{F}_{. u}(u, v) \Lambda \boldsymbol{F}_{. v}(u, v) /\left\|\boldsymbol{F}_{. u}(u, v) \Lambda \boldsymbol{F}_{. v}(u, v)\right\| \\
& n_{3}(u, v)
\end{align*}\right.
$$

The function $\psi(z)$ for $z \in E_{3}$ is written in the form:

$$
\begin{aligned}
\psi(z) & =\psi\left(z_{1}, z_{2}, z_{3}\right) \\
& =\psi\left(F_{1}(u, v)+w \cdot n_{1}(u, v), F_{2}(u, v)+w \cdot n_{2}(u, v), F_{3}(u, v)+w \cdot n_{3}(u, v)\right) .
\end{aligned}
$$

The restriction of $\psi$ on $S$ is then:

$$
\begin{equation*}
\psi(y \in S)=\psi\left(F_{1}(u, v), F_{2}(u, v), F_{3}(u, v)\right) \equiv \phi(u, v) \tag{26}
\end{equation*}
$$

The unknown of the problem is $\phi(u, v)$; it is to be proved that only the derivatives of $\phi(u, v)$ with respect to either $u$ or $v$ actually appear in the right-hand side of (22) or (22bis). We have:

$$
\left[\begin{array}{c}
\phi_{i, u}(u, v)  \tag{27}\\
\phi_{i, u}(u, v) \\
\frac{\partial \psi_{i}}{\partial n_{2}}(y \in S)
\end{array}\right]=\left[\begin{array}{ccc}
F_{1, u}(u, v) & F_{2, u}(u, v) & F_{3, u}(u, v) \\
F_{1, v}(u, v) & F_{2, v}(u, v) & F_{3, v}(u, v) \\
n_{1}(u, v) & n_{2}(u, v) & n_{3}(u, v)
\end{array}\right]\left[\begin{array}{l}
\psi_{i, 1}(y \in S) \\
\psi_{i, 2}(y \in S) \\
\psi_{i, 3}(y \in S)
\end{array}\right]
$$

We recall that: $\psi_{i, j}(y \in S)=\left.\frac{\partial \psi_{i}(z)}{\partial z_{j}}\right|_{z=y \in S}$
The system (27) can be inverted since $\boldsymbol{F}_{, u}, \boldsymbol{F}_{. v}$ and $\boldsymbol{n}$ are linearly independent, the determinant of the system is equal to: $\left(\boldsymbol{F}_{, u}, \boldsymbol{F}_{, v}, \boldsymbol{n}\right)=\left\|\boldsymbol{F}_{, u} \Lambda \boldsymbol{F}_{, v}\right\|$. We obtain:

$$
\left[\begin{array}{c}
\psi_{i, 1}(y \in S)  \tag{28}\\
\psi_{i, 2}(y \in S) \\
\psi_{i, 3}(y \in S)
\end{array}\right]=\left[\begin{array}{ccc}
A_{11} & A_{12} & n_{1} \\
A_{21} & A_{22} & n_{2} \\
A_{31} & A_{32} & n_{3}
\end{array}\right]\left[\begin{array}{c}
\phi_{i . u}(u, v) \\
\phi_{i, v}(u, v) \\
\frac{\partial \psi_{i}}{\partial n_{z}}(y \in S)
\end{array}\right]
$$

Thus:

$$
\begin{equation*}
\psi_{i j}(y \in S)=n_{j} \cdot \frac{\partial \psi_{i}}{\partial n_{z}}(y \in S)+(\ldots) \tag{29}
\end{equation*}
$$

where the parenthesis does not include $\frac{\partial \psi_{i}}{\partial n_{z}}(y \in S)$, but only $\phi_{i, u}$ and $\phi_{i, v}$. From (29), we have.

$$
\begin{equation*}
\left.\left(\operatorname{grad}_{z} \psi\right)(y \in S) \equiv \operatorname{grad}_{z} \psi(z)\right|_{z=y \in S}=\frac{\partial \psi}{\partial n_{z}}(y \in S) \otimes n_{y}+(\ldots) \tag{30a}
\end{equation*}
$$

and:

$$
\begin{equation*}
\left.\left(\operatorname{div}_{z} \psi\right)(y \in S) \equiv \operatorname{div}_{z} \psi(z)\right|_{z=y \in S}=\frac{\partial \psi}{\partial n_{z}}(y \in S) \cdot n_{y}+(\ldots) \tag{30b}
\end{equation*}
$$

Using the relations (30a) and (30b), one can easily verify that $\frac{\partial \psi}{\partial n_{z}}(y \in S)$ are actually not involved in the kernel of the surface integral of (22) and (22 bis). As was expected, only the derivatives of the restriction of $\psi$ on $S, \phi_{i, u}$ and $\phi_{i, v}$, appear in (22) to (22 bis). This point is important for the effective resolution of the integral equations.

Finally, in the usual case when $\boldsymbol{F}_{. u}$ is perpendicular to $\boldsymbol{F}_{. v}$, one can obtain from (22 bis) the integral equation for a general crack:

$$
\begin{align*}
& \boldsymbol{t}\left(\boldsymbol{x}_{0}, \boldsymbol{n}_{x_{0}}\right)=\frac{\mu}{8 \pi(1-\nu)} p v \int_{S} \frac{1}{r^{2}} \cdot \frac{1}{\left\|\boldsymbol{R}_{, u}\right\| \cdot\left\|\boldsymbol{F}_{. v}\right\|} \cdot \\
& \left\{\begin{array}{l}
2\left(\boldsymbol{\Phi}_{, u}, \boldsymbol{e}_{r}, \boldsymbol{F}_{. v}\right) \boldsymbol{n}_{x_{0}}-(1-2 \nu)\left(\boldsymbol{\Phi}_{, u}, \boldsymbol{e}_{r}, \boldsymbol{n}_{x_{0}}\right) \boldsymbol{F}_{, v}-(1-2 \nu)\left(\boldsymbol{F}_{. v} \cdot \boldsymbol{n}_{x_{0}}\right) \boldsymbol{\Phi}_{, u} \wedge \boldsymbol{e}_{r} \\
\quad+3\left(\boldsymbol{e}_{r} \cdot \boldsymbol{\Phi}_{. u}\right)\left[\left(\boldsymbol{F}_{. v}, \boldsymbol{n}_{x_{0}}, \boldsymbol{e}_{r}\right) \boldsymbol{e}_{r}+\left(\boldsymbol{n}_{x_{0}} \cdot \boldsymbol{e}_{r}\right) \boldsymbol{e}_{r} \wedge \boldsymbol{F}_{, v}\right] \\
\quad-2\left(\boldsymbol{\Phi}_{. v}, \boldsymbol{e}_{r}, \boldsymbol{F}_{, u}\right) \boldsymbol{n}_{x_{0}}+(1-2 \nu)\left(\boldsymbol{\Phi}_{, v}, \boldsymbol{e}_{r}, \boldsymbol{n}_{x_{0}}\right) \boldsymbol{F}_{, u}+(1-2 \nu)\left(\boldsymbol{F}_{, u} \cdot \boldsymbol{n}_{x_{0}}\right) \boldsymbol{\Phi}_{, v} \wedge \boldsymbol{e}_{r} \\
\left.\quad-3\left(\boldsymbol{e}_{r} \cdot \boldsymbol{\Phi}_{. v}\right)\left[\left(\boldsymbol{F}_{, u}, \boldsymbol{n}_{x_{0}}, \boldsymbol{e}_{r}\right) \boldsymbol{e}_{r}+\left(\boldsymbol{n}_{x_{0}} \cdot \boldsymbol{e}_{r}\right) \boldsymbol{e}_{r} \wedge \boldsymbol{F}_{. u}\right]\right\} \mathrm{d} S \boldsymbol{y} \\
\quad \frac{\mu}{8 \pi(1-\nu)} \int \frac{1}{L r^{2}}\left\{2\left(\boldsymbol{\Psi}, \boldsymbol{e}_{r}, \boldsymbol{d l}\right) \boldsymbol{n}_{x_{0}}+(1-2 \nu)\left[\left(\boldsymbol{e}_{r}, \boldsymbol{\Psi}, \boldsymbol{n}_{x_{0}}\right) \boldsymbol{d l}+\left(\boldsymbol{d l} \cdot \boldsymbol{n}_{x_{0}}\right) \boldsymbol{e}_{r} \wedge \boldsymbol{\Psi}\right]\right. \\
\quad\left\{+3\left(\boldsymbol{e}_{r} \cdot \boldsymbol{\Psi}\right)\left[\left(\boldsymbol{n}_{x_{0}}, \boldsymbol{e}_{r}, \boldsymbol{d l}\right) \boldsymbol{e}_{r}+\left(\boldsymbol{n}_{x_{0}} \cdot \boldsymbol{e}_{r}\right) \boldsymbol{e}_{r} \wedge \boldsymbol{d l}\right]\right\} \text {. }
\end{array}\right. \text { (22ter)}
\end{align*}
$$

## 6. Particular case of a plane crack

Let us consider a crack lying in the plane $P$ (Fig. 3). A natural choice of the coordinate system is so that $e_{3}$ is the normal orientating $P$, and $e_{1}, e_{2}$ lie in the plane. We may choose the following parametrization of $S$ :

$$
\boldsymbol{y} \in S=\boldsymbol{F}(u, v)=\left|\begin{array}{l}
F_{1}(u, v) \\
F_{2}(u, v) \\
F_{3}(u, v)
\end{array}=\right| \begin{aligned}
& u \\
& v=\left\{\begin{array}{l}
y_{1} \\
y_{2} \\
y_{3}=0
\end{array} ~\right.
\end{aligned}
$$

which obviously yields:

$$
\boldsymbol{F}_{, u}=(1,0,0), \boldsymbol{F}_{, v}=(0,1,0) \quad \text { and } \boldsymbol{n}(u, v)=(0,0,1)=\boldsymbol{e}_{3}
$$

From (26), the restriction of $\psi$ on $S$ is:

$$
\phi\left(y_{1}, y_{2}\right)=\psi\left(y_{1}, y_{2}, 0\right)
$$

According to the former discussion, the normal derivative $\frac{\partial \psi}{\partial n_{z}}(\boldsymbol{y} \in S)=\psi_{, 3}\left(y_{1}, y_{2}, 0\right)$ will not be involved, only the derivatives of the two-variables function $\phi$ remain:

$$
\phi_{i, 1}\left(y_{1}, y_{2}\right)=\psi_{i, 1}\left(y_{1}, y_{2}, 0\right) \quad \text { and } \phi_{i, 2}\left(y_{1}, y_{2}\right)=\psi_{i, 1}\left(y_{1}, y_{2}, 0\right)
$$

As:

$$
\begin{aligned}
& \boldsymbol{e}_{r}=\left(r_{, 1}, r_{, 2}, 0\right) \\
& \boldsymbol{n}_{y}=\boldsymbol{n}_{x_{0}}=\boldsymbol{e}_{3}=(0,0,1) \\
& \boldsymbol{e}_{r} \Lambda \mathrm{~d} \boldsymbol{l}=\sin \boldsymbol{\theta} \cdot \mathrm{d} l \cdot \boldsymbol{n}_{x_{0}}, \quad \boldsymbol{\theta} \equiv\left(\boldsymbol{e}_{r}, \hat{d} l\right) \\
& \boldsymbol{n}_{x_{0}}\left(\boldsymbol{e}_{r} \Lambda \mathrm{~d} \boldsymbol{l}\right)=\sin \boldsymbol{\theta} \cdot \mathrm{d} \boldsymbol{l}
\end{aligned}
$$

(22ter) is reduced to the following in a Cartesian coordinates system:

$$
\begin{aligned}
& \boldsymbol{t}\left(\boldsymbol{x}_{0}, \boldsymbol{n}_{x_{0}}\right)=\frac{\mu}{8 \pi(1-\nu)} p v \int_{S} \left\lvert\, \begin{array}{l}
\frac{1}{r^{2}}\left[(1-2 \nu)\left(\phi_{1,2} r_{, 2}-\phi_{2,2} r_{, 1}\right)+3 r_{, 1} r_{, \alpha} \phi_{\alpha, \beta} r_{, \beta}\right] \\
\frac{1}{r^{2}}\left[(1-2 \nu)\left(\phi_{2,1} r_{, 1}-\phi_{1,1} r_{, 2}\right)+3 r_{, 2} r_{, \alpha} \phi_{\alpha, \beta} r_{, \beta}\right] \\
\frac{2}{r^{2}} \phi_{3, \alpha} r_{, \alpha} .
\end{array}\right. \\
& -\frac{\mu}{8 \pi(1-\nu)} \int_{L} \frac{1}{r^{2}} \left\lvert\, \begin{array}{l}
{\left[(1-2 \nu)\left(\phi \Lambda n_{x_{0}}\right) \mathrm{d} \boldsymbol{l}+3\left(\boldsymbol{e}_{r} \phi\right) \sin \theta \mathrm{d} l\right] r_{, 1}+(1-2 \nu) \sin \theta \mathrm{d} l \phi_{1}} \\
{\left[(1-2 \nu)\left(\phi \Lambda \boldsymbol{n}_{x_{0}}\right) \mathrm{d} \boldsymbol{l}+3\left(\boldsymbol{e}_{r} \boldsymbol{\phi}\right) \sin \theta \mathrm{d} l\right] r_{, 2}+(1-2 \nu) \sin \theta \mathrm{d} l \phi_{2}} \\
(1+2 \nu)\left(\phi n_{x_{0}}\right) \sin \theta \mathrm{d} l+(1-2 \nu) \sin \theta \mathrm{d} l \phi_{3}
\end{array}\right.
\end{aligned}
$$

where the Greek indices take the value 1 or 2 .

Figure 3. Case of a plane crack.
a) In the case when the crack is embedded in the body, the line integral vanishes, the surface integral taken on $S$ only remains. The third equation of (31) is visibly identical to that of Bui [4]. Let us prove that the first two equations are also equivalent to those of Bui.

We make use of the formulae of integration by parts:

$$
\begin{align*}
& \iint \psi \phi_{, 1} \mathrm{~d} y_{1} \mathrm{~d} y_{2}=-\iint \psi_{, 1} \phi \mathrm{~d} y_{1} \mathrm{~d} y_{2}+\oint \psi \phi \mathrm{d} y_{2}  \tag{32}\\
& \iint \psi \phi_{, 2} \mathrm{~d} y_{1} \mathrm{~d} y_{2}=-\iint \psi_{, 2} \phi \mathrm{~d} y_{1} \mathrm{~d} y_{2}-\oint \psi \phi \mathrm{d} y_{1}
\end{align*}
$$

Having in mind that (22ter) involves a principal value, the surface integral in (32) must be performed over $S$ except a circle $\sigma\left(x_{0}, \boldsymbol{\epsilon}\right)$ with centre at $\boldsymbol{x}_{0}$, the radius $\epsilon$ of the circle tending to zero; the line integral in (32) must be for the same reason taken along the boundary of $\sigma\left(x_{0}, \epsilon\right)$. By these formulae, one may prove for instance:

$$
\begin{equation*}
3 p v \int_{S} \frac{r_{, 1} r_{, \alpha} r_{, \beta} \phi_{\alpha, \beta}}{r^{2}} \mathrm{~d} S_{y}=p v \int_{S}\left(\phi_{1,1}+\phi_{2,2}\right) \frac{r_{.1}}{r^{2}} \mathrm{~d} S_{y}+p v \int_{S} \phi_{1, \alpha} \frac{r_{, \alpha}}{r^{2}} \mathrm{~d} S_{y} \tag{33}
\end{equation*}
$$

One obtains then:

$$
\begin{align*}
& t_{1}\left(x_{0}, n_{x_{0}}\right)=\frac{\mu}{4 \pi} p v \int_{S} \frac{1}{r^{2}} \phi_{1, \alpha} r_{, \alpha} \mathrm{d} S_{y}+\frac{\mu \lambda}{4 \pi(\lambda+2 \mu)} .  \tag{34}\\
& p v \int_{S} \frac{1}{r^{2}} r_{, 1}\left(\phi_{1,1}+\phi_{2,2}\right) \mathrm{d} S_{y}
\end{align*}
$$

which is identical to that of [4].
It should be noticed that in this case of plane cracks, the mode I is uncoupled from modes II and III.
b) In some special problems, the density could take the form:

$$
\psi=\left(0,0, \psi_{3}\right)=\psi_{3} \cdot \boldsymbol{n}_{x_{0}}
$$

The first two equations are identically satisfied, as to the third one, it is reduced to:

$$
\begin{equation*}
t_{3}\left(x_{0}, \boldsymbol{n}_{x_{0}}\right)=\frac{\mu}{4 \pi(1-\nu)} p v \int_{S} \frac{\phi_{3}{ }_{3} r_{. \alpha}}{r^{2}} \mathrm{~d} S_{y}-\frac{\mu}{4 \pi(1-\nu)} \int_{L} \frac{\phi_{3} \sin \theta}{r^{2}} \mathrm{~d} l \tag{35}
\end{equation*}
$$

Putot studied in [5] the plane crack at a free surface in opening mode and obtained a system of equations without the line integral: he has considered the crack $S$ made of the union of the surface crack $F$ in question and its mirror image $\bar{F}$ through the plane of the free surface (Fig. 4). The symmetry of the problem, in particular the fact that $\psi_{3}$ successively defined on $F$ and $\bar{F}$ takes the same value at each point of $L$ whereas the associated line integrals are taken along opposite directions, implies that the line integral vanishes. When the free surface is not plane, a mirror image is meaningless and the line integral differs from zero.

## 7. Particular case of a cylindrical crack

Use will be made in this section of cylindrical coordinates ( $\rho, \theta, z$ ). Let us consider a crack curved in the shape of part of a cylindrical surface (Fig. 5), defined by:

$$
\left.y_{1}^{2}+y_{2}^{2}=R^{2}=\text { const., } \quad \theta \in\right]-\theta_{0}, \theta_{0}[, z \in]-z_{0}, z_{0}[.
$$

Following the notations of (23) to (30), we may choose a parametric representation of $S$ :

Figure 4. [5] Crossed-cracks configuration

$$
S=F \cup \bar{F}
$$

Figure 5. Case of a crack curved in the shape of part of a cylindrical surface.
which yields:

$$
\boldsymbol{F}_{, \theta}=R \boldsymbol{e}_{\theta}, \boldsymbol{F}_{, z}=\boldsymbol{e}_{3}, \boldsymbol{n}(\theta, z)=\boldsymbol{n}(\theta)=\boldsymbol{e}_{\rho} \quad \text { and } z \in E_{3}=\left|\begin{array}{l}
z_{1} \\
z_{2} \\
z_{3}
\end{array}=\right| \begin{aligned}
& (R+w) \sin \theta \\
& (R+w) \sin \theta \\
& z
\end{aligned}
$$

as $\boldsymbol{n}=\boldsymbol{e}_{\rho}$, and $\rho=R+w$, we have:

$$
\left.\frac{\partial \psi}{\partial n_{z}}(y \in S) \equiv \frac{\partial \psi((R+w) \cos \theta,(R+w) \sin \theta, z)}{\partial w}\right|_{w=0} \equiv \frac{\partial \psi}{\partial \rho}(y \in S)
$$

The restriction of $\psi$ on $S$ is:

$$
\phi(\theta, z)=\psi(R \cos \theta, R \sin \theta, z)
$$

The partial derivatives of $\psi$ with respect to $z_{1}, z_{2}, z_{3}$, calculated at a point $\boldsymbol{y} \in S$ are expressed by:

$$
\left[\begin{array}{c}
\psi_{i, 1}(y \in S)  \tag{36}\\
\psi_{i .2}(y \in S) \\
\psi_{i, 3}(y \in S)
\end{array}\right]=\left[\begin{array}{ccc}
-\frac{\sin \theta}{R_{\theta}} & 0 & \cos \theta \\
\frac{\cos \theta}{R} & 0 & \sin \theta \\
0 & 1 & 0
\end{array}\right]\left[\begin{array}{c}
\phi_{i, \theta}(\theta, z) \\
\phi_{i, z}(\theta, z) \\
\frac{\partial \psi_{i}}{\partial \rho}(y \in S)
\end{array}\right]
$$

It follows from the discussion in $\S 5$ that the normal derivative $\psi_{i, \rho}(y \in S)$ must eventually disappear in the integral equations (22) or (22bis), only the derivatives of the restriction $\phi$ of $\psi$ on $S$, with respect to $\theta$ and $z$ remain.

Equation (36) differs from (29) and (30) of [6], even though it leads to the same final result.

## 8. Problem of a through crack in a cylindrical thick tube

Let us consider a cylindrical tube with the axis $e_{3}$, its outer and inner faces are $\Sigma_{1}$ and $\Sigma_{2}$ respectively, the tube contains a through crack $S$ lying in a cross section (Fig. 6).

Figure 6. Through crack in a thick tube.

Let:

$$
\begin{aligned}
& L_{1}=\Sigma_{1} \cap S \\
& L_{2}=\Sigma_{2} \cap S \\
& L=L_{1} \cup L_{2}
\end{aligned}
$$

It is assumed that the tube is infinite along the $e_{3}$-axis, that $\Sigma_{1}, \Sigma_{2}$ are free surfaces, and the crack is subjected to the prescribed loading $t\left(x_{0}, \boldsymbol{n}_{\mathrm{x}_{0}}=\boldsymbol{e}_{3}\right)$.

Let the surface $S$ be oriented by $e_{3}$. One can imagine that the two faces $\Sigma_{1}, \Sigma_{2}$ are also two crack surfaces, and these three cracks $S, \Sigma_{1}, \Sigma_{2}$ are imbedded in an infinite elastic medium. Let us define the displacement field as the sum of three double-layer potentials (cf. (3)):

$$
\begin{align*}
\forall x \in R^{3}: u(x)= & \int_{S} \overline{\bar{T}}^{T}\left(\boldsymbol{y}-\boldsymbol{x}, \boldsymbol{n}_{y}\right) \psi^{1}(\boldsymbol{y}) \mathrm{d} S_{y}+\int_{\Sigma_{1}} \overline{\bar{T}}^{T}\left(\boldsymbol{y}-\boldsymbol{x}, \boldsymbol{n}_{y}\right) \psi^{2}(\boldsymbol{y}) \mathrm{d} \Sigma_{y} \\
& +\int_{\Sigma_{2}} \overline{\bar{T}}^{T}\left(\boldsymbol{y}-\boldsymbol{x}, \boldsymbol{n}_{y}\right) \psi^{3}(\boldsymbol{y}) \mathrm{d} \Sigma_{y} \tag{37}
\end{align*}
$$

where $n_{y}=e_{3}$ for $y \in S, n_{y}=e_{\rho}$ for $y \in \Sigma_{1}, n_{y}=-e_{\rho}$ for $y \in \Sigma_{2}$.
The densities $\psi^{1}, \psi^{2}, \psi^{3}$ are defined on three open sets containing respectively $S, \Sigma_{1}$ and $\Sigma_{2}$; their respective restrictions constitute the unknowns of the problems. The boundary conditions are to be specified separately:
a) on the crack surface $S$ : for each point $\boldsymbol{x}_{0} \in S$, the prescribed tension $\boldsymbol{t}\left(\boldsymbol{x}_{0}, \boldsymbol{n}_{x_{0}}=\boldsymbol{e}_{3}\right)$ must be in equilibrium on the one hand with the stress, (31), yielded by the density $\psi^{1}$ on $S$, on the other hand with the stresses, (19) yielded by the densities $\psi^{2}, \psi^{3}$ on $\Sigma_{1}$ and $\Sigma_{2}$ respectively. The associate integral equation has the form:

$$
\begin{align*}
& \forall x_{0} \in S \backslash L=S: p v \int_{S}[\ldots] \mathrm{d} S_{y}-\int_{L}[\ldots] \mathrm{d} l+\mathscr{T}\left(\partial_{x}, \boldsymbol{n}_{x}=\boldsymbol{e}_{3}\right) \\
& \left(\int_{\Sigma_{1}} \overline{\bar{T}}^{T} \psi^{2} \mathrm{~d} \Sigma_{y}+\int_{\Sigma_{2}} \overline{\bar{T}}^{T} \psi^{3} \mathrm{~d} \Sigma_{y}\right)=t\left(\boldsymbol{x}_{0}, \boldsymbol{n}_{x_{0}}=\boldsymbol{e}_{3}\right) \tag{38a}
\end{align*}
$$

where the brackets [ ], too long to be explicit, stand for the kernel of (31).
b) on the free surface $\Sigma_{1}$ : for each point $x_{0} \in \Sigma_{1}$, the sum of the stress generated by $\psi^{2}$ on $\Sigma_{1}$, and those by $\psi^{1}$ on $S$ and $\psi^{3}$ on $\Sigma_{2}$, is equal to zero. This gives the second integral equation which has the form:

$$
\begin{align*}
& V x_{0} \in \Sigma_{1} \backslash L_{1}: p v \int_{\Sigma_{1}}[\ldots] \mathrm{d} \Sigma_{y}+\mathscr{T}\left(\partial_{x}, \boldsymbol{n}_{x}=\boldsymbol{e}_{\boldsymbol{\rho}}\right) \\
& \left(\int_{S} \overline{\bar{T}}^{T} \psi^{1} \mathrm{~d} S_{y}+\int_{\Sigma_{2}} \overline{\bar{T}}^{T} \psi^{3} \mathrm{~d} \Sigma_{y}\right)=\mathbf{0} \tag{38b}
\end{align*}
$$

The first integral given by (22ter) involves now the density $\psi^{2}$, we notice that there is no line integral associated with the integral over $\Sigma_{1}$, the free surface being assumed to be infinite along the $e_{3}$-axis.
c) on the free surface $\Sigma_{2}$ : by the same way we obtain the third integral equations:

$$
\begin{align*}
& \forall x_{0} \in \Sigma_{2} \backslash L_{2}: p v \int_{\Sigma_{2}}[\ldots] \mathrm{d} \Sigma_{y}+\mathscr{T}\left(\partial_{x}, \boldsymbol{n}_{x}=-\boldsymbol{e}_{\rho}\right) \\
& \left(\int_{S} \overline{\bar{T}}^{T} \psi^{1} \mathrm{~d} S_{y}+\int_{\Sigma_{1}} \overline{\bar{T}}^{T} \psi^{2} \mathrm{~d} \Sigma_{y}\right)=\mathbf{0} \tag{38c}
\end{align*}
$$

where the first integral involves $\psi^{3}$.

Equations (38a) to (38c) constitute the integral equations system of the problem. The coupling between the crack $S$ and the free surfaces is well illustrated.

For numerical purposes, let $n_{S}, n_{\Sigma_{1}}, n_{\Sigma_{2}}$ be the respective nodes numbers on $S, \Sigma_{1}, \Sigma_{2}$, there are $3\left(n_{S}+n_{\Sigma_{1}}+n_{\Sigma_{2}}\right)$ unknowns which are the values of $\psi_{i / S}$ at the nodes.

At each node, the prescribed stress is given, thus the system (38) becomes an algebraic equation system with $3\left(n_{S}+n_{\Sigma_{1}}+n_{\Sigma_{2}}\right)$ equations.

## 9. Conclusions

In general cases the derived integral equations system involves both surface and line integrals. Whereas Bui used two Kupradze potentials, a simple-layer and a double-layer, we limited ourselves to only one double-layer potential by analogy with V. and J. Sládek. The latter generates a point singularity of the type $r^{-3}$ that we then transformed into a point singularity of the type $r^{-2}$, after which we were able to utilize known results of double-layer potentials.

We also demonstrated integral equations are not ill-conditioned, i.e. although the unknown density $\psi$ was formerly defined on an open set containing the crack, only the restriction of $\psi$ and its derivatives with respect to suitable variables appeared in the final integral equations.

By extension of Putot's point of view according to which a free boundary can be considered as an unloaded crack, we dealt with the problem of a finite body containing a three-dimensional arbitrarily shaped crack. It can be a through or a part-through crack.

The example tackled in the last section, devoted to the coupling between a crack and free boundaries, showed that the same reasoning can be applied to more general cases including the particular one of an inclined surface crack.

Numerical applications are being investigated. The relevant main difficulty is the computation of the singular surface integrals taken in the sense of the Cauchy principal value. Another difficulty results from the presence of free boundaries which increase both the size of the equations system and the number of unknowns.

## Résumé

A l'aide des potentiels de Kupradzé on formule sous forme d'équations intégrales le problème d'une fissure tridimensionnelle dans un solide fini ou non. Le solide a un comportement élastique linéaire homogène et isotrope et la fissure peut être débouchante ou non ou même traversante. Dans les équations finales apparaissent dans le cas général à la fois des intégrales de surface et des intégrales curvilignes. Pour une fissure débouchante, l'intégrale curviligne est prise sur une portion du front de fissure. Pour une fissure plane, immergée, on retrouve les équations intégrales développées par Bui. Une autre application concerne le cas d'une fissure traversante dans un tube circulaire.
