Relaxed persistent flow/jump conditions for uniform global asymptotic stability

Christophe Prieur, Andrew R. Teel, Luca Zaccarian

Abstract—For hybrid systems, sufficient conditions are derived for the uniform global asymptotic stability of a given closed set. These conditions are written in terms of a Lyapunov function candidate and assume a semiglobal practical persistent flow (resp. persistent jump) property of the solutions to the hybrid system. The use of the new conditions is illustrated via the stability analysis of a physically inspired example and of an event-triggered control algorithm.

Index Terms—hybrid dynamical systems, Lyapunov methods, uniform global asymptotic stability, event-triggered control

I. INTRODUCTION

HYBRID dynamical systems can characterize continuous evolution (or flow) and discrete evolution (or jump) of their solutions. Examples of hybrid dynamical systems include, e.g., systems having an internal clock (such as the flashing fireflies), or mechanical objects experiencing mixed discrete and continuous dynamics (such as the bouncing ball). (See [4, Chap. 1] for more examples.) While many mathematical frameworks have been proposed to suitably represent hybrid dynamics (see, e.g., the ones cited in [5]), a suggestive one is that recently surveyed in [4, 5] which is capable of covering the well understood continuous- and discrete-time dynamical systems as special cases.

In [4, Chap. 3] it is proven that if a Lyapunov function candidate strictly decreases along flows and across jumps, then the attractor is uniformly globally pre-asymptotically stable (UGpAS). Some relaxed conditions are then given in [4, Sec. 3.3] where it is shown that one may relax the strict decrease across jumps (respectively along flows) if a suitable persistent flow (respectively persistent jump) condition is satisfied by the solutions. The aim of this paper is to show that a relaxed semiglobal practical notion of persistent flow/jump is still sufficient to establish UGpAS. Our main results, given in Section III-B, illustrate the use of practical persistent flow by providing a more elegant proof of the main result in [11], in the context of event-triggered controllers (see, e.g., [2], [3], [11], [12]). The algorithm of [11] satisfies our semiglobal practical persistent flow condition (but not the persistent flow condition of [4, Sec. 3.3]), and thus we can apply the results of this paper to prove UGpAS of the attractor. This result generalizes [11] since uniformity of GAS could not be proven with the approach adopted in [11]. Moreover, we require milder regularity conditions than [11] and prove a robustness result, stated in Section V. This last result strengthens the result in [1, Claim 5.1] and is of interest on its own.

Notation: A function \( \alpha : [0, \infty) \rightarrow \mathbb{R} \) is of class \( \mathcal{K} \) if it is zero at zero, continuous and strictly increasing. It is of class \( \mathcal{K}_\infty \) if it is of class \( \mathcal{K} \) and is unbounded. A function \( \rho : [0, \infty) \rightarrow \mathbb{R} \) belongs to \( \mathcal{P}\mathcal{D} \) (positive definite) if it is continuous, \( \rho(s) > 0 \) for all \( s > 0 \) and \( \rho(0) = 0 \). Given a set \( C \subset \mathbb{R}^n \), \( \mathcal{T} \) denotes its closure. Given a set \( A \subset \mathbb{R}^n \), and a point \( x \in \mathbb{R}^n \), \( |x|_A := \inf_{z \in A} |x - z| \). For any integer \( m \) and any scalar \( \delta > 0 \), the set \( \delta \mathcal{B}^m := \{ x \in \mathbb{R}^m : |x| < \delta \} \) denotes the (open) \( \delta \)-ball centered at the origin and \( \delta \mathcal{B} \) denotes its closure. Given two sets \( X, Y \subset \mathbb{R}^n \), the set \( X \cap Y \) comprises all vectors \( z = x + y \) for some \( x \in X \) and \( y \in Y \).

II. MAIN RESULTS

Consider the following nonlinear hybrid dynamical system \( \mathcal{H} = (C, F, D, G) \):

\[
\mathcal{H} = \begin{cases}
\dot{x} & \in F(x), \quad x \in C \\
x^+ & \in G(x), \quad x \in D
\end{cases}
\tag{1}
\]

where \( F \) and \( G : \mathbb{R}^n \rightarrow \mathbb{R}^n \) are locally bounded set-valued mappings and \( C \) and \( D \) are subsets of \( \mathbb{R}^n \). Let \( A \) be a closed subset of \( \mathbb{R}^n \). For an introduction to hybrid systems notation and precise definitions of solutions to (1) and hybrid time domains, the reader is referred to [4, §2.2–2.3]. We recall here the following from [4, Definition 3.6]:

Definition 1: (Uniform global stability concepts)

- The set \( A \) is uniformly globally stable (UGS) for (1) if there exists a class \( \mathcal{K}_\infty \) function \( \alpha \) such that any solution \( x \) to (1) satisfies \( |x(t, j)|_A \leq \alpha(|x(0, 0)|_A) \), for all \( t, j \in \text{dom} x \);
- the set \( A \) is uniformly globally pre-attractive (UGPa) for (1) if for each \( \varepsilon > 0 \) and \( \tau > 0 \), there exists \( T > 0 \) such that for any solution \( x \) to (1),

\[
|x(0, 0)|_A \leq \tau \Rightarrow |x(t, j)|_A \leq \varepsilon, \quad \forall (t, j) \in \text{dom} x, \quad t + j \geq T.
\tag{2}
\]

- the set \( A \) is uniformly globally pre-asymptotically stable (UGpAS) for (1) if it is both uniformly globally stable and uniformly globally pre-attractive.
- the set \( A \) is uniformly globally asymptotically stable (UGAS) if it is uniformly globally pre-asymptotically stable and all maximal solutions to (1) are complete.
Note that once UGS of $A$ for $\mathcal{H}$ is established, the remaining UGpA property amounts to checking uniform convergence in a semiglobal practical way (that is, for each pair $r > 0$, $\epsilon > 0$). Then we can build a set of relaxed conditions ensuring UGpA of $A$ by introducing, for each pair $0 < \delta < \Delta$ of positive scalars, the following set

$$S_{\delta, \Delta} := (A + \Delta B) \setminus (A + \delta B^\circ),$$

(3a)

which is closed, not necessarily bounded, and is bounded if and only if $A$ is bounded and introducing the following hybrid system

$$\mathcal{H}_{\delta, \Delta} = (C_{\delta, \Delta}, F, D_{\delta, \Delta}, G),$$

(3b)

which corresponds to restricting the flow and jump sets to the closed set $S_{\delta, \Delta}$.

In [4, §3.2], Lyapunov-based sufficient conditions for UGAS of a closed set $A$ are given in terms of the so-called “strict” Lyapunov conditions, namely strict decrease of a Lyapunov function both across jumps and along flows. Then, in [4, §3.3], several relaxations of the strict Lyapunov conditions are given, among which we focus here on the ones called “persistent jumping” [4, Prop. 3.24] and “persistent flowing” [4, Prop. 3.27]. In light of the restriction in (3), we introduce a relaxed semiglobal practical formulation of persistent jump/flow.

**Property 1:** (Semiglobal practical persistent flow [respectively, persistent jump]) Given system (1), for each pair $\delta, \Delta$ of positive scalars, there exist a class $K_{\infty}$ function $\gamma$ and a scalar $N \geq 0$ such that each solution $x$ to hybrid system $\mathcal{H}_{\delta, \Delta}$ in (3) satisfies the following for all $(t, j) \in \text{dom} x$:

$$t \geq \gamma(j) - N,$$

(4a)

[respectively, $j \geq \gamma(t) - N$].

(5a)

Semiglobal practical persistent flow [respectively, jump] is useful because it still allows to assess UGpAS of an attractor when strict decrease of a candidate Lyapunov function is only established along flows [respectively, across jumps] and only non-increase of the Lyapunov function is established across jumps [respectively, along flows] (see [4, Props. 3.27 and 3.24]). In other words these properties allow establishing UGpAS in the presence of nonstrict (weakened) Lyapunov conditions. The following main results of this paper, generalize [4, Props. 3.27 and 3.24]. They are proven in Section IV.

**Theorem 1:** Consider hybrid system $\mathcal{H} = (C, F, D, G)$ in (1) and a closed set $A \subset \mathbb{R}^n$. Assume that there exist a function $V$, continuously differentiable on a neighborhood of $\overline{C}$, two class $K_{\infty}$ functions $\alpha_1$ and $\alpha_2$, and a function $\rho \in \mathcal{P}D$ satisfying (6a) and

$$\langle \nabla V(x), f \rangle \leq 0, \quad \forall x \in C, \forall f \in F(x),$$

(7a)

$$V(g) - V(x) \leq -\rho(|x|_A), \quad \forall x \in D, \forall g \in G(x).$$

(7b)

Assume also that the semiglobal practical persistent jump Property 1 holds for (1). Then the set $A$ is uniformly globally pre-asymptotically stable for system (1).

Theorems 1 and 2 differ in a few ways from the results in [4, Props. 3.27 and 3.24] as clarified next.

- First, using the restriction in (3), we are allowed to disregard a neighborhood of the attractor $A$ for the persistent flow/jump. This is useful to rule out defective solutions only occurring inside the attractor. Examples of such cases correspond to the situations addressed in Sections III-A and III-B, the reset rules proposed in [8], the bouncing ball example (see [4, Example 3.19]) or the homogeneous approximations in [7] where the attractor $A = \{0\}$ necessarily belongs to both the jump and flow sets which are closed cones.

- In [4, Props. 3.27 and 3.24], the argument of the class $K_{\infty}$ function $\gamma$ in (4) [respectively, (5)] is $t + j$. The new formulation in Property 1 seems to be easier to establish, due to the fact that the variable $t$ [respectively, $j$] appearing at the left hand side does not appear at the right hand side. It certainly leads to an easier proof of Propositions 1 and 2 in Section III. The next lemma shows that the two formulations are equivalent.

**Lemma 1:** Given a hybrid time domain $E$, there exist $\gamma \in K_{\infty}$ and $N \geq 0$ satisfying (4) [respectively, (5)] for all $(t, j) \in E$, if and only if there exist $\hat{\gamma} \in K_{\infty}$ and $N \geq 0$ satisfying, for all $(t, j) \in E$:

$$t \geq \hat{\gamma}(t + j) - \hat{N},$$

(8a)

[respectively, $j \geq \hat{\gamma}(t + j) - \hat{N}$].

(9a)

**Proof.** We only prove the case corresponding to (4), (8). The other proof is identical with $t$ and $j$ exchanged. If (8) holds for some $\hat{\gamma} \in K_{\infty}$ and $N \geq 0$, then it suffices to pick $\gamma = \hat{\gamma}$ and $N = \hat{N}$ for (4) to hold, because $t \geq 0$ and $\hat{\gamma} \in K_{\infty}$ implies $t \geq \hat{\gamma}(t + j) - \hat{N} \geq \hat{\gamma}(t) - \hat{N}$. Conversely, assume that (4) holds for some $\gamma \in K_{\infty}$ and $N \geq 0$. Then the choice $\hat{N} = \frac{N}{2}$ and $\hat{\gamma}(s) = \frac{1}{2}\gamma_m(\frac{s}{2})$ with $\gamma_m(s) = \min\{\gamma(s), \gamma(s)\}$ satisfies (8). To see this, add $t$ to both sides of (4) to get

$$t \geq \hat{\gamma}(t + j) - \hat{N},$$

(10a)

which implies

$$t \geq \frac{1}{2}(t + \gamma(j)) - \frac{N}{2} \geq \frac{1}{2}(\gamma_m(t) + \gamma_m(j)) - \hat{N},$$

(10b)

$$\geq \frac{1}{2}\gamma_m \left(\frac{t + j}{2}\right) - \hat{N} = \hat{\gamma}(t + j) - \hat{N}.$$
is moving along the horizontal axis with a position \( p \geq 0 \) and a velocity \( v = \dot{p} \). Assume moreover that the mass is impacting with a vertical wall at \( p = 0 \), where each dissipative damping \( h \in \mathbb{Z} \) is associated to the restitution coefficient \( 0 \leq \Gamma(h) < 1 \). This gives the following hybrid model which uses the counter \( h \in \mathbb{Z} \) and the state \( x = (p, v, h) \):

\[
\begin{align*}
\dot{p} &= -k(p), & x \in C &:= \{ x \in \mathbb{R}^2 \times \mathbb{Z}, \text{s.t. } p \geq 0 \} \\
\dot{h} &= 0, \\
\dot{v} &= -\Gamma(h) v, & x \in D &:= \{ x \in \mathbb{R}^2 \times \mathbb{Z}, \text{s.t. } p = 0 \text{ and } v \leq 0 \}, \\
\end{align*}
\]

(10)

and that satisfies the following assumption characterizing a very general nonlinear spring with the only requirements that at rest \((p, 0)\) the spring exerts no force and that extending the spring one experiences an increase of elastic force.

**Assumption 1:** Function \( k \) is of class \( K \) and \(^4\) there exists a scalar \( \Gamma_0 \in (0, 1) \) such that \( 0 \leq \Gamma(h) \leq \Gamma_0 \) for all \( h \in \mathbb{Z} \).

From the simulation of Figure 1, corresponding to the selection \( k(p) = p^3 \) and \( \Gamma(h) = \frac{1}{2} \), \( \forall h \), one gets a clear impression that the attractor

\[
A := \{(p, v, h) \in \mathbb{R}^2 \times \mathbb{Z} : (p, v) = (0, 0)\}
\]

(11)

is globally asymptotically stable for the dynamics. Nevertheless, formally proving this fact may be complicated because no dissipation happens during flow and the impacts, which dissipate, may happen increasingly seldom as the mass approaches zero, especially for specific defective shapes of the very general function \( k \). Nevertheless, we may prove UGAS of the origin by exploiting Theorem 2 as formally stated next.

**Proposition 1:** Under Assumption 1, the closed set \( A \) in (11) is UGAS for system (10).

**Proof:** The proof uses Theorem 2 with \( F \) and \( G \) being the two right hand sides in (10), \( C \) and \( D \) as defined in (10) and the closed attractor \( A \) in (11). To construct the Lyapunov function \( V \), we consider the energy of the system during flow, that is \( V(x) := \int_0^t k(s) ds + \frac{1}{2} v^2 \). For this \( V \), after noticing that \( |x|_A = |(p, v)| \), we may establish (6a) as follows:

\[
\min \left\{ \int_0^t k(s) ds, \frac{1}{4} |x|_A^2 \right\} \leq V(x) \leq \int_0^t k(s) ds + \frac{1}{2} |x|_A^2,
\]

indeed the right inequality is easily checked by writing an upper bound for each term of \( V \) and the left inequality can be checked by first noticing that in \( C \cup D \cup G(D) \) one always has \( p = |p| \) and then splitting the analysis in two cases: 1) if \( |p| \geq |v| \), then \(|p| \geq |x|_A \) and thus \( V(x) \geq \int_0^{|x|_A} k(s) ds \) and 2) if \(|v| \geq |p| \), then \(|v| \geq |x|_A \) and thus \( V(x) \geq \frac{1}{2} |x|_A^2 \). Let us now show equations (7). The flow inequality (7a) is easily established by noticing that, for all \( x \in C, \) \( \langle \nabla V(x), \left[-k(p) \right] \rangle = 0 \). The jump inequality (7b) is established with \( \rho(s) = (1 - \Gamma_0)^2 s^2 \), indeed for all \( x \in D \) we have \( V(-\Gamma(h) v) - V(x) = -(1 - (\Gamma(h)^2)) v^2 = -\rho(|x|_A) \).

The last thing to establish is that \( A \) in (11) is UGAS, and \( \mu \) is a scalar \( \Gamma_0 \in (0, 1) \) such that \( 0 \leq \Gamma(h) \leq \Gamma_0 \) for all \( h \in \mathbb{Z} \).

**Proposition 1:** Under Assumption 1, the closed set \( A \) in (11) is UGAS for system (10).

**Proof:** The proof uses Theorem 2 with \( F \) and \( G \) being the two right hand sides in (10), \( C \) and \( D \) as defined in (10) and the closed attractor \( A \) in (11). To construct the Lyapunov function \( V \), we consider the energy of the system during flow, that is \( V(x) := \int_0^t k(s) ds + \frac{1}{2} v^2 \). For this \( V \), after noticing that \( |x|_A = |(p, v)| \), we may establish (6a) as follows:

\[
\min \left\{ \int_0^t k(s) ds, \frac{1}{4} |x|_A^2 \right\} \leq V(x) \leq \int_0^t k(s) ds + \frac{1}{2} |x|_A^2,
\]

indeed the right inequality is easily checked by writing an upper bound for each term of \( V \) and the left inequality can be checked by first noticing that in \( C \cup D \cup G(D) \) one always has \( p = |p| \) and then splitting the analysis in two cases: 1) if \( |p| \geq |v| \), then \(|p| \geq |x|_A \) and thus \( V(x) \geq \int_0^{|x|_A} k(s) ds \) and 2) if \(|v| \geq |p| \), then \(|v| \geq |x|_A \) and thus \( V(x) \geq \frac{1}{2} |x|_A^2 \). Let us now show equations (7). The flow inequality (7a) is easily established by noticing that, for all \( x \in C, \) \( \langle \nabla V(x), \left[-k(p) \right] \rangle = 0 \). The jump inequality (7b) is established with \( \rho(s) = (1 - \Gamma_0)^2 s^2 \), indeed for all \( x \in D \) we have \( V(-\Gamma(h) v) - V(x) = -(1 - (\Gamma(h)^2)) v^2 = -\rho(|x|_A) \).

The last thing to establish is that \( A \) in (11) is UGAS, and \( \mu \) is a scalar \( \Gamma_0 \in (0, 1) \) such that \( 0 \leq \Gamma(h) \leq \Gamma_0 \) for all \( h \in \mathbb{Z} \).
Since all the assumptions of Theorem 2 hold, then the origin is is UGpAS for (10). To show UGAS, note that from [6, Prop. 2.1], we have local existence of solutions and so the only way a maximal solution would not be complete is if, along flows, it escapes to infinity in finite time. From (7a), the function $V$ is non-increasing along all solutions to (16) and $V$ is radially unbounded in $(p, v)$. Thus finite-time escapes of $V$ are avoided. Moreover $\dot{h}$ does not escape in finite time because $\dot{h} = 0$. Therefore, UGpAS implies UGAS of $A$. □

B. An event-triggered control scheme

Based on the results in [11], we consider the following nonlinear continuous-time plant with control input $u \in \mathbb{R}^m$:

$$\dot{x} = f_p(x_p, u) \quad (12)$$

where $f_p : \mathbb{R}^n_p \times \mathbb{R}^m \rightarrow \mathbb{R}^n_p$ is continuous in both arguments. Paralleling [11], we assume for (12) the existence of a stabilizing state feedback control law $u = \kappa(x_p)$, where $\kappa$ is only required to be locally bounded.

**Assumption 2:** Function $f_p$ is continuous in both arguments and there exist a compact set $A_p \subset \mathbb{R}^n_p$, a locally bounded function $\kappa : \mathbb{R}^n_p \rightarrow \mathbb{R}^m$, a continuously differentiable function $V_p : \mathbb{R}^n_p \rightarrow \mathbb{R}$, two class $K_\infty$ functions $\alpha_1$ and $\alpha_2$, and a function $\rho_0 \in \mathcal{P}D$ such that, for all $x_p \in \mathbb{R}^n_p$, the following holds for all $x_p \in \mathbb{R}^n_p$:

$$\begin{align*}
\alpha_1(|x_p|_{A_p}) & \leq V_p(x_p) \leq \alpha_2(|x_p|_{A_p}), \\
\langle \nabla V_p(x_p), f_p(x_p, \kappa(x_p)) \rangle & \leq -\rho_0(|x_p|_{A_p}).
\end{align*}$$

Different from [11], we enforce mild assumptions on the stabilizer $\kappa$. Therefore, we will use its outer semi-continuous regularization (see [4, Lemma 5.16] and references therein):

$$K(x_p) := \bigcap_{\delta > 0} \kappa(x_p + \delta \mathbb{B}) \quad (15)$$

Then, inspired by [11], we establish robust stability properties of an event-triggered hybrid implementation of the stabilizing law $\kappa$, whose state is $x = [x_p^T \ u^T]^T$ and whose (perturbed) dynamics can be written as:

$$\begin{align*}
\mathcal{H} := \{ & \begin{cases} 
\dot{x}_p = f_p(x_p, u), \\
\dot{u} = f_u(x_u), \\
x_p^+ = x_p \\
u^+ = K(x_p + \chi(x_p)\mathbb{B}) + \chi(x_p)\mathbb{B},
\end{cases} & (x_p, u) \in C \}
\end{align*}$$

$$\begin{align*}
\{ & \begin{cases} 
(x_p, u) : \langle \nabla V_p(x_p), f_p(x_p, u) \rangle \leq -\rho(|x_p|_{A_p}) \\
(x_p, u) : \langle \nabla V_p(x_p), f_p(x_p, u) \rangle \geq -\rho(|x_p|_{A_p})
\end{cases} \\
C = \{ & \{x_p, u\} : \langle \nabla V_p(x_p), f_p(x_p, u) \rangle \leq -\rho(|x_p|_{A_p}) \}
\end{align*}$$

D = \{ & \{x_p, u\} : \langle \nabla V_p(x_p), f_p(x_p, u) \rangle \geq -\rho(|x_p|_{A_p}) \}
\end{align*}$$

(16a)

and $\rho \in \mathcal{P}D$ is such that $\rho(s) < \rho_0(s)$ for all $s > 0$. This event-triggered algorithm was proposed in [12] and used in many later works. As in [11], we study here the stability properties of the closed (but noncompact) set $A = A_p \times \mathbb{R}^m$ for dynamics (16).

**Remark 1:** As compared to [11, Thm 3.1], we address here a more general case. In particular, we assume only continuity of $f_p$ (while a locally Lipschitz $f_p$ was considered there); we allow for a very general flow map for $u$, by way of the continuous function $f_u$, while only the case $f_u = 0$ was considered there; finally we allow for stabilizing laws $\kappa$ satisfying local boundedness only, whereas in [11] continuity of the stabilizer was required. The reason for these relaxations is that not more than those weak properties is required to prove our stability results and the general formulation used here allows to establish robust stability of a larger class of systems. Note however that the special case where $\dot{u} = 0$ and $u^+ = \kappa(x_p)$ is captured by dynamics (16a) by selecting $f_u = 0$ and noticing that $\kappa(x_p) \in K(x_p)$ for all $x_p$. The extra elements of $K(x_p)$ introduced by the regularization (15) are needed to ensure outer semicontinuity of the right hand side of the jump equation which, based on the developments in [4, Chap. 6] ensures well posedness of the hybrid system. This well posedness property enables us to also introduce the perturbation function $\chi$ in the jump equation of (16a) to characterize robustness of UGAS in the presence of small measurement errors (captured by the inner inflation of $K$) and round-off errors in the transmission of the signal $u$ (captured by the outer inflation of $K$). Note that this robustness result can not be established using [4, Thm 7.21] because the attractor $A$ is not compact.

Besides the generalizations highlighted in Remark 1, the event-triggered implementation (16) of the stabilizer $\kappa$ has been proven in [11, Thm 3.1] to induce global asymptotic stability (GAS) of $A = A_p \times \mathbb{R}^m$ with $A_0 = \{0\}$. However, due to the invariance principle based proof adopted there, appropriately since solutions are bounded, there is no guarantee of the uniformity and robustness of GAS of $A$. Indeed, since $A$ is not compact, it is not possible to use the results of [4, Ch. 7]. (See, e.g., [4, Thms 7.12 & 7.21] establishing uniformity and robustness of pre-asymptotic stability with compact attractors.) Instead, using our Theorem 1, it is possible to prove uniformity and robustness of GAS of the attractor by relying on the semiglobal practical persistent flow property established in the proposition below whose proof uses the result of the next claim. The proof of the claim is given in Section V.

**Claim 1:** Under Assumption 2, letting $n = n_p + m$, and $A = A_p \times \mathbb{R}^m$, there exists a small enough function $\chi : \mathbb{R}^n_p \rightarrow \mathbb{R}_{> 0}$ which is positive in $\mathbb{R}^n_p \setminus A_0$, such that system $\mathcal{H}$ in (16) satisfies the semiglobal practical persistent flow in Property 1.

**Remark 2:** Note that due to the very mild conditions required by Assumption 2, there is no possibility to prove that there is a minimum intersample behavior guaranteed by the event-triggered implementation of [11, Thm 3.1] (namely a uniform persistent flow property, rather than the practical one established above). Indeed, for very defective nonlinear selections of $f_p$ and $\kappa$, one may run into the need of arbitrarily fast sampling close to the origin or at infinity (notice however that for those defective selections no periodic sampling implementation would work either). Nevertheless, if a lower bound on the maximum intersample time is imposed by technological needs, one may still use the robustness properties established here to conclude some kind of semiglobal practical uniform
asymptotic 2 stability results.

**Proposition 2.** Under Assumption 2, there exists a small enough function \( \chi : \mathbb{R}^n \to \mathbb{R} \geq 0 \) which is positive in \( \mathbb{R}^n \setminus A_p \), such that the set \( A = A_p \times \mathbb{R}^m \) is UGAS for system (16).

**Proof.** Introduce the function \( V(x) = V((x_p, u)) = V_p(x_p) \) and note that due to the definition of the set \( A \) we have \(|(x_p, u)|_A = |x_p|_A \) and from (13), we have

\[
\alpha_1(|x|_A) \leq V(x) \leq \alpha_2(|x|_A).
\] (17)

Moreover, from the definition of the flow in (16b), we have

\[
\langle \nabla V(x), [f_n(x_p, u)] \rangle \leq -\rho(|x|_A), \quad \forall (x_p, u) \in C, \forall w \in f_u(x_p)B, \tag{18a}
\]

and since \( x_p^+ = x_p \), we also have

\[
V(x^+) - V(x) = V_p(x_p^+) - V_p(x_p) = 0, \quad \forall (x_p, u) \in D. \tag{18b}
\]

Then, by the semiglobal practical persistent flow property established in Claim 1 and by Theorem 1, set \( A \) is UGAS for \( H \). To show UGAS, note that from [6, Prop. 2.1], \( C \cup D = \mathbb{R}^n \) implies local existence of solutions and so the only way a maximal solution would not be complete is if it escapes to infinity during flows. From (18), the function \( V \) is non-increasing along all solutions to (16) so the \( x \) component of each solution is bounded. Moreover, from continuity of \( f_{x_p} \), boundedness of \( x_p \) implies also boundedness of \( \dot{u} \) along flows and thus forward completeness follows. Therefore, UGAS implies UGAS of \( A \).

\[ \square \]

**IV. PROOF OF THEOREMS 1 AND 2.**

The following lemma is needed to prove Theorems 1 and 2, and is similar to [14, Theorem 1, 3 \rangle 1].

**Lemma 2:** A closed set \( A \) is UGAS for \( H := (C, F, D, G) \) in (1) if it is UGS for \( H \) and, for each pair \( \Delta > 0, \delta > 0 \), it is UGPA for \( H_{\delta, \Delta} \) in (3).

**Proof.** According to Definition 1, UGAS of \( A \) follows from UGS (which is assumed) and UGPA, which is established next. With reference to Definition 1, select any pair \( r, \varepsilon \) of positive scalars and select \( \Delta = \alpha(r) \), \( \delta = \alpha^{-1}(\varepsilon) \) (where \( \alpha \) is the class \( K_{\infty} \) function establishing UGS of \( H \)). By assumption, \( H_{\delta, \Delta} \) is UGPA, therefore there exists \( T \) such that (2) holds for all solutions \( x \) to \( H_{\delta, \Delta} \). For that same \( T \), all solutions to \( H \) with \( |x(0)|_A \leq r \) satisfy (2) as well. Indeed, denote by \( x \) any such solution and two cases may occur: 1) \( |x(t, j)|_A > \delta \) for all \( (t, j) \in \text{dom} x \), in which case notice from UGS of \( H \) we have \( |x(t, j)|_A \leq \alpha(r) = \Delta \) for all \( (t, j) \in \text{dom} x \). Then, \( x \) is also a solution to \( H_{\delta, \Delta} \) and (2) holds by definition.

2) there exists \( (t, j) \in \text{dom} x \) such that \( |x(t, j)|_A \geq \delta \) and \( |x(t, j)|_A \leq \delta \) for all \( (t, j) \in \text{dom} x \) satisfying \( t + j < t + j \). Then \( x(t, j) \) is also a solution to \( H_{\delta, \Delta} \) for all \( (t, j) \in \text{dom} x \) with \( t + j < t + j \) (so that it satisfies (2) by definition for all such times) while from UGS we have \( |x(t, j)|_A \leq \alpha(\delta) = \varepsilon \) for all \( (t, j) \in \text{dom} x \) with \( t + j < t + j \) which implies (2) for the remaining part of \( \text{dom} x \).

\[ \square \]

**Proof of Theorems 1 and 2.** We only prove Theorem 1 as the proof of Theorem 2 is identical. Conditions (6) imply UGS of \( H \) following the same proof technique as in [4, Theo. 3.18]. Then using [4, Prop. 3.27] and Property 1 with Lemma 1, we conclude UGPA of \( H_{\delta, \Delta} \) for each pair of positive scalars \((\delta, \Delta)\). Finally the result follows from Lemma 2.

\[ \square \]

**V. PROOF OF CLAIM 1**

To the end of proving Claim 1, we provide a robustness statement which strengthens the result in [1, Claim 5.1] (see also [13, Pages 332-333] for a similar result) establishing that under Assumption 2 the flow inequality (14) can be strengthened to hold robustly, as clarified below. The proof uses the regularity of \( V_p \) and the continuity of \( f_p \).

**Lemma 3:** Under Assumption 2, the following strengthened flow condition holds for all \( x_p \in R^m \)

\[
f \in \bigcap_{f_p} f_p(x_p, K(x_p)) \leq -\rho_0(|x_p|_{A_p}), \tag{19}
\]

where \( \bar{\omega} \) denotes the closed convex hull.

Moreover, for each \( \rho \in P \) such that \( \rho(s) < \rho_0(s), \forall s > 0 \), there exists a continuous function \( \eta : R^m \to [0, \infty) \) which is strictly positive on \( R^m \setminus A_p \), such that for all \( x_p \in R^m \)

\[
\langle \nabla V_p(x_p), \dot{x} \rangle \leq -\rho_0(|x_p|_{A_p}) + \rho(|x_p|_{A_p}), \quad \forall \dot{x} \in F_\eta(x_p), \tag{20a}
\]

where the set-valued mapping \( F_\eta \) is defined as follows:

\[
F_\eta(x_p) := \bar{\omega} f_p(x_p, K(x_p) + \eta(|x_p|_{B})). \tag{20b}
\]

**Proof.** Proof of (19). Fix \( x_p \in R^m \). By definition of the closed convex hull, for each \( \dot{x} \in \bigcap_{f_p} f_p(x_p, K(x_p)) \), there exists a sequence \( \{f_i\}_{i \in N} \in R^m \) such that \( f_i \to f \), as \( i \to \infty \) satisfying, for each \( i \geq 1 \), the existence of two sequences \( (x_{i,j}^{i,j})_{j=1,\ldots,i} \) in \([0,1]\) with \( \sum_{j=1}^{i} x_{i,j}^{i,j} = 1 \) and \((k^{i,j})_{j=1,\ldots,i} \in K(x_p)\) such that

\[
f^i = \sum_{j=1}^{i} \lambda_j x_{i,j}^{i,j} \dot{f}_p(x_p, k^{i,j}). \tag{21}
\]

Now recalling (15), for each \( i \in N \) and for each \( 1 \leq j \leq i \), there exists a sequence \( (x_{i,j}^{i,j,n})_{n \in N} \) such that

\[
\max \{ |x_p - x_{i,j}^{i,j,n}|, |k^{i,j,n} - k^{i,j}|, \forall n \geq 1 \}.
\]

Then, using continuity of \( \nabla V_p, f_p \) and \( \rho_0 \), (14), and (19), we get

\[
\langle \nabla V_p(x_p), \dot{x} \rangle \leq \lim_{i \to \infty} \left| \sum_{j=1}^{i} \lambda_j \langle \nabla V_p(x_p), f_p(x_p, k^{i,j}) \rangle \right|
\]

\[
= \lim_{i \to \infty} \left| \sum_{j=1}^{i} \lambda_j \langle \nabla V_p(x_{i,j}^{i,j,n}), f_p(x_{i,j}^{i,j,n}, k^{i,j,n}) \rangle \right|
\]

\[
\leq \lim_{i \to \infty} \left| \sum_{j=1}^{i} \lambda_j \rho_0(|x_{i,j}^{i,j,n}|_{A_p}) \right|
\]

\[
\leq -\lim_{i \to \infty} \left| \sum_{j=1}^{i} \lambda_j \rho_0(|x_p|_{A_p}) \right|
\]

where in the last line we used \( \sum_{j=1}^{i} \lambda_j = 1 \).

**Proof of (20).** Using (19), the function \( \eta \) is constructed following the proof technique of [1, Claim 5.1] (see also [13, Pages 332-333]), recognizing that in (20) we have
\[ \rho_c(|x_p(t_j)|_A) + \rho_d(|x_p(t)|_A) < \rho_c(|x_p|_A) \] for all \( x_p \notin A_p \), while in [1, Claim 5.1] we have \[ \frac{1}{2}V_p(x_p) < V_p(x_p), \forall x_p \notin A_p. \] First select the function \( \chi \) in (16a) as any continuous function satisfying \( \chi(x_p) < \eta(x_p) \) for all \( x_p \notin A_p \), where \( \eta \) is the continuous function introduced in Lemma 3. To prove the claim for hybrid system \( H \) with such a selection of \( \chi \), fix scalars \( \delta > 0 \) and \( \Delta > 0 \) as in Property 1. Below we determine parameters \( \gamma \in \mathbb{K}_\infty \) and \( N > 0 \) satisfying (4) for all solutions \( x \in \mathcal{H}_{\delta, \Delta} \). If the solution never jumps, then (4) trivially follows with any \( N \geq 0 \) and any class \( \mathcal{K}_\infty \) function \( \gamma \). If the solution jumps at least once, then by the restriction of the flow and jump sets of \( \mathcal{H}_{\delta, \Delta} \), we have \( |x(t,j)|_A = |x_p(t,j)|_A \leq \Delta \), for all \( (t,j) \in \text{dom} \, x, (t,j) \neq (0,0) \). Therefore, the (sub-state) \( x_p \) is uniformly bounded as follows:

\[
|x_p(t,j)|_A \leq \Delta, \quad \forall (t,j) \in \text{dom} \, x, j \geq 1. \tag{22}
\]

Since from (22) \( x_p \) is bounded, then also \( f_\nu(x_p) \) has a uniform upper bound and local boundedness of \( K \) (inherited from \( \kappa \)) and continuity of \( f_p \) and \( f_\nu \) imply that there exist positive scalars \( L_x \) and \( L_u \), such that, for all \( (t,j) \in \text{dom} \, x, j \geq 1, \)

\[
\begin{align*}
|x_p(t,j) - x_p(t_j)| &\leq L_x |t - t_j|, \\
|u(t,j)| &\leq L_u |t - t_j|.
\end{align*}
\]

Since \( \chi \) is continuous on \( \mathbb{R}^n \), it is uniformly continuous on each compact set, namely there exists \( L_\chi > 0 \) such that, for all \( x_p \in \mathbb{R}^n, |x_p|_A \leq \Delta, \quad i = 1,2, \)

\[
|\chi(x^1_p) - \chi(x^2_p)| \leq L_\chi |x^1_p - x^2_p|.
\] (25)

Use now the result of Lemma 3 and, in particular, the continuous function \( \eta \) satisfying (20) and the function \( \chi \) in (16a) which is smaller by \( \eta \) by construction. Select

\[
\eta_\chi \,:= \frac{1}{2} \min_{x_p \in \Delta, \, \sigma_{\delta,\Delta}} \eta(x_p) - \chi(x_p) \tag{26}
\]

\[
\sigma_{\delta,\Delta} \,:= \min \left\{ \frac{\eta_\chi}{L_x}, \frac{\eta_\chi}{L_u} \right\},
\] (27)

and note that \( \eta_\chi > 0 \) (because \( \chi(x_p) < \eta(x_p) \) for all \( x_p \notin A_p \)), implying \( \sigma_{\delta,\Delta} > 0 \).

Then from (24) and the right bound of (27), we get for all \( t \in [t_j, t_j + \sigma_{\delta,\Delta}] \)

\[
f_p(x_p(t,j), u(t,j)) \in f_p(x_p(t_j), u(t_j) + \eta_\chi B).
\] (28)

Moreover, applying (26) first and then the left two bounds in (27) and (23), we get

\[
\chi(x_p) + 2\eta_\chi \leq \eta(x_p), \tag{29a}
\]

\[
x_p(t,j) \in x_p(t_j, j) + \min \left\{ \frac{\eta_\chi}{L_x}, \frac{\eta_\chi}{L_u} \right\}, \tag{29b}
\]

and the right bound of (29b) together with (25) gives

\[
\chi(x_p(t,j)) = \chi(x_p(t,j)) + \chi(x_p(t_j, j)) - \chi(x_p(t,j)) \leq \chi(x_p(t_j, j)) + \min \left\{ \frac{\eta_\chi}{L_x}, \frac{\eta_\chi}{L_u} \right\} B.
\] (29c)

Combining (29) with (28) we get the following relations where for compactness of notation we use \( x_p \) for \( x_p(t,j) \) and \( \xi_p \) for \( x_p(t_j, j) \):

\[
f_p(x_p(t,j), u(t,j)) \in f_p(x_p(t_j, j), \xi_p), \tag{29d}
\]

\[
\begin{align*}
& \subset f_p(x_p(t_j, j), K(\xi_p + \chi(x_p(t_j, j))B + \eta_\chi B) \\
& \in f_p(x_p(t_j, j), K(\xi_p + \chi(\xi_p)B + 2\eta_\chi B) + \chi(\xi_p)B + 2\eta_\chi B) \\
& \subset f_p(x_p(t_j, j), K(\xi_p + \eta_\chi B) + \eta(\xi_p)B) = F_\eta(x_p(t_j, j)),
\end{align*}
\]

for all \( t \in [t_j, t_j + \sigma_{\delta,\Delta}] \). Then from (20) we obtain

\[
\begin{align*}
\langle \nabla V_p(x(t,j), f_p(x(t,j), u(t,j))) \rangle \\
\leq -\frac{1}{2} \rho_p(|x_p(t,j)|_A) + \rho(|x_p(t,j)|_A) \\
\leq -\rho(|x_p(t,j)|_A).
\end{align*}
\]

Combined with (16b) this latter inequality implies that the solution is not in the jump set for all \( t \in [t_j, t_j + \sigma_{\delta,\Delta}] \). This dwell time for all \( j \geq 1 \), suggests the selection of \( \gamma(s) = \sigma_{\delta,\Delta} s \) that, combined with the selection \( N = \sigma_{\delta,\Delta} \) (ensuring that the right hand side of (4) is non-positive for \( (t,j) \in \text{dom} \, x, (t,j) = 0 \)), implies (4). (Note that establishing condition (8) would require additional steps in this proof. This shows that (4) is a simpler condition to check for this example.)

REFERENCES
