HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

1. Introduction

Detection of microemboli is of great clinical importance to prevent cerebro-vascular events and to identify the causes of such events. As standard detection techniques implemented in the most commonly used systems cannot detect all of microemboli events whose energy is lower than the systolic energy, new techniques are proposed.

Joint used of synchronous and linear prediction techniques could detect very small microemboli. If we periodically take and compare the values of the energy of the prediction error (or autoregressive parameters) at different time points in the cardiac cycle, we can therefore detect the presence of non-periodic events such as microemboli.

In our study, we tested and compared our new technique to the standard technique (Fourier) using simulated and in vivo signals from patients with stenosis of high degrees of severity.

2. Materials

TansCranial Doppler system (TCD)

- ▶ Velocity of blood flow through the brain's arteries
- ▶ Pulsed Doppler probe
- ▶ Examination in the temporal region
- ▶ used TCD : WakiTM (Atys Medical, Soucieu en Jarrest, France)

Doppler signals

- ▶ The Doppler signals are cyclo-stationary
- ▶ Synthesized Embolus Doppler signal proposed by Wedling
- ▶ *In vivo* Doppler signals from patients stenosis of degrees IV of severity

3. Methods

Gold standard test

Manual embolus detection by audible detection and sonogram visualization

standard technique

1. Computation of energy by Short Time Fourier Transform
2. Constant threshold λ set between 3 to 9 dB above the maximal energy $\rightarrow$ reduce the false alarm probability
3. Embolus detection when energy upper than the threshold λ

Synchronous linear prediction technique (SLP)

1. Computation of energy by Short Time Fourier Transform
2. Model of signal with 2nd-order AR model

$$x(n) = -a_1(n)x(n-1) - a_2(n)x(n-2) + \varepsilon(n)$$

3. Error Autocorrelation $\Gamma_{\varepsilon\varepsilon}(n) = \sum_{m=-\infty}^{+\infty} \varepsilon(m)\varepsilon^*(m-n)$
4. Synchronization with the cardiac cycle
5. Detection by a time-varying threshold $\lambda(t) = \mu(t) + \beta\sigma(t)$ with $\mu(t)$ the average and $\sigma(t)$ the standard deviation

4. Results and Discussion

In simulation

	Gold standard	standard	SLP	
			a_1	error
embolus detection	100 %	100 %	100 %	100 %
false alarm rate	0 %	32.37 %	7.49 %	5.80 %

In vivo

	Gold standard	standard	SLP
embolus detection	100 %	67 %	100 %
false alarm detection	0 %	0 %	0 %

Discussion

- ▶ Best detection with SLP : embolus can be detected even if it was inaudible up to now
- ▶ Synchronous error autocorrelation does not improve the detection: the error does not vary with the cardiac cycle

5. Conclusion

- ▶ Large microemboli are all detected
- ▶ Small microemboli are only detected with our new technique
- ▶ incorporate "on line" technique
