#### Abstract

: - Multiple Correspondence Analysis (MCA) and log-linear modeling are two techniques for multi-way contingency table analysis having different approaches and fields of applications. Log-linear models are interesting when applied to a small number of variables. Multiple Correspondence Analysis is useful in large tables. This efficiency is balanced by the fact that MCA is not able to explicit the relations between more than two variables, as can be done through log-linear modeling. The two approaches are complementary. We present in this paper the distribution of eigenvalues in MCA when the data fit a known log-linear model, then we construct this model by successive applications of MCA. We also propose an empirical procedure, fitting progressively the log-linear model where the fitting criterion is based on eigenvalue diagrams. The procedure is validated on several sets of data used in the literature.

Key-Words:

- Multiple Correspondence Analysis; eigenvalues; log-linear models; graphical models; normal distribution.

AMS Subject Classification:

- 49A05, 78B26.

[^0]
## 1. INTRODUCTION

Multiple Correspondence Analysis and log-linear modeling are two very different, but mutually beneficial approaches to analyzing multi-way contingency tables: log-linear models are profitably applied to a small number of variables. Multiple Correspondence Analysis is useful in large tables. This efficiency is balanced by the fact that MCA is not able to explicit relations between more than two variables, as can be done through log-linear modeling. The two approaches are complementary. After a short reminder on MCA and log-linear approaches, we study the distribution of eigenvalues in MCA under modeling hypotheses, especially in the case of independence. At the end we propose an algorithmic approach for fitting log-linear models where the fitting criterion is based on eigenvalues diagram.

## 2. A SHORT SURVEY OF MULTIPLE CORRESPONDENCE ANALYSIS AND LOG-LINEAR MODELS

We first introduce MCA and log-linear modelling, then we present some works using both methods.

### 2.1. Multiple Correspondence Analysis

Correspondence Analysis (CA) has quite a long history as a method for the analysis of categorical data. The starting point of this history is usually set in 1935 [28], and since then CA has been reinvented several times. We can distinguish simple CA (CA of contingency tables) and MCA or Multiple Correspondence Analysis (CA of so-called indicator matrices). MCA traces back to Guttman [23], Burt [8] or Hayashi [25]. In France, in the 1960s, Benzecri [6] proposes, other developments of this method. Outside France, MCA has been developed by J. de Leeuw since 1973 [22] under the name of Homogeneity Analysis, and the name of Dual Scaling by Nishisato [38].

Multiple Correspondence Analysis (MCA) is a multidimensional descriptive technique of categorical data. A theoretical version of Multiple Correspondence Analysis of $p$ variables can be defined as the limit, when the number of statistical units increases, of the CA of a complete disjunctive table.

Let $X$ be a complete disjunctive table of $p$ categorical variables $X_{1}, X_{2}, \ldots$, $X_{p}$, with respectively $m_{1}, m_{2}, \ldots, m_{p}$ modalities observed over a sample of $n$ individuals. CA of this complete disjunctive table is equivalent to the analysis of $B$ [8], where $B=X^{\prime} X$ is the Burt table associated with $X$. The two analyses have the same factors, but the eigenvalues in MCA equal to the squared
root of the eigenvalues in the CA of the associated Burt table. MCA of $X$ corresponds to the diagonalization of the matrix $\frac{1}{p}\left(D^{-1} X^{\prime} X\right)=\frac{1}{p}\left(D^{-1} B\right)$ where $D=\operatorname{Diag}\left(X^{\prime} X\right)=\operatorname{Diag}(B)$.

The structure of the eigenvalue diagram depends on the variable interactions. It is well known that in the case of pairwise independent variables, the $q$ non-trivial eigenvalues are theoretically equal to to $\frac{1}{p}$, where

$$
\begin{equation*}
q=\sum_{i=1}^{p} m_{i}-p \tag{1}
\end{equation*}
$$

### 2.2. Log-linear modeling

Log-linear modeling is a well-known method for studying structural relationships between categorical variables in a multiple contingency table when all the variables have no particular role. Relatively recent and not as well known in France as MCA, log-linear modeling has many classical references. After first works of Birch [7] in 1963 and Goodman [17], we must mention the basic books of Haberman [24], Bishop, Fienberg \& Holland [8], Fienberg [15].

More Recently, Dobson [12], Agresti [1], Christensen [10] have written syntheses on the subject supplemented with personal contributions.

Whittaker [41] devotes a large part of his book to log-linear models before defining associated graphical models.

### 2.2.1. Log-linear modeling in the binomial case

Let $X=\left(X_{1}, X_{2}, \ldots, X_{p}\right)$ be a $k$-dimensional random vector, with values in $\{0,1\}^{k}$. The expression for the $k$-dimensional probability density of X is:

$$
\begin{aligned}
f_{k}(X)= & p(0,0, \ldots, 0)^{\left(1-x_{1}\right)\left(1-x_{2}\right) \cdots\left(1-x_{k}\right)} \cdot p(1,0, \ldots, 0)^{x_{1}\left(1-x_{2}\right) \cdots\left(1-x_{k}\right)} \\
& \cdot p(0,1, \ldots, 0)^{\left(1-x_{1}\right) x_{2} \cdots\left(1-x_{k}\right)} \cdots p(0,0, \ldots, 1)^{\left(1-x_{1}\right)\left(1-x_{2}\right) \cdots x_{k}} \\
& \cdots p(1,1, \ldots, 0)^{x_{1} x_{2} \cdots\left(1-x_{k}\right)} \cdots p(1,1, \ldots, 1)^{x_{1} x_{2} \cdots x_{k}}
\end{aligned}
$$

We can write the density function as a log-linear expansion:

$$
\begin{aligned}
\log \left[f_{k}(X)\right]= & u_{o}+\sum_{i=1}^{k} u_{i} x_{i}+\sum_{\substack{i, j=1, i \neq j}}^{k} u_{i j} x_{i} x_{j}+\sum_{\substack{i, j, l=1, i \neq j \neq l}}^{k} u_{i j l} x_{i} x_{j} x_{l} \\
& +\cdots+u_{123 \ldots k} x_{1} x_{2} \cdots x_{k}
\end{aligned}
$$

where $u_{o}=\log [p(0,0, \ldots, 0)], u_{i}=\log \left[\frac{p(0,0, \ldots, 0,1,0, \ldots 0)}{p(0,0, \ldots, 0)}\right]$ and the u-terms $u_{i j}, \ldots, u_{123 \ldots k}$ are a log cross product ratio in the $(k, k)$ probability table. The $u$-term $u_{i j}$ is set to zero when $X_{i}$ and $X_{j}$ are independent variables.

### 2.2.2. Log-linear modeling in the multinomial case

Let $X=\left(X_{1}, X_{2}, \ldots, X_{k}\right)$ be a $k$-dimensional random vector, with values in $\left\{0,1, \ldots, m_{1}-1\right\} \times\left\{0,1, \ldots, m_{2}-1\right\} \times \ldots \times\left\{0,1, \ldots, m_{k}-1\right\}$ instead of in $\{0,1\}^{k}$ as in the preceding case.

The generalisation to the $k$-dimensional cross-classified multinomial distribution is the log-linear expansion:
$\log \left[f_{k}(X)\right]=u_{o}+\sum_{i=1}^{k} u_{i}(x)+\sum_{\substack{i, j=1, i \neq j}}^{k} u_{i j}(x)+\sum_{\substack{i, j, l=1, i \neq j \neq l}}^{k} u_{i j l}(x)+\cdots+u_{123} \ldots k(x)$.
Each $u$-term is a coordinate projection function with the coordinates indicated by its index; and each $u$-term is constrained to be zero whenever one of its indicated coordinates is zero.

The importance of log-linear expansions rests with the fact that many interesting hypotheses can be generated by setting some $u$-terms to zero.

We are interested particularly in this paper with graphical and hierarchical log-linear models.

### 2.2.2.1. Graphical log-linear models

Let $G=(K, E)$ be the independence graph of the $k$-dimensional random vector $X$, with $k$ vertices in $K=\{1,2, \ldots, k\}$ and edge set $E . G$ is the set of pairs $(i, j)$ such that whenever $(i, j)$ is not in $E$ the variables $X_{i}$ and $X_{j}$ are independent conditionally on the other variables.

Given an independence graph $G$, the cross classified multinomial distribution for the random vector $X$ is a graphical model for $X$, if the distribution of $X$ is different from constraints of the form that for all pair of coordinates not in the edge set $E$ of $G$, the $u$-terms constraining the selected coordinates are identically zero.

### 2.2.2.2. Hierarchical log-linear models

A graphical model satisfies constraints of the form that all $u$-terms 'above' a fixed point have to be zero to get conditional independence. A larger class of models, the hierarchical models, is obtained by allowing more flexibility in setting the $u$-terms to zero.

A $\log$-linear model is hierarchical if, whenever one particular $u$-term is constrained to zero then all higher $u$-terms containing the same set of subscripts are also set to zero.

We note here that every distribution with a log-linear expansion has an interaction (or independence) graph, and a hierarchical log-linear model is graphical if and only if its maximal $u$-terms correspond to cliques in the independence graph.

When all the $u$-terms are non-zero, we have the saturated model.
In the case when only the $u_{i}$ are non-zero, the model is called the mutual independence model:

$$
\log \left[f_{k}(X)\right]=u_{o}(x)+\sum_{i=1}^{k} u_{i}(x)
$$

When only $u_{i}$ and some of $u_{i j}$ are non-zero, the model is called a conditional independence model:

$$
\log \left[f_{k}(X)\right]=u_{o}(x)+\sum_{i=1}^{k} u_{i}(x)+\sum_{i, j} u_{i j}(x) .
$$

These conditional independence models refer to simple interactions between some variables.

### 2.2.3. Parameters estimation and related tests

Theoretical frequencies are generally estimated using the maximum-likelihood method. Weighted regression, or iterative methods can be also used as well since log-linear models are particular cases of the generalized linear model. Usually the classical $\chi^{2}$ or the $G^{2}$ tests (the likelihood ratio) are used to assess $\log$-linear models. The values of the two statistics increase with the number of variables, and decrease with the number of interactions. The closer the statistics are to zero, the better the models.

Model selection becomes difficult when the number of variables grow: e.g. with four variables there are 167 different hierarchical models. To avoid the "combinatory explosion" we can use criterions based on the Kullback information like the Akaike criterion:

$$
A I C=-2 \log (\widehat{L})+2 k \quad(\text { An Information criterion }),
$$

or the Schwartz criterion:

$$
\text { BIC }=-2 \log (\widehat{L})+k \log (n) \quad(\text { Bayesian Information criterion }),
$$

where $\widehat{L}$ is the maximum of the likelihood function $(L)$, and k the number of parameters maximising $L$.

### 2.3. Multiple Correspondence Analysis and log-linear model as complementary tools of analysis

In this section, we present some works that show how CA (or MCA) and log-linear modeling can be related. This leads to a better understanding of CA, and to a combined use of both methods.

CA is often introduced without any reference to other methods of statistical treatment of categorical data with proven usefulness and flexibility.

A major difference between CA and most other techniques for categorical data analysis lies in the use of probability models. In log-linear analysis (LLA), for example, a distribution is assumed under which the data are collected, then a log-linear model for the data is hypothesized and estimations are made under the assumption that this probability model is true, and finally these estimates are compared with the observed frequencies to evaluate the log-linear model. In this way it is possible to make inferences about the population on the basis of the sample data.

In CA, it is claimed that no underlying distribution has to be assumed and no model has to be hypothesized, but a decomposition of the data is obtained to study the 'structure' in the data.

A vast literature has been devoted to the assessment of CA (or MCA) and LLA. We briefly report here some of that literature.

Several works compare CA or MCA and LLA. Daudin and Trecourt [11] demonstrate empirically that LLA is better adapted to study global relationships between the variables, in the sense that marginal liaisons are eliminated in the computation of profiles.

Goodman [17],[18],[19],[20],[21] defines two models belonging to the same family: the saturated row column correspondence analysis model as a generalization of MCA, and the row column association model as a generalization of LLA. He demonstrates, with illustrations by examples, that using these models is better than using the classical methods.

Baccini, Mathieu and Mondot [3] use an example to compare the two methods. Jmel [30], De Falguerolles, Jmel and Whittaker [13],[14] use graphical models compared to MCA.

Other works use CA or MCA and LLA as a combined approach to contingency table analysis: Van der Heijden and de Leeuw [26],[27],[28], Novak and Hoffman [39] and others, use CA as a tool for the exploration of the residuals from log-linear models, and give an example of the procedure.

Worsley [42] shows that in certain cases CA leads directly to the appropriate log-linear model.

Lauro and Decarli [31] used AC as a procedure for the identification of best log-linear models.

## 3. EIGENVALUES IN CORRESPONDENCE ANALYSIS

It is well known that MCA is an extension of CA, although we first present eigenvalues in CA, and some simple rules for the selection of the number of eigenvalues.

### 3.1. Asymptotic distribution of eigenvalues in Correspondence Analysis

Let $N$ be a contingency table with $m_{1}$ rows and $m_{2}$ columns, and let us assume that $N$ is the realization of a multinomial distribution $M\left(n, p_{i j}\right)$ which is realistic. In this framework the observed eigenvalues $\mu_{i}$ are estimators of the eigenvalues $\lambda_{i}$ of $n P$, where $P$ is the table of unknown joint probabilities.

Lebart [32] and O'Neill [34],[35],[36] proved the following result:
if $\mu_{i}=0$ then $\lambda_{i}$ has the same distribution as the corresponding eigenvalues of a $\left(m_{1}-1\right)\left(m_{2}-1\right)$ degrees of freedom from the Wishart matrix: $W_{\left(m_{1}-1\right)\left(m_{2}-1\right)}(r, l)$ where $r=\min \left(m_{1}-1, m_{2}-1\right)$.

If $\mu_{j}=0$ then $\sqrt{\lambda_{j}}$ is asymptotically normally distributed, but with parameters depending on the unknown $p_{i j}$. Since it is difficult to test this hypothesis, some authors have proposed a bootstrap approach, which unfortunately is not valid: since the empirical eigenvalues, on which the replication is based, are generally not null, we cannot observe the distribution based on the Wishart matrix.

### 3.2. Malinvaud's test

Based upon the reconstitution formula, which is a weighted singular value decomposition of $N$ :

$$
n_{i j}=\frac{\left(n_{i \cdot} n_{\cdot j}\right)}{n}\left(1+\frac{\sum_{k}\left(a_{i k} b_{k i}\right)}{\sqrt{\lambda_{k}}}\right)
$$

where $a_{i k}, b_{i k}$ are the factorial components associated to the row and column profiles.

We may use a chi-square test comparing the observed $n_{i j}$ from a sample of size $n$ to the expected frequencies under the null-hypothesis $H_{k}$ of only $k$ non zeros. The $\mu_{i}$ weighted least squares estimates of these expectations are precisely the $\widetilde{n_{i j}}$ of the reconstitution formula with its first $k$ terms. We then compute the
classical chi-square goodness of fit statistic:

$$
Q_{k}=\sum_{i} \sum_{j} \frac{\left(\widetilde{n}_{i j}-n_{i j}\right)^{2}}{\widetilde{n}_{i j}}
$$

If $k=0$ (independence), $Q_{0}$ is compared to a chi-square with $\left(m_{1}-1\right)\left(m_{2}-1\right)$ degrees of freedom. Under $H_{k}, Q_{k}$ is asymptotically distributed like a chi-square with $\left(m_{1}-k-1\right)\left(m_{2}-k-1\right)$ degrees of freedom. However $Q_{k}$ suffers from the following drawback: if $n_{i j}$ is small, $\widetilde{n}_{i j}$ can be negative and the test statistic cannot be used. This is not the case for the modification proposed by E. Malinvaud [37] who proposed to use $\frac{\left(n_{i} \cdot n_{j}\right)}{n}$ instead of $\widetilde{n}_{i j}$ for the denominator. Furthermore, this leads to a simple relation with the sum of the discarded eigenvalues:

$$
Q_{k}^{\prime}=\sum_{i} \sum_{j} \frac{\left(\widetilde{n}_{i j}-n_{i j}\right)^{2}}{\frac{\left(n_{i} \cdot n_{j}\right)}{n}}=n\left(\lambda_{k+1}+\lambda_{k+2}+\ldots+\lambda_{r}\right) .
$$

$Q_{k}^{\prime}$ is also asymptotically distributed like a chi-square with $(p-k-1)(q-k-1)$ degrees of freedom.

## 4. BEHAVIOUR OF EIGENVALUES IN MCA UNDER MODELING HYPOTHESES

Let $X=\left(X_{1}\left|X_{2}\right| \ldots \mid X_{p}\right)$ be a disjunctive table of $p$ categorical variables $X_{i}$ (with respectively $m_{i}$ modalities) observed on a sample of $n$ individuals, and $q$ the number of non trivial eigenvalues (as defined in §2.1).

Multiple Correspondence Analysis is the CA of disjunctive table $X$.
The rank of $X: \operatorname{rank}(X)=\min (q+1 ; n)$, so equals $q+1$ if $n>q+1$.
We suppose, without loss of generality, that $n$ is large enough, which is the usual case. CA factors are the eigenvectors of the matrix $\frac{1}{p} D^{-1} B$ (where $B$ and $D$ are defined in §2.1). So $D^{-1} B$ is a diagonal unit matrix.

Its trace is: $\operatorname{Tr}\left(D^{-1} B\right)=\sum_{i=1}^{p} m_{i}$ and $\frac{1}{p} \operatorname{Tr}\left(D^{-1} B\right)=\frac{1}{p} \sum_{i=1}^{p} m_{i}$.
Since $\sum_{i=1}^{q} \mu_{i}=\frac{1}{p} \sum_{i=1}^{p} m_{i}-1$, we can conclude that

$$
\begin{equation*}
\frac{1}{q} \sum_{i=1}^{q} \mu_{i}=\frac{1}{p} \tag{2}
\end{equation*}
$$

and

$$
\begin{equation*}
\sum_{i=1}^{q}\left(\mu_{i}\right)^{2}=\frac{1}{p^{2}} \sum_{i=1}^{p}\left(m_{i}-1\right)+\frac{1}{p^{2}} \sum_{i \neq j} \sum \varphi_{i j}^{2} \tag{3}
\end{equation*}
$$

where $\varphi_{i j}^{2}$ is the observed Pearson's $\varphi^{2}$ crossing of $X_{i}$ with $X_{j}$, and

$$
\varphi^{2}=\frac{1}{n} \sum_{i} \sum_{j} \frac{\left(n_{i j}-\frac{n_{i \cdot n \cdot j}}{n}\right)^{2}}{\frac{n_{i \cdot n} \cdot n_{j}}{n}}=\frac{\chi^{2}}{n}
$$

( $n_{i}$. and $n_{\cdot j}$ are margin effectives).
Although MCA is an extension of CA, the results of $\S 3$ are not valid and one cannot use Malinvaud's test: elements of $X$ being 0 or 1 and not frequencies, $Q_{k}$ and $Q_{k}^{\prime}$ do not follow a chi-square distribution.

However it is possible to get information about the dispersion of the $q$ eigenvalues in particular cases [5].

### 4.1. Distribution of eigenvalues in MCA under independence hypothesis

Under the hypothesis of pairwise independence of the variables $X_{i}$, all $\varphi_{i j}^{2}=0$ and equation (3), becomes

$$
\sum_{i=1}^{q}\left(\mu_{i}\right)^{2}=\frac{1}{p^{2}} \sum_{i=1}^{p}\left(m_{i}-1\right)
$$

Using (2) we get

$$
\sum_{i=1}^{q}\left(\mu_{i}\right)^{2}=\frac{1}{p^{2}} q
$$

and finally:

$$
\sum_{i=1}^{q}\left(\mu_{i}\right)^{2}=\frac{1}{p^{2}}=\left[\frac{1}{q} \sum_{i}\left(\mu_{i}\right)\right]^{2}
$$

Since the mean of the squared $\mu_{i}$ equals their squared means only if all the terms are equal, we can conclude that all the eigenvalues have the same value, so that:

$$
\mu_{i}=\frac{1}{p}, \quad \forall i
$$

We conclude that the theoretical MCA (i.e. for the population), under the hypothesis of pairwise independence of the variables $X_{i}$ leads to one $q$-multiple non-trivial non-zero eigenvalue $\lambda=\frac{1}{p}$. And the eigenvalue diagram has the particular shape shown in Figure 1:

| $\lambda_{I}$ | Eigenvalues diagram |
| :---: | :---: |
| $\lambda_{1}$ | $* * * * * * * * * * * * * * * * * * * * * * * * * * * *$ |
| $\lambda_{2}$ | $* * * * * * * * * * * * * * * * * * * * * * * * * *$ |
| $\lambda_{3}$ | $* * * * * * * * * * * * * * * * * * * * * * * * * * *$ |
| $\lambda_{4}$ | $* * * * * * * * * * * * * * * * * * * * * * * * * *$ |
| $\lambda_{5}$ | $* * * * * * * * * * * * * * * * * * * * * * * * *$ |
| $\vdots$ | $* * * * * * * * * * * * * * * * * * * * * * * * *$ |
| $\lambda_{q}$ | $* * * * * * * * * * * * * * * * * * * * * * * * *$ |

Figure 1: Theoretical eigenvalues diagram in the independence case.

This result is not true when we have a finite sample, since sampling fluctuations make the observed $\varphi_{i j}^{2} \neq 0$. Although the trace of $\frac{1}{p}\left(D^{-1} B\right)$ and $\bar{\mu}$ the mean of the observed non-trivial eigenvalues, are constants, we observe $q$ different non-trivial eigenvalues $\mu_{i} \neq \frac{1}{p}$, and the eigenvalue diagram takes the shape shown in Figure 2:

| $\lambda_{I}$ | Eigenvalues diagram |
| :---: | :--- |
| $\lambda_{1}$ | $* * * * * * * * * * * * * * * * * * * * * * * * * * * * *$ |
| $\lambda_{2}$ | $* * * * * * * * * * * * * * * * * * * * * * * * *$ |
| $\lambda_{3}$ | $* * * * * * * * * * * * * * * * * * * * * * * * *$ |
| $\lambda_{4}$ | $* * * * * * * * * * * * * * * * * * * * * *$ |
| $\lambda_{5}$ | $* * * * * * * * * * * * * * * * * * * * *$ |
| $\vdots$ | $* * * * * * * * * * * * * * * * * * * *$ |
| $\lambda_{q}$ | $* * * * * * * * * * * * * * * * * * * *$ |

Figure 2: Observed eigenvalues diagram in the independence case.

### 4.1.1. Dispersion of eigenvalues

Let $S_{\mu}^{2}$ be the measure of $\mu_{i}$ around $\frac{1}{p}$ given by:

$$
S_{\mu}^{2}=\frac{1}{q} \sum_{i=1}^{q}\left(\mu_{i}-\frac{1}{p}\right)^{2}=\frac{1}{q} \sum_{i=1}^{q}\left(\mu_{i}\right)^{2}-\frac{1}{p^{2}}
$$

which implies

$$
\sum_{i=1}^{q}\left(\mu_{i}\right)^{2}=q\left(S_{\mu}^{2}+\frac{1}{p^{2}}\right)
$$

Using equations (1) $\&(3)$, we have:

$$
\sum_{i=1}^{q}\left(\mu_{i}\right)^{2}=\frac{q}{p^{2}}+\frac{1}{p^{2}} \sum_{i \neq j} \sum \varphi_{i j}^{2}=\frac{q}{p^{2}}+\frac{1}{n p^{2}} \sum_{i \neq j} \sum \chi_{i j}^{2}
$$

Under the hypothesis of pairwise independence of the variables, the $\chi_{i j}^{2}$ are realizations of $\chi_{\left(m_{i}-1\right)\left(m_{j}-1\right)}^{2}$ variables, so their expected values are $\left(m_{i}-1\right)\left(m_{j}-1\right)$.

We can then easily compute $E\left(\sum_{i=1}^{q}\left(\mu_{i}\right)^{2}\right)$, and get:

$$
E\left(\sum_{i=1}^{q}\left(\mu_{i}\right)^{2}\right)=\frac{q}{p^{2}}+\frac{1}{p^{2}} \frac{1}{n} \sum_{i \neq j} \sum\left(m_{i}-1\right)\left(m_{j}-1\right) .
$$

Finally:

$$
E\left(S_{\mu}^{2}\right)=\frac{1}{q} E\left(\sum_{i=1}^{q}\left(\mu_{i}\right)^{2}\right)-\frac{1}{p^{2}}
$$

and we obtain:

$$
E\left(S_{\mu}^{2}\right)=\frac{1}{p^{2}} \frac{1}{n} \frac{1}{q} \sum_{i \neq j} \sum\left(m_{i}-1\right)\left(m_{j}-1\right) .
$$

Now, since $E\left(S_{\mu}^{2}\right)=\sigma^{2}$, we may assume that $\frac{1}{p} \pm 2 \sigma$ contains roughly $95 \%$ of the eigenvalues. Moreover, since the kurtosis of the set of eigenvalues is lower than for a normal distribution, this proportion is actually probably larger then $95 \%$.

### 4.1.2. Estimation of the Burt table

Let $X$ be the disjunctive table associated to $p$ categorical variables $X_{i}$, with $m_{i}$ modalities respectively, observed on a sample of $n$ individuals, where $X_{i}=\left(X_{i 1}, X_{i 2}, \ldots, X_{i m_{i}}\right), X$ is a matrix made (of $p$-block) of $p$ blocks $X_{i}$

$$
X=\left(X_{1}\left|X_{2}\right| \ldots\left|X_{i}\right| \ldots \mid X_{p}\right) .
$$

Let $\left(X_{i 1}^{j}, X_{i 2}^{j}, \ldots, X_{i p}^{j}\right)$ be the observed value of $X_{i}$ on the $j^{\text {th }}$ individual.
We can write

$$
X=\left[\begin{array}{cccccccccc}
X_{11}^{1} & \cdots & X_{1 m_{1}}^{1} & X_{21}^{1} & \cdots & X_{2 m_{2}}^{1} & \cdots & X_{p 1}^{1} & \cdots & X_{p m_{p}}^{1} \\
X_{11}^{2} & \cdots & X_{1 m_{1}}^{2} & X_{21}^{2} & \cdots & X_{2 m_{2}}^{2} & \cdots & X_{p 1}^{2} & \cdots & X_{p m_{p}}^{2} \\
\vdots & & & \vdots & & \vdots & \vdots & \\
X_{11}^{n} & \cdots & X_{1 m_{1}}^{n} & X_{21}^{n} & \cdots & X_{2 m_{2}}^{n} & \cdots & X_{p 1}^{n} & \cdots & X_{p m_{p}}^{n}
\end{array}\right] .
$$

The Burt table of X is then

$$
B=\left[\begin{array}{cccc}
X_{1}^{\prime} X_{1} & X_{1}^{\prime} X_{2} & \cdots & X_{1}^{\prime} X_{p} \\
X_{2}^{\prime} X_{1} & X_{2}^{\prime} X_{2} & \cdots & X_{2}^{\prime} X_{p} \\
\vdots & \vdots & \ddots & \vdots \\
X_{p}^{\prime} X_{1} & X_{p}^{\prime} X_{2} & \cdots & X_{p}^{\prime} X_{p}
\end{array}\right]=\left[\begin{array}{cccc}
B_{11} & B_{12} & \cdots & B_{1 p} \\
B_{21} & B_{22} & \cdots & B_{2 p} \\
\vdots & \vdots & \ddots & \vdots \\
B_{p 1} & B_{p 2} & \cdots & B_{p p}
\end{array}\right],
$$

where
$B_{i}=B_{i i}$
$=X_{i}^{\prime} X_{i}=\left[\begin{array}{llll}\sum_{j=1}^{n}\left(X_{1 i}^{j}\right)^{2} & \sum_{j=1}^{n}\left(X_{1 i}^{j}\right)\left(X_{2 i}^{j}\right) & \cdots & \sum_{j=1}^{n}\left(X_{1 i}^{j}\right)\left(X_{m_{i} i}^{j}\right) \\ \sum_{j=1}^{n}\left(X_{2 i}^{j}\right)\left(X_{1 i}^{j}\right) & \sum_{j=1}^{n}\left(X_{2 i}^{j}\right)^{2} & \cdots & \sum_{j=1}^{n}\left(X_{2 i}^{j}\right)\left(X_{m_{i} i}^{j}\right) \\ \vdots & \vdots & \ddots & \vdots \\ \sum_{j=1}^{n}\left(X_{m_{i} i}^{j}\right)\left(X_{1 i}^{j}\right) & \sum_{j=1}^{n}\left(X_{m_{i} i}^{j}\right)\left(X_{2 i}^{j}\right) & \cdots & \sum_{j=1}^{n}\left(X_{m_{i} i}^{j}\right)^{2}\end{array}\right]$
and

$$
X_{k i}^{j}=\left\{\begin{array}{l}
0 \\
1
\end{array}\right.
$$

with $\sum_{k=1}^{m_{i}} X_{k i}^{j}=1$. Since there is only one $k$ in $\left\{1, \ldots, m_{i}\right\}$ such as $X_{j i}^{k}=1$, all other being zero, we obtain:

$$
\sum_{k=1}^{n}\left(X_{k i}^{j}\right)^{2}=\sum_{k=1}^{n} X_{k i}^{j} \quad \text { in } \quad\{1, \ldots, n\}, \quad \forall k \in\left\{1, \ldots, m_{i}\right\}
$$

and

$$
\sum_{k=1}^{n}\left(X_{k i}^{j}\right)\left(X_{k^{\prime} i}^{j}{ }^{j}\right)=0 \quad \forall k, \quad k \in\left\{1, \ldots, m_{i}\right\}
$$

And so can conclude that $\forall i=1, \ldots, p$ the diagonal sub-matrices of the Burt table are themselves diagonal matrices:

$$
X_{i}^{\prime} X_{i}=B_{i}=\left[\begin{array}{ccccc}
\sum_{j=1}^{n}\left(X_{1 i}^{j}\right)^{2} & & & & 0 \\
& \ddots & & & \\
& & \sum_{j=1}^{n}\left(X_{k i}^{j}\right)^{2} & & \\
& & & & \ddots
\end{array}\right]
$$

Furthermore, we know that

$$
\sum_{k=1}^{m_{i}}\left(\sum_{j=1}^{n} X_{k i}^{j}\right)=\sum_{k=1}^{m_{i}}\left(n_{k i}\right)=n
$$

where

$$
n_{k i}=\sum_{j=1}^{n} X_{k i}^{j}=n_{i}^{k}
$$

is the number of individuals that have the $k^{\text {th }}$ modality of the $i^{\text {th }}$ variable (for $1 \leq i \leq p$ and $1 \leq k \leq m_{i}$ ).

So the diagonal sub-matrices of the Burt table are:

$$
B_{i}=B_{i i}=\left[\begin{array}{ccccc}
n_{i}^{1} & & & & 0 \\
& \ddots & & & \\
& & n_{i}^{k} & & \\
& & & \ddots & \\
0 & & & & n_{i}^{m_{i}}
\end{array}\right] \quad \text { where } \sum_{k=1}^{m_{i}} \frac{n_{k i}}{n}=1 \quad \forall i=1, \ldots, p
$$

Consider now two independent variables $X_{\alpha}$ and $X_{\beta}$ amongst the p variables having respectively $m_{\alpha}$ and $m_{\beta}$ modalities.

Let $B_{\alpha}$ be the $\left(m_{\alpha}, m_{\alpha}\right)$ square matrix $B_{\alpha}=X_{\alpha}^{\prime} X_{\alpha}$, and $B_{\alpha \beta}$ the $\left(m_{\alpha}, m_{\beta}\right)$ rectangular matrix $B_{\alpha \beta}=X_{\alpha}^{\prime} X_{\beta}$.

We have

$$
\left(B_{\alpha}\right)_{i i}=\sum_{k=1}^{n} X_{i \alpha}^{k}=X_{\cdot i}^{\alpha} \quad \text { and } \quad\left(B_{\alpha}\right)_{i j}=0 \quad \text { if } i \neq j
$$

and where $\left(B_{\alpha \beta}\right)_{i j}=X_{i \alpha}^{k} X_{i \beta}^{k} \leq n$.
Under the hypothesis that $X_{\alpha}$ and $X_{\beta}$ are independent

$$
\left(B_{\alpha \beta}\right)_{i j}=\frac{\left(B_{\alpha}\right)_{i j}\left(B_{\beta}\right)_{i j}}{n}=\frac{X_{\cdot i}^{\alpha} X_{\cdot i}^{\beta}}{n}
$$

Since $X_{\cdot i}^{\alpha}=n_{i}^{\alpha}$ and $X_{\cdot i}^{\beta}=n_{i}^{\beta}$, we can write

$$
\left[\left(B_{\alpha \beta}\right)_{i j}=\sum_{k=1}^{n} X_{k i}^{\alpha} X_{k j}^{\beta}=\frac{X_{\cdot i}^{\alpha} X_{\cdot i}^{\beta}}{n}=\frac{n_{i}^{\alpha} n_{j}^{\beta}}{n}\right]
$$

and, more generally, we can conclude that

$$
X_{i}^{\prime} X_{j}=B_{i j}=\left[\begin{array}{cccc}
\frac{n_{1}^{i} n_{1}^{j}}{n} & \frac{n_{1}^{i} n_{2}^{j}}{n} & \cdots & \frac{n_{1}^{i} n_{m_{j}}^{j}}{n} \\
\frac{n_{2}^{i} n_{1}^{j}}{n} & \frac{n_{2}^{i} n_{2}^{j}}{n} & \cdots & \frac{n_{2}^{i} n_{m_{j}}^{j}}{n} \\
\vdots & \vdots & & \vdots \\
\frac{n_{m_{i}}^{i} n_{1}^{j}}{n} & \frac{n_{m_{i}}^{i} n_{2}^{j}}{n} & \cdots & \frac{n_{m_{i}}^{i} n_{m_{j}}^{j}}{n}
\end{array}\right]
$$

if the $p$ variables are mutually independent.

Now consider a sample of $p$ multinomial random variables $X_{i}$. Let $p_{i}^{k}=p_{i k}$ be the probability that an individual be in the $k^{\text {th }}$ category of the $i^{\text {th }}$ variable, and $p_{i j}^{k}$ be the probably that the $j^{\text {th }}$ individual be in the $k^{\text {th }}$ category of the $i^{\text {th }}$ variable.

The observed Burt table is:

$$
B=X^{\prime} X=\left[\begin{array}{cccc}
X_{1}^{\prime} X_{1} & X_{1}^{\prime} X_{2} & \cdots & X_{1}^{\prime} X_{p} \\
X_{2}^{\prime} X_{1} & X_{2}^{\prime} X_{2} & \cdots & X_{2}^{\prime} X_{p} \\
\vdots & \vdots & \vdots & \vdots \\
X_{p}^{\prime} X_{1} & X_{p}^{\prime} X_{2} & \cdots & X_{p}^{\prime} X_{p}
\end{array}\right]
$$

with
$X_{i}^{\prime} X_{i}=N_{i}=\left[\begin{array}{ccccc}\sum_{j=1}^{n}\left(X_{i j}^{1}\right)^{2} & & & & \\ & \ddots & & & \\ & & \sum_{j=1}^{n}\left(X_{k i}^{j}\right)^{2} & & \\ & & & \ddots & \\ & & & & \\ & & & & \\ & & & & \\ & & & \\ & & & \\ & & & \\ m_{i} i\end{array}\right)=\operatorname{diag}\left\{n_{i}^{1}, \ldots, n_{i}^{m_{i}}\right\}$.

But $n_{i}^{k}=\sum_{j=1}^{n}\left(X_{k i}^{i}\right)^{2}=n p_{i}^{k}$ and $\sum_{k=1}^{m_{i}} p_{i}^{k}=1$, so that $\sum_{k=1}^{m_{i}} n_{i}^{k}=n \sum_{k=1}^{m_{i}} p_{i}^{k}=n, \forall i=1, \ldots, p$
and $\quad X_{i}^{\prime} X_{j}=\left[\begin{array}{ccccc}n p_{i}^{1} & & & & 0 \\ & \ddots & & & \\ & & n p_{i}^{k} & & \\ & & & \ddots & \\ 0 & & & & n p_{i}^{m_{i}}\end{array}\right]$.
Since $X_{i}$ and $X_{j}$ are independent variables, $X_{i}^{\prime} X_{j}=N_{i j}$ and $\left(N_{i j}\right)_{k k^{\prime}}=$ $\left(X_{i}^{\prime} X_{j}\right)_{k k^{\prime}}=n p_{i}^{k} p_{j}^{k^{\prime}}$, which implies

$$
X_{i}^{\prime} X_{j}=N_{i j}=\left[\begin{array}{cccc}
n p_{1}^{i} p_{1}^{j} & n p_{1}^{i} p_{2}^{j} & \cdots & n_{1}^{i} n_{m_{j}}^{j} \\
n p_{2}^{i} p_{1}^{j} & n p_{2}^{i} p_{2}^{j} & \cdots & n p_{2}^{i} p_{m_{j}}^{j} \\
\vdots & \vdots & & \vdots \\
n p_{m_{i}}^{i} p_{1}^{j} & n p_{m_{i}}^{i} p_{2}^{j} & \cdots & n p_{m_{i}}^{i} p_{m_{j}}^{j}
\end{array}\right]
$$

The maximum-likelihood estimator of $p_{i}^{k}$ is $\hat{p}_{i}^{k}=\frac{n_{i}^{k}}{n}$, so

$$
\hat{N}_{i}=\left[\begin{array}{ccccc}
n_{i}^{1} & & & & 0 \\
& \ddots & & & \\
& & n_{i}^{k} & & \\
& & & \ddots & \\
0 & & & & n_{i}^{m_{i}}
\end{array}\right]=B_{i i}
$$

and

$$
\hat{N}_{i j}=\left[\begin{array}{cccc}
\frac{n_{1}^{i} n_{1}^{j}}{n} & \frac{n_{1}^{i} n_{2}^{j}}{n} & \cdots & \frac{n_{1}^{i} n_{m_{j}}^{j}}{n} \\
\frac{n_{2}^{i} n_{1}^{j}}{n} & \frac{n_{2}^{i} n_{2}^{j}}{n} & \cdots & \frac{n_{2}^{i} n_{m_{j}}^{j}}{n} \\
\vdots & \vdots & & \vdots \\
\frac{n_{m_{i} i}^{i} n_{1}^{j}}{n} & \frac{n_{m_{i}}^{i} n_{2}^{j}}{n} & \cdots & \frac{n_{m_{i}}^{i} n_{m_{j}}^{j}}{n}
\end{array}\right]=B_{i j} .
$$

We can conclude that the the maximum-likelihood estimator $\hat{B}$ of the theoretical Burt table is $\tilde{B}$ the observed one. Using the invariance functional propriety we can affirm that the maximum-likelihood estimators of the eigenvalues of $D^{-1} B$ are the eigenvalues of $D^{-1} \tilde{B}$, so that each $\mu_{i}$ is the maximum-likelihood estimator of $\lambda_{i}=\lambda$.

Maximum-likelihood estimators are asymptotically normal, and so, asymptotically, each $\mu_{i}$ is normally distributed. But due to the fact that eigenvalues are ordered, the eigenvalues are not identically and independently distributed. However:

$$
E\left(\mu_{1}\right)>\frac{1}{p}, \quad E\left(\mu_{q}\right)<\frac{1}{p} \quad \text { but } E\left(\mu_{1}\right) \underset{n \rightarrow \infty}{\longrightarrow} \frac{1}{p} \quad \text { and } \quad E\left(\mu_{q}\right) \underset{n \rightarrow \infty}{\longrightarrow} \frac{1}{p} .
$$

Furthermore the eigenvalue variances are not the same. And from simulations of large samples of $n$ observations ( $n=100, \ldots, n=10000$ ), we notice that the convergence of the eigenvalue distribution to a normal one is slow, especially for the extremes ( $\mu_{1}$ and $\mu_{q}$ ), even for very large samples [4].

### 4.2. Distribution of eigenvalues in MCA under non-independence hypotheses

### 4.2.1. Distribution of the theoretical eigenvalues

Let $\mu$ be an eigenvalue of $D^{-1} X^{\prime} X$. Since $\mu$ can be also obtained by diagonalization of $\frac{1}{p} X D^{-1} X^{\prime}, \mu$ is a solution of $\frac{1}{p} X D^{-1} X^{\prime} z=z$, where $z$ is an eigenvector associated to $\mu$.

So

$$
\frac{1}{p}\left(\sum_{i=1}^{p} X_{i}\left(X_{i}^{\prime} X_{i}\right)^{-1} X_{i}^{\prime}\right) z=\mu z \quad \Longleftrightarrow \quad \frac{1}{p} \sum_{i=1}^{p} P_{i} z=\mu z
$$

where $P_{i}=\sum_{i=1}^{p} X_{i}\left(X_{i}^{\prime} X_{i}\right)^{-1} X_{i}^{\prime}$ is the orthogonal projector on the space spanned by linear combinations of the indicators of variables categories $X_{i}$.

Let $A_{i}$ the centered projector associated to $P_{i}$ :

$$
A_{i}=P_{i}-\frac{1_{m_{i} m_{i}}}{n} \quad \text { where } 1_{m_{i} m_{i}}=\left[\begin{array}{cccc}
1 & 1 & \cdots & 1 \\
\vdots & \vdots & & \vdots \\
1 & 1 & \cdots & 1
\end{array}\right]
$$

And so we get

$$
\begin{equation*}
\frac{1}{p} \sum_{i=1}^{p} A_{i} z=\mu z . \tag{4}
\end{equation*}
$$

### 4.2.1.1. The Case of two-way interactions

Let us assume that among the $p$ studied variables, there is a two-way interaction between $X_{j}$ and $X_{k}$, and that the $(p-2)$ reminding variables are mutually independent. Multiplying equation (4) by $A_{j}$ we get:

$$
\frac{1}{p}(\underbrace{A_{j} A_{1}}_{0}+\underbrace{A_{j} A_{2}}_{0}+\cdots+\underbrace{A_{j} A_{j}}_{A j}+\cdots+A_{j} A_{k}+\cdots+\underbrace{A_{j} A_{p}}_{0}) z=\mu A_{j} z
$$

since all variables are pairwise independent except $X_{j}, X_{k}$, and the $A_{i}$ are orthogonal projectors. Thus:

$$
\begin{equation*}
A_{j} A_{k} z=(p \mu-1) A_{j} z \tag{5}
\end{equation*}
$$

Similarly, multiplying (4) by $A_{k}$, we get:

$$
\begin{equation*}
A_{k} A_{j} z=(p \mu-1) A_{k} z \tag{6}
\end{equation*}
$$

Now let us multiply (5) by $A_{k}$ to get:

$$
A_{k} A_{j} A_{k} z=(p \mu-1) A_{k} A_{j} z
$$

Using (6) we obtain

$$
A_{k} A_{j} \underbrace{A_{k} z}_{z_{1}}=(p \mu-1)^{2} \underbrace{A_{k} z}_{z_{1}} .
$$

With the notation $\lambda=(p \mu-1)^{2}$, we finally write:

$$
\begin{equation*}
A_{k} A_{j} z_{1}=\lambda z_{1} \tag{7}
\end{equation*}
$$

Equation (7) implies that $\lambda$ is an eigenvalue of the product of the centered projector $A_{k} A_{j}$ associated to the eigenvector $z_{1}$.

In general: $\forall j, k=1, \ldots, p$, if there is an interaction between $X_{j}$ and $X_{k}$, the orthogonal projector $A_{j} A_{k}$ admits a non zero eigenvalue $\lambda=(p \mu-1)^{2}$. If $\lambda \neq 0 \Leftrightarrow \mu \neq \frac{1}{p}$, the trace of Burt table being constant, there is, at least, another eigenvalue not equal to $\frac{1}{p}$.

Let $n_{0}$ be the number of eigenvalue non equal to $\frac{1}{p}$, so that $\sum_{i=1}^{n_{0}} \lambda_{i}=\frac{n_{0}}{p}$.
Theoretically, (except for the particular case, where $\lambda=1$, for which we have $\mu=\frac{2}{p}$ and $\mu^{\prime}=0$ ), the number of non-trivial-eigenvalues greater than $\frac{1}{p}$ is equal to the number of non-trivial eigenvalues smaller than $\frac{1}{p}$.

The eigenvalue diagram shape is shown on Figure 3:

| $\lambda_{I}$ | Eigenvalues diagram |
| :---: | :--- |
| $\lambda_{1}$ | $* * * * * * * * * * * * * * * * * * * * * * * * * * * *$ |
| $\lambda_{2}$ | $* * * * * * * * * * * * * * * * * * * * * * * * * *$ |
| $\lambda_{3}$ | $* * * * * * * * * * * * * * * * * * * * * * *$ |
| $\lambda_{4}$ | $* * * * * * * * * * * * * * * * * * * * * * *$ |
| $\lambda_{5}$ | $* * * * * * * * * * * * * * * * * * * * * * *$ |
| $\vdots$ | $* * * * * * * * * * * * * * * * *$ |
| $\lambda_{q}$ | $* * * * * * * * * * * * * * * * *$ |

Figure 3: Theoretical eigenvalues diagram in two-way interaction case.

The number $n_{0}$ depends on the number of categories of $X_{j}$ and $X_{k}$, on the number of variables and on the number of dependent variables.

Let $n_{1}$ be the multiplicity of $\frac{1}{p}$, we will show that $n_{1}=q-2 \min \left(\left(m_{j}-1\right)\right.$; $\left(m_{k}-1\right)$ ), when $p>2$, and when there is only one two-way interaction between the variables.

This result can be shown as follows:
Let us consider equation (4), and suppose, without loss of generality, that $X_{1}$ and $X_{2}$ are dependant. So, upon multiplication by $A_{3}: \frac{1}{p} \sum_{i=1}^{p} A_{i} z=\mu z$ becomes $\frac{1}{p}\left(A_{3} A_{1}+A_{3} A_{2}+A_{3} A_{3}+\cdots+A_{3} A_{P}\right) z=\mu A_{3} z$, and we get $\mu=\frac{1}{p}$.

Now multiply equation (4) by $A_{2}$ and $A_{1}$ in turn to get:

$$
\begin{aligned}
&\left\{\begin{aligned}
\left(A_{1} A_{1}+A_{1} A_{2}+A_{1} A_{3}+\cdots+A_{1} A_{P}\right) z & =p \mu A_{1} z \\
\left(A_{2} A_{1}+A_{2} A_{2}+A_{2} A_{3}+\cdots+A_{2} A_{P}\right) z & \Longleftrightarrow p \mu A_{2} z
\end{aligned}\right. \\
& \Longleftrightarrow\left\{\begin{array}{l}
\left(A_{1}+A_{1} A_{2}\right) z=p \mu A_{1} z \\
\left(A_{2} A_{1}+A_{2}\right) z=p \mu A_{2} z
\end{array}\right. \\
& \Longleftrightarrow\left\{\begin{array}{l}
A_{1} A_{2} b=\lambda z \\
A_{2} A_{1} b=\lambda z
\end{array}\right.
\end{aligned}
$$

where $\lambda=(p \mu-1)^{2}, a=A_{1} z$ and $b=A_{2} z$.
We recognize here the CA equations, so that the CA of Burt tables, when only two variables are dependent is equivalent to the CA of the contingency tables crossing the two dependent variables. It is well known that the number of eigenvalue in CA equals $q-2 \min \left(\left(m_{j}-1\right) ;\left(m_{k}-1\right)\right)$, and for all non trivial $\lambda_{i}$, there corresponds the values $\mu_{i}$ and $\mu_{i}^{\prime}$ such that:

$$
\mu_{i}=\frac{1+\sqrt{\lambda_{i}}}{p} \quad \text { and } \quad \mu_{i}^{\prime}=\frac{1-\sqrt{\lambda_{i}}}{p}
$$

Finally, the CA of the Burt table may have $2 \min \left(\left(m_{j}-1\right) ;\left(m_{k}-1\right)\right)$ eigenvalues non trivial and not equal to $\frac{1}{p}$, associated to the CA of the contingency table. So the number of supplementary eigenvalues equals $q-2 \min \left(\left(m_{j}-1\right) ;\left(m_{k}-1\right)\right)$.

There is, in addition, one $n_{1}$ multiple eigenvalue, where $n_{1}$ is at least $q-2 \min \left(\left(m_{j}-1\right) ;\left(m_{k}-1\right)\right)$.

### 4.2.1.2. The case of higher order interactions

Since the Burt table is constructed with pairwise cross products of variables, its observation cannot give us information about multiway interactions.

However the observation of the bi-dimensional theoretical Burt sub-tables, for all pairwise variable combinations, can provide us with all the two-way interactions.

The theoretical Burt table can reveal the existence of higher order interactions in the following case:

If $B_{i j} \neq B_{i i} 1_{m_{j} m_{j}} B_{j j}$ and $B_{i k} \neq B_{i i} 1_{m_{k} m_{k}} B_{k k}$ : there may be a triple interaction between $X_{i}, X_{j}$ and $X_{k}$.

In general, a Burt table doesn't give either the order of the interactions, or supplementary information on the eigenvalue behavior.

### 4.2.2. Distribution of observed eigenvalues

Exceptionally, with a small number of interactions, we observe the particular shape of the eigenvalue diagram exhibited in Figure 4, where we can distinguish eigenvalues near $\frac{1}{p}$ (theoretically equal to $\frac{1}{p}$ ), and so we are able to recognize the existence of the independent variables in the analysis.

| $\lambda_{I}$ | Eigenvalues diagram |
| :---: | :--- |
| $\lambda_{1}$ | $* * * * * * * * * * * * * * * * * * * * * * * * * * * *$ |
| $\lambda_{2}$ | $* * * * * * * * * * * * * * * * * * * * * * * * * *$ |
| $\lambda_{3}$ | $* * * * * * * * * * * * * * * * * * * * * * *$ |
| $\lambda_{4}$ | $* * * * * * * * * * * * * * * * * * * *$ |
| $\lambda_{5}$ | $* * * * * * * * * * * * * * * * * * * *$ |
| $\vdots$ | $* * * * * * * * * * * * *$ |
| $\vdots$ | $* * * * * * * * * * *$ |
| $\lambda_{q}$ | $* * * * * * * * * * *$ |

Figure 4: Observed eigenvalues diagram in a two-way interaction case.

When the number of interaction grows, we cannot distinguish eigenvalues theoretically equal to $\frac{1}{p}$ from the eigenvalues non equal to $\frac{1}{p}$.

To detect the existence or interactions, we can first check if the observed variables are mutually independent. In that case, the eigenvalues distribution diagram should have a particular shape (see §4.1.), with more than $95 \%$ of the eigenvalues within the confidence interval $\frac{1}{p} \pm 2 \sigma$ (see $\S$ 4.1.1).

If there is one or more eigenvalues out of the confidence interval, we can then assume the existence of one or more two-way interaction between variables.

## 5. AN EMPIRICAL PROCEDURE FOR FITTING LOG-LINEAR MODELS BASED ON THE MCA EIGENVALUE DIAGRAM

We propose an empirical procedure for progressively fitting a log-linear model where the fitting test at each step is based on the MCA eigenvalues diagram.

Let $X_{i}, X_{j}$ and $X_{k}$, three categorical variables, with respectively $m_{i}, m_{j}$ and $m_{k}$ modalities, and let a cross variable with $\left(m_{i} \times m_{j}\right)$ modalities. We suppose that $X_{i j}$ and $X_{k}$, have the same behavior if $m_{k}=m_{i} \times m_{j}$.

Under the hypothesis that two dependant variables $X_{i}$ and $X_{j}$ have the same behaviour as the variable $X_{k}$ with the same characteristics of the cross variable $X_{i j}$, we propose here an empirical procedure for fitting progressively, with $p$ steps, the log-linear model where the fitting criterion at each step is based on the MCA eigenvalue diagram. Distribution of observed eigenvalues

### 5.1. Description of the procedure steps

The first step of the procedure consist to test the pairwise independence hypothesis of the variables. To detect existence of interactions, we must first check if all variables are mutually independent. For that matter, we calculate the eigenvalues of MCA on all the $p$ variables, and construct the related confidence interval: the eigenvalue distribution diagram should have a particular shape (cf. $\S 4.1$.$) . If all the eigenvalues belong to the confidence interval \frac{1}{p} \pm 2 \sigma$ (cf. §4.1.1), we can conclude that the $p$ variables are mutually independent. The log-linear model associated to the variables is a simple additive one:

$$
\log \left[f_{p}(X)\right]=u_{0}(x)+\sum_{i=1}^{p} u_{i}(x)
$$

and the procedure is stopped.
If one or more eigenvalue are not in the confidence interval, we conclude that there is at least one double interaction between variables, and we go to the second step of the procedure.

In the second step, we look at all two-way interaction $u$-terms. We isolate one variable amongst the $p$ variables that we note $X_{p}$, without loss of generality, and so we obtain a set of $(p-1)$ variables $X_{i}$, and apply the first step to test pairwise independence of the $(p-1)$ variables.

If the $(p-1)$ variables are independent, we can conclude that the doubles interactions are amongst $X_{p}$ and at least one of the $X_{i}$, so we construct correspondent cross variables $X_{i p}$ by using the first step to test independence between variables ( $X_{i}, X_{p}$ ) where $i=1, \ldots, p-1$. The log-linear model associated to the variables is:

$$
\log \left[f_{p}(X)\right]=u_{0}(x)+\sum_{i=1}^{p} u_{i}(x)+\sum_{i=1}^{p-1} u_{i p}(x) \delta_{i p}
$$

and the procedure stopped, (with $\delta_{i p}=1$ if the interaction between $X_{p}$ and $X_{i}$ exists, otherwise it is set to zero.)

If the ( $p-1$ ) variables are not independent, we can conclude that there is double interaction between $X_{i}$ and $X_{j}$ where $i, j=1, \ldots, p-1$, and perhaps between $X_{i}$ and $X_{p}$.

We can construct correspondent cross variables $X_{i p}$ and $X_{i j}$ by using the first step to test independence of variables $\left(X_{i}, X_{p}\right)$ and variables $\left(X_{i}, X_{j}\right)$ where $i, j=1, \ldots, p-1$. The $\log$-linear model associated to the variables is:

$$
\log \left[f_{p}(X)\right]=u_{0}(x)+\sum_{i=1}^{p} u_{i}(x)+\sum_{i=1}^{p-1} u_{i p}(x) \delta_{i p}+\begin{aligned}
& \text { terms due to the interaction } \\
& \text { between three or more variables }
\end{aligned}
$$

and we go to the third step of the procedure
In the third step, we look at three-way interaction $u$-terms, by testing the dependence of variables $X_{i}$ and cross variables $X_{j k}$, where $i, j, k=1, \ldots, p$ and $i, j, k$ are different, and construct cross variables $X_{i j k}$. The independence test is based on the eigenvalue pattern of the related MCA as described in the first step.

Continuing this way, in the $k^{\text {th }}$ step, we look at $k$-way interaction $u$-terms, ... and in the least step we look at the $p$-way interaction $u$-term.

This algorithm is summarized in Figure 5.

### 5.2. An example for a graphical model

For this example we use a data set given by Haberman [24] that was used in Falguerolles et al. [14] to fit a graphical model. The data reports attitudes toward non therapeutic abortions among white subjects crossed with three categorical variables describing the subjects.

The data set is a contingency table observed for 3181 individuals, crossing four three modality variables $X_{1}, X_{2}, X_{3}$ and $X_{4}$, defined in Table 1 .

The first step of the procedure consists of testing the pairwise independence hypothesis of the variables. We first transform the contingency table in a complete disjunctive table, then calculate the parameters (defined in § 2.1 and §4.1.1) needed for the test (Table 2).

MCA on the four variables gives the eigenvalues diagram of Figure 6 .
The shape of eigenvalues diagram refers clearly to the existence of dependent variables.

Eigenvalues $\lambda_{1}, \lambda_{7}$ and $\lambda_{8}$ are not in the interval $I_{c}$, so there is at least two dependent variables: there is one or more two-way interactions between variables.

Figure 5: Block diagram for the Empirical procedure.

Table 1: Attitudes toward non therapeutic abortions among white.

| Year | Religion: | Education |  |  | Attitude: $X_{4}$ |  |  |
| :---: | :---: | :---: | :---: | :---: | ---: | :---: | :---: |

| $\lambda_{8}=0.1823$ | $* * * * * * * * * * *$ |

Figure 6: Eigenvalues diagram
(first step of the example for a graphical model).

The second step consists of the detection of two-way interactions. In a first time, we use our first step with only three variables $X_{1}, X_{2}$ and $X_{3}$.

With the values of $n$ and $m_{i}$ (for $i=1, \ldots, 3$ ) still the same, the other parameters become (Table 3):

Table 3: Parameters for the test (second step of the example for a graphical model).

| $q$ | $m$ | $\sigma$ | $I_{c}$ |
| :---: | :---: | :---: | :---: |
| 6 | 0.33333 | 0.0118 | $[0.3097,0.3569]$ |

We get the following eigenvalue diagram (Figure 7):

Figure 7: Eigenvalues diagram
(second step of the example for a graphical model).
$\lambda_{1}$ and $\lambda_{5}$ are not in interval $I_{c}$, so there is one or more two-way interaction between $X_{1}, X_{2}$ and $X_{3}$, as also as interactions between $X_{4}$ and others.

In a second step we look at the interactions between $X_{4}$ and $X_{i}(i=1,2,3)$.
For $i=1$ to $i=3$ we look at the eigenvalues of the MCA of $X_{4}$ with $X_{i}$, and calculate their variances and intervals $I_{c}$.

Crossing $X_{1}$ with $X_{4}$ we get (Table 4):

Table 4: MCA on $X_{1}$ and $X_{4}$ (parameters and eigenvalues).

| $q$ | $m$ | $\sigma$ | $I_{c}$ | $\lambda_{1}$ | $\lambda_{2}$ | $\lambda_{3}$ | $\lambda_{4}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 4 | 0.5 | 0.0125 | $[0.4750,0.5250]$ | 0.5389 | 0.5156 | 0.4644 | 0.4611 |

Crossing $\mathrm{X}_{2}$ with $\mathrm{X}_{4}$ we get (Table 5):

Table 5: MCA on $X_{2}$ and $X_{4}$ (parameters and eigenvalues).

| $q$ | $m$ | $\sigma$ | $I_{c}$ | $\lambda_{1}$ | $\lambda_{2}$ | $\lambda_{3}$ | $\lambda_{4}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 4 | 0.5 | 0.0125 | $[0.4750,0.5250]$ | 0.5741 | 0.5076 | 0.4924 | 0.4259 |

Crossing $X_{3}$ with $X_{4}$ we get (Table 6 ):

Table 6: MCA on $X_{3}$ and $X_{4}$ (parameters and eigenvalues).

| $q$ | $m$ | $\sigma$ | $I_{c}$ | $\lambda_{1}$ | $\lambda_{2}$ | $\lambda_{3}$ | $\lambda_{4}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 4 | 0.5 | 0.0125 | $[0.4750,0.5250]$ | 0.6112 | 0.5041 | 0.4959 | 0.3979 |

In the three cases, $\lambda_{1}$ and $\lambda_{4}$ are not in the intervals $I_{c}$, so there is a twoway interaction between $X_{1}$ and $X_{4}, X_{2}$ and $X_{4}$ and between $X_{3}$ and $X_{4}$, so we can construct cross variables $X_{4 i}$ having 9 modalities $(i=1,2,3)$.

Now, we use the first step with only two variables $X_{1}$ and $X_{2}$, after we look for interactions between $X_{3}$ and $X_{i}(i=1,2)$.

Crossing $X_{1}$ with $X_{2}$ we get (Table 7):
Table 7: MCA on $X_{1}$ and $X_{2}$ (parameters and eigenvalues).

| $q$ | $m$ | $\sigma$ | $I_{c}$ | $\lambda_{1}$ | $\lambda_{2}$ | $\lambda_{3}$ | $\lambda_{4}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 4 | 0.5 | 0.0125 | $[0.4750,0.5250]$ | 0.5153 | 0.5045 | 0.4955 | 0.4848 |

All the eigenvalues are in the confidence interval, so $X_{1}$ and $X_{2}$ are independent conditionally on the other, and there is no cross variable $X_{12}$. The corresponding $u$-term $u_{12}$ equals to zero.

Let us now look, when $i=1$ and $i=2$, at the eigenvalues of the MCA of $X_{3}$ with $X_{i}$, with their variances and intervals $I_{c}$ :

Crossing $X_{1}$ with $X_{3}$ we get (Table 8):
Table 8: MCA on $X_{1}$ and $X_{3}$ (parameters and eigenvalues).

| $q$ | $m$ | $\sigma$ | $I_{c}$ | $\lambda_{1}$ | $\lambda_{2}$ | $\lambda_{3}$ | $\lambda_{4}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 4 | 0.5 | 0.0125 | $[0.4750,0.5250]$ | 0.5134 | 0.5023 | 0.4978 | 0.4866 |

All the eigenvalues are in the confidence interval $I_{c}$, so $X_{1}$ and $X_{3}$ are independent conditionally on the other, and there is no cross variable $X_{13}$ : the corresponding $u$-term $u_{13}$ equals to zero.

Crossing now $X_{2}$ with $X_{3}$ we get (Table 9):

Table 9: MCA on $X_{2}$ and $X_{3}$ (parameters and eigenvalues).

| $q$ | $m$ | $\sigma$ | $I_{c}$ | $\lambda_{1}$ | $\lambda_{2}$ | $\lambda_{3}$ | $\lambda_{4}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 4 | 0.5 | 0.0125 | $[0.4750,0.5250]$ | 0.5401 | 0.5128 | 0.4872 | 0.4599 |

Here, $\lambda_{1}$ and $\lambda_{4}$ are not in the interval $I_{c}$, so there is a two-way interaction between $X_{2}$ and $X_{3}, u_{23}$ is not set to zero, and we can add the cross variable $X_{32}$ (as well as $X_{23}$ ) with 9 modalities to the model.

The third step consists of the detection of triple interactions between variables, that is to two-way interactions between the variables $X_{i}$ and the cross variables $X_{j k}$.

We first put the cross variables $\left(X_{41}, X_{42}, X_{43}, X_{32}\right)$ with the initial variables that were deemed non dependent in the second step of the procedure, i.e. $X_{1}$ and $X_{2}$, and then we use the first step of the procedure with the set of obtained variables.

So we get the following results (Table 10 and Figure 8):

Table 10: MCA on $X_{1}, X_{2}, X_{41}, X_{42}, X_{43}$ and $X_{32}$ (parameters third step of the example for a graphical model).

| $q$ | $m$ | $\sigma$ | $I_{c}$ |
| :---: | :---: | :---: | :---: |
| 36 | 0.1667 | 0.0168 | $[0.1331,0.2003]$ |

| $\lambda_{1}=0.5201$ | $* * * * * * * * * * * * * * * * * * * * * * * * * * * *$ |
| :--- | :--- |
| $\lambda_{2}=0.5006$ | $* * * * * * * * * * * * * * * * * * * * * * * * * *$ |
| $\lambda_{3}=0.3447$ | $* * * * * * * * * * * * * * * * *$ |
| $\lambda_{4}=0.3347$ | $* * * * * * * * * * * * * * * * *$ |
| $\lambda_{5}=0.3303$ | $* * * * * * * * * * * * * * * * * *$ |
| $\lambda_{6}=0.3193$ | $* * * * * * * * * * * * * * * * * *$ |
| $\lambda_{7}=0.1810$ | $* * * * * * * * * * * *$ |
| $\lambda_{8}=0.1796$ | $* * * * * * * * * * *$ |
| $\lambda_{9}=0.1732$ | $* * * * * * * * * * *$ |
| $\lambda_{10}=0.1710$ | $* * * * * * * * * * *$ |
| $\lambda_{11}=0.1664$ | $* * * * * * * * * * *$ |
| $\lambda_{12}=0.1627$ | $* * * * * * * * * * *$ |
| $\lambda_{13}=0.1626$ | $* * * * * * * * * * *$ |
| $\lambda_{14}=0.1578$ | $* * * * * * * * * *$ |
| $\lambda_{15}=0.1538$ | $* * * * * * * * * *$ |
| $\lambda_{16}=0.1423$ | $* * * * * * * * *$ |

Figure 8: MCA on $X_{1}, X_{2}, X_{41}, X_{42}, X_{43}$ and $X_{32}$
(eigenvalues diagram, third step of the example for a graphical model).

The first six eigenvalues are not in $I_{c}$ : there is one or more two-way interaction between the initial variables $X_{i}$, and the crossed ones $X_{i k}$, so there exists a triple interaction between simple variables.

We drop $X_{32}$ and use the first step with the five other variables to get the following results (Table 11 and Figure 9):

Table 11: MCA on $X_{1}, X_{2}, X_{41}, X_{42}$ and $X_{43}$
(parameters for the test).

| $q$ | $m$ | $\sigma$ | $I_{c}$ |
| :---: | :---: | :---: | :---: |
| 28 | 0.2 | 0.0162 | $[0.1671,0.2324]$ |

| $\lambda_{1}=0.6105$ | $* * * * * * * * * * * * * * * * * * * * * * * * * *$ |
| :--- | :--- | :--- |
| $\lambda_{2}=0.6006$ | $* * * * * * * * * * * * * * * * * * * * * * * * * *$ |
| $\lambda_{3}=0.4143$ | $* * * * * * * * * * * * * * * *$ |
| $\lambda_{4}=0.4028$ | $* * * * * * * * * * * * * * * *$ |
| $\lambda_{5}=0.3982$ | $* * * * * * * * * * * * * * * *$ |
| $\lambda_{6}=0.3831$ | $* * * * * * * * * * * * * * *$ |
| $\lambda_{7}=0.2262$ | $* * * * * * * * * *$ |
| $\lambda_{8}=0.2220$ | $* * * * * * * * * *$ |
| $\lambda_{9}=0.2162$ | $* * * * * * * * * *$ |
| $\lambda_{10}=0.2083$ | $* * * * * * * * *$ |
| $\lambda_{11}=0.2054$ | $* * * * * * * * *$ |
| $\lambda_{12}=0.2017$ | $* * * * * * * * *$ |
| $\lambda_{13}=0.1952$ | $* * * * * * * * *$ |
| $\lambda_{14}=0.1986$ | $* * * * * * * * *$ |
| $\lambda_{15}=0.1952$ | $* * * * * * * * *$ |
| $\lambda_{16}=0.1928$ | $* * * * * * * * *$ |
| $\lambda_{17}=0.1878$ | $* * * * * * * *$ |
| $\lambda_{18}=0.1837$ | $* * * * * * * *$ |
| $\lambda_{19}=0.1815$ | $* * * * * * * *$ |
| $\lambda_{20}=0.1711$ | $* * * * * * * *$ |
|  | $*$ |

Figure 9: MCA on $X_{1}, X_{2}, X_{41}, X_{42}$ and $X_{43}$
(eigenvalues diagram, third step of the example for a graphical model).

The first six eigenvalues are not in $I_{c}$, so there is at least one two-way interaction between the variables. We know that simple variables $X_{1}, X_{2}$ and the crossed variables $X_{41}, X_{42}, X_{43}$ are dependent so we have to test dependence between $X_{1}$ and $X_{32}$ only. Crossing $X_{1}$ and $X_{32}$ we get the following results (Table 12):

Table 12: MCA on $X_{1}$ and $X_{32}$ (parameters and eigenvalues).

| $q$ | $m$ | $\sigma$ | $I_{c}$ |
| :---: | :---: | :---: | :---: |
| 10 | 0.5 | 0.0159 | $[0.4682,0.5318]$ |

| $\lambda_{1}$ | $\lambda_{2}$ | $\lambda_{3}$ | $\lambda_{4}$ | $\lambda_{5}$ | $\lambda_{6}$ | $\lambda_{7}$ | $\lambda_{8}$ | $\lambda_{9}$ | $\lambda_{10}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 0.5287 | 0.5194 | 0.5000 | 0.5000 | 0.5000 | 0.5000 | 0.5000 | 0.5000 | 0.4806 | 0.4713 |

All the eigenvalues are in the confidence interval $I_{c}$, so $X_{1}$ and $X_{32}$ are independent conditionally on the other, and there is no cross variable $X_{132}$. The corresponding $u$-term $u_{123}$ equals zero.

Now we can drop the cross variable $X_{43}$. The remaining variables $X_{1}, X_{2}$, $X_{41}, X_{42}$ are dependent by construction. We have only to test for dependence between $X_{1}$ and $X_{43}$.

Crossing $X_{1}$ with $X_{43}$, we get the same parameter as the crossing of $X_{1}$ and $X_{32}$, and the following eigenvalues (Table 13):

Table 13: MCA on $X_{1}$ and $X_{43}$ (eigenvalues).

| $\lambda_{1}$ | $\lambda_{2}$ | $\lambda_{3}$ | $\lambda_{4}$ | $\lambda_{5}$ | $\lambda_{6}$ | $\lambda_{7}$ | $\lambda_{8}$ | $\lambda_{9}$ | $\lambda_{10}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 0.5445 | 0.5232 | 0.5000 | 0.5000 | 0.5000 | 0.5000 | 0.5000 | 0.5000 | 0.4768 | 0.4555 |

We remark that $\lambda_{1}$ and $\lambda_{10}$ are not in the interval $I_{c}$, so $X_{1}$ and $X_{43}$ seem to be dependent. But we have to fit a graphical model, that is a particular case of hierarchical models (as defined in $\S 2.2 .2 .2$, a log-linear models is hierarchical if, whenever one particular $u$-term is constrained to zero then all higher $u$-terms containing the same set of subscripts are also set to zero).

Here the $u$-term $u_{13}$ is set to zero, so the $u$-term $u_{134}$ is also set to zero.
Crossing $X_{2}$ with $X_{43}$, we get the same parameter as the crossing of $X_{1}$ and $X_{32}$, and the following eigenvalues (Table 14):

Table 14: MCA on $X_{2}$ and $X_{43}$ (eigenvalues).

| $\lambda_{1}$ | $\lambda_{2}$ | $\lambda_{3}$ | $\lambda_{4}$ | $\lambda_{5}$ | $\lambda_{6}$ | $\lambda_{7}$ | $\lambda_{8}$ | $\lambda_{9}$ | $\lambda_{10}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 0.5871 | 0.5466 | 0.5000 | 0.5000 | 0.5000 | 0.5000 | 0.5000 | 0.5000 | 0.4534 | 0.4143 |

Eigenvalues $\lambda_{1}, \lambda_{2}, \lambda_{9}$ and $\lambda_{10}$ are not in the interval $I_{c}$, the $u$-terms $u_{23}$ and $u_{24}$ are not set to zero, and since $X_{2}$ and $X_{43}$ are not dependent the $u$-term $u_{234}$ is not set to zero.

Crossing $X_{1}$ with $X_{42}$ (or equivalently $X_{2}$ with $X_{41}$ ) we get the same parameter as the crossing of $X_{1}$ and $X_{32}$, and the following eigenvalues:

Table 15: MCA on $X_{1}$ and $X_{42}$ (eigenvalues).

| $\lambda_{1}$ | $\lambda_{2}$ | $\lambda_{3}$ | $\lambda_{4}$ | $\lambda_{5}$ | $\lambda_{6}$ | $\lambda_{7}$ | $\lambda_{8}$ | $\lambda_{9}$ | $\lambda_{10}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 0.5434 | 0.5289 | 0.5000 | 0.5000 | 0.5000 | 0.5000 | 0.5000 | 0.5000 | 0.4711 | 0.4566 |

Eigenvalues $\lambda_{1}$ and $\lambda_{10}$ are not in the interval $I_{c}$, the $u$-term $u_{14}$ is equal to zero, $X_{1}$ and $X_{42}$ are dependent, and the $u$-term $u_{124}$ is set to zero.

Finally, variables $X_{1}$ and $X_{41}$ are dependent by construction.
The procedure stops here because we can't have more than triple interactions in a hierarchical model when all the two-way interactions are not present. We obtain the following model (see Figure 10 for the associated graph):

Figure 10: Lattice diagram (example for a graphical model).

$$
\begin{aligned}
\log \left[f_{4}(X)\right]= & u_{0}+u_{1} x_{1}+u_{2} x_{2}+u_{3} x_{3}+u_{4} x_{4}+u_{32} x_{2} x_{3}+u_{41} x_{4} x_{1}+u_{42} x_{4} x_{2} \\
& +u_{43} x_{4} x_{3}+u_{432} x_{4} x_{3} x_{2}
\end{aligned}
$$

### 5.3. An example for a saturated model

Here we use a data set given by Israëls [29] that was also used by Van der Heijden et al. [28] about 'shop-lifting' habits.

Table 16 is a contingency table crossing three variables: sex ( 2 modalities), age ( 9 modalities) and type of goods ( 13 modalities: Clothing (C), Clothing accessories (Ca), Provision-Tobacco (PT), Writing materials (Wm), Books (B), Records (R), Household goods (Hg), Sweets (S), Toys (T), Jewellery (J), Perfume $(\mathrm{P})$, Hobbies tools $(\mathrm{Ht})$, and Others(O)) observed over 33101 individuals.

In the first step, we test the pairwise independence of variables $X_{1}, X_{2}$ and $X_{3}$. We first transform the contingency table in a complete disjunctive table, then compute the parameters (defined in $\S 2.2 \& \S 4.1 .1$ ) needed for the test to get (Table 17).

A MCA on the three variables gives the eigenvalue diagram of Figure 11.
The eigenvalue diagram shows clearly that the variables are not independent: only 8 eigenvalues $\left(\lambda_{7}, \ldots, \lambda_{15}\right)$ are in the confidence interval.

Using the second step of the procedure, we get the two-way interactions.

Table 16: Multicontingency table for the shop-lifting data.

| $\begin{gathered} \hline \text { Sex: } \\ X_{1} \end{gathered}$ | $\begin{gathered} \text { Age: } \\ X_{2} \end{gathered}$ | Goods: $X_{3}$ |  |  |  |  |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

Figure 12: MCA on $X_{1}$ and $X_{3}$
(eigenvalues diagram, second step of the example for a saturated model).

The first and the last eigenvalues are not in the confidence interval so the $u$-term $u_{13}$ is not set to zero.

We notice here the peculiar form of the eigenvalues diagram, due to the fact that multiple eigenvalue $\lambda=\frac{1}{2}$ that have a multiplicity $11=m_{3}-m_{1}$ is an artificial one (cf. §4.2.1.1).

MCA of $X_{2}$ and $X_{3}$ gives the following results (Table 19 and Figure 13):

Table 19: MCA on $X_{2}$ and $X_{3}$ (parameters).

| $n$ | $p$ | $q$ | $m$ | $\sigma$ | $I_{c}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 33101 | 2 | 20 | 0.5 | 0.0001 | $[0.4998,0.5002]$ |

The 8 first and the 8 last eigenvalues are not in the confidence interval so the $u$-term $u_{23}$ is not set to zero.

| $\lambda_{1}=0.7852$ | $* * * * * * * * * * * * * * * * * * * * * * * * * * * * * * * * * * * * * * * *$ |
| :--- | :--- |

| $\lambda_{18}=0.4097$ | $* * * * * * * * * * * *$ |
| $\lambda_{19}=0.3926$ | $* * * * * * * * * * *$ |
| $\lambda_{20}=0.2148$ | $* * * * * *$ |

Figure 13: MCA on $X_{2}$ and $X_{3}$
(eigenvalues diagram, second step of the example for a saturated model).

MCA of $X_{1}$ and $X_{2}$ gives the following eigenvalue results (Table 20, Figure 14):

Table 20: MCA on $X_{1}$ and $X_{2}$ (parameters).

| $n$ | $p$ | $q$ | $m$ | $\sigma$ | $I_{c}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 33101 | 2 | 9 | 0.5 | 0.0037 | $[0.4926,0.5074]$ |

| $\lambda_{1}=0.6241$ | $* * * * * * * * * * * * * * * * * * * * * * * * * * * * * * * * * * * * * * * *$ |
| :--- | :--- |
| $\lambda_{2}=0.5000$ | $* * * * * * * * * * * * * * * * * * * * * * * * *$ |
| $\lambda_{3}=0.5000$ | $* * * * * * * * * * * * * * * * * * * * * * * * *$ |
| $\lambda_{4}=0.5000$ | $* * * * * * * * * * * * * * * * * * * * * * * * *$ |
| $\lambda_{5}=0.5000$ | $* * * * * * * * * * * * * * * * * * * * * * * * *$ |
| $\lambda_{6}=0.5000$ | $* * * * * * * * * * * * * * * * * * * * * * * * *$ |
| $\lambda_{7}=0.5000$ | $* * * * * * * * * * * * * * * * * * * * * * * * *$ |
| $\lambda_{8}=0.5000$ | $* * * * * * * * * * * * * * * * * * * * * * * * *$ |
| $\lambda_{9}=0.3759$ | $* * * * * * * * * *$ |

Figure 14: MCA on $X_{1}$ and $X_{2}$
(eigenvalues diagram, second step of the example for a saturated model).

The first and the last eigenvalues are not in the confidence interval so the $u$-term $u_{12}$ is not set to zero. At the end of the second step, we obtain all three
two-way interactions. To know if the model is a saturated one we can built one of the crossed variables and test its dependence with the remaining simple variable.

MCA of $X_{32}$ with $X_{1}$ gives the following eigenvalues:

$$
\begin{aligned}
\lambda_{1}=0.7285, \quad \lambda_{2}=\lambda_{3}=\cdots= & \lambda_{116}
\end{aligned}=0.5, \quad \text { and } \quad I_{c}=[0.4615,0.5384] .
$$

The first and the last eigenvalues are not in the confidence interval so the $u$-term $u_{123}$ is not set to zero.

At the end we get the following saturated model:

$$
\begin{aligned}
\log \left[f_{3}(X)\right]= & u_{0}+u_{1} x_{1}+u_{2} x_{2}+u_{3} x_{3}+u_{12} x_{1} x_{2}+u_{23} x_{2} x_{3}+u_{13} x_{1} x_{3} \\
& +u_{123} x_{1} x_{2} x_{3} .
\end{aligned}
$$

### 5.4. An example for a mutual independence model

Here we use a data set given by Andersen [2] as a contingency table crossing four variables observed over 299 individuals corresponding to a retrospective study of ovary cancer, defined in Table 21:

Table 21: Retrospective study of ovary cancer.

| $X_{1}$ <br> stage | $X_{2}$ <br> operation | $X_{3}$ <br> survival | $X_{4}$ <br> X-ray |  |
| :---: | :---: | :---: | ---: | ---: |
|  |  |  | No | Yes |
| Early | radical | no | 10 | 17 |
|  | limited | yes | 41 | 64 |
|  |  | no | 1 | 3 |
|  |  | yes | 13 | 9 |
| Advanced | radical | no | 38 | 64 |
|  | limited | yes | 6 | 11 |
|  |  | no | 3 | 13 |
|  |  | yes | 1 | 5 |

In the first step of procedure, we test for the pairwise independence of variables $X_{1}, X_{2}, X_{3}$ and $X_{4}$. We first transform the contingency table in a complete disjunctive table, then compute the parameters (see §4.1.1) needed for the test.

The MCA on the four variables gives the following results (Table 22 and Figure 15):

Table 22: Parameters needed for the test (first step of the example for a mutual independence model).

| $n$ | $p$ | $m_{1}$ | $m_{2}$ | $m_{3}$ | $m_{4}$ | $q$ | $m$ | $\sigma$ | $I_{c}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 299 | 4 | 2 | 2 | 2 | 2 | 4 | 0.25 | 0.0250 | $[0.2000,0.3000]$ |

$$
\begin{array}{|l|l|}
\hline \lambda_{1}=0.4145 & * * * * * * * * * * * * * * * * * * * * * * * * * * * * * * * * * * \\
\lambda_{2}=0.2512 & * * * * * * * * * * * * * * * * \\
\lambda_{3}=0.2449 & * * * * * * * * * * * * * * * * \\
\lambda_{4}=0.0894 & * * * * * * * * \\
\hline
\end{array}
$$

Figure 15: MCA on $X_{1}, X_{2}, X_{3}$ and $X_{4}$
(eigenvalues diagram, first step of the example for a mutual independence model).

The eigenvalue diagram shows clearly that variables are not independent, only $\lambda_{2}$ and $\lambda_{3}$ are in the confidence interval.

Let's drop $X_{4}$ and use the second step of the procedure. MCA on the three remaining variables gives the following results (Table 23 and Figure 16):

Table 23: MCA on $X_{1}, X_{2}$ and $X_{3}$
(parameters).

| $n$ | $p$ | $q$ | $m$ | $\sigma$ | $I_{c}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 299 | 3 | 3 | 0.3333 | 0.0273 | $[0.2787,0.3879]$ |

| $\lambda_{1}=0.3639$ | $* * * * * * * * * * * * * * * * * * * * * *$ |
| :--- | :--- |
| $\lambda_{2}=0.3342$ | $* * * * * * * * * * * * * * * *$ |
| $\lambda_{3}=0.3019$ | $* * * * * * * * * * * * * * * * * *$ |

Figure 16: MCA on $X_{1}, X_{2}$ and $X_{3}$ (eigenvalues diagram).

The eigenvalue diagram shows clearly that variables are independent, since all the eigenvalues are in the confidence interval, so there is surely one or more interaction $X_{4}$ and $X_{i}, i=1, \ldots, 3$.

The MCA on $X_{4}$ and $X_{i}$ gives the following results (Table 24 and Figure 17):

Table 24: MCA on $X_{4}, X_{i}$
(parameters).

| $n$ | $p$ | $q$ | $m$ | $\sigma$ | $I_{c}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 299 | 2 | 2 | 0.5 | 0.0283 | $[0.4434,0.5566]$ |

| $X_{4}$ and $X_{1}$ |  | $X_{4}$ and $X_{2}$ | $X_{4}$ and $X_{3}$ |
| :--- | :--- | :--- | :--- |
| $\lambda_{1}=0.5365$ | $* * * * * * * * * *$ | $\lambda_{1}=0.8198$ | $* * * * * * * * * *$ |
| $\lambda_{2}=0.4635$ | $* * * * * * * * *$ | $\lambda_{2}=0.1802$ | $* * *$ |

Figure 17: Eigenvalues diagram for MCA on $X_{4}$ and $X_{1}$, MCA on $X_{4}$ and $X_{2}$ and MCA on $X_{4}$ and $X_{3}$.

It's clear that there exists only an interaction between $X_{4}$ and $X_{2}, X_{1}$ and $X_{3}$ are non dependent of $X_{4}$, then $u_{14}=u_{13}=0$ and $u_{24} \neq 0$ and we build the crossed variable $X_{24}$.

The MCA of $X_{1}, X_{3}$ and $X_{24}$ gives the following results (Table 25 and Figure 18):

Table 25: MCA on $X_{1}, X_{3}$ and $X_{24}$
(parameters).

| $n$ | $p$ | $q$ | $m$ | $\sigma$ | $I_{c}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 299 | 3 | 5 | 0.3333 | 0.0273 | $[0.2787,0.3879]$ |

| $\lambda_{1}=0.3647$ | $* * * * * * * * * * * * * * * * * * * * * * *$ |
| :--- | :--- |
| $\lambda_{2}=0.3624$ | $* * * * * * * * * * * * * * * * * * * * *$ |
| $\lambda_{3}=0.3333$ | $* * * * * * * * * * * * * * * * * * * *$ |
| $\lambda_{4}=0.3047$ | $* * * * * * * * * * * * * * * * * * * *$ |
| $\lambda_{5}=0.3016$ | $* * * * * * * * * * * * * * * * * * * *$ |

Figure 18: Eigenvalues diagram for MCA on $X_{1}, X_{3}$ and $X_{24}$.

The eigenvalue diagram shows that the variables are independent, all the eigenvalues being within the confidence interval, and there is no triple interaction between variables.

We finally obtain the same model as Andersen:

$$
\log \left[f_{4}(X)\right]=u_{0}+u_{1} x_{1}+u_{2} x_{2}+u_{3} x_{3}+u_{4} x_{4}+x_{24} x_{4} x_{2}
$$

## 6. CONCLUSION

Log-linear modeling and MCA are two complementary techniques for the analysis of categorical data. In this framework, we propose a method for fitting progressively log-linear models, using the eigenvalue shape of MCA.

We show that, in MCA, under the independence hypothesis for the variables, each observed eigenvalue is asymptotically normally distributed. These distributions have the same mean, different variances and converge to normal distributions. In this case, the eigenvalue diagram takes a peculiar shape. This shape is different if there is one or more interactions between variables, and we can recognize the log-linear model fitted for the data in some special cases.

Then, based on these results, we propose a simple procedure for progressively fitting log-linear models, where the fitting criterion is based on MCA eigenvalue diagrams: the chosen model is constructed by successive utilizations of MCA (non constrained by the variables number). Finally, we validate this procedure on three sets of data drawn from the literature.
