**Abstract**— This paper presents the design and demonstration of linearly-polarized and circularly-polarized transmit-arrays operating in the 60-GHz band. The arrays are fabricated with standard printed-board technology and are designed with a fairly simple structure using three metal layers. The experimental results show very good performances for both arrays with a gain of 22-23 dBi, a -3 dB gain-bandwidth of 11-13%, and low cross-polarization level.

## I. INTRODUCTION

Many different configurations of transmit-arrays have been proposed using various technologies (laminates, glass) from C- to K-band [4-6]. Reconfigurable arrays based on semiconductor or RF-MEMS devices have also been introduced recently; they exhibit very promising features despite the fabrication complexity of active structures.

To our knowledge, this paper is the first one reporting on transmit-array antennas operating in V-band around 60 GHz. Their fabrication with a standard printed-board technology demonstrates their promising capabilities for low-cost fabrication and integration in vehicles, building or portable terminals for the above-mentioned applications. Both linear and circular-polarization arrays are studied

## II. TRANSMIT-ARRAY DESIGN

The design of the linear polarization transmit-array was performed with an analytical model previously presented in [6] and using the results of electromagnetic simulations of the focal source (radiation pattern) and the unit-cells (S-parameters and radiation patterns). The simulation results show that maximum gain values of about 23 dBi are obtained for  $F/D \sim 0.5-1$ , as a result of trade-off between amplitude taper losses and spill-over losses which are decreasing and increasing respectively with the focal distance.

A circular-polarization transmit-array was designed using the four linearly-polarized unit-cells (sequential rotation). In this design, the four unit-cells correspond to four transmission phase states,  $90^\circ$  apart (2-bit design), with respect to a circular polarization.

A prototype has been fabricated with  $F/D = 0.5$ , the computed directivity and gain are 24.7 dBi and 22.1 dBi respectively, corresponding to an efficiency of 55.5%.

A maximum gain of 22 dBi is reached at 61.5 GHz. The simulated and measured -3 dB gain-bandwidth are 6.6 GHz (11%) and 8.2 GHz (13.3%) respectively. The cross-

polarization level is below -15 dB across the whole bandwidth.

A good agreement between simulation and measurement is obtained with a beamwidth of  $7^\circ/6.75^\circ$  (sim./meas.). Sidelobe levels are -20 dB/-16 dB (sim./meas.).

## III. CONCLUSIONS

Two 60-GHz transmit-arrays have been designed in linear and circular polarization. They are fabricated with standard printed-board technology and materials. Gain levels of about 22-23 dBi have been demonstrated with an array aperture of  $10\lambda_x \times 10\lambda_y$ , and a 10 dBi focal source. Their wide bandwidth (11-13%) makes them very appropriate for high-data rate communications in V- and E-bands. Another significant advantage demonstrated with these structures is the possibility to generate very good circular polarization quality from a simple linearly-polarized focal source.
