24 ABSTRACT

25

Manuscrit d'auteur / Author manuscript

Manuscrit d'auteur / Author manuscript

Manuscrit d'auteur / Author manuscript

26 The muscle growth in mammals is regulated by several growth factors including myostatin 27 (MSTN), a member of the transforming growth factor-beta (TGF-beta) superfamilly. To date, it is 28 unknown in fish whether MSTN could have any effect on proliferation or differentiation of 29 myogenic cells. Using culture of trout satellite cells, we showed that *mstn1a* and *mstn1b* mRNA are 30 expressed in myoblasts and that their expression decreased in differentiating myoblasts. We also 31 demonstrated that a treatment with huMSTN decreased the proliferation of IGF1-stimulated 32 myoblasts in a dose-dependent manner. By contrast, treatment of myoblasts with 100 nM of 33 huMSTN for 3 days, did not affect the percentage of positive cells for myogenin neither the 34 percentage of nuclei in myosin positive cells. Moreover, our results clearly indicated that huMSTN 35 treatment had no effect on MyoD and Myogenin protein levels, which suggests that huMSTN did 36 not strongly affect MyoD activity.

In conclusion, we showed that huMSTN inhibited proliferation but not differentiation of trout
myoblasts, probably resulting from a lack of huMSTN effect on MyoD activity. Altogether, these
results show high interspecies differences in the function of MSTN.

40 INTRODUCTION

41

Manuscrit d'auteur / Author manuscript

By contrast to the mammals and model fish species (zebrafish, medaka), salmonids such as trout exhibit an indeterminate muscle growth pattern, with muscle mass increasing until mortality or senescence occurs (Johnston 1999; Mommsen 2001). This increase in myotomal muscle mass throughout their life cycle is allowed by a continuous production of muscle fibers (hyperplasia) in addition to an increase of fibers size (hypertrophy). However, the molecular mechanisms involved in these interspecies differences are complex and not well understood.

48 In mammals, muscle growth is regulated by several growth factors including myostatin (MSTN), a 49 member of the transforming growth factor-beta (TGF-beta) superfamilly. The mstn gene, expressed 50 mostly in skeletal muscle, was first identified in mice by McPherron et al., (1997) and has been 51 demonstrated to negatively regulate skeletal muscle growth in several mammalian species. The 52 knockout of *mstn* or the overexpression of *follistatin*, its endogenous inhibitor, induces a dramatic increase of muscle mass, resulting from a combination of hyperplasia and hypertrophy (McPherron 53 54 et al., 1997; Lee and McPherron 2001). MSTN acts through its binding to the activin type II 55 receptor which in turn binds to and activates the activin receptor type I that phosphorylates the 56 transcription factors Smad2 and Smad3 (Lee and McPherron 2001; Zhu et al., 2004). In vitro 57 studies demonstrated that MSTN inhibits the proliferation and the differentiation of myogenic cells 58 (Thomas et al., 2000; Ríos et al., 2001; Langley et al., 2002). The inhibition of differentiation is 59 accomplished by decreasing the level of MyoD protein as well as its activity (Langley et al., 2002). 60 Indeed, it has been shown that TGF-beta inhibits MyoD activity through a physical interaction 61 between MyoD and Smad3 (Liu et al., 2001).

In fish, the *mstn* cDNA has been cloned in numerous species such as trout (Rescan et al., 2001;
Roberts and Goetz 2001; Garikipati et al., 2006; Garikipati et al., 2007), zebrafish (Xu et al., 2003;
Kerr et al., 2005), medaka (Sawatari et al., 2010), tilapia (Rodgers et al., 2001), white bass (Rodgers

Manuscrit d'auteur / Author manuscript

Version définitive du manuscrit publié dans / Final version of the manuscript published in : Molecular and Cellular Endocrinology 2012, 351 (2) : 220-226

et al., 2001), striped bass (Rodgers and Weber 2001), white perch (Rodgers and Weber 2001), sea 65 bass (Terova et al., 2006), Orange spotted grouper (Ko et al., 2007) and sea bream (Funkenstein and 66 67 Rebhan 2007). As a result of the recent genome duplication in salmonids (Brunelli et al., 2001), four 68 distinct *mstn* genes (*mstn1a*, *mstn1b*, *mstn2a*, *mstn2b*) were found in trout (Garikipati et al., 2006; 69 Garikipati et al., 2007). Nevertheless, only *mstn1a* and *mstn1b* are readily detectable in white 70 muscle since *mstn2a* muscle expression is 20-fold lower. In contrast to what is observed in 71 mammals, *mstn* genes are expressed in most teleost fish tissues (Garikipati et al., 2006). 72 Comparison of MSTN sequences indicates that bioactive MSTN sequence is extremely well 73 conserved throughout evolution. In fact, trout MSTN sequence is 90% identical to human MSTN 74 (Garikipati et al., 2006). Several attempts have been made to elucidate the function of MSTN in fish 75 by decreasing MSTN activity but the result are somewhat divergent between species and even 76 within species. Injection of morpholinos in zebrafish embryos increases the number and size of 77 somites (Amali et al., 2004) as well as the expression of the regulatory factor MyoD and myogenin. 78 The overexpression of the prodomain of MSTN (a negative regulator of the active protein) fails to 79 increase the muscle mass of zebrafish and induces a moderate increase (10%) of the fiber number 80 (Xu et al., 2003). Similarly, the overexpression of a dominant negative form of MSTN does not 81 have any strong consequences for medaka muscle mass (Sawatari et al., 2010). However, a recent 82 study in zebrafish carrying a stable heritable myostatin knockdown genotype, reports a "double-83 muscled" phenotype (Lee et al., 2009). In trout, the overexpression of follistatin, an inhibitor of the 84 TGF-beta family member, induces an increase of muscle mass (Medeiros et al., 2009), but it 85 remains to be established whether the effect is due to solely myostatin inhibition or to another TGF-86 beta inhibition. Despite these in vivo data, the function of MSTN in fish remains elusive.

Therefore, in order to gain deeper insight into the function of MSTN in fish, we aimed at determining whether MSTN inhibits the proliferation and the differentiation of myogenic cells, using an in vitro system of trout satellite cells culture.

90 MATERIALS AND METHODS

91

92 Animals

93 Rainbow trout were maintained at the "Station Commune de Recherches en 94 Ichtyophysiologie, Biodiversité et Environnement" (SCRIBE, Rennes, France) in 0.6-m³ 95 tanks in a re-circulated system at 18°C. All experiments were carried out in accordance with 96 legislation governing the ethical treatment of animals (Decret N° 2001-464, May 29, 2001), 97 and investigators were certified by the French Government to carry out animal experiments 98 (N° agrément 35-47). All animal work was approved by the Ministère de l'Enseignement 99 Supérieur et de le Recherche (Autorisation N°A352386).

100

Manuscrit d'auteur / Author manuscript

Manuscrit d'auteur / Author manuscript

101 Chemicals

Dulbecco's modified Eagle's medium (DMEM#D7777) and F10 (#N6635) were purchased 102 103 from SIGMA. Anti-MyoD (#NB100-80899) antibody was purchased from Novus Biological, anti-Myogenin (#SC-567) from Santa-Cruz Biotechnology, anti-P-Smad3 (Ser^{423/425}) from 104 105 Cell Signalling (#9520), anti-Smad7 from Abgent (#AP6753b). For immunofluorescence 106 analysis, the secondary antibody anti-mouse Alexa488 (#A21441) and anti-rabbit Alexa594 (#A11001) were purchased from Invitrogen. Recombinant trout IGF1 (#WU100) was 107 108 purchased from GroPep and recombinant human MSTN (CYT-418) was purchased from 109 ProSpec and the specific inhibitor of Activin Receptor-Like kinases SB431542 (Inman et al., 110 2002) from SIGMA (#S4317).

112 Satellite cells isolation and culture

Primary cultures of skeletal muscle cells were carried out as follows: for each culture, 30 to 60animals, each weighing approximately 5 g, were killed by a blow to the head and then

Version définitive du manuscrit publié dans / Final version of the manuscript published in : Molecular and Cellular Endocrinology 2012, 351 (2) : 220-226

115 immersed for 30 s in 70% ethanol to sterilize external surfaces. Cells were isolated, pooled, 116 and cultured following previously described protocols (Gabillard et al., 2010). Briefly, after removal of the skin, dorsal white muscle was isolated under sterile conditions and collected in 117 118 Dulbecco's modified Eagle's medium (DMEM) containing 9 mM NaHCO₃, 20 mM HEPES, 15% horse serum, and antibiotic-antimycotic cocktail (100 U/ml penicillin, 100 µg/ml 119 streptomycin, 0.25 g/ml fungizone) at pH 7.4. After mechanical dissociation of the muscle in 120 small pieces, the tissue was enzymatically digested with a 0.2% collagenase solution in 121 DMEM for 1 h at 18°C and gentle shaking. The suspension was centrifuged (300 g for 5 min 122 at 15° C) and the resulting pellet was subjected to two rounds of enzymatic digestion with a 123 124 0.1% trypsin solution in DMEM for 20 min at 18°C with gentle agitation. After each round of trypsinization the suspension was centrifuged and the supernatant was diluted in 2 volumes of 125 cold DMEM supplemented with 15% horse serum and the same antibiotic-antimycotic 126 127 cocktail mentioned above. After two washes with DMEM, the cellular suspension was filtered 128 through 100- and 40-µm nylon filters. All experiments were conducted with cells seeded at a 129 density of 160 000/cm², in six-wells or 24-wells plastic plates (Nunc, Roskilde, Denmark) and left for 30 min before medium change. Plates and coverslips were previously treated with 130 poly-L-lysine and laminin to facilitate satellite cells adhesion. Cells were incubated at 18°C, 131 132 the optimal temperature for culture, with DMEM or F10 containing 9 mM NaHCO₃, 20 mM 133 HEPES, 10% fetal bovine serum, and antibiotic-antimycotic cocktail under an air atmosphere. According to the experiments, the cells were cultivated in proliferating medium 134 135 (F10+10%FCS) or differentiating medium (DMEM+2%FCS). The medium was renewed 136 every 2 days and observations of morphology were regularly made to control the state of the 137 cells.

139 *Gene expression analysis*

140 The medium was removed, and wells were washed twice with PBS. The cells were lysed with 141 the lysis buffer of the Nucleospin RNA XS kit (Macherey-Nagel, #N0740-902-50) and total **RNA** were extracted according to the manufacturer's recommendations. The total amount of 142 RNA was determined as a function of absorbance at 260 nm (Nanodrop ND-1000 143 144 spectrophotometer). The cDNA was generated with 0.5 µg total RNA using a commercial kit 145 (Applied Biosystems, #4368813). Briefly, 0.5 µg of total RNA was incubated in a 25 µl mixture (10x RT buffer, 25x dNTPs, 10x random primers, 50UI/µl MultiScribeTM Reverse 146 147 Transcriptase, nuclease-free water) at 25°C for 10 min and then at 37°C for 120 min. The 148 reaction was set at 200 µl by the addition of nuclease-free water. Target gene expression levels 149 were determined by quantitative RT-PCR using a StepOnePlus system (Applied Biosystems). 150 Analyses were carried out using a real-time PCR kit (Fast SyberGreen Master mix, #4385612 151 – Applied Biosystems) with 300 nM of each primer. The primer sequences (Table 1) for *mstn1a*, *mstn1b* and *elongation factor* 1α (*eF1* α) were already published and validated 152 153 (Seiliez et al., 2011). All the primers span exon-bondaries to prevent genomic DNA amplification. Amplification was then performed using the following cycle: 95°C for 3 s, 154 155 60°C for 15 s, 40 times for all primers. The melting curves systematically monitored at the end of the last amplification cycle, show one peak which confirm the specificity of the 156 157 amplification reaction. Each PCR run included replicate samples (duplicate of reverse 158 transcription and PCR amplification). Relative quantity (Arbitrary unit, A.U.) was determined 159 from a standard curve consisting of a serial dilutions of a pool of cDNA. The efficiencies 160 obtained with the primers pairs ranged from 85 to 100%. EF1 α mRNA abundance was not 161 significantly affected by the treatments and was thus used for the normalization of qPCR data.

162

Version définitive du manuscrit publié dans / Final version of the manuscript published in : Molecular and Cellular Endocrinology 2012, 351 (2) : 220-226

163 Protein extraction and Western blotting

164 After two washes with cold PBS, proteins were extracted with RIPA Buffer (50 mM Tris pH8, 165 1 mM EDTA, 0.5 mM EGTA, 1% NP-40, 0.5% Sodium deoxyclolate, 0.1% SDS, 150 mM NaCl) supplemented with 5mM NaF, 1 mM NaVO4 and protease inhibitors cocktail (Roche). 166 167 Laemmli Buffer was added to the sample and heated at 90°C for 5 min. Cell lysates were 168 subjected to SDS-PAGE and Western blotting using the appropriate antibody. Antibody 169 against MyoD and myogenin have been previously validated in trout (Gabillard et al., 2010). The antibody against P-Smad3 (Ser^{423/425}) recognize the human amino acid sequence around 170 Ι Ser^{423/425} that is very well conserved in trout (MGSPS / RCSS / S). Similarly, the antibody 171 V Μ 172 against Smad7 recognize the sequence between 362~392 as that is very well conserved in Y Y Μ trout (PGFSIKAFD / EKA / SLQRPNDHEF / QQP / T). Then, preliminary western 173 174 blot with the anti-P-Smad3 and Anti-Smad7 antibodies were performed with lysates from 175 murine C2C12 cell line and from trout. With trout satellite cells lysate, we obtained a single band for each antibody (P-Smad3 : 55-60 kDa; Smad7 : 45-50 kDa) with the same size as that 176 177 of C2C12 (data not shown). After washing, the membrane was incubated 1 h with secondary 178 antibody (1/15000) linked to HRP (Jackson Immunoresearch). Immunoreactive bands were 179 visualized by ECL and images were obtained with an image acquisition system (Fusion FX7,

180 Vilbert Lourmat).

181

Manuscrit d'auteur / Author manuscript

Manuscrit d'auteur / Author manuscript

182 Immunofluorescence analysis

183 Cells on glass coverslips were briefly washed twice with PBS and fixed 10 min with 184 paraformaldehyde 4%. For permeabilization, cells were incubated 3 min in 0.1% 185 TritonX100/PBS. After three washes, cells were saturated for 1 h with 3% BSA, 0.1% 186 Tween20 in PBS (PBST). Cells were incubated 3 h with the primary antibodies anti-myosin

Version définitive du manuscrit publié dans / Final version of the manuscript published in : Molecular and Cellular Endocrinology 2012, 351 (2) : 220-226

and anti-myogenin diluted in blocking buffer. The secondary antibodies were diluted in PBST and applied for 1 h. Cells were mounted with Mowiol 4-88 (#475904, Calbiochem) containing Hoescht (0.5 μ g/ml). Cells were photographed using a Canon digital camera coupled to a Canon 90i microscope.

191

192 Analysis of cell proliferation

193 The mature myostatin protein is extremely well conserved between fish and mammals and 194 trout MSTN is 90% identical to human MSTN (Rescan et al., 2001; Garikipati et al., 2006). 195 Thus, we used recombinant human MSTN (#CYT-418, ProSpec) in our experiments. From 196 the day of extraction, the cells were incubated in F10 (+10% FCS) medium. At day 1, cells 197 were cultivated in F10 alone, and at day 2 cells were cultivated in F10+2%FCS and recombinant trout IGF1 (50 nM) and human MSTN (0.1, 1 or 10 nM) were added. At day 3, 198 199 BrdU was added for the following 24 h. The cells were fixed with ethanol/glycine buffer (70% ethanol, 50 mM glycine, pH 2). The proliferation of the cells was measured by using the 200 201 BrdU labeling and detection kit (Roche Diagnostics, no. 1 296 736). Briefly, the cells were 202 incubated for 30 min at 37°C with mouse anti-BrdU, washed, and then incubated with the 203 secondary antibody anti-mouse FITC. Cells were mounted in Mowiol containing 0.5 µg/ml 204 DAPI.

205 Statistical analysis

Results are presented as means \pm SD. Treatment effect was assessed using the non-parametric Kruskall-Wallis ANOVA (Statistica 7.0, StatSoft). When ANOVA revealed significant effect Mann-Whitney test was performed. All the experiments were performed at least 2 times.

Version définitive du manuscrit publié dans / Final version of the manuscript published in : Molecular and Cellular Endocrinology 2012, 351 (2) : 220-226

209 **RESULTS**

210

211 Mstn1a and mstn1b gene expression decreases during in vitro differentiation of trout

212 *myoblasts*

213 We monitored the expression of *mstnla* and *mstnlb* genes by quantitative PCR during proliferation and differentiation of myoblasts. Our results (Figure 1) showed that *mstn1a* and 214 *mstn1b* were expressed in myoblasts. During the first week of culture in proliferation 215 216 medium, no significant change of *mstn1a* and *mstn1b* mRNA levels was observed. By 217 contrast, as soon as 2 days after induction of differentiation (DM2), mstnla and mstnlb mRNA levels significantly decreased (~ 4-fold). After 4 days in differentiation medium 218 219 (DM4), the levels of *mstnla* and *mstnlb* were similar to that of observed at DM2. These 220 results indicated that both *mstn* genes were regulated during the proliferation and the 221 differentiation phases suggesting a role of MSTN on trout myoblast proliferation and (or) 222 differentiation.

223

224 HuMSTN activates Smad3 phosphorylation in myoblasts and myotubes of trout

225 Sequence analysis showed that the sequences of trout myostatins were very similar to that of 226 human (90%) as previously reported (Rescan et al., 2001; Garikipati et al., 2006). To validate 227 the use of heterologous myostatin in our in vitro system, we monitored the activity of 228 recombinant human MSTN (HuMSTN) by measuring the phosphorylation status of Smad3 a 229 key factor in the MSTN signaling pathway (Sartori et al., 2009). As shown in figure 2A and 230 2B, the stimulation of both trout myoblasts and myotubes with 100 nM of huMSTN for 1h induced the phosphorylation of Smad3. Furthermore, to demonstrate the specificity of this 231 232 hormonal response, we used a chemical inhibitor (SB431542) specific to the activin receptor 233 type I (ActRI) known to transduce MSTN signal (Lee et al., 2005; Miyake et al., 2010). The

Version définitive du manuscrit publié dans / Final version of the manuscript published in : Molecular and Cellular Endocrinology 2012, 351 (2) : 220-226

treatment of the cells with this chemical inhibitor completely abolished the huMSTN-induced phosphorylation of Smad3 in myoblasts as well as in myotubes (Figure 2A and 2B). Therefore the huMSTN specifically phosphorylated Smad3 through the activation of the ActRI as expected and our results showed that trout myoblasts and myotubes were able to transduce the huMSTN signal.

240 HuMSTN inhibits proliferation of myoblasts in vitro

241 To determine whether huMSTN inhibits the proliferation of myoblasts, we treated the cells 242 with huMSTN during 48h and monitored the cell proliferation by mean of the BrdU incorporation technique (Gabillard et al., 2010). To limit the putative non-specific effect of the 243 serum, we cultivated the cells in F10 with only 2% of fetal calf serum (FCS). Under these 244 245 conditions the basal level of proliferation was low (~10%) and huMSTN treatment had no 246 effect on proliferation whatever the doses (0.1 to 10 nM) (Figure 3). Then, to increase the 247 proliferation, we treated the cells with 50 nM recombinant trout IGF1 (rtIGF1) given that it has been shown to stimulate the proliferation of myoblasts (Gabillard et al., 2010). Under 248 249 these conditions, rtIGF1 treatment strongly stimulated proliferation (10% versus 60%) and we 250 observed a dose-dependent decrease of proliferation in presence of increasing doses of 251 huMSTN (Figure 3). These results clearly showed that huMSTN was able to decrease the 252 proliferation of trout myoblasts.

254 HuMSTN has no effect on the differentiation of trout myoblasts

In order to determine whether huMSTN inhibited the differentiation of myoblasts, we treated the cells with huMSTN during the induction of differentiation. The differentiation index (% of nuclei in myosin or myogenin positive cells) was determined by immunofluorescence analysis. Preliminary experiments indicated that low doses of huMSTN (0.5, 5, 50 nM) did

²³⁹

Version définitive du manuscrit publié dans / Final version of the manuscript published in : Molecular and Cellular Endocrinology 2012, 351 (2) : 220-226

not have an effect (data not shown). Therefore, a higher dose of huMSTN was tested (100 nM) that is within the range previously reported (Langley et al., 2002). Our results (Figure 4A and 4B) showed that after 3 days in the differentiation medium (DMEM+2%FCS), myoblasts were clearly differentiated into myotubes. Indeed after 3 days in differentiating medium, the percentage of nuclei in myosin positive cells (1% versus 23%) and the percentage of

myogenin positive nuclei increased (20% versus 39%). Moreover, treatment of the cells with 100 nM huMSTN (Figure 4A and 4B) did not significantly affect the differentiation of myogenic cells (23% versus 20% of nuclei in myosin positive cells) and (39% versus 37% of myogenin positive nuclei). Altogether, these results showed that huMSTN treatment did not inhibit differentiation of trout myoblasts in vitro.

269

270 HuMSTN has no effect on the level of MyoD protein

271 It has been shown in mammals, that MSTN inhibits differentiation by decreasing MyoD 272 protein level as well as MyoD activity (Langley et al., 2002). Our results (Figure 5) showed 273 that huMSTN treatment during 48h increased the amount of Smad7, a protein known to be 274 responsive to TGFb treatment Zhao et al., (2000). Surprisingly, huMSTN did not affect MyoD 275 protein level in our cell culture model (Figure 5). Because MSTN inhibits also MyoD activity, 276 we measured the protein level of myogenin which function downstream of MyoD as a key 277 regulator of myoblast differentiation. Again western blot analysis clearly showed that 278 huMSTN treatment had no effect on myogenin protein level (Figure 5). Altogether, these 279 results indicated that treatment of trout muscle cells with huMSTN did not affect MyoD 280 activity.

281

Manuscrit d'auteur / Author manuscript

Version définitive du manuscrit publié dans / Final version of the manuscript published in : Molecular and Cellular Endocrinology 2012, 351 (2) : 220-226

282 **DISCUSSION**

In mammals, MSTN belongs to the TGF-beta familly and is well known as a potent inhibitor 283 284 of the muscle growth (McPherron et al., 1997; Lee and McPherron 2001). Indeed, it has been 285 shown that MSTN inhibits both proliferation and differentiation of mammalian myogenic 286 cells (Thomas et al., 2000; Langley et al., 2002; Joulia et al., 2003; Trendelenburg et al., 2009). In fish, several works report an increase of muscle mass after decreasing MSTN 287 activity (Lee et al., 2009; Medeiros et al., 2009), while others failed to observe a strong (if 288 289 any) effect on muscle mass (Amali et al., 2004; Acosta et al., 2005; Sawatari et al., 2010). To 290 date, it is unknown in fish whether MSTN could have any effect on proliferation or 291 differentiation of myogenic cells. Therefore, the purpose of the present work was to determine 292 whether MSTN can affect the proliferation and the differentiation using an in vitro system of 293 trout satellite cells culture.

294 As a first step, we measured the expression of both *mstnla* and *mstnlb* during the 295 differentiation of myoblasts. In agreement with our previous study (Seiliez et al., 2011), we 296 showed that *mstn1a* and *mstn1b* genes were expressed in trout myoblasts and myotubes. This 297 result is in accordance with the published data showing that *mstnla* and *mstnlb* were 298 expressed in muscle of rainbow trout (Rescan et al., 2001; Garikipati et al., 2006). 299 Furthermore, our results demonstrate that the expression of *mstnla* and *mstnlb* genes 300 decreased during the differentiation of myoblasts. This result contrasts with the observations 301 made in higher vertebrates where *mstn* gene expression increases during the differentiation of myogenic cells (Ríos et al., 2001; Kocamis and Killefer 2002; Artaza et al., 2005; McFarland 302 303 et al., 2006; Theil et al., 2006; McFarland et al., 2007). This observation shows that the 304 regulation of *mstn* genes in a lower vertebrate such as the rainbow trout is different than in 305 higher vertebrates. Indeed, in mammals *mstn* is expressed nearly exclusively in skeletal 306 muscle whereas in fish *mstn* mRNA have been detected in a wide range of tissues (Rescan et

Version définitive du manuscrit publié dans / Final version of the manuscript published in : Molecular and Cellular Endocrinology 2012, 351 (2) : 220-226

al., 2001; Rodgers et al., 2001; Garikipati et al., 2006). Moreover, we recently demonstrated
that contrary to mouse *mstn* gene, trout *mstn* genes were not regulated by FoxO1 transcription
factor (Seiliez et al., 2011). Altogether, these results show that at least in trout, the MSTN
protein is present in different tissues and at different cellular process than in mammals, which
may suggest that endogenous MSTN protein may have a different function in fish than in
mammals.

313 In an attempt to elucidate the function of MSTN in trout, we determined whether recombinant 314 human MSTN can inhibit the proliferation of trout myoblasts. When the cells were cultivated 315 with only 2% of FCS, the basal level of proliferation is too low to observe any inhibitory 316 effect of huMSTN. However, under IGF1 stimulation, we were able to observe an inhibitory 317 effect of huMSTN on the proliferation of myoblasts in good agreement with published data 318 obtained with mammalian (Thomas et al., 2000; Joulia et al., 2003) and avian (McFarland et 319 al., 2006; McFarland et al., 2007) models. Altogether, this result shows that endogenous trout 320 MSTN could inhibit the proliferation of myoblasts in vivo.

MSTN has been shown in mammals to inhibit not only the proliferation but also the differentiation of myogenic cells in vitro (Langley et al., 2002; Joulia et al., 2003; Trendelenburg et al., 2009). Using our in vitro system of satellite cells culture, we showed for the first time in fish that huMSTN failed to inhibit the differentiation of the myogenic cells in contrast to what is observed in mammals. This may explain the decrease of *mstn1a* and *mstn1b* gene expressions observed during the differentiation of trout myoblasts, and supports the hypothesis that endogenous MSTN has no effect on trout myoblast differentiation.

The MSTN action is mediated first by its binding to the activin type II receptors (ActRIIB and ActRIIA) resulting in the phosphorylation of Smad2 and Smad3 (Lee and McPherron 2001; Zhu et al., 2004). Our results clearly showed that huMSTN stimulation induced a specific phosphorylation of Smad3 both in myotubes and myoblasts. Moreover, the phosphorylation of

Version définitive du manuscrit publié dans / Final version of the manuscript published in : Molecular and Cellular Endocrinology 2012, 351 (2) : 220-226

332 Smad3 is completely abolished in presence of the ActRI inhibitor. These results show that 333 phosphorylation of Smad3 is fully mediated by the activin type I receptor as in mammals (Lee 334 and McPherron 2001; Zhu et al., 2004). The high sequence identity (90%) of huMSTN with 335 trout MSTN together with the specificity of the signal validate the use of human MSTN in our 336 in vitro system. Our results indicate that myotubes are well responsive to huMSTN 337 stimulation and that an absence of functional MSTN signaling pathway can not explain the 338 absence of inhibitory effect of huMSTN on differentiation of trout myoblasts.

339 To determine the reasons of the lack of inhibitory effect of huMSTN on differentiation, we 340 focused on the myogenic regulatory factor MyoD given that in mammals, MSTN inhibits differentiation by decreasing MyoD protein level as well as MyoD activity (Liu et al., 2001; 341 342 Langley et al., 2002). Our results show that huMSTN stimulation did not induce a decrease 343 of MyoD protein level nor of myogenin which is dependent on MyoD activity (Edmondson et 344 al., 1992). Therefore, our results indicate that despite an effective activation of the MSTN 345 signaling pathway, the activity of MyoD was not modified which explains the lack of 346 inhibitory effect of huMSTN treatment on differentiation. It has been shown that TGF-beta, 347 belonging to the same family of MSTN, inhibits MyoD activity through a physical interaction 348 between MyoD and Smad3 (Liu et al., 2001). Thus, we can hypothesize that at least in trout, 349 Smad3 does not interact with MyoD preventing the inhibition of differentiation of trout 350 myoblasts by a huMSTN treatment. Further studies are required to verify the reason for the 351 lack of decrease of myoD protein level in huMSTN treated cells.

Overall, our work show for the first time that stimulation of the MSTN pathway inhibits the proliferation of trout myoblasts in vitro. This result appears in good agreement with results obtained in vivo in which overexpression of follistatin, an endogenous inhibitor of MSTN, induces an increase of muscle mass mainly due to hyperplasia in trout (Medeiros et al., 2009). By contrast, in zebrafish overexpressing an antisense RNA of *mstn*, the increase of muscle

Version définitive du manuscrit publié dans / Final version of the manuscript published in : Molecular and Cellular Endocrinology 2012, 351 (2) : 220-226

mass is mainly due to hypertrophy of muscle fiber (Lee et al., 2009). The discrepancy of the results obtained between these species may come from the specificities of their muscle growth. Indeed, trout exhibits indeterminate growth with continued hyperplasia throughout much of its life cycle, whereas zebrafish exhibits determinate growth. This hypothesis is reminiscent of the very interesting data showing that *mstn* is differentially regulated in two closely related zebrafish species exhibiting either indeterminate (*Danio aequipinnatus*) or determinate (*Danio rerio*) growth (Biga and Meyer 2009).

364 Another interesting result is the absence of inhibitory effect of huMSTN on the differentiation 365 of trout myoblasts by contrast to what is observed in mammals (Langley et al., 2002; Joulia et al., 2003; Trendelenburg et al., 2009). This result strongly suggests that the function of 366 367 endogenous MSTN in trout is partly different from that of mammals. In this context it is 368 relevant to point out that the fish mstn genes are widely expressed and that numerous non-369 muscle tissues express *mstn* as much as in the muscle (Rescan et al., 2001; Roberts and Goetz 370 2001; Amali et al., 2004; Garikipati et al., 2006; Ko et al., 2007). Moreover, we recently showed that the mechanisms involved in mstn expression in trout are different from that of 371 mammals (Seiliez et al., 2011). Finally, it is surprising that upon physiological conditions, no 372 373 changes of *mstn* expression in accordance with a strong inhibitory effect of MSTN on muscle 374 growth, has been reported in trout (Rescan et al., 2001; Chauvigné et al., 2003; Martin and 375 Johnston 2005).

Overall these data highlight interspecies differences in the function of MSTN. In this context, the trout with an indeterminate growth, is an interesting model to better understand of the mechanisms involved in muscle growth.
