Abstract

In this paper we revisit the issue of copredication from the perspective of modern type theories. Specifically, we look at: a) the counting properties of dot-types, and b) the case of a complex dot-type that has remained unsolved in the literature, i.e. that of *newspaper*. As regards a), we show that the account proposed in (Luo, 2010) for dot-types makes the correct predictions as regards counting. In order to verify this, we implement the account in the Coq proof-assistant and check that the desired inferences follow. Then, we look at the case of b), the case of a dot-type which is both resource and context sensitive. We propose a further resource sensitive version of the dot-type, in effect a linear dot-type. This along with local coercions can account for the behaviour attested.

1 Copredication: Dot Types and Individuation Criteria

One of the issues that should be taken care of when giving an account of co-predication, concerns cases of coordination like the one shown below:

- (1) John picked up and mastered three books

In the above sentence, the CN book is used in its physical sense (PHY) with respect to the predicate

* This work is partially supported by the research grants from Leverhulme, Royal Academy of Engineering, the CAS/SAFEA International Partnership Program for Creative Research Teams as well as the ANR ContInt Polymnie project in France.

picked up, while for the predicate mastered it is rather used in its informational content sense (INFO). A theory of co-predication should be able to take care of these facts. This is true for the account by means of the dot-types proposed by (Luo, 2010; Luo, 2012b). However, besides capturing this behaviour of dot objects, there is an additional property that has to be captured. The account provided must also make the correct predictions as regards individuation and counting. Let us explain. Consider the following sentences:

- (2) John picked up three books
- (3) John mastered three books
- (4) John picked up and mastered three books

The first example (2) is true in case John picked three distinct physical objects. Thus, it is compatible with a situation where John picked up three copies of the same book. (3) is true in case three distinct informational objects are mastered but does not impose any restrictions on whether these three informational objects should be different physical objects or not. To the contrary, (4) is only compatible with an interpretation where three distinct physical objects as well as three distinct informational objects is involved.¹

Another issue pertaining to dot types concerns cases of what Retoré (2014) calls rigid and flexible coercions in co-predication cases. These cases in contrast to cases like *Book* where both senses can

¹This is basically an issue of how complex objects, i.e. dot-types, are individuated and stems from the work of (Asher, 2008; Asher, 2011).

be coordinated, involve examples where if one of the senses is used the other one cannot be used anymore:

- (5) Liverpool is spread out and voted (last Sunday).
- (6) # Liverpool voted and won (last Sunday).

Perhaps a better example for such cases is Pustejovsky's *newspaper* examples. The CN *newspaper* is associated with three senses: a) physical object, b) informational object and c) institution. It is a strange fact that whereas senses a) and b) can appear together in a coordinated structure, sense c) cannot appear with any of the other two (examples taken from (Antunes and Chaves, 2003)):

- (7) # That newspaper is owned by a trust and is covered with coffee.
- (8) # The newspaper fired the reporter and fell off the table.
- (9) # John sued and ripped the newspaper.

Pustejovsky's proposal (Pustejovsky, 1995) to treat newspaper as a composite dot object does not explain the above facts. Likewise, the proposal of using (ordinary) dot-types in (Luo, 2010) has a similar problem: one would consider *newspaper* to be a subtype of the dot-type $INST \bullet (PHY \bullet INFO)$, which would not disallow the above bad examples. The picture gets complicated in the light of examples like the following, in which it seems that the institutional sense can be used together with one of the two other senses in some cases:

- (10) The newspaper you are reading is being sued by Mia.

As far as we know, no satisfactory account has been provided to these questions yet. In this paper, following earlier work on dot-types in MTTs (Luo, 2010; Luo, 2012b; Xue and Luo, 2012) and coordination (Chatzikyriakidis and Luo, 2012), we take up the challenge of providing an account that correctly predicts the individuation criteria in cases of co-predication while it furthermore provides a first look at capturing the behaviour of problematic cases like *newspaper*.

2 Formal Semantics in Modern Type Theories: a Brief Introduction

The term Modern Type Theories (MTTs) refers to type theories studied and developed within the tradition of Martin-Löf, which include predicative type theories such as Martin-Löf's type theory (Nordström et al., 1990) and impredicative type theories such as CIC_p as implemented in Coq (The Coq team, 2007) and UTT (Luo, 1994). Formal semantics in Modern Type Theories (MTT-semantics for short) was first studied by Ranta in his pioneering work (Ranta, 1994).² It has been further developed in the last several years, including the crucial employment of the theory of coercive subtyping (Luo, 1999; Luo, Soloviev and Xue, 2012) among other developments and made MTT-semantics a viable and full-blown alternative to the traditional Montagovian framework. In this paper, we use one such modern type theory, UTT with Coercive Subtyping (Luo, 1994; Luo, 1999), whose application to linguistic semantics was first discussed in (Luo, 2010).

Two features of MTTs are worth being mentioned, both important for being a foundational language for linguistic semantics. The first is that an MTT has a consistent internal logic according to the propositions-as-types principle (Curry and Feys, 1958; Howard, 1980).³ For instance, the higher-order logic is embedded in UTT and it is essentially used when we employ UTT for linguistic semantics (just like how higher-order logic is used in Montague's semantics.)

The second feature of MTTs is that it has rich type structures, which have been recognised by many researchers as very useful in formal semantics. In this

²Potentially, even further back, with the work of Sundholm (Sundholm, 1986; Sundholm, 1989), but Ranta (Ranta, 1994) was the first systematic study of formal semantics in a modern type theory.

³Having such an internal logic is a basic requirement for a type theory to be employed for linguistic semantics and we need to be careful to keep the internal logic to be consistent when trying to extend an existing type theory to do linguistic semantics, for otherwise, we could be in a muddle situation if the basic requirement is violated. For instance, the framework of Type Theory with Records (TTR) (Cooper, 2011) is based on set theory and, as a consequence, TTR does not have such an internal logic based on the propositions-as-types principle (to see this, it suffices to note that TTR's $a : A$ is just the set-theoretical membership relation $a \in A$ and undecidable).

section, we shall briefly discuss some of these distinctive features of MTTs, specifically the ones most relevant to this paper.

2.1 Type Many-sortedness and CNs as Types

The domain of individuals in MTTs is multi-sorted and not single-sorted as in Church’s simple type theory (Church, 1940). Instead of using one coarse-grained domain of entities, like it is done in the Montague Semantics (MS) (Montague, 1974), MTTs contain many types that allow one to make fine-grained distinctions between individuals and further use those different types to interpret subclasses of individuals. For example, one can find *John* : $\llbracket man \rrbracket$ and *Mary* : $\llbracket woman \rrbracket$, where $\llbracket man \rrbracket$ and $\llbracket woman \rrbracket$ are different types.

A further difference closely related to type many-sortedness concerns the interpretation of CNs. In MS, CNs are interpreted as predicates of type $e \rightarrow t$, whereas in MTTs CNs are interpreted as *types*. Thus, in MTTs, CNs *man*, *human*, *table* and *book* are interpreted as types $\llbracket man \rrbracket$, $\llbracket human \rrbracket$, $\llbracket table \rrbracket$ and $\llbracket book \rrbracket$, respectively. (Such types may be defined by means of type constructors such as Σ etc – see below.) Then, individuals are interpreted as being of one of the types used to interpret CNs. Such interpretations of CNs as types would not work without a proper subtyping mechanism that extends MTTs – coercive subtyping provides us with such a framework.⁴

2.2 Rich Typing

Type structures in MTTs are very rich. They can be used to represent collections of objects (or constructive sets, informally) in a model-theoretic sense, although they are syntactic entities in MTTs. Elaborating on the expressiveness of typing structures of MTTs, we briefly mention the following type structures:

- Dependent sum types (Σ -types $\Sigma(A, B)$ which have product types $A \times B$ as a special case). Σ -types have been used to interpret intersective and subsecutive adjectives without the need

⁴See (Luo, 1999; Luo, Soloviev and Xue, 2012) for the formal details of coercive subtyping. Also see (Luo, 2012a) and the next section for further argumentation on interpreting CNs as types.

of resorting to meaning postulates. The inferences follow directly from typing (Ranta, 1994; Chatzikyriakidis and Luo, 2013). Note that subtyping is essential for the Σ -type to work (Luo, 2012b).

- Dependent product types (Π -types $\Pi(A, B)$, which have arrow-types $A \rightarrow B$ as a special case). These are basic dependent types that, together with universes (see below), provide polymorphism among other things. To give an example, verb modifying adverbs are typed by means of dependent Π -types (together with the universe CN of common nouns) (Luo, 2012b; Chatzikyriakidis, 2014).
- Disjoint union types ($A + B$). Disjoint union types have been proposed to give interpretations of privative adjectives (Chatzikyriakidis and Luo, 2013).
- Universes. These are types of types, basically collections of types. Typical examples of universes in MTT-semantics include, among others, the universe *Prop* of logical propositions as found in impredicative type theories and the universe CN of (the interpretations of) common nouns (Luo, 2012b). Further uses of universes can be seen in (Chatzikyriakidis and Luo, 2012) where the universe *LType* of all linguistic types is used in order to deal with co-ordination.
- Dot-types ($A \bullet B$). These are special types introduced to study co-predication (Luo, 2012b). It is worth mentioning that coercive subtyping is essentially employed in the formulation of dot-types.⁵

2.3 MTT-semantics is Both Proof-theoretic and Model-theoretic

It has been noted recently (Luo, 2014) that one of the advantages of MTT-semantics as compared to traditional Montagovian approaches is that MTT-semantics can be seen as being both model-theoretic and proof-theoretic. NL semantics can first be represented in an MTT in a model-theoretic way and then

⁵See (Bassac et al., 2010) for another proposal of using coercions to deal with co-predication.

these semantic representations can be understood inferentially in a proof-theoretic way (Luo, 2014).

In particular, since MTTs are proof-theoretically specified, it is not surprising that many proof assistants implement MTTs. Perhaps, the most advanced of these proof-assistants is the Coq proof-assistant (The Coq team, 2007). Coq is a state-of-the-art proof assistant that has produced a number of impressive results. Some of these include a complete mechanized proof of the four colour theorem (Gonthier, 2005), the odd order theorem (Gonthier et al., 2013) as well as CompCert, a formally verified compiler for C (Leroy, 2013). Because Coq has a powerful reasoning ability and that it implements an MTT, a new avenue of research is opened up – to use Coq as an NL reasoner. This has been attempted in (Chatzikyriakidis and Luo, 2014a; Chatzikyriakidis and Luo, 2014b) with a number of promising results as regards NL inference. In this paper, we also exemplify the way proof-assistants can be used to help in checking the inferences that semantic accounts give rise to.

3 CNs as Types and Individuation Criteria

As already discussed in our introduction to MTTs, CNs are interpreted as types in MTTs. This proposal has also some nice consequences concerning what Geach (1962) has called the criterion of identity, which is pretty much the individuation criterion that we have been referring to in this paper. Intuitively, a CN determines a concept that beside having a criterion of application to be employed to determine whether the concept applies to an object, it further involves a criterion of identity, to be employed to determine whether two objects of the concept are the same. It has been argued that CNs are distinctive in this as other lexical terms like verbs and adjectives do not have such criteria of identity (cf. the arguments in (Baker, 2003)). There seems to be a close link between the constructive notion of a set (Type) and criteria of identity/individuation. This is because, in constructive mathematics, a set is a ‘preset’, which involves its application criterion, together with an equality, which further gives its criterion of identity determining whether two objects of the set are the same (Bishop, 1967; Beeson, 1985). Modern type theories such as Martin-Löf’s

type theory (Martin-Löf, 1975; Martin-Löf, 1984) were originally developed for the formalisation of constructive mathematics, where each type is associated with such an equality or criterion of identity. The identification of CNs as types thus provides CNs their criteria of application and identity. We cannot go into the details of how this is to be achieved formally. but the interested reader is directed to (Luo, 2012a) for a detailed exposition of the CNs as Types idea.

In order to proceed, firstly we have to discuss the existing account of dot-types as this was given by (Luo, 2010; Luo, 2012b; Xue and Luo, 2012). Specifically, we have to see whether this account predicts the counting criteria correctly in examples like (4) repeated below:

(11) John picked up and mastered three books

As we have said, the only possible interpretation of (11) we receive is one where three distinct physical as well as informational objects are involved. The sentences cannot be interpreted as involving three distinct informational objects but one physical object or vice versa as involving three distinct physical objects but one informational object. The question is whether this account captures that. First of all, let us say something about coordination, since this would be needed in discussing the examples in a compositional manner. The approach we suggest for coordination, based on earlier work in (Chatzikyriakidis and Luo, 2012) involves a type universe of linguistic types, $LType$:⁶

(12) $\Pi A : LType. A \rightarrow A \rightarrow A$

As regards typing the above is a natural way to encode coordination. However, we need a way to further encode the semantics of coordination in each case. For this paper, we show this for VP coordination only. In order to define VP coordination, we first define an auxiliary object AND :

(13) $AND : \Pi A : LType. \Pi x, y : A. \Sigma a : A. \forall p : A \rightarrow Prop. p(a) \supset p(x) \wedge p(y)$.

The auxiliary entities read as follows: for any type A in $LType$ and forall $x, y : A$, $AND(A, (x, y))$ is a

⁶See (Chatzikyriakidis and Luo, 2012) for more details on the universe $LType$, its motivation as well as (some of) its introduction rules.

pair (a, f) such that for all $p:A \rightarrow Prop$, $f(p)$ is a proof that $p(a)$ implies both $p(x)$ and $p(y)$. Then, *and* is defined as the first projection π_1 of the auxiliary object:

$$(14) \text{ and} = \lambda A:LTtype.\lambda x, y, z:A.\pi_1(AND(A, x, y))$$

With these in mind, let us now look at the existing proposal as regards dot-types and its proper formalization as this was provided in (Luo, 2010). The whole idea of forming a dot-type is informally based on the fact that to form a dot-type $A \bullet B$, its constituent types A and B should not share common parts/components. For example, the following two cases cannot be dot-types since they both share components:

$$(15) \text{ PHY} \bullet \text{PHY}$$

$$(16) \text{ PHY} \bullet (\text{PHY} \bullet \text{INFO})$$

Definition 3.1 (components) Let $T : Type$ be a type in the empty context. Then, $\mathcal{C}(T)$, the set of components of T , is defined as:

$$\mathcal{C}(T) =_{df} \begin{cases} \text{SUP}(T) & \text{if the NF of } T \text{ is not } X \bullet Y \\ \mathcal{C}(T_1) \cup \mathcal{C}(T_2) & \text{if the NF of } T \text{ is } T_1 \bullet T_2 \end{cases}$$

where $\text{SUP}(T) = \{T' \mid T \leq T'\}$.

The rules for the dot-types are given in Figure 1, as given in (Luo, 2012b). The notion of dot-type captures copredication in a nice way: it is both formal and suitable for MTT-semantics. The question is whether this account gives us correct individuation criteria. In order to test this, we check it against the Coq proof-assistant (The Coq team, 2007), based on the formal development as considered in (Luo, 2011). In effect, we define in Coq the dot-type $\text{PHY} \bullet \text{INFO}$ and define *Book* to be the Σ -type that encodes Pustejovsky's qualia structure; as a consequence, *Book* is a subtype of $\text{PHY} \bullet \text{INFO}$. We further define *mastered* and *picked up* to be of type $\text{INFO} \rightarrow Prop$ and $\text{PHY} \rightarrow Prop$, respectively, and further provide a tactic to enhance automation, the details of which are out of the scope of this paper. Lastly, the quantifier *three* is defined.⁷

⁷*Three* is defined as follows: for all A of type CN and given a predicate $P:A \rightarrow Prop$, there exist three elements, x, y and z , that are different, which are true of P .

```

x<>z)).
```

With these in line, let us see whether the correct predictions are being made with respect to individuation criteria. What we need to capture is the following entailment:

$$(17) \text{ John picked up and mastered three books} \Rightarrow \text{John picked up three books and John mastered three books}$$

Basically, what we need to be able to get is a situation where three distinct informational as well as

Formation Rule

$$\frac{\Gamma \text{ valid } \langle \rangle \vdash A : \text{Type} \quad \langle \rangle \vdash B : \text{Type} \quad \mathcal{C}(A) \cap \mathcal{C}(B) = \emptyset}{\Gamma \vdash A \bullet B : \text{Type}}$$

Introduction Rule

$$\frac{\Gamma \vdash a : A \quad \Gamma \vdash b : B \quad \Gamma \vdash A \bullet B : \text{Type}}{\Gamma \vdash \langle a, b \rangle : A \bullet B}$$

Elimination Rules

$$\frac{\Gamma \vdash c : A \bullet B}{\Gamma \vdash p_1(c) : A} \quad \frac{\Gamma \vdash c : A \bullet B}{\Gamma \vdash p_2(c) : B}$$

Computation Rules

$$\frac{\Gamma \vdash a : A \quad \Gamma \vdash b : B \quad \Gamma \vdash A \bullet B : \text{Type}}{\Gamma \vdash p_1(\langle a, b \rangle) = a : A} \quad \frac{\Gamma \vdash a : A \quad \Gamma \vdash b : B \quad \Gamma \vdash A \bullet B : \text{Type}}{\Gamma \vdash p_2(\langle a, b \rangle) = b : B}$$

Projections as Coercions

$$\frac{\Gamma \vdash A \bullet B : \text{Type}}{\Gamma \vdash A \bullet B <_{p_1} A : \text{Type}} \quad \frac{\Gamma \vdash A \bullet B : \text{Type}}{\Gamma \vdash A \bullet B <_{p_2} B : \text{Type}}$$

Coercion Propagation

$$\frac{\Gamma \vdash A \bullet B : \text{Type} \quad \Gamma \vdash A' \bullet B' : \text{Type} \quad \Gamma \vdash A <_{c_1} A' : \text{Type} \quad \Gamma \vdash B = B' : \text{Type}}{\Gamma \vdash A \bullet B <_{d_1[c_1]} A' \bullet B' : \text{Type}}$$

where $d_1[c_1](x) = \langle c_1(p_1(x)), p_2(x) \rangle$.

$$\frac{\Gamma \vdash A \bullet B : \text{Type} \quad \Gamma \vdash A' \bullet B' : \text{Type} \quad \Gamma \vdash A = A' : \text{Type} \quad \Gamma \vdash B <_{c_2} B' : \text{Type}}{\Gamma \vdash A \bullet B <_{d_2[c_2]} A' \bullet B' : \text{Type}}$$

where $d_2[c_2](x) = \langle p_1(x), c_2(p_2(x)) \rangle$.

$$\frac{\Gamma \vdash A \bullet B : \text{Type} \quad \Gamma \vdash A' \bullet B' : \text{Type} \quad \Gamma \vdash A <_{c_1} A' : \text{Type} \quad \Gamma \vdash B <_{c_2} B' : \text{Type}}{\Gamma \vdash A \bullet B <_{d[c_1, c_2]} A' \bullet B' : \text{Type}}$$

where $d[c_1, c_2](x) = \langle c_1(p_1(x)), c_2(p_2(x)) \rangle$.

Figure 1: The rules for dot-types.

physical objects are involved. We formulate this as a theorem to be proven in Coq:

```
Theorem DT: (Three Book) (and (PhyInfo
->Prop) (picked_up John) (mastered
John)) -> (Three Book) (picked_up
John) /\ (Three Book) (mastered John).
```

This can be proven in Coq.⁸ Indeed, what we need with respect to examples like (22), as Gotham (2012) mentions, is an interpretation where the two objects are double distinct, both informationally and physically. Gotham (2012) shows this in discussing the account as proposed by (Asher, 2011), which provides weaker semantics for this example. In effect, Asher’s (2011) account predicts situations where three informational and one physical object are involved (or vice versa) to be possible. The idea developed is roughly as follows: In every situation like (22) the hearer has to option to choose between the physical and the informational individuation criterion. If the former is chosen, then a situation where three physical objects but one informational object are involved is possible. If the hearer chooses the latter criterion, then a situation where three distinct informational objects but only one physical object is involved is possible. If this is true, one can indeed use (22) to refer to let us say one informational and three physical objects (or vice versa), then the double-distinct judgments should be the result of some pragmatic strengthening and thus should be cancelable. This is however not the case as the examples below show (taken from Gotham, 2012):

- (18) John picked up and mastered three books, but he didn’t pick up three books.
- (19) John picked up and mastered three books; in fact, he picked up exactly one book.
- (20) John picked up and mastered three books, but he didn’t master three books.
- (21) John picked up and mastered three books; in fact, he mastered exactly one book.

Most interestingly, what we can further prove is the entailment that from John picked up and mastered three books, it follows that John picked up

⁸Those that wish to prove this on their own, the tactics to prove both of the examples are: *compute*, *intro*, *destruct AND*, *case a with (ThreeBook)*, *AUTO*, *AUTO*.

three physical objects and mastered three informational objects. In Coq notation:

```
Theorem DT: (Three Book) (and (PhyInfo
->Prop) (picked_up John) (mastered
John)) -> (Three Phy) (picked_up John)
/\ (Three Info) (mastered John).
```

This can be proven as well.⁹

It seems in this respect, that the account gives the correct predictions as regards individuation criteria and counting. This can be seen as an advantage compared to approaches like Asher’s (2011), which gives the correct results after some additional assumptions on accommodation are made (which really complicate the account), while they further make it too permissive as to allow the following (see (Gotham, 2014)):

- (22) # Fred picked up and mastered a stone.

On the other hand, the claim made by (Gotham, 2014) that the dot-type account as this is given by (Luo, 2010) cannot capture the facts, is shown to be incorrect on the basis of what we have presented here. Gotham’s account predicts the correct results as well, but we believe at the expense of additional complications (e.g. the introduction of *R – compressible* pluralities), that the present account does not introduce.

Thus, the account proposed for dot-types is not only formally sound but also gives the correct results with respect to counting and individuation criteria without the need of additional machinery. We take this to be a clear advantage over the other accounts. On a more general level, it seems that using the rich typing structures that MTTs have to offer, provides us with considerable advantages over problematic issues in lexical semantics.

4 The Case of *newspaper*: a Proposal for Linear Dot-types

Cases like *book* or *lunch*, being subtypes of dot-types, seem to have clear properties that are captured

⁹In order to prove this, one has to add an additional axiom in Coq that deals with equalities under subtyping. In general, when $X <_c Y$, we do not have $x \neq_X y \implies (x \neq_Y y)$ unless c is injective. For the atomic types like *Book* and *PHY*, the equality on a subtype coincides with that of the supertype and so we can axiomatically assume this. See Appendix A for the Coq code and some explanation.

with the existing formalization given for dot-types. There is however a more problematic case, famously exemplified by the word *newspaper*, which seem to require a different, more restrictive treatment. First of all, *newspaper* is associated with three rather than two senses, i.e. institution (23), informational object (24) and physical object (25) as the examples below illustrate:¹⁰

(23) The newspaper was sued on moral grounds.

(24) He read the newspaper.

(25) He picked up the newspaper.

Now, when it comes to the use of two different senses in the context of the same sentence, a number of strange restrictions appear. The physical object sense can be used along with the informational sense, in the same way as in the case of *book*, but the organizational sense (newspaper as an institution) cannot be used copredicatively with any of the other two senses (examples from (Antunes and Chaves, 2003)):¹¹

(26) # That newspaper is owned by a trust and is covered with coffee.

(27) # The newspaper fired the reporter and fell off the table.

¹⁰An anonymous reviewer asks whether there are other analogous cases with three-way polysemy. Words similar to newspaper also exist, e.g. *magazine*, *journal*. Other cases with more than two meaning are mentioned in (Retoré, 2014) but it is not clear whether they constitute examples of a similar phenomenon. For example, the case of Liverpool, mentioned in (Retoré, 2014) as having the senses *Place*, *Town* and *People*. It is not however clear whether the justification for these types is well-founded. For example the sense *Town* and *People* could be very well reduced into one sense. Unfortunately, this needs discussion that we cannot perform in this paper. However, this is an extremely important question and the range of examples that are similar to newspaper should be investigated in order to end up with a fuller classification of dot-types according to their properties.

¹¹As an anonymous reviewer notes, all these examples involve a conjunction of the organizational and the physical aspect. He further asks what happens in case we have a conjunction of the informational and the organizational aspect. These cases are also infelicitous, e.g. # *He mastered and sued the newspaper* or # *That newspaper is owned by a trust and is very badly written*, so the pattern described in the paper is not violated.

(28) # John sued and ripped the newspaper.

Similar words with multiple senses that further involve similar restrictions are also discussed in (Retoré, 2014). There, a multi-sorted higher order logic is used¹² and every word is associated with a kind of basic type along with a number of coercions that can coerce this basic type into additional types. So in the case of book one gets the principal lambda-term $\lambda x.const(x):v \rightarrow t$ where v stands for event and two optional lambda-terms, $Id:v \rightarrow v$ and $f_a:v \rightarrow a$ where a stands for type *artifact*, a subtype of physical objects. The optional terms are declared as rigid, meaning that if one of the coercions is used, the other one cannot and vice versa. For the case of dot-types like *book* the optional lambda terms are dubbed as flexible, meaning that the coercions can be used simultaneously. This is indeed an interesting account. However, the exact nature of the rigid and flexible coercions are not defined formally, and it is rather unclear how such a specification can be made. Furthermore, for cases like *newspaper*, such an approach will not work. This is because, in the case of the coercion from $f_a:a \rightarrow i$ (artifact to informational object), this has to be defined as both rigid and flexible at the same time. Flexible, because we want this to be possible with the physical sense, while rigid because we want this not to be possible with the organizational sense. Furthermore, the account is based on the idea that there is always a principal lambda term. For example, in the case of *Book* the physical sense is chosen. How is this sense chosen is something that it is not explained. The question of why the physical rather than the informational aspect is chosen as the principal sense is something that is left unanswered.

The data with respect to *newspaper* get further complicated. As we have seen, the organizational aspect cannot be used with any of the other two aspects. However, this is not without exceptions. There are cases this restriction seems to disappear, allowing the organizational aspect to appear with any of the two other senses:

¹²The meta-language for the system in (Retoré, 2014) is Girard's system F rather than the simply typed λ -calculus as in Church's simple type theory (Church, 1940) as used by Montague.

- (29) The newspaper you are reading is being sued by Mia.

However, if one looks at the examples that allow this kind of constructions, it seems that they are of a specific kind. Most specifically all these cases involve some kind of modification, e.g. a relative clause as in the above example, or adjectival modification as in (30):

- (30) The most provocative newspaper of the year has been sued by the government.
(31) The newspaper he just grabbed from the newsstand is doing well in the stock market.

The pattern seems to be the following: the organizational aspect cannot be used with any of the other two aspects, unless one aspect is taking part in a modified CN construction. In case this happens the organizational aspect can be used along the other aspects. The account as proposed in (Pustejovsky, 1995) for *newspaper* cannot deal with these phenomenon and as far as we know, no formal account has been proposed for these cases. This is what we want to discuss here. The original account of dot-types in (Luo, 2010) among others will face similar problems. The dot-type $\text{INST} \bullet (\text{PHY} \bullet \text{INFO})$ will suffer the problem of predicting examples (23)-(25) to be ok contrary to fact. In what follows, we discuss a solution to this extent by proposing to treat these cases by extending the dot-type system to further include resource sensitive dot-types, i.e. linear dot-types.

Linear Dot-types: a Tentative Proposal. It is clear from what we see from the data that we are dealing with a situation where the dot-type is resource sensitive, in the sense of linear logic (Girard, 1987) or Lambek calculus (Lambek, 1958). For example, in linear logic, the rules of weakening and contraction are not available and this has a number of consequences. One of them is that one is has to use an assumption exactly once. An assumption, once used, is not re-usable anymore. It seems that this idea, is quite close to what we need for the

newspaper case.¹³ We need an additional version of the dot-type, more specifically a linear version of the dot-type. This version will be closed related to the tensor product in linear logic and the usual dot-type, one of the important feature being that if one of its components has been used, the other one cannot be used any more.

Let us represent this linear dot-type as $A \ominus B$. We can further have combinations of regular and linear dot-types. In the case of *newspaper* what we need is the type $\text{INST} \ominus (\text{PHY} \bullet \text{INFO})$. With this type, we can take care of examples like (23) to (25) (these are also taken care of with a regular dot-type), while at the same time excluding examples (26-28) (that would be predicted to be ok with a regular dot-type).

Note that the examples like (29) can be accounted for without employing the linear version of dot-types. For instance, the semantics of (29) can be given as $sue(n)$ where $n : \Sigma(\text{Newspaper}, read)$ and $sue : \text{Inst} \rightarrow \text{Prop}$, because we have $\Sigma(\text{Newspaper}, read) < \text{Newspaper} < \text{INST} \bullet (\text{PHY} \bullet \text{INFO}) < \text{INST}$. The question of course is when do we use a linear dot-type and when a regular dot-type. In order to solve this problem, one can use local coercions, i.e. subtyping assumptions localized in terms (or judgments), as proposed in (Luo, 2010; Luo, 2012b). Local coercions have been used in (Luo, 2011) to deal with cases of homophony and in (Asher and Luo, 2012) to give semantics of linguistic coercions in sophisticated situations. Local coercions are only effective locally for some terms (expressions in type theory). They may be introduced into terms by the following rule (intuitively, the coercions declared locally are only effective in the expressions in the scope of the keyword **in**):

$$\frac{\Gamma, A <_c B \vdash J}{\Gamma \vdash \text{coercion } A <_c B \text{ in } J}$$

where J is any of the following four forms of judgement:

$$k : K, \quad k = k' : K, \quad K \text{ kind}, \quad \text{and} \quad K = K'.$$

For instance, with $J \equiv k : K$, we have

$$\frac{\Gamma, A <_c B \vdash k : K}{\Gamma \vdash \text{coercion } A <_c B \text{ in } k : K}$$

¹³This is based on the fact that in case the organizational aspect is used, no other aspect can be used any more within the same context. This is a kind of resource sensitivity.

In the case of *newspaper*, what we need is to consider two local coercions: $Newspaper < INST \bullet (PHY \bullet INFO)$ in interpreting the cases where the ordinary dot-type should be used and $Newspaper < INST \ominus (PHY \bullet INFO)$ in interpreting the cases where the linear dot-type should be used. For example, the following (32) will give a correct interpretation of (29):

(32) **coercion** $Newspaper < INST \bullet (PHY \bullet INFO)$ in $[(29)]$

while the following would not be accepted:

(33) **# coercion** $Newspaper < INST \ominus (PHY \bullet INFO)$ in $[(26)]$

We believe that this gives a satisfactory account of a problem that as far as we know has not received a treatment up to now.¹⁴

However, it has to be kept in mind that we have not formally treated the linear dot-type $A \ominus B$. One of the reasons for this is that, in order to do this, we need to formally study how to incorporate coercive subtyping into a resource sensitive logical system. Put in another way, one needs to study an MTT augmented with resource sensitive contextual segments and its coercive subtyping extension. We leave this as future work.

5 Conclusion

We have discussed dot-types with respect to their counting criteria and have shown that the MTT account proposed captures the fact correctly. The proof-assistant Coq was used in order to verify that the correct inferences are predicted. The account was shown not only to produce the correct results but to do so without resorting to serious extra complications of the original account (actually none is

¹⁴Another solution that has been proposed to us by an anonymous reviewer, is the following: One basically assumes that the organizational aspect is just a different lexical entry, in effect as we understand it (even though the reviewer has not phrased it in this way) a case of homonymy. We have thought of this possibility. In case this idea is put forth within the framework discussed in this paper, one will use the account by (Luo, 2011) for cases of homonymy like *bank* where local coercions are used to either use $Bank < Institution$ or the $Bank < Riverside$ sense. In the case of *newspaper*, we would use either $Newspaper < INST$ or $Newspaper < PHY \bullet INFO$.

needed). Furthermore, the case of *newspaper* was discussed and a solution based on the introduction of linear dot-types combined with local coercions was provided. The issue of introducing linear dot-types in a formal way presupposes a linear version of type theory that at the moment we do not have. Thus, we leave this issue as a subject of future research. A related piece of work is that the second author has recently developed Lambek dependent types (Luo, 2015), with the motivation of studying a uniform basis for NL analysis: from automated syntactic analysis to logical reasoning in proof assistants based on MTT-semantics.

A Some notes on a Coq proof

In order to prove:

```
Theorem DT: (Three Book) (and (PhyInfo
->Prop) (picked_up John) (mastered
John)) -> (Three Phy) (picked_up John)
/\ (Three Info) (mastered John)
```

We first need to introduce the axiom in order to deal with the subtyping equality problem. We introduce this in a new local context:

```
Section Book.
Variable PHY: forall x:Book, forall
y:Book, not(x=y:>Book) -> not(x=y:>Phy).
Variable INFO: forall x:Book, forall
y:Book, not(x=y:>Book) -> not(x=y:>Info).
```

We show the proof of:

```
Theorem DT:(Three Book)(and(PhyInfo  
->Prop)(picked_up John)(mastered  
John))->(Three Phy)( picked_up John)
```

We use the following:

```
compute.intro.destruct AND1.case a with  
(Three Book). AUTO. AUTO.destruct H0.  
destruct H0.destruct H2.destruct H2.  
destruct H3.destruct H3.destruct H4.  
destruct H5.exists x0.AUTO.exists x1.  
AUTO.
```

The interested reader can check for him-
self/herself for the other cases.
