Abstract

In this note we describe the solution of perfect square placement problems with CHIP. A set of 207 perfect square placement problems from [BD92] is used. We present the constraint model in CHIP, which uses the global constraints diffn and cumulative together with a specific labeling routine for perfect placement problems. We show that all problems can be solved and present backtracking count and execution times for finding the first solution and for exploring the complete search space.

Problem

We discuss the following perfect square placement problem (also called squared square problem [CFG91][LW92]):

Pack a set of squares with given integer sizes into a bigger square in such a way that no squares overlap each other and all square borders are parallel to the border of the big square. For a perfect placement problem, all squares have different sizes. The sum of the square surfaces is equal to the surface of the packing square, so that there is no spare capacity. The problem data come from [BD92], which lists all simple perfect square placement problems of order 21 to 25. Simple in this context means that the problems do not contain a subset of squares (greater than one) which are placed in a rectangle.

Duijvestijn has shown in 1962 that no instances exist with less than 21 squares [Dui78]. A single problem exists with 21 squares. In this problem, the squares have sizes [2,4,6,7,8,9,11,15,16,17,18,19,24,25,27,29,33,35,37,42,50] and must be packed into a square of size 112. A solution is shown below. There are 8 problems of order 22, 12 of order 23, 26 of order 24, and 160 of order 25. A constraint approach for this problem was already studied in [AB93], where a solution is found in 38 seconds. The same problem was mentioned in [VH94], where a solution was found in 60 seconds. Both results were obtained on SUN workstations. With the program shown here, we find a solution in 0.3 seconds on a PC.

Program

The CHIP program to solve the square placement problem is given below. Each square is defined by two domain variables X and Y and integer Width and Height values. The predicate run has an input parameter, which is the problem instance number and two output parameters, the lists of the X and Y values for the coordinates

of the bottom left corners of the squares. The predicate `gen_data/6` reads the problem definition of the instance and generates lists of domain variables for the X and Y values. The square sizes are given in decreasing order, the largest square is the first entry in the lists. The predicate `gen_rect/5` creates a list of rectangles (each a list of four variables X, Y, Width and Height) from the four parameter lists.

The `diffn` [BC94] constraint states that the set of squares do not overlap and fit into the available space. The first argument is a list of rectangles, generated by `gen_rect/5`. The fourth argument defines the available space.

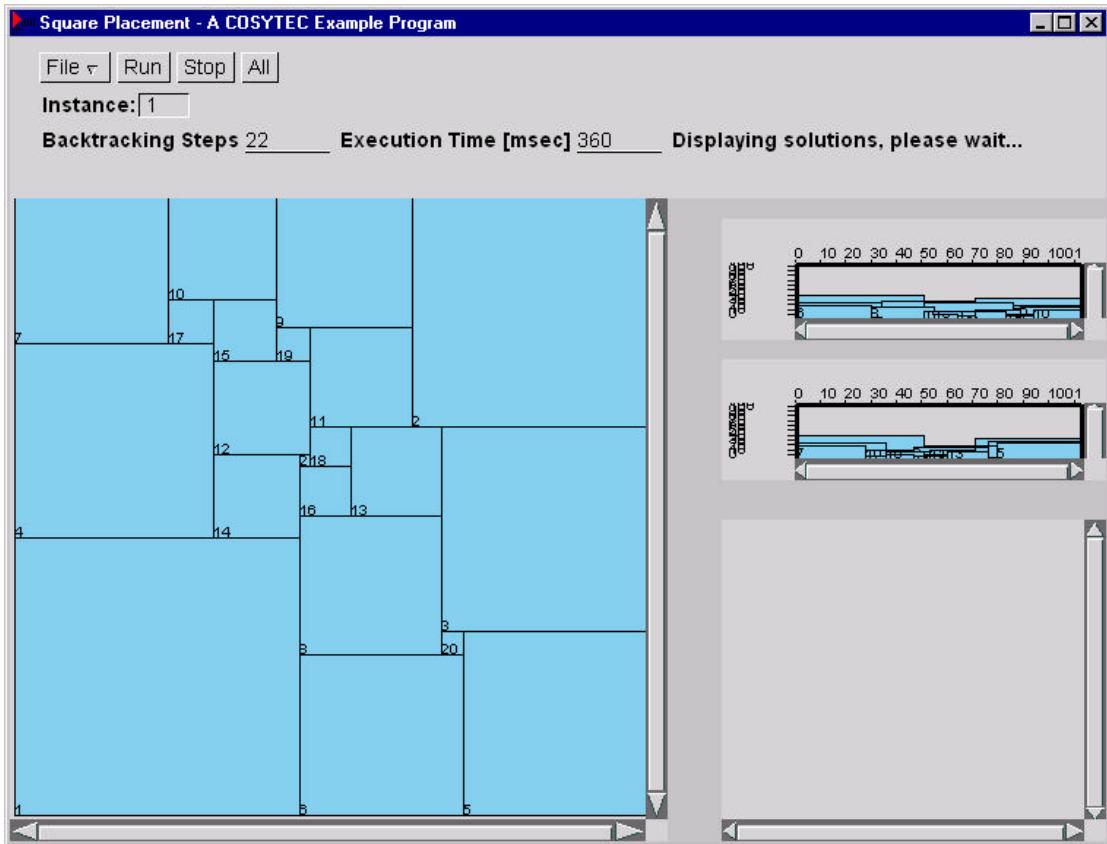

Figure 1: Solution of the 21 square problem

We also use two redundant cumulative [AB93] constraints which project the placement in x or y dimension. The first argument gives the origin, the second argument the size and the third argument the height of the squares to be placed. Arguments 6 and 7 define the available placement space. The argument 8 enforces an additional constraint that the available space must be completely used.

The labeling routine is described in [AB93]. We first find an assignment of all X variables, and then find an assignment for the Y variables. Many other assignment strategies are possible, the one shown here gives the best results on perfect placement problems. The labeling method works by finding the smallest value in the domain of the unassigned variables and then assigning this value to some variable. On backtracking, other variables will be assigned to this value. The predicate `lmindomain/2/3` finds the smallest value a list of domain variables. The predicate `fix_min/3` is a non-deterministic predicate which either fixes a variable to the minimal value

```

run(Nr,LX,LY) :-
    gen_data(Nr,LX,LY,LW,LH,Max),
    gen_rect(LX,LY,LW,LH,Lrect),
    Max1 is Max + 1,
    diffn(Lrect,unused,unused,[Max1,Max1]),
    cumulative(LX,LW,LH,unused,unused,Max,Max1,[Max,0,1]),
    cumulative(LY,LH,LW,unused,unused,Max,Max1,[Max,0,1]),
    labeling(LX),
    labeling(LY).

    domain_info(H, Min, _, _, _, _),
    lmindomain(T, Min, M).

lmindomain([], M, M).
lmindomain([X|Y], M, Mend) :-
    domain_info(X, Min, _, _, _, _),
    M1 is min(M,Min),
    lmindomain(Y, M1, Mend).

inc_choice.
inc_choice:-
    incval(choice,_),
    fail.

```

Program 1 : Square placement program in CHIP

Results

The table below gives the results for CHIP V5.2 on the benchmark set. The results were obtained with the commercial CHIP version on a Pentium MMX 233MHz PC, running WindowsNT 4.0 with 64 Mb of memory. The table shows the instance number, the number of backtracking steps and the execution time required to find a first solution, the total number of solutions found and the backtracking count and execution times to find all solutions by complete enumeration of the search space. Note that for most problems 8 solutions are found, these correspond to one solution under all plane symmetries. Problems 166 and 167 (also 168 and 169, and 182 and 183) have identical data, but two independent (non-isomorphic) solutions. These problems are given in this form in the original data set.

The maximum time to find a first solution was spent on problem 59 with 32.5 seconds (3877 backtracking steps), the maximum time to explore the complete search space was spent in problem 48 with 503 seconds (66100 backtracking steps). On the other hand, for 38 problems a first solution was found without backtracking, and 94 problems were explored completely with less than 2000 backtracking steps.

| Instance | Backtrack for first solution | Time for first solution [ms] | Number of solutions | Backtrack for all solutions and proof | Time for all solutions and proof [ms] |

Possible Improvements

A major decrease of the total execution time is possible by introducing constraints to avoid redundant, symmetrical solutions. For each problem in the data-set, there are 8 symmetrical solutions obtained by applying the symmetries in the plane. We choose not to attempt this in this benchmarking problem, in order to simplify comparisons between different systems.

Summary

In this note we have presented the solution of a set of perfect square placement problems with CHIP. A rather simple CHIP program can be used to find solutions to all problem instances.

Appendix A

The following table contains all the data for all problem instances from [BD92]. The fields describe the problem number, the number of squares, the size of the master square and a list of the square sizes. The problem number corresponds to the page number in [BD92]. Problems 166 and 167, 168 and 169, 182 and 183 are identical, but have two non-isomorphic solutions.
