# Topological properties of Hilbert schemes of almost-complex fourfolds (I) 

the date of receipt and acceptance should be inserted later

#### Abstract

In this article, we study topological properties of Voisin's Hilbert schemes of an almost-complex four-manifold $X$. We compute in this setting their Betti numbers and construct Nakajima operators. We also define tautological bundles associated with any complex bundle on $X$, which are shown to be canonical in $K$-theory.

## 1. Introduction

The aim of the present paper is to extend some constructions and results related to Hilbert schemes of points for projective surfaces to the case of almost-complex compact manifolds of real dimension four.

If $X$ is any smooth irreducible complex projective surface and if $n$ is any positive integer, the Hilbert scheme of points $X^{[n]}$ is the set of all zero-dimensional subschemes of $X$ of length $n$. By a result of Fogarty [8], $X^{[n]}$ is a smooth irreducible projective variety of complex dimension $2 n$. This implies that $X^{[n]}$ can be seen as a smooth compactification of the set of distinct unordered $n$-tuples of points in $X$. Besides, if $X^{(n)}$ denotes the $n$-fold symmetric power of $X$, the Hilbert-Chow map $\Gamma: X^{[n]} \longrightarrow X^{(n)}$ defined by $\Gamma(\xi)=\sum_{x \in \operatorname{supp}(\xi)} l_{x}(\xi) x$ is a resolution of singularities of $X^{(n)}$.

In the papers [19] and [20], Voisin constructs Hilbert schemes $X^{[n]}$ associated with any almost-complex compact four-manifold. Each Hilbert scheme $X^{[n]}$ is a compact differentiable manifold of dimension $4 n$ endowed with a stable almostcomplex structure, and there exists a continuous Hilbert-Chow map $\Gamma$ from $X^{[n]}$ to $X^{(n)}$ whose fibers are homeomorphic to the fibers of the usual Hilbert-Chow map. Furthermore, if $X$ is a symplectic compact four-manifold, the differentiable Hilbert schemes $X^{[n]}$ are also symplectic (this is a differentiable analog of a result of Beauville [1]).

Using ideas of Voisin concerning relative integrable complex structures, which are the main technical ingredient of [19], we study the local topological structure

of the Hilbert-Chow map. This allows us to compute the Betti numbers of $X^{[n]}$, which extends Göttsche's classical formula [10].

Theorem 1. Let $(X, J)$ be an almost-complex compact four-manifold and, for any positive integer $n$, let $\left(b_{i}\left(X^{[n]}\right)\right)_{i=0, \ldots, 4 n}$ be the sequence of Betti numbers of the almost-complex Hilbert scheme $X^{[n]}$. Then the generating function for these Betti numbers is given by the formula

$$
\sum_{n=0}^{\infty} \sum_{i=0}^{4 n} b_{i}\left(X^{[n]}\right) t^{i} q^{n}=\prod_{m=1}^{\infty} \frac{\left[\left(1+t^{2 m-1} q^{m}\right)\left(1+t^{2 m+1} q^{m}\right)\right]^{b_{1}(X)}}{\left(1-t^{2 m-2} q^{m}\right)\left(1-t^{2 m+2} q^{m}\right)\left(1-t^{2 m} q^{m}\right)^{b_{2}(X)}}
$$

The proof of Theorem 1 follows closely the argument of Göttsche and Soergel [11] and relies on the decomposition theorem of Deligne, Beilinson, Bernstein, Gabber [2], which describes derived direct images of DGM-sheaves under proper morphisms between complex algebraic varieties (see [5, Th. 5.4.10]). If $f: Y \longrightarrow Z$ is a proper semi-small morphism and if $Y$ is rationally smooth, the decomposition theorem has a particularly nice form: it gives a canonical quasiisomorphism between $R f_{*} \mathbb{Q}_{Y}$ and a direct sum of explicit intersection complexes on $Z$. This statement has been proved by Le Potier [14] using neither characteristic $p$ methods nor étale cohomology (which are heavily used in [2]), and his proof can be naturally extended to the case of continuous maps which are locally equivalent on the base to semi-small maps. Since Le Potier's proof is enlightening in many respects and appears only in unpublished lecture notes, we take the opportunity to reproduce it here in an appendix.

The second part of the paper is devoted to the definition and the study of the Nakajima operators associated with an arbitrary almost-complex compact fourmanifold $X$. These operators act on the total cohomology ring $\bigoplus_{n \in \mathbb{N}} H^{*}\left(X^{[n]}, \mathbb{Q}\right)$ of the Hilbert schemes of points by correspondences associated with incidence varieties. We prove that the Nakajima commutation relations established in [16] can be extended to the almost-complex setting:

Theorem 2. For any pair $(i, j)$ of integers and any pair $(\alpha, \beta)$ of cohomology classes in $H^{*}(X, \mathbb{Q})$ we have

$$
\left[\mathfrak{q}_{i}(\alpha), \mathfrak{q}_{j}(\beta)\right]=i \delta_{i+j, 0}\left(\int_{X} \alpha \beta\right) \mathrm{id} .
$$

It follows from Theorems 1 and 2 that the Nakajima operators define a highest weight irreducible representation of the Heisenberg super-algebra $\mathcal{H}\left(H^{*}(X, \mathbb{Q})\right)$ on the infinite-dimensional graded vector space $\bigoplus_{n \in \mathbb{N}} H^{*}\left(X^{[n]}, \mathbb{Q}\right)$.

In the last part of the paper, we carry out the construction of tautological bundles $E^{[n]}$ on the complex Hilbert schemes $X^{[n]}$ associated with any complex vector bundle $E$ on an almost-complex compact four-manifold $X$. To do so, we use relative holomorphic structures on $E$ in the same spirit as the relative integrable complex structures considered in [19].

Let us now give an idea of our strategy to prove the results. If $(X, J)$ is an almost-complex compact manifold and $n$ is a positive integer, Voisin's construction of the Hilbert scheme of $n$-points associated with $X$ is not canonical and depends on the choice of a relative integrable complex structure $J^{\text {rel }}$ on $X$ parameterized by the $n$-th symmetric power $X^{(n)}$ of $X$ (which means essentially that for all $x$ in $X^{(n)}, J_{x}^{\text {rel }}$ is an integrable complex structure in a neighbourhood of the points of $\underline{x}$ in $X$ varying smoothly with $x$ ). If $J^{\text {rel }}$ is such a structure and if $X_{J \text { rel }}^{[n]}$ is the associated Hilbert scheme, then $X_{J \text { rel }}^{[t]}$ is naturally a differentiable manifold provided that $J^{\text {rel }}$ satisfies some additional complicated geometric conditions. We don't use at all the differentiable structure of $X_{J \text { rel }}^{[n]}$ in the paper, because it is not necessary for our purpose: indeed, the cohomology rings of the Hilbert schemes only depend on their homotopy type.

In $\S 3$ we study, first locally and then globally, relative integrable structures. The local study is achieved in $\S 3.1$ using the existence of relative holomorphic coordinates for relative integrable complex structures. It allows us to prove that $X_{J \text { rel }}^{[n]}$ is locally homeomorphic to the integral model $\left(\mathbb{C}^{2}\right)^{[n]}$, and is therefore a topological manifold. As explained earlier, Göttsche's formula (proved in § 3.2) can be deduced thereof. The aim of the global study of relative integrable complex structures on $X$ (§3.3) is to show that the homeomorphism type of $X_{J \text { rel }}^{[n]}$ is independent of $J^{\text {rel }}$. Using standard gluing techniques, we prove a slightly stronger result, namely that the Hilbert schemes $X_{J \text { rel }}^{[n]}$ vary topologically trivially if $J^{\text {rel }}$ varies smoothly. In the case of relative integrable complex structures considered in [19], this fact is a straightforward consequence of Ehresmann's fibration theorem; but this argument is no longer valid for arbitrary relative integrable complex structures.

Our main concern in $\S 4$ is to define and study incidence varieties. Even if a variant of Voisin's relative construction can be used to define these objects for almost-complex four-manifolds (this is done in §4.1), some new difficulties appear. Indeed the incidence variety $X^{\left[n^{\prime}, n\right]}$ cannot be naturally embedded into a product of Hilbert schemes, even for well-chosen relative complex structures. This problem is solved using the product Hilbert schemes $X^{[n] \times\left[n^{\prime}\right]}$ introduced at the end of $\S 3.3$. As it is the case for Hilbert schemes, the incidence variety $X^{\left[n^{\prime}, n\right]}$ is locally homeomorphic to the integrable model $\left(\mathbb{C}^{2}\right)^{\left[n^{\prime}, n\right]}$, which allows to endow $X^{\left[n^{\prime}, n\right]}$ with a topological stratification locally modeled on the standard stratification of an analytic set. Thus, incidence varieties carry a fundamental homology class and Nakajima operators can be defined via the action by correspondence of incidence varieties. In $\S 4.2$, we prove that these operators satisfy the Heisenberg commutation relations. Our proof follows closely Nakajima's original one, even if compatibility problems between various relative integrable complex structures make our argument somehow heavy. The main idea underlying the proof is that intersection of cycles can be understood locally as soon as there is no excess intersection components (such a component would yield an excess cohomology class on the set-theoretical intersection of the cycles, which is no longer a local datum). There is only one case where excess contributions appear, corresponding to the commutator $\left[\mathfrak{q}_{i}(\alpha), \mathfrak{q}_{-i}(\beta)\right]$. However, this case can be handled easily because the
excess term becomes simply a multiplicity at the end of the computation, hence is a local datum.

In §5.1, we develop the theory of relative holomorphic structures (or equivalently of relative holomorphic connections) on any complex vector bundle $E$ on $X$. This allows us to define a tautological vector bundle $E^{[n]}$ on $X^{[n]}$ (which is a new construction, even if $J$ is integrable, because $E$ is not assumed to be holomorphic). We prove that the class of $E^{[n]}$ in $K\left(X^{[n]}\right)$ is independent of the auxiliary structures used to define it, and we compute in geometric terms the first Chern class of the vector bundle $\mathbb{T}^{[n]}$, where $\mathbb{T}$ is the trivial complex line bundle on $X$. In $\S 5.2$, using methods already present in $\S 4$, we establish the induction relation comparing the classes of $E^{[n]}$ and $E^{[n+1]}$ through the incidence variety $X^{[n+1, n]}$.

Acknowledgement. I sincerely thank my advisor Claire Voisin whose work on almost-complex Hilbert schemes is at the origin of this article. Her deep knowledge of the subject and her frequent and judicious advice have been most valuable to me. I also wish to thank her for her kindness and her patience. Finally, I thank the referee for his/her useful comments.

## 2. Notations and conventions

Throughout the paper, $(X, J)$ is an almost-complex compact four-manifold.

### 2.1. Symmetric powers

- If $n$ is a positive integer, let $\mathfrak{S}_{n}$ be the symmetric group on $n$ symbols. The $n$-fold symmetric power $X^{(n)}$ of $X$ is the quotient of $X^{n}$ by the action of $\mathfrak{S}_{n}$. It is endowed with the sheaf $\mathcal{C}_{X^{(n)}}^{\infty}$ of smooth functions on $X^{n}$ invariant under $\mathfrak{S}_{n}$.
- Elements of the symmetric powers appear most of the time as underlined letters. For any $x$ in $X^{(n)}$, the support of $x$ is the subset of $X$ consisting of points in $\underline{x}$; we denote $\overline{i t}$ by $\operatorname{supp}(\underline{x})$.
-For any positive integers $p$ and $q$, we denote by $(\underline{x}, \underline{y}) \longmapsto \underline{x} \cup \underline{y}$ the natural map from $X^{(p)} \times X^{(q)}$ to $X^{(p+q)}$.
-For any positive integer $n$ and any $x$ in $X$, we denote by $n x$ the unique element in $X^{(n)}$ satisfying $\operatorname{supp}(n x)=\{x\}$.
- If $k, n_{1}, \ldots, n_{k}$ are positive integers, the incidence set $Z_{n_{1} \times \ldots \times n_{k}}$ is the subset of $X^{\left(n_{1}\right)} \times \cdots \times X^{\left(n_{k}\right)} \times X$ defined by

$$
\begin{aligned}
& Z_{n_{1} \times \ldots \times n_{k}}=\left\{\left(\underline{x}_{1}, \ldots, \underline{x}_{k}, x\right) \text { in } X^{\left(n_{1}\right)} \times \cdots \times X^{\left(n_{k}\right)} \times X\right. \\
&\text { such that } \left.x \in \operatorname{supp}\left(\underline{x}_{1} \cup \cdots \cup \underline{x}_{k}\right)\right\} .
\end{aligned}
$$

### 2.2. Hilbert-Douady schemes

- If $Y$ is a smooth complex surface and $n$ is a positive integer, $Y^{[n]}$ is the Hilbert-Douady scheme of $n$-points in $Y$ (i.e. the moduli space parameterizing zero-dimensional subschemes of $Y$ of length $n$ ); $Y^{[n]}$ is smooth of dimension $2 n$ and is irreducible if $Y$ is irreducible [8], [3].
- The Hilbert-Chow morphism from $Y^{[n]}$ to $Y^{(n)}$ (also called Douady-Barlet morphism in the analytic setting) is denoted by $\Gamma$.
- If $E$ is a holomorphic vector bundle on $Y, E^{[n]}$ denotes the $n$-th tautological vector bundle on $Y$; it satisfies that for any $\xi$ in $Y^{[n]}, E_{\mid \xi}^{[n]}=H^{0}(\xi, E)$.
- If $n, n^{\prime}$ are positive integers such that $n^{\prime}>n$, the incidence variety $Y^{\left[n^{\prime}, n\right]}$ (in the notation of [15]) is the set of pairs $\left(\xi, \xi^{\prime}\right)$ in $X^{[n]} \times X^{\left[n^{\prime}\right]}$ such that $\xi$ is a subscheme of $\xi^{\prime}$. Remark that some authors (e.g. [6]) use the other possible notation $Y^{\left[n, n^{\prime}\right]}$.

### 2.3. Morphisms

- Let $\pi: Y \longrightarrow Z$ be a given morphism. For any $z$ in $Z$, the fiber $\pi^{-1}(z)$ of $z$ is denoted by $Y_{z}$.
- Let $\pi: Y \longrightarrow Z, \pi^{\prime}: Y^{\prime} \longrightarrow Z$ and $f: Y \longrightarrow Y^{\prime}$ be three morphisms such that $\pi^{\prime} \circ f=\pi$. For any $z$ in $Z$, the restriction of $f$ to the fiber $Y_{b}$ is denoted by $f_{b}$; it is a morphism from $Y_{b}$ to $Y_{b}^{\prime}$.
- If $f: Y \underset{(n)}{ } Z$ is a morphism, then for any positive integer $n, f$ induces a morphism $f^{(n)}: Y^{(n)} \longrightarrow Z^{(n)}$. If $Y$ and $Z$ are complex surfaces and if $f$ is a biholomorphism, $f$ induces a biholomorphism $f_{*}: Y^{[n]} \longrightarrow Z^{[n]}$ given at the level of ideal sheaves by the composition with $f^{-1}$.

### 2.4. Relative integrable complex structures

- Let $k, n_{1}, \ldots, n_{k}$ be positive integers and $W$ be a neighbourhood of the incidence set $Z_{n_{1} \times \cdots \times n_{k}}$ in $X^{\left(n_{1}\right)} \times \cdots \times X^{\left(n_{k}\right)} \times X$ (see $\S 2.1$ ). A relative integrable complex structure $J^{\text {rel }}$ on $W$ is a smooth family of integrable complex structures on the fibers of $\mathrm{pr}_{1}: W \longrightarrow X^{\left(n_{1}\right)} \times \cdots \times X^{\left(n_{k}\right)}$. In other words, for any element $\left(\underline{x}_{1}, \ldots, \underline{x}_{k}\right)$ in $X^{\left(n_{1}\right)} \times \cdots \times X^{\left(n_{k}\right)}, J_{\underline{x}_{1}, \ldots, \underline{x}_{k}}^{\text {rel }}$ is an integrable complex structure on $W_{\underline{x}_{1}, \ldots, \underline{x}_{k}}$ varying smoothly with the $\underline{x}_{j}{ }_{j}$, ${ }^{-k}$.
- We use in a systematic way the following notation throughout the paper: a relative integrable structure in a neighbourhood of $Z_{n_{1} \times \cdots \times n_{k}}$ is identified by an index " $n_{1} \times \cdots \times n_{k}$ ". Thus, the occurrence of such a term as $J_{n_{1} \times \cdots \times n_{k}, \underline{x}_{1}, \ldots, \underline{x}_{k}}^{\text {rel }}$ means that:
* $J_{n_{1} \times \cdots \times n_{k}}^{\mathrm{rel}}$ is a relative integrable complex structure in a neighbourhood of

$$
Z_{n_{1} \times \cdots \times n_{k}} \text { in } X^{\left(n_{1}\right)} \times \cdots \times X^{\left(n_{k}\right)} \times X \text {. }
$$

${ }^{*} \underline{x}_{1} \in X^{\left(n_{1}\right)}, \ldots, \underline{x}_{k} \in X^{\left(n_{k}\right)}$.
In this case, $J_{n_{1} \times \cdots \times n_{k}, x_{1}, \ldots, \underline{x}_{k}}^{\text {rel }}$ is an integrable complex structure in a neighbourhood of $\operatorname{supp}\left(\underline{x}_{1} \cup \cdots \cup \underline{x}_{k}\right)$ in $X$. When $k=1$, we use the notation $J^{\text {rel }}$ instead of $J_{n}^{\text {rel }}$ if no confusion is possible.

- We deal several times with compatibility conditions between relative integrable complex structures parameterized by different products of symmetric powers of $X$. This is possible because relative integrable complex structures are families of integrable complex structures on open subsets of the same manifold $X$, even if the parameter spaces can be different.
- Let $g$ be a Riemannian metric on $X, n_{1}, \ldots, n_{k}$ be positive integers and $J_{n_{1} \times \cdots \times n_{k}}^{\mathrm{rel}}$ be a relative integrable complex structure in a neighbourhood $W$ of $Z_{n_{1} \times \cdots \times n_{k}}$. We define

$$
\left\|J_{n_{1} \times \cdots \times n_{k}}^{\mathrm{rel}}-J\right\|_{C^{0}, g, W}=\sup _{\substack{\left.\underline{x}_{1}, \ldots, \underline{x}_{k}\right) \in X^{\left(n_{1}\right)} \times \cdots \times X^{\left(n_{k}\right)} \\ p \in W_{\underline{x}_{1}}, \ldots, \underline{x}_{k}}}\left\|J_{n_{1} \times \cdots \times n_{k}, \underline{x}_{1}, \ldots, \underline{x}_{k}}^{\mathrm{rel}}(p)-J(p)\right\|_{\widetilde{g}(p)}
$$

where $\widetilde{g}$ is the Riemannian metric on $\operatorname{End}(T X)$ associated with $g$. The relative integrable complex structure $J_{n_{1} \times \cdots n_{k}}^{\mathrm{rel}}$ is said to be close to $J$ if $\left\|J_{n_{1} \times n_{k}}^{\mathrm{rel}}-J\right\|_{C^{0}, g, W}$ is sufficiently small.

## 3. The Hilbert schemes of an almost-complex compact four-manifold

### 3.1. Voisin's construction

In this section, we recall Voisin's construction of the almost-complex Hilbert scheme and establish some complementary results. We use the notations and the terminology introduced in § 2.

Definition 1. If $g$ is a Riemannian metric on $X$ and if $\varepsilon$ is a positive real number, let $\mathcal{B}_{g, \varepsilon}$ be the set of pairs $\left(W, J^{\text {rel }}\right)$ such that $W$ is a neighbourhood of the incidence set $Z_{n}$ in $X^{(n)} \times X, J^{\text {rel }}$ is a relative integrable complex structure on $W$ and $\left\|J^{\text {rel }}-J\right\|_{C^{0}, g, W}<\varepsilon$.
For $\varepsilon$ small enough, $\mathcal{B}_{g, \varepsilon}$ is connected and weakly contractible (i.e. $\pi_{i}\left(\mathcal{B}_{\varepsilon}\right)=0$ for $i \geq 1$ ). We choose such an $\varepsilon$ and write $\mathcal{B}$ instead of $\mathcal{B}_{g, \varepsilon}$.

Let $\pi:\left(W_{\text {rel }}^{[n]}, J^{\mathrm{rel}}\right) \longrightarrow X^{(n)}$ be the relative Hilbert scheme of $\left(W, J^{\mathrm{rel}}\right)$ over $X^{(n)}$; the fibers of $\pi$ are the smooth analytic sets $\left(W_{\underline{x}}^{[n]}, J_{\underline{x}}^{\text {rel }}\right), \underline{x} \in X^{(n)}$. We denote by $\Gamma_{\text {rel }}: W_{\text {rel }}^{[n]} \longrightarrow W_{\text {rel }}^{(n)}$ the associated relative Hilbert-Chow morphism over $X^{(n)}$.

Definition 2. The topological Hilbert scheme $X_{J \text { rel }}^{[n]}$ is defined by

$$
X_{J_{\mathrm{rel}}}^{[n]}=\left(\pi, \mathrm{pr}_{2} \circ \Gamma_{\mathrm{rel}}\right)^{-1}\left(\Delta_{X^{(n)}}\right),
$$

where $\Delta_{X^{(n)}}$ is the diagonal of $X^{(n)}$ in $X^{[n]} \times X^{[n]}$. More explicitly,

$$
X_{J}^{[n]}=\left\{(\xi, \underline{x}) \text { such that } \underset{\underline{x}}{ } \in X^{(n)}, \xi \in\left(W_{\underline{x}}^{[n]}, J_{\underline{x}}^{\mathrm{rel}}\right) \text { and } \Gamma(\xi)=\underline{x}\right\} .
$$

To put a differentiable structure on $X_{J \text { rel }}^{[n]}$, Voisin uses specific relative integrable structures which are invariant by a compatible system of retractions on the strata of $X^{(n)}$. These relative structures are differentiable for a differentiable structure $\mathfrak{D}_{J}$ on $X^{(n)}$ which depends on $J$ (and on other additional data) and is weaker than the quotient differentiable structure, i.e. $\mathfrak{D}_{J} \subseteq \mathcal{C}_{X^{(n)}}^{\infty}$. Voisin's main results are the following ones:

Theorem 1. [19], [20]
(i) $X^{[n]}$ is a $4 n$-dimensional differentiable manifold, well-defined modulo diffeomorphisms isotopic to the identity.
(ii) The Hilbert-Chow map $\Gamma: X^{[n]} \longrightarrow\left(X^{(n)}, \mathfrak{D}_{J}\right)$ is differentiable and its fibers $\Gamma^{-1}(\underline{x})$ are homeomorphic to the fibers of the usual Hilbert-Chow morphism for any integrable structure near $\operatorname{supp}(x)$.
(iii) $X^{[n]}$ can be endowed with a stable almost-complex structure, hence defines an almost-complex cobordism class. When $X$ is symplectic, $X_{J \text { rel }}^{[n]}$ is symplectic.

The first point is the analogue of Fogarty's result [8] in the differentiable case. In this article we do not use differentiable properties of $X^{[n]}$ but only topological ones, which allow us to work with $X_{J \text { rel }}^{[n]}$ for any $J^{\text {rel }}$ in $\mathcal{B}$. Without any assumption on $J^{\text {rel }}$, the first point of Theorem 1 has the following topological version:

Proposition 1. For any $J^{\text {rel }}$ in $\mathcal{B}, X_{J_{\text {rel }}^{[n]}}^{[s}$ a topological manifold of dimension $4 n$.

Proof. Let $W$ be the neighbourhood of $Z_{n}$ associated with $J^{\text {rel }}, \underline{x}_{0}$ be any element in $X^{(n)}$ and $x_{0}$ be a lift of $\underline{x}_{0}$ in $X^{n}$. We write $x_{0}=\left(y_{1}, \ldots, y_{1}, \ldots, y_{k}, \ldots, y_{k}\right)$ where the points $y_{j}$ are pairwise distinct for $1 \leq j \leq k$ and each $y_{j}$ appears $n_{j}$ times. If $\Omega$ is a small neighbourhood of $\operatorname{supp}\left(\underline{x}_{0}\right)$ in $X$, we can assume that $\Omega$ is an open subset of $\mathbb{C}^{2}$. For $\epsilon>0$ small enough, the balls $B\left(y_{j}, \varepsilon\right)$ are contained in $\Omega$ and are also pairwise disjoint in $X$. If $H=\mathfrak{S}_{n_{1}} \times \cdots \times \mathfrak{S}_{n_{k}}$ is the stabilizer of $x_{0}$ in $\mathfrak{S}_{n}$, we put $V_{x_{0}}=B\left(y_{1}, \varepsilon\right)^{n_{1}} \times \cdots \times B\left(y_{k}, \varepsilon\right)^{n_{k}}$. Then $V_{\underline{x}_{0}}=V_{x_{0}} / H$ is a neighbourhood of $\underline{x}_{0}$ in $X^{[n]}$. If $U=\cup_{j=1}^{k} B\left(y_{j}, \varepsilon\right)$, a sufficiently small choice of $\varepsilon$ guarantees that for every $\underline{x}_{\underline{x}}$ in $V_{\underline{x}_{0}}, U \subseteq W_{\underline{x}}$. By the Newlander-Nirenberg theorem with parameters, there exists a smooth map $\phi: V_{x_{0}} \times U \longrightarrow \mathbb{C}^{2}$ invariant under $H$ such that for any $x$ in $V_{x_{0}}$, if $\underline{x}$ is the image of $x$ in $V_{\underline{x}_{0}}$, then $\phi(x,$.$) is a$ biholomorphism between $\left(U, J_{\underline{x}}^{\mathrm{rel}}\right)$ and its image in $\mathbb{C}^{2}$ endowed with the standard complex structure; we can even ${ }^{-\quad}$ assume that $\phi\left(x_{0},.\right)=$ id.

If we put $\phi(x, p)=\left(z_{\underline{x}}(p), w_{\underline{x}}(p)\right)$, this means that $\left(z_{\underline{x}}, w_{\underline{x}}\right)$ are relative holomorphic coordinates on $\left(\bar{U}, J_{\underline{x}}^{\text {rel }}\right)$. Let us introduce new holomorphic coordinates on $U$ : if $D_{1} \phi$ is the partial differential of $\phi$ with respect to the variable $x$ in $V_{x_{0}}$, we define a function $\widetilde{\phi}: V_{x_{0}} \times U \longrightarrow \mathbb{C}^{2}$ as follows: for $1 \leq j \leq k$ and $p$ in

$$
\begin{aligned}
& B\left(y_{j}, \varepsilon\right), \widetilde{\phi}(x, p)=\phi(x, p)-D_{1} \phi\left(x_{0}, y_{j}\right)\left(x-x_{0}\right) . \text { If } \\
& \Psi: B\left(y_{1}, \varepsilon\right)^{n_{1}} \times \cdots \times B\left(y_{k}, \varepsilon\right)^{n_{k}} \longrightarrow\left(\mathbb{C}^{2}\right)^{n}
\end{aligned}
$$

is defined by

$$
\Psi\left(x_{1}, \ldots, x_{n}\right)=\left(\widetilde{\phi}\left(x_{1}, \ldots, x_{n}, x_{1}\right), \ldots, \widetilde{\phi}\left(x_{1}, \ldots, x_{n}, x_{n}\right)\right)
$$

then $\Psi$ is $H$ - equivariant and its differential at $x_{0}$ is the identity map, so that $\Psi$ induces a local homeomorphism $\psi$ of $\left(\mathbb{C}^{2}\right)^{(n)}$ with itself around $\underline{x}_{0}$. We can now construct a topological chart $\varphi: \Gamma^{-1}\left(V_{\underline{x}_{0}}\right) \longrightarrow \Gamma^{-1}\left(\psi\left(V_{\underline{x}_{0}}\right)\right)$ on $X_{J^{\text {rel }}}^{[n]}$ : for $\xi$ in $\Gamma^{-1}\left(V_{\underline{x}_{0}}\right)$, if $\underline{x}=\Gamma(\xi), \varphi(\xi)=\widetilde{\phi}(\underline{x}, .)_{*} \xi$. The inverse of $\varphi$ is given for any $\eta$ in $\psi\left(V_{x_{0}}\right)^{[n]}$ by the formula $\varphi^{-1}(\eta)=\left(\widetilde{\phi}(\underline{y}, .)^{-1}\right)_{*} \eta$, where $\underline{y}=\psi^{-1}(\Gamma(\eta))$.

Remark 1. Let $J_{0}^{\text {rel }}$ and $J_{1}^{\text {rel }}$ be two elements in $\mathcal{B}$ and fix $\underline{x}_{0}$ in $X^{(n)}$. We use the notations of the preceding proof. If $W_{\underline{x}_{0}}$ is a small neighbourhood of $\underline{x}_{0}$ in $\left(\mathbb{C}^{2}\right)^{(n)}$, we can assume that $W_{\underline{x}_{0}} \subseteq V_{0, \underline{x}_{0}}$, and that $\psi_{0}\left(W_{\underline{x}_{0}}\right) \subseteq \psi_{1}\left(V_{1, \underline{x}_{0}}\right)$. Besides, we can choose $\varepsilon_{0}$ and $\varepsilon_{1}$ in order that $\widetilde{\phi}_{0}\left(V_{0, \underline{x}} \times U_{0}\right) \subseteq \widetilde{\phi}_{1}\left(V_{1, \underline{x}_{0}} \times U_{1}\right)$. If we define two functions $\widehat{\psi}: V_{0, \underline{x}_{0}} \longrightarrow V_{1, \underline{x}_{0}}$ and $\widehat{\phi}: V_{0, \underline{x}_{0}} \times U_{0} \longrightarrow V_{1, \underline{x}_{0}} \times U_{1}$ by $\widehat{\psi}(\underline{x})=\psi_{1}^{-1} \psi_{0}(\underline{x})$ and $\widehat{\phi}(\underline{x}, p)=\widetilde{\phi}_{1}^{-1}\left(\psi(\underline{x}), \widetilde{\phi}_{0}(\underline{x}, p)\right)$, then we obtain a commutative diagram

and $\widehat{\psi}$ is a stratified isomorphism. This proves that $X_{J_{0}^{\text {rel }}}^{[n]}$ and $X_{J_{1}^{\text {rel }}}^{[n]}$ are locally homeomorphic over a neighbourhood of $\underline{x}_{0}$.

### 3.2. Göttsche's formula

We now turn our attention to the cohomology of $X_{J \text { rel }}^{[n]}$. The first step is the computation of the Betti numbers of $X^{[n]}$. We first recall the proof of Göttsche and Soergel [11] for projective surfaces, and then we show how to adapt it in the nonintegrable case.

Let $Y$ and $Z$ be irreducible algebraic complex varieties and $f: Y \longrightarrow Z$ be a proper morphism. We assume that $Z$ is stratified in such a way that $f$ is a topological fibration over each stratum $Z_{\nu}$. If $Y_{\nu}=f^{-1}\left(Z_{\nu}\right)$, let $d_{\nu}$ be the real dimension of the largest irreducible component of $Y_{\nu}$. Then $R^{d \nu} f_{*} \mathbb{Q}_{Y_{\nu}}$ is the associated monodromy local system on $Z_{\nu}$, we denote it by $\mathcal{L}_{\nu}$.

## Definition 3.

- The map $f$ is semi-small iffor all $\nu, \operatorname{codim}_{Z} Z_{\nu} \geq d_{\nu}$.
- If $f$ is semi-small, a stratum $Z_{\nu}$ is relevant if $\operatorname{codim}_{Z} Z_{\nu}=d_{\nu}$.

Theorem 2. (Decomposition theorem for semi-small maps [2]) If $Y$ is rationally smooth and $f: Y \longrightarrow Z$ is a proper semi-small morphism, there exists a canonical quasi-isomorphism

$$
R f_{*} \mathbb{Q}_{Y} \xrightarrow{\sim} \bigoplus_{\nu \text { relevant }} j_{\nu *} I C_{\bar{Z}_{\nu}}^{\bullet}\left(\mathcal{L}_{\nu}\right)\left[-d_{\nu}\right]
$$

in the bounded derived category of $\mathbb{Q}$-constructible sheaves on $Z$, where $I C_{\bar{Z}}{ }^{\bullet}\left(\mathcal{L}_{\nu}\right)$ is the intersection complex on $\bar{Z}_{\nu}$ associated to the monodromy local system $\mathcal{L}_{\nu}$ and $j_{\nu}: \bar{Z}_{\nu} \longrightarrow Z$ is the inclusion. In particular,

$$
H^{k}(Y, \mathbb{Q})=\bigoplus_{\nu \text { relevant }} I H^{k-d_{\nu}}\left(\bar{Z}_{\nu}, \mathcal{L}_{\nu}\right)
$$

Remark 2. A topological proof of Theorem 2 can be found in the unpublished lecture notes [14], we reproduce it in Appendix 6. This proof shows that there exists a canonical quasi-isomorphism

$$
R f_{*} \mathbb{Q}_{Y} \simeq \bigoplus_{\nu \text { relevant }} j_{\nu *} I C_{\bar{Z}_{\nu}}^{\bullet}\left(\mathcal{L}_{\nu}\right)\left[-d_{\nu}\right]
$$

under the following weaker topological hypotheses: $Y$ is a rationally smooth connected topological space (which means that the dualizing complex $\omega_{Y}$ of $Y$ with rational coefficients is a local system concentrated in a single degree), $Z$ is a stratified topological space and $f: Y \longrightarrow Z$ is a proper continuous map which is locally homeomorphic over $Z$ (in a stratified way) to a semi-small map between complex algebraic varieties. This is the key of the proof of Theorem 3 below.

If $X$ is a quasi-projective surface, the Hilbert-Chow morphism is semi-small with irreducible fibers [3], so that the monodromy local systems are trivial; and $X^{[n]}$ is smooth. Then Göttsche's formula for the generating series of the Betti numbers $b_{i}\left(X^{[n]}\right)$ follows directly from the decomposition theorem. We now extend this result for almost-complex Hilbert schemes.

Theorem 3 (Göttsche's formula). If $(X, J)$ is an almost-complex compact fourmanifold, then for any integrable complex structure $J^{\text {rel }}$,

$$
\sum_{n=0}^{\infty} \sum_{i=0}^{4 n} b_{i}\left(X_{J \text { rel }}^{[n]}\right) t^{i} q^{n}=\prod_{m=1}^{\infty} \frac{\left[\left(1+t^{2 m-1} q^{m}\right)\left(1+t^{2 m+1} q^{m}\right)\right]^{b_{1}(X)}}{\left(1-t^{2 m-2} q^{m}\right)\left(1-t^{2 m+2} q^{m}\right)\left(1-t^{2 m} q^{m}\right)^{b_{2}(X)}}
$$

Proof. The topological charts on $X_{J \text { rel }}^{[n]}$ constructed in Proposition 1 show that the Hilbert-Chow maps $\Gamma: X_{J \text { rel }}^{[n]} \longrightarrow X^{(n)}$ and $\Gamma:\left(\mathbb{C}^{2}\right)^{[n]} \longrightarrow\left(\mathbb{C}^{2}\right)^{(n)}$ are locally homeomorphic. The latter map being a semi-small morphism, the decomposition theorem applies by Remark 2; and the computations are the same as in the integrable case (see [17, § 6.2]).

### 3.3. Variation of the relative integrable structure

Theorem 3 implies in particular that the Betti numbers of $X_{J \text { rel }}^{[n]}$ are independent of $J^{\text {rel }}$. We now prove a stronger result, namely that the Hilbert schemes corresponding to different relative integrable complex structures are homeomorphic.

## Proposition 2.

(i) Let $\left(J_{t}^{\mathrm{rel}}\right)_{t \in B(0, r) \subseteq \mathbb{R}^{d}}$ be a smooth path in $\mathcal{B}$. Then the associated relative Hilbert scheme $\left(X^{[n]},\left\{J_{t}^{\mathrm{rel}}\right\}_{t \in B(0, r)}\right)$ over $B(0, r)$ is a topological fibration.
(ii) If $J_{0}^{\mathrm{rel}}, J_{1}^{\mathrm{rel}}$ are two elements of $\mathcal{B}$, then there exist canonical isomorphisms

$$
H^{*}\left(X_{J_{0}^{\text {rel }},}^{[n]}, \mathbb{Q}\right) \simeq H^{*}\left(X_{J_{1}^{\text {rel }}}^{[n]}, \mathbb{Q}\right) \quad \text { and } \quad K\left(X_{J_{0}}^{[n]}\right) \simeq K\left(X_{J_{1}^{\text {rel }}}^{[n]}\right) .
$$

In order to prove Proposition 2, we start with a technical result:
Proposition 3. Let $\left(J_{t}^{\mathrm{rel}}\right)_{t \in B(0, r) \subseteq \mathbb{R}^{d}}$ be a smooth family of relative integrable complex structures in a neighbourhood of $Z_{n}$ varying smoothly with $t$. Then there exist a positive real number $\varepsilon$, a neighbourhood $W$ of $Z_{n}$ in $X^{(n)} \times X$ and a smooth map $\psi:(t, \underline{x}, p) \longmapsto \psi_{t, \underline{x}}(p)$ from $B(0, \varepsilon) \times W$ to $X$ such that:
(i) $\psi_{0, x}(p)=p$,
(ii) For any couple $(t, \underline{x})$ in $B(0, \varepsilon) \times X^{(n)}, \psi_{t, x}$ is a biholomorphism between $W_{\underline{x}}$ and its image, these two open subsets of $X$ being endowed with the integrable complex structures $J_{0, \underline{x}}^{\mathrm{rel}}$ and $J_{t, \psi_{t, \underline{x}(\underline{x}}^{(n)}}^{\mathrm{rel}}$ respectively.
(iii) For all $t$ in $B(0, \varepsilon)$, the map $\underline{x} \longmapsto \psi_{t, x}^{(n)}(\underline{x})$ is a homeomorphism of $X^{(n)}$ with itself.

Proof. We can find two neighbourhoods $W^{\prime}$ and $W$ of $Z_{n}$ in $X^{(n)} \times X$ as well as a smooth map $\theta_{t}:(t, \underline{x}, p) \longrightarrow \theta_{t, x}(p)$ from $B(0, r) \times W^{\prime}$ to $X$ such that for any $(t, x)$ in $B(0, r) \times W^{\prime}$, the conditions below are satisfied:
$-W_{\underline{x}} \subseteq \theta_{t, \underline{x}}\left(W_{\underline{x}}^{\prime}\right) \cap W_{\underline{x}}^{\prime}$,
$-\theta_{t, \underline{x}}:\left(W_{\underline{x}}^{\prime}, J_{\left.t, \theta_{t, \underline{x}(\underline{x}}\right)}^{\mathrm{rel}}\right) \longrightarrow\left(\phi_{t, \underline{x}}\left(W_{\underline{x}}^{\prime}\right), J_{0, \psi_{t, \underline{x}}(\underline{x})}^{\mathrm{rel}}\right)$ is a biholomorphism.

- if $t=0, \theta_{0, \underline{x}}=\mathrm{id}$.

Let us take a covering $\left(U_{i}\right)_{1 \leq i \leq N}$ of $X^{(n)}$ and relative holomorphic coordinates on $W^{\prime}$ above each $U_{i}$ given by maps $\phi_{i}: W^{\prime} \cap p r_{1}^{-1}\left(U_{i}\right) \longrightarrow \mathbb{C}^{2}$ such that for each $i$, the map $\underline{x} \longmapsto \phi_{i, x}^{(n)}(\underline{x})$ is a homeomorphism between $U_{i}$ and its image $V_{i}$ in $\left(\mathbb{C}^{2}\right)^{(n)}$ (see the proof of Proposition 1). Then we define relative holomorphic coordinates $\left(\phi_{i, t, \underline{x}}\right)_{1 \leq i \leq N}$ for the relative integrable complex structure $J_{t}^{\mathrm{rel}}$ on $W \cap p r_{1}^{-1}\left(U_{i}\right)$ by the formula $\phi_{i, t, \underline{x}}(p)=\phi_{i, \underline{x}}\left(\theta_{t, \underline{x}}(p)\right)$. For small $t$, after shrinking $U_{i}$ if necessary, the map $\left.\underline{x} \longmapsto \phi_{i, t, \underline{x}}^{(n)} \underline{x}\right)$ is still a homeomorphism of $U_{i}$ with its image: indeed the map $\underline{x} \longmapsto \phi_{i, t, \underline{x}}^{(n)}(\underline{x})$ is obtained from the $\mathfrak{S}_{n_{1}} \times \cdots \times$ $\mathfrak{S}_{n_{k}}$-equivariant smooth map

$$
\left(x_{1}, \ldots, x_{n}\right) \longrightarrow\left(\phi_{t}\left(x_{1}, \ldots, x_{n}, x_{1}\right), \ldots, \phi_{t}\left(x_{1}, \ldots, x_{n}, x_{n}\right)\right)
$$

and we use the fact that a sufficiently small smooth perturbation of a smooth diffeomorphism remains a smooth diffeomorphism. If $\widetilde{Z}_{n} \subseteq\left(\mathbb{C}^{2}\right)^{(n)} \times \mathbb{C}^{2}$ is the incidence set of $\mathbb{C}^{2}$, the map $\check{\phi}_{i, t}:(\underline{x}, p) \longmapsto\left(\phi_{i, t, \underline{x}}^{(n)}(\underline{x}), \phi_{i, t, \underline{x}}(p)\right)$ is a homeomorphism between $W \cap p r_{1}^{-1}\left(U_{i}\right)$ and its image, which is a neighbourhood of $\widetilde{Z}_{n}$ over $V_{i}$.

Let us introduce the following notation: for any map $\varphi$ defined on an open set $\Omega$ of $X^{(n)} \times X$ with values in $X$ or in $\mathbb{C}^{2}$, we denote by $\check{\varphi}$ the map from $\Omega$ to $X^{(n)} \times X$ given by $(\underline{x}, p) \longmapsto\left(\varphi_{t, \underline{x}}^{(n)}(\underline{x}), \varphi_{t, \underline{x}}(p)\right)$. Then the condition (ii) of the proposition means that $\check{\phi}_{i, t} \circ \check{\psi}_{t} \circ\left(\check{\phi}_{i, 0}\right)^{-1}=\check{u}_{t}$, where $\left(\check{u}_{t}\right)_{t \in B(0, \varepsilon)}$ is a smooth family of smooth maps from $\check{\phi}_{i, 0}\left(U_{i}\right)$ to $\mathbb{C}^{2}$ such that for every $\underline{y}$ in $V_{i}, u_{t, \underline{y}}$ is a biholomorphism between $\check{\phi}_{i, 0}\left(U_{i}\right)_{\underline{y}}$ and its image, both being endowed with the standard complex structure of $\mathbb{C}^{2}$. The condition (i) means that $u_{0, \underline{y}}=\mathrm{id}$. Thus $\left(\psi_{t}\right)_{\| t| | \leq \varepsilon}$ can be constructed on each open set $U_{i}$ (it suffices to choose $u_{t, \underline{y}}=\mathrm{id}$ ).

Since biholomorphisms close to the identity form a contractible set, we can, using cut-off functions, glue together the local solutions on $X^{(n)}$ to obtain a global one. The map $\underline{x} \longrightarrow \psi_{t, \underline{x}}^{(n)}(\underline{x})$ is induced by a smooth $\mathfrak{S}_{n}$-equivariant map of $X^{n}$ into $X^{n}$ (and is a small perturbation of the identity map if $\|t\|$ is small enough), thus a $\mathfrak{S}_{n}$-equivariant diffeomorphism of $X^{n}$. We have therefore defined a family of maps $\left(\psi_{t}\right)_{\| t| | \leq \varepsilon}$ satisfying the conditions (i), (ii) and (iii).
We can now prove Proposition 2.
Proof of Proposition 2. (i) We have

$$
\begin{aligned}
&\left(X^{[n]},\left\{J_{t}^{\mathrm{rel}}\right\}_{t \in B(0, r)}\right)=\left\{(\xi, \underline{x}, t) \text { such that } \underset{\underline{x}}{ } \in X^{(n)}, t \in B(0, r)\right. \\
&\left.\xi \in\left(W_{\underline{x}}^{[n]}, J_{t, \underline{x}}^{\mathrm{rel}}\right) \text { and } \Gamma(\xi)=\underline{x}\right\}
\end{aligned}
$$

A topological trivialization of this family over $B(0, r)$ near zero is given by the map

$$
\Phi: X_{J_{0}^{\text {rel }}}^{[n]} \times B(0, \varepsilon) \longrightarrow\left(X^{[n]},\left\{J_{t}^{\text {rel }}\right\}_{t \in B(0, \varepsilon)}\right)
$$

defined by $\Phi(\xi, \underline{x}, t)=\left(\psi_{t, \underline{x} *} \xi, \psi_{t, \underline{x}}(\underline{x}), t\right)$, where $\psi$ is given by Proposition 3. This proves that the relative Hilbert scheme is locally topologically trivial over $B(0, r)$.
(ii) The set $\mathcal{B}$ being connected, point (i) shows that $X_{J_{0}^{\text {rel }}}^{[n]}$ and $X_{J_{1}^{\text {rel }}}^{[n]}$ are homeomorphic. Let us consider two smooth paths $\left(J_{0, t}^{\mathrm{rel}}\right)_{0 \leq t \leq 1}$ and $\left(J_{1, t}^{\mathrm{rel}}\right)_{0 \leq t \leq 1}$ between $J_{0}^{\mathrm{rel}}$ and $J_{1}^{\mathrm{rel}}$. Since $\pi_{1}(\mathcal{B})=0$, we can find a smooth family $\left(J_{s, t}^{\mathrm{rel}}\right)_{\substack{0 \leq s \leq 1 \\ 0 \leq t \leq 1}}^{\substack{\text { n }}}$ which is an homotopy between the two paths. The associated relative Hilbert scheme over $[0,1] \times[0,1]$ is locally topologically trivial, hence globally trivial since $[0,1] \times[0,1]$ is contractible. This shows that the homeomorphisms between $X_{J_{0}^{\text {rel }}}^{[n]}$ and $X_{J_{1} \mathrm{rel}}^{[n]}$ constructed by choosing a path between $J_{0}^{\text {rel }}$ and $J_{1}^{\text {rel }}$ and taking a topological trivialization of the relative Hilbert scheme associated with this path belong to a canonical homotopy class.

As a consequence of this proposition, there exists a ring $H^{*}\left(X^{[n]}, \mathbb{Q}\right)$ (resp. $K\left(X^{[n]}\right)$ ) such that for any $J^{\text {rel }}$ close to $J, H^{*}\left(X^{[n]}, \mathbb{Q}\right)\left(\right.$ resp. $\left.K\left(X^{[n]}\right)\right)$ and $H^{*}\left(X_{J \mathrm{rel}}^{[n]}, \mathbb{Q}\right)\left(\right.$ resp. $\left.K\left(X_{J \mathrm{rel}}^{[n]}\right)\right)$ are canonically isomorphic.

In the sequel, we will deal with products of Hilbert schemes. We could of course consider products of the type $X_{J_{n}^{\text {rel }}}^{[n]} \times X_{J_{m}^{\text {rel }}}^{[m]}$, but it is necessary in practice to work with pairs of relative integrable complex structures parameterized by elements in the product $X^{(n)} \times X^{(m)}$. Let $W$ be a small neighbourhood of $Z_{n \times m}$ (see $\S 2.1$ ) in $X^{(n)} \times X^{(m)} \times X$ and let $J^{1, \text { rel }}$ and $J^{2, \text { rel }}$ be two relative integrable complex structures on the fibers of $\mathrm{pr}_{1}: W \longrightarrow X^{(n)} \times X^{(m)}$.
Definition 4. The product Hilbert scheme ( $\left.X^{[n] \times[m]}, J^{1, \text { rel }}, J^{2, \text { rel }}\right)$ is defined by

$$
\begin{aligned}
& \left(X^{[n] \times[m]}, J^{1, \text { rel }}, J^{2, \text { rel }}\right)=\left\{(\xi, \eta, \underline{x}, \underline{y}) \text { such that } \underline{x} \in X^{(n)}, \underline{y} \in X^{(m)},\right. \\
& \left.\quad \xi \in\left(W_{\underline{x}, \underline{y}}^{[n]}, J_{\underline{x}, \underline{y}}^{1, \text { rel }}\right), \eta \in\left(W_{\underline{x}, \underline{y}}^{[m]}, J_{\underline{x}, \underline{y}}^{2, \text { rel }}\right), \Gamma(\xi)=\underline{x} \text { and } \Gamma(\eta)=\underline{y}\right\} .
\end{aligned}
$$

The same definition holds for products of the type

$$
\left(X^{\left[n_{1}\right] \times \cdots \times\left[n_{k}\right]}, J^{1, \text { rel }}, \ldots, J^{k, \text { rel }}\right)
$$

If there exist two relative integrable complex structures $J_{n}^{\text {rel }}$ and $J_{m}^{\text {rel }}$ in neighbourhoods of $Z_{n}$ and $Z_{m}$ such that for all $\underline{x}$ in $X^{(n)}$ and all $\underline{y}$ in $X^{(m)}, J_{\underline{x}, \underline{y}}^{1, \text { rel }}=J_{n, \underline{x}}^{\mathrm{rel}}$ and $J_{\underline{x}, \underline{y}}^{2, \text { rel }}=J_{m, \underline{y}}^{\text {rel }}$ in small neighbourhoods of $\operatorname{supp}(\underline{x})$ and $\operatorname{supp}(\underline{y})$ respectively, then

$$
\left(X^{[n] \times[m]}, J^{1, \text { rel }}, J^{2, \text { rel }}\right)=X_{J_{n}^{\text {rel }}}^{[n]} \times X_{J_{m}^{\text {rel }}}^{[m]} .
$$

If $\left(J_{t}^{1, \text { rel }}, J_{t}^{2, \text { rel }}\right)_{t \in B(0, r)}$ is a smooth family of relative integrable complex structures, it can be shown as in Propositions 2 and 3 that the relative product Hilbert scheme $\left(X^{[n] \times[m]},\left\{J_{t}^{1, \text { rel }}\right\}_{t \in B(0, r)},\left\{J_{t}^{2 \text {,rel }}\right\}_{t \in B(0, r)}\right)$ is topologically trivial over
$B(0, r)$. Thus the product Hilbert schemes $\left(X^{[n] \times[m]}, J^{1, \text { rel }}, J^{2, \text { rel }}\right)$ are homeomorphic to products $X_{J_{n}^{\text {rel }}}^{[n]} \times X_{J_{m}^{\text {rel }}}^{[m]}$ of usual Hilbert schemes. If the structures $J^{1, \text { rel }}$ and $J^{2, \text { rel }}$ are equal, then $\left(X^{[n] \times[m]}, J^{1, \text { rel }}, J^{2, \text { rel }}\right)$ consists of pairs of schemes of given support (parameterized by $X^{(n)} \times X^{(m)}$ ) for the same integrable structure. These product Hilbert schemes are therefore well adapted for the study of incidence relations.

## 4. Incidence varieties and Nakajima operators

### 4.1. Construction of incidence varieties

If $J$ is an integrable complex structure on $X$, the incidence variety $X^{\left[n^{\prime}, n\right]}$ defined in $\S 2.2$ is smooth for $n^{\prime}=n+1$ [18]. We have three maps

$$
\lambda: X^{\left[n^{\prime}, n\right]} \longrightarrow X^{[n]}, \quad \nu: X^{\left[n^{\prime}, n\right]} \longrightarrow X^{\left[n^{\prime}\right]} \quad \text { and } \quad \rho: X^{[n, n]} \longrightarrow X^{\left(n^{\prime}-n\right)}
$$

given by $\lambda\left(\xi, \xi^{\prime}\right)=\xi, \nu\left(\xi, \xi^{\prime}\right)=\xi^{\prime}$ and $\rho\left(\xi, \xi^{\prime}\right)=\operatorname{supp}\left(\mathcal{I}_{\xi} / \mathcal{I}_{\xi^{\prime}}\right)$. Note that $(\lambda, \nu)$ is injective by definition.

If $J$ is not integrable, we can define $X^{\left[n^{\prime}, n\right]}$ using the relative construction as explained below. For doing this, we choose a relative integrable complex structure $J_{n \times\left(n^{\prime}-n\right)}^{\text {rel }}$ in a neighbourhood $W$ of $Z_{n \times\left(n^{\prime}-n\right)}$ in $X^{(n)} \times X^{\left(n^{\prime}-n\right)} \times X$ (see § 2.1 ).

Definition 5. The incidence variety $\left(X^{\left[n^{\prime}, n\right]}, J_{n \times\left(n^{\prime}-n\right)}^{\mathrm{rel}}\right)$ is defined by

$$
\begin{aligned}
& \left(X^{\left[n^{\prime}, n\right]}, J_{n \times\left(n^{\prime}-n\right)}^{\mathrm{rel}}\right)=\left\{\left(\xi, \xi^{\prime}, \underline{x}, \underline{y}\right) \text { such that } \underline{x} \in X^{(n)}, \underline{y} \in X^{\left(n^{\prime}-n\right)},\right. \\
& \xi \in\left(W_{\underline{x}, \underline{y}}^{[n]}, J_{n \times\left(n^{\prime}-n\right), \underline{x}, \underline{y}}^{\mathrm{rel}}\right), \xi^{\prime} \in\left(W_{\underline{x}, \underline{y}}^{\left[n^{\prime}\right]}, J_{n \times\left(n^{\prime}-n\right), \underline{x}, \underline{y}}^{\mathrm{rel}}\right) \\
& \\
& \left.\quad \xi \text { is a subscheme of } \xi^{\prime}, \Gamma(\xi)=\underline{x} \text { and } \rho\left(\xi, \xi^{\prime}\right)=\underline{y}\right\}
\end{aligned}
$$

Let $J_{n \times n^{\prime}}^{\mathrm{rel}}$ be a relative integrable complex structure in a neighbourhood of $Z_{n \times n^{\prime}}$ such that for every $(\underline{u}, \underline{v})$ in $X^{(n)} \times X^{\left(n^{\prime}-n\right)}, J_{n \times n^{\prime}, \underline{u}, \underline{u} \cup \underline{v}}^{\mathrm{rel}}=J_{n \times\left(n^{\prime}-n\right), \underline{u}, \underline{v}}^{\mathrm{rel}}$ in a neighbourhood of $\operatorname{supp}(\underline{u} \cup \underline{v})$. Then

$$
\left(X^{\left[n^{\prime}, n\right]}, J_{n \times\left(n^{\prime}-n\right)}^{\mathrm{rel}}\right) \subseteq\left(X^{[n] \times\left[n^{\prime}\right]}, J_{n \times n^{\prime}}^{\mathrm{rel}}, J_{n \times n^{\prime}}^{\mathrm{rel}}\right)
$$

If $\left\{J_{t, n \times n^{\prime}}^{\mathrm{rel}}\right\}_{t \in B(0, r)}$ is a smooth family of relative complex structures, we can take, as in Proposition 2, a topological trivialization of the family

$$
\left(X^{[n] \times\left[n^{\prime}\right]},\left\{J_{t, n \times n^{\prime}}^{\mathrm{rel}}\right\}_{t \in B(0, r)},\left\{J_{t, n \times n^{\prime}}^{\mathrm{rel}}\right\}_{t \in B(0, r)}\right) .
$$

If we define $J_{t, n \times\left(n^{\prime}-n\right)}^{\mathrm{rel}}$ in a neighbourhood of $Z_{n \times\left(n^{\prime}-n\right)}$ by the formula

$$
J_{t, n \times\left(n^{\prime}-n\right), \underline{u}, \underline{v}}^{\mathrm{rel}}=J_{t, n \times n^{\prime}, \underline{u}, \underline{u} \cup \underline{v}}^{\mathrm{rel}} \quad\left(\underline{u} \in X^{(n)}, \underline{v} \in X^{\left(n^{\prime}-n\right)}\right),
$$

then the subfamily $\left(X^{\left[n^{\prime}, n\right]},\left\{J_{t, n \times\left(n^{\prime}-n\right)}^{\mathrm{rel}}\right\}_{t \in B(0, r)}\right)$ is sent by the trivialization to a product $U^{\left[n^{\prime}, n\right]} \times B(0, \varepsilon)$, where $U$ is an open set of $\mathbb{C}^{2}$. This means that the pair

$$
\left\{\left(X^{\left[n^{\prime}, n\right]},\left\{J_{n \times\left(n^{\prime}-n\right)}^{\mathrm{rel}}\right\}_{t \in B(0, r)}\right),\left(X^{[n] \times\left[n^{\prime}\right]},\left\{J_{n \times n^{\prime}}^{\mathrm{rel}}\right\}_{t \in B(0, r)},\left\{J_{n \times n^{\prime}}^{\mathrm{rel}}\right\}_{t \in B(0, r)}\right)\right\}
$$

is locally, hence globally topologically trivial over $B(0, r)$.
The natural morphism from $\left(X^{\left[n^{\prime}, n\right]}, J_{n \times\left(n^{\prime}-n\right)}\right)$ to $X^{(n)} \times X^{\left(n^{\prime}-n\right)}$ is locally homeomorphic over $X^{(n)} \times X^{\left(n^{\prime}-n\right)}$ to the morphism

$$
(H C \circ \lambda, \rho):\left(\mathbb{C}^{2}\right)^{\left[n^{\prime}, n\right]} \longrightarrow\left(\mathbb{C}^{2}\right)^{(n)} \times\left(\mathbb{C}^{2}\right)^{\left(n^{\prime}-n\right)}
$$

This enables us to define a stratification on $X^{\left[n^{\prime}, n\right]}$ by patching together the analytic stratifications of a collection of $U_{i}^{\left[n^{\prime}, n\right]}$, where the $U_{i}$ 's are open subsets of $\mathbb{C}^{2}$. In this way, $\left(X^{\left[n^{\prime} n\right]}, J_{n \times\left(n^{\prime}-n\right)}^{\text {rel }}\right)$ becomes a stratified $C W$-complex such that for each stratum $S, \operatorname{dim}(\bar{S} \backslash S) \leq \operatorname{dim} S-2$. In particular, each stratum has a fundamental homology class.
Let us introduce the following notations:
(i) The inverse image of the small diagonal of $X^{(n)}$ by $\Gamma: X_{J_{n}^{\text {rel }}}^{[n]} \longrightarrow X^{(n)}$ is denoted by $\left(X_{0}^{[n]}, J_{n}^{\mathrm{rel}}\right)$.
(ii) The inverse image of the small diagonal of $X^{\left(n^{\prime}-n\right)}$ by the residual map

$$
\rho:\left(X^{\left[n^{\prime}, n\right]}, J_{n \times\left(n^{\prime}-n\right)}^{\mathrm{rel}}\right) \longrightarrow X^{\left(n^{\prime}-n\right)}
$$

is denoted by $\left(X_{0}^{\left[n^{\prime}, n\right]}, J_{n \times\left(n^{\prime}-n\right)}^{\mathrm{rel}}\right)$.
In the integrable case, $X_{0}^{\left[n^{\prime}, n\right]}$ is stratified by analytic sets $\left(Z_{l}\right)_{l \geq 0}$ defined by

$$
\begin{equation*}
Z_{l}=\left\{\left(\xi, \xi^{\prime}\right) \in X_{0}^{[n, n]} \text { such that if } x=\rho\left(\xi, \xi^{\prime}\right), \ell_{x}(\xi)=l\right\} \tag{1}
\end{equation*}
$$

$Z_{0}$ is irreducible of complex dimension $n^{\prime}+n+1$, and all the other $Z_{l}$ have smaller dimensions (see [15]). By the same argument we have used to stratify almostcomplex Hilbert schemes, this stratification also exists in the almost complex case. We prove the topological irreducibility of $Z_{0}$ in the following lemma:

Lemma 1. Let $\left[\bar{Z}_{0}\right]$ be the fundamental homology class of $\bar{Z}_{0}$. Then

$$
H_{2\left(n^{\prime}+n+1\right)}\left(X_{0}^{\left[n^{\prime}, n\right]}, J_{n \times\left(n^{\prime}-n\right)}^{\mathrm{rel}}, \mathbb{Z}\right)=\mathbb{Z} \cdot\left[\bar{Z}_{0}\right]
$$

Proof. It is enough to prove that $H_{2\left(n^{\prime}+n+1\right)}^{\mathrm{lf}}\left(Z_{0}, \mathbb{Z}\right) \simeq \mathbb{Z}$ (where $H^{\text {lf }}$ denotes Borel-Moore homology), since all the remaining strata $\left(Z_{l}\right)_{l \geq 1}$ have dimensions smaller than $2\left(n^{\prime}+n+1\right)-2$. Let

$$
\begin{aligned}
& \widetilde{Z}_{0}=\left\{(\xi, \eta, \underline{x}, p) \text { such that } \underline{x} \in X^{(n)}, p \in X,\right. \\
& \quad \xi \in\left(W_{\underline{x},\left(n^{\prime}-n\right) p}^{[n]}, J_{n \times\left(n^{\prime}-n\right), \underline{x},\left(n^{\prime}-n\right) p}^{\mathrm{rel}}\right), \Gamma(\xi)=\underline{x}, \\
& \\
& \left.\quad \eta \in\left(W_{\underline{x},\left(n^{\prime}-n\right) p}^{\left[n^{\prime}-n\right]}, J_{n \times\left(n^{\prime}-n\right), \underline{x},\left(n^{\prime}-n\right) p}^{\mathrm{rel}}\right) \text { and } \Gamma(\eta)=\left(n^{\prime}-n\right) p\right\} .
\end{aligned}
$$

There is a natural inclusion $Z_{0} \hookrightarrow \widetilde{Z}_{0}$ given by

$$
\left(\xi, \xi^{\prime}, \underline{x},\left(n^{\prime}-n\right) p\right) \longmapsto\left(\xi, \xi_{\mid p}^{\prime}, \underline{x}, p\right) .
$$

Remark that $\widetilde{Z}_{0}$ is compact. Since $\operatorname{dim}\left(\widetilde{Z}_{0} \backslash Z_{0}\right) \leq 4 n+2\left(n^{\prime}-n-1\right)$, it suffices to show that $H_{2\left(n^{\prime}+n+1\right)}\left(\widetilde{Z}_{0}, \mathbb{Z}\right)=\mathbb{Z}$. Besides, $\widetilde{Z}_{0}$ is a product-type Hilbert scheme homeomorphic to $X_{J_{n}^{\text {rel }}}^{[n]} \times\left(X_{0}^{\left[n^{\prime}-n\right]}, J_{n^{\prime}-n}^{\text {rel }}\right)$ for any relative integrable complex structures $J_{n}^{\mathrm{rel}}$ and $J_{n^{\prime}-n}^{\mathrm{rel}}$. Since $\left(X_{0}^{\left[n^{\prime}-n\right]}, J_{n^{\prime}-n}^{\mathrm{rel}}\right)$ is, by Briançon's theorem [3], a topological fibration over $X$ whose fiber is homeomorphic to an irreducible algebraic variety of complex dimension $n^{\prime}-n-1$, we obtain the result.

### 4.2. Nakajima operators

We are now going to construct Nakajima operators $\mathfrak{q}_{n}(\alpha)$ for almost-complex fourmanifolds. If $n^{\prime}>n$ and if $J_{n \times n^{\prime}}^{\text {rel }}$ is a relative integrable complex structure in a neighbourhood of $Z_{n \times n^{\prime}}$, let us define

$$
\begin{equation*}
Q^{\left[n^{\prime}, n\right]}=\bar{Z}_{0} \subseteq\left(X^{[n] \times\left[n^{\prime}\right]}, J_{n \times n^{\prime}}^{\mathrm{rel}}, J_{n \times n^{\prime}}^{\mathrm{rel}}\right) \times X \tag{2}
\end{equation*}
$$

where the map on the last coordinate is given by the relative residual morphism and $Z_{0}$ is defined by (1). Since the pair $\left(Q^{\left[n^{\prime}, n\right]}, X^{[n] \times\left[n^{\prime}\right]} \times X\right)$ is topologically trivial when $J_{n \times n^{\prime}}^{\text {rel }}$ varies, the cycle class $\left[Q^{[n, n]}\right]$ in $H_{2\left(n^{\prime}+n+1\right)}\left(X^{[n]} \times X^{\left[n^{\prime}\right]} \times X, \mathbb{Z}\right)$ is independent of $J_{n \times n^{\prime}}^{\mathrm{rel}}$.

Definition 6. Let $\alpha$ be a rational cohomology class on $X$ and $j$ be a positive integer. We define the Nakajima operators $\mathfrak{q}_{j}(\alpha)$ and $\mathfrak{q}_{-j}(\alpha)$ as follows:

$$
\begin{aligned}
\mathfrak{q}_{j}(\alpha): \bigoplus_{n \in \mathbb{N}} H^{*}\left(X^{[n]}, \mathbb{Q}\right) & \longrightarrow \bigoplus_{n \in \mathbb{N}} H^{*}\left(X^{[n+j]}, \mathbb{Q}\right) \\
\tau & \longmapsto P D^{-1}\left[\operatorname{pr}_{2 *}\left(\left[Q^{[n+j, n]}\right] \cap\left(\operatorname{pr}_{3}^{*} \alpha \cup \operatorname{pr}_{1}^{*} \tau\right)\right)\right] \\
\mathfrak{q}_{-j}(\alpha): \bigoplus_{n \in \mathbb{N}} H^{*}\left(X^{[n+j]}, \mathbb{Q}\right) & \longrightarrow \bigoplus_{n \in \mathbb{N}} H^{*}\left(X^{[n]}, \mathbb{Q}\right) \\
\tau & \longmapsto P D^{-1}\left[\operatorname{pr}_{1 *}\left(\left[Q^{[n+j, n]}\right] \cap\left(\operatorname{pr}_{3}^{*} \alpha \cup \operatorname{pr}_{2}^{*} \tau\right)\right)\right]
\end{aligned}
$$

where $\mathrm{pr}_{1}, \mathrm{pr}_{2}$ and $\mathrm{pr}_{3}$ are the projections from $X^{[n]} \times X^{[n+j]} \times X$ to each factor and $P D$ is the Poincaré duality isomorphism between cohomology and homology. We also set $\mathfrak{q}_{0}(\alpha)=0$

Remark 3. If $\alpha$ is a homogeneous rational cohomology class on $X$, let $|\alpha|$ denotes its degree. Then $q_{j}(\alpha)$ maps $H^{i}\left(X^{[n]}, \mathbb{Q}\right)$ to $H^{i+|\alpha|+2 j-2}\left(X^{[n+j]}, \mathbb{Q}\right)$.

We now prove the following extension to the almost-complex case of Nakajima's relations [16]:

Theorem 4. For all integers $i, j$ and all homogeneous rational cohomology classes $\alpha$ and $\beta$ on $X$, we have:

$$
\mathfrak{q}_{i}(\alpha) \mathfrak{q}_{j}(\beta)-(-1)^{|\alpha||\beta|} \mathfrak{q}_{j}(\beta) \mathfrak{q}_{i}(\alpha)=i \delta_{i+j, 0}\left(\int_{X} \alpha \beta\right) \mathrm{id} .
$$

Proof. We adapt Nakajima's proof to our situation. Let us detail the most interesting case, which is the computation of $\left[\mathfrak{q}_{-i}(\alpha), \mathfrak{q}_{j}(\beta)\right]$ when $i$ and $j$ are positive. We introduce the classes $P_{i j}$ (resp. $Q_{i j}$ ) in
$H_{*}\left(X^{[n]}, \mathbb{Q}\right) \otimes H_{*}\left(X^{[n-i]}, \mathbb{Q}\right) \otimes H_{*}\left(X^{[n-i+j]}, \mathbb{Q}\right) \otimes H_{*}(X, \mathbb{Q}) \otimes H_{*}(X, \mathbb{Q})$,
(resp.
$\left.H_{*}\left(X^{[n]}, \mathbb{Q}\right) \otimes H_{*}\left(X^{[n+j]}, \mathbb{Q}\right) \otimes H_{*}\left(X^{[n-i+j]}, \mathbb{Q}\right) \otimes H_{*}(X, \mathbb{Q}) \otimes H_{*}(X, \mathbb{Q})\right)$,
as follows:

$$
\begin{aligned}
P_{i j} & :=p_{13 *}\left(p_{124}^{*}\left[Q^{[n, n-i]}\right] \cdot p_{235}^{*}\left[Q^{[n-i+j, n-i]}\right]\right), \\
\left(\text { resp. } \quad Q_{i j}\right. & \left.\left.:=p_{13 *}\left(p_{124}^{*}\left[Q^{[n+j, n]}\right] \cdot p_{235}^{*}\left[Q^{[n+j, n-i+j]}\right]\right]\right)\right),
\end{aligned}
$$

where $Q^{[r, s]}$ is defined in (2). Then $\mathfrak{q}_{j}(\beta) \mathfrak{q}_{-i}(\alpha)$, (resp. $\mathfrak{q}_{-i}(\alpha) \mathfrak{q}_{j}(\beta)$ ), is given by

$$
\begin{aligned}
& \tau \longmapsto P D^{-1}\left[\operatorname{pr}_{3 *}\left(P_{i j} \cap\left(\operatorname{pr}_{5}^{*} \beta \cup \operatorname{pr}_{4}^{*} \alpha \cup \operatorname{pr}_{1}^{*} \tau\right)\right)\right], \quad \text { (resp. } \\
& \left.\tau \longmapsto P D^{-1}\left[\operatorname{pr}_{3 *}\left(Q_{i j} \cap\left(\operatorname{pr}_{5}^{*} \alpha \cup \operatorname{pr}_{4}^{*} \beta \cup \operatorname{pr}_{1}^{*} \tau\right)\right)\right]\right) .
\end{aligned}
$$

First we deform all the relative integrable complex structures into a single one parameterized by $X^{(n)} \times X^{(n-i)} \times X^{(n-i+j)} \times X^{(2)}$.

Let $J_{n \times(n-i) \times(n-i+j) \times 2}^{\text {rel }}$ be a relative integrable complex structure in a neighbourhood of $Z_{n \times(n-i) \times(n-i+j) \times 2}$, and let us define $J_{n \times(n-i) \times(n-i+j) \times 1 \times 1}^{\text {rel }}$ by the formula $J_{n \times(n-i) \times(n-i+j) \times 1 \times 1, \underline{x}, \underline{y}, \underline{z}, s, t}^{\mathrm{rel}} n \times(n-i) \times(n-i+j) \times 2, J_{n \times(n-i) \times(n-i+j) \times 2, \underline{x}, \underline{y}, \underline{z}, s \cup t}^{\mathrm{rel}} J_{n \times(n-i) \times(n-i+j) \times 1 \times 1}$.

If $Y=\left(X^{[n] \times[n-i] \times[n-i+j] \times[1] \times[1]}, J_{n \times(n-i) \times(n-i+j) \times 1 \times 1}^{\mathrm{rel}} \leftarrow 5\right.$ times $)$ is the product Hilbert scheme obtained by taking the same relative integrable complex structure $J_{n \times(n-i) \times(n-i+j) \times 1 \times 1}^{\mathrm{rel}}$ five times (see Definition 4), there is a canonical isomorphism between $H_{*}(Y, \mathbb{Q})$ and
$H_{*}\left(X^{[n]}, \mathbb{Q}\right) \otimes H_{*}\left(X^{[n-i]}, \mathbb{Q}\right) \otimes H_{*}\left(X^{[n-i+j]}, \mathbb{Q}\right) \otimes H_{*}(X, \mathbb{Q}) \otimes H_{*}(X, \mathbb{Q})$.
Since incidence varieties vary trivially in families, the class $p_{124}^{*}\left[Q^{[n, n-i]}\right]$ is the homology class of the cycle

$$
A=\left\{\left(\xi, \xi^{\prime}, \xi^{\prime \prime}, s, t\right) \text { in } Y \text { such that } \xi^{\prime} \subseteq \xi \text { and } \rho\left(\xi^{\prime}, \xi\right)=s\right\}
$$

In the same way, $p_{235}^{*}\left[Q^{[n-i+j, n-i]}\right]$ is the homology class of the cycle

$$
B=\left\{\left(\xi, \xi^{\prime}, \xi^{\prime \prime}, s, t\right) \text { in } Y \text { such that } \xi^{\prime} \subseteq \xi^{\prime \prime} \text { and } \rho\left(\xi^{\prime}, \xi^{\prime \prime}\right)=t\right\}
$$

Let us study the intersection of the cycles $A$ and $B$ : choose relative holomorphic coordinates $\phi_{\underline{x}, \underline{y}, \underline{z}, s, t}$ for $J_{n \times(n-i) \times(n-i+j) \times 2}^{\mathrm{rel}}$ such that the map

$$
\begin{aligned}
&(\underline{x}, \underline{y}, \underline{z}, s, t) \longmapsto\left(\phi_{\underline{x}, \underline{y}, \underline{z}, s, t}^{(n)}(\underline{x}), \phi_{\underline{x}, \underline{y}, \underline{z}, s, t}^{(n-i)}(\underline{y}),\right. \\
& \phi_{\underline{x}, \underline{y}, \underline{z}, s, t}^{(n-i+j)}(\underline{z}) \\
&\left.\phi_{\underline{x}, \underline{y}, \underline{z}, s, t}(s), \phi_{\underline{x}, \underline{y}, \underline{z}, s, t}(t)\right)
\end{aligned}
$$

defined in an open subset $V$ of $X^{(n)} \times X^{(n-i)} \times X^{(n-i+j)} \times X \times X$ with values in $\left(\mathbb{C}^{2}\right)^{(n)} \times\left(\mathbb{C}^{2}\right)^{(n-i)} \times\left(\mathbb{C}^{2}\right)^{(n-i+j)} \times \mathbb{C}^{2} \times \mathbb{C}^{2}$ is a homeomorphism between $V$ and its image, and is equivariant for the $\mathbb{Z} / 2 \mathbb{Z}$-action which permutes the two last factors in the domain and in the range. If $p$ is a point in $A \cap B$ lying over $V$, the map given by

$$
\begin{aligned}
\left(\xi, \underline{x}, \xi^{\prime}, \underline{y}, \xi^{\prime \prime}, \underline{z}, s, t\right) \longmapsto\left(\phi_{\underline{x}, \underline{y}, \underline{z}, s, t *}^{(n)}, \phi_{\underline{x}, \underline{y}, \underline{z}, s, t *}^{(n-i)} \xi^{\prime}, \phi_{\underline{x}, \underline{y}, \underline{z}, s, t *}^{(n-i+j)} \xi^{\prime \prime},\right. \\
\left.\phi_{\underline{x}, \underline{y}, \underline{z}, s, t}(s), \phi_{\underline{x}, \underline{y}, \underline{z}, s, t}(t)\right)
\end{aligned}
$$

is a homeomorphism from a neighbourhood of $p$ in the product Hilbert scheme $Y$ to its image in $\left(\mathbb{C}^{2}\right)^{[n]} \times\left(\mathbb{C}^{2}\right)^{[n-i]} \times\left(\mathbb{C}^{2}\right)^{[n-i+j]} \times \mathbb{C}^{2} \times \mathbb{C}^{2}$ and maps $A$ and $B$ to the classical cycles $p_{124}^{-1} Q^{[n, n-i]}$ and $p_{235}^{-1} Q^{[n-i+j, n-i]}$. In the integrable case, we know that in the open set $\{s \neq t\}, p_{124}^{-1} Q^{[n, n-i]}$ and $p_{235}^{-1} Q^{[n-i+j, n-i]}$ intersect generically transversally. Thus, this property still holds in our context. If $(A \cap B)_{s \neq t}=C_{i j}$ we can write $[A] \cdot[B]=\left[\overline{C_{i j}}\right]+\iota_{*} R$, where $\iota: Y_{\{s=t\}} \hookrightarrow Y$ is the natural injection and $R$ is in $H_{2(2 n-i+j+2)}\left(Y_{\{s=t\}}, \mathbb{Q}\right)$.

We can proceed similarly in the product Hilbert scheme

$$
Y^{\prime}=\left(X^{[n] \times[n+j] \times[n-i+j] \times[1] \times[1]}, J_{n \times(n+j) \times(n-i+j) \times 1 \times 1}^{\mathrm{rel}} \leftarrow 5 \text { times }\right)
$$

with the cycles $A^{\prime}$ and $B^{\prime}$ defined by

$$
\begin{aligned}
& A^{\prime}=\left\{\left(\xi, \xi^{\prime}, \xi^{\prime \prime}, s, t\right) \text { in } Y^{\prime} \text { such that } \xi \subseteq \xi^{\prime} \text { and } \rho\left(\xi, \xi^{\prime}\right)=s\right\} \\
& B^{\prime}=\left\{\left(\xi, \xi^{\prime}, \xi^{\prime \prime}, s, t\right) \text { in } Y^{\prime} \text { such that } \xi^{\prime \prime} \subseteq \xi^{\prime} \text { and } \rho\left(\xi^{\prime \prime}, \xi^{\prime}\right)=t\right\}
\end{aligned}
$$

Let $D_{i j}=\left(A^{\prime} \cap B^{\prime}\right)_{s \neq t}$. Then, we can write $\left[A^{\prime}\right] \cdot\left[B^{\prime}\right]=\left[\overline{D_{i j}}\right]+\iota_{*}^{\prime} R^{\prime}$, where $\iota^{\prime}: Y_{\{s=t\}}^{\prime} \hookrightarrow Y^{\prime}$ is the injection and $R^{\prime}$ is in $H_{2(2 n-i+j+2)}\left(Y_{\{s=t\}}^{\prime}, \mathbb{Q}\right)$. The homology class $R$ (resp. $R^{\prime}$ ) can be chosen supported in $A \cap B \cap Y_{\{s=t\}}$ (resp. in $\left.A^{\prime} \cap B^{\prime} \cap Y_{\{s=t\}}^{\prime}\right)$.

The following lemma describes the situation outside the diagonal $\{s=t\}$ :

## Lemma 2.

$p_{1345 *}\left(\left[\overline{C_{i j}}\right] \cap\left(\operatorname{pr}_{5}^{*} \beta \cup \operatorname{pr}_{4}^{*} \alpha\right)\right)=(-1)^{|\alpha||\beta|} p_{1345 *}\left(\left[\overline{D_{i j}}\right] \cap\left(\operatorname{pr}_{5}^{*} \alpha \cup \operatorname{pr}_{4}^{*} \beta\right)\right)$.

Proof. We introduce the incidence varieties

$$
\begin{aligned}
T=\left\{(\underline{x}, \underline{y}, \underline{z}, s, t) \text { in } X^{(n)} \times X^{(n-i)}\right. & \times X^{(n-i+j)} \times X \times X \\
& \text { such that } \underline{x}=\underline{y} \cup i s \text { and } \underline{z}=\underline{y} \cup j t\} \\
T^{\prime}=\left\{(\underline{x}, \underline{y}, \underline{z}, s, t) \text { in } X^{(n)} \times X^{(n+j)}\right. & \times X^{(n-i+j)} \times X \times X \\
& \text { such that } \underline{y}=\underline{x} \cup j s=\underline{z} \cup i t\} .
\end{aligned}
$$

We choose two small neighbourhoods $\Omega, \Omega^{\prime}$ of $T$ and $T^{\prime}$ and a neighbourhood $W$ of $Z_{n \times(n-i+j) \times 2}$ such that for any $(\underline{x}, \underline{y}, \underline{z}, s, t)$ in $\Omega$ (resp. $\left.\Omega^{\prime}\right), \underline{y}$ is in $W_{\underline{x, z}, s \cup t}$. Let $J_{n \times(n-i+j) \times 2}^{\mathrm{rel}}$ be a relative integrable complex structure on $W$. After shrinking $\Omega$ and $\Omega^{\prime}$ if necessary, we can consider two relative structures $J_{n \times(n-i) \times(n-i+j) \times 2}^{\text {rel }}$ and $J_{n \times(n+j) \times(n-i+j) \times 2}^{\mathrm{rel}}$ such that

$$
\left\{\begin{array}{l}
\forall(\underline{x}, \underline{y}, \underline{z}, s, t) \in \Omega, J_{n \times(n-i) \times(n-i+j) \times 2, \underline{x}, \underline{y}, \underline{z}, s \cup t}^{\mathrm{rel}}=J_{n \times(n-i+j) \times 2, \underline{x}, \underline{z}, s \cup t}^{\mathrm{rel}} \\
\forall(\underline{x}, \underline{y}, \underline{z}, s, t) \in \Omega^{\prime}, J_{n \times(n+j) \times(n-i+j) \times 2, \underline{x}, \underline{y}, \underline{z}, s \cup t}^{\mathrm{rel}}=J_{n \times(n-i+j) \times 2, \underline{x}, \underline{z}, s \cup t}^{\mathrm{rel}}
\end{array}\right.
$$

Let $U\left(\right.$ resp. $\left.U^{\prime}\right)$ be the points of $Y\left(\right.$ resp. $\left.Y^{\prime}\right)$ lying over $\Omega$ (resp. $\left.\Omega^{\prime}\right)$. We define a relative integrable complex structure $J_{n \times(n-i) \times(n-i+j) \times 1 \times 1}^{\mathrm{rel}}$ by the formula

$$
J_{n \times(n-i) \times(n-i+j) \times 1 \times 1, \underline{x}, \underline{y}, \underline{z}, s, t}^{\mathrm{rel}}=J_{n \times(n-i) \times(n-i+j) \times 2, \underline{x}, \underline{y}, \underline{z}, s \cup t}^{\mathrm{rel}}
$$

as well as two maps $u$ and $v$ :

$$
\begin{aligned}
u: U & \longrightarrow\left(X^{[n] \times[n-i+j] \times[1] \times[1]}, J_{n \times(n-i+j) \times 1 \times 1}^{\mathrm{rel}} \leftarrow 4 \text { times }\right) \\
\left(\xi, \xi^{\prime}, \xi^{\prime \prime}, s, t\right) & \longmapsto\left(\xi, \xi^{\prime \prime}, s, t\right), \\
v: U^{\prime} & \longrightarrow\left(X^{[n] \times[n-i+j] \times[1] \times[1]}, J_{n \times(n-i+j) \times 1 \times 1}^{\mathrm{rel}} \leftarrow 4 \text { times }\right), \\
\left(\xi, \xi^{\prime}, \xi^{\prime \prime}, s, t\right) & \longmapsto\left(\xi, \xi^{\prime \prime}, s, t\right)
\end{aligned}
$$

If we take three homeomorphisms

$$
\left\{\begin{aligned}
X^{[n]} \times X^{[n-i]} \times X^{[n-i+j]} \times X^{2} & \simeq X^{[n] \times[n-i] \times[n-i+j] \times[1] \times[1]} \\
X^{[n]} \times X^{[n+j]} \times X^{[n-i+j]} \times X^{2} & \simeq X^{[n]} \times X^{[n-i+j]} \times X^{2} \\
X^{[n]} \times X^{[n-i+j]} \times X^{2} & \simeq X^{[n] \times[n-i+j] \times[1] \times[1]}
\end{aligned}\right.
$$

then $u$ and $v$ can be extended to global maps which are in the homotopy class of $p_{1345}$.

As in the integrable case, there is a natural isomorphism $\phi: C_{i j} \xrightarrow{\simeq} D_{i j}$ described as follows: if $\left(\xi, \xi^{\prime}, \xi^{\prime \prime}, s, t\right)$ is an element of $C_{i j}$ with $\Gamma\left(\xi^{\prime}\right)=\underline{y}$, $\Gamma(\xi)=\underline{y} \cup i s$ and $\Gamma\left(\xi^{\prime \prime}\right)=\underline{y} \cup j t$, then $\phi\left(\xi, \xi^{\prime}, \xi^{\prime \prime}, s, t\right)=\left(\xi, \widetilde{\xi}, \xi^{\prime \prime}, t, s\right)$ where $\widetilde{\xi}$ is defined by

$$
\left\{\begin{array}{l}
\widetilde{\xi}_{\mid p}=\xi_{\mid p}^{\prime} \text { for } p \in \underline{y}, p \notin\{s, t\} \\
\widetilde{\xi}_{\mid s}=\xi_{\mid s} \text { and } \widetilde{\xi}_{\mid t}=\xi_{\mid t}^{\prime \prime}
\end{array}\right.
$$

these schemes being considered for the complex structure $J_{n \times(n-i+j) \times 2, \underline{x}, \underline{z}, s \cup t}^{\mathrm{rel}}$.
Let $\partial C_{i j}=\overline{C_{i j}} \backslash C_{i j}, \partial D_{i j}=\overline{D_{i j}} \backslash D_{i j}$ and $S=u\left(\partial C_{i j}\right)=v\left(\partial D_{i j}\right)$; we define a map $\pi: Y^{\prime} \longrightarrow Y^{\prime}$ by $\pi\left(\xi, \xi^{\prime}, \xi^{\prime \prime}, s, t\right)=\left(\xi, \xi^{\prime}, \xi^{\prime \prime}, t, s\right)$. Then we have the following diagram, where all the maps are proper:

Thus we obtain $u_{*}\left(\left[C_{i j}\right] \cap\left(\operatorname{pr}_{5}^{*} \beta \cup \operatorname{pr}_{4}^{*} \alpha\right)\right)=v_{*}\left(\left[D_{i j}\right] \cap\left(\operatorname{pr}_{4}^{*} \beta \cup \operatorname{pr}_{5}^{*} \alpha\right)\right)$ in the Borel-Moore homology group $H_{2(2 n-i+j+2)}^{\mathrm{lf}}\left(X^{[n] \times[n-i+j] \times[1] \times[1]} \backslash S, \mathbb{Q}\right)$.

Since $\operatorname{dim} S \leq 2(2 n-i+j+2)-2$, we get
$p_{1345 *}\left(\left[\overline{C_{i j}}\right] \cap\left(\operatorname{pr}_{5}^{*} \beta \cup \operatorname{pr}_{4}^{*} \alpha\right)\right)=(-1)^{|\alpha||\beta|} p_{1345 *}\left(\left[\overline{D_{i j}}\right] \cap\left(\operatorname{pr}_{5}^{*} \alpha \cup \operatorname{pr}_{4}^{*} \beta\right)\right)$.

By this lemma, the terms coming from $\overline{C_{i j}}$ and $\overline{D_{i j}}$ in $\left[\mathfrak{q}_{-i}(\alpha), \mathfrak{q}_{j}(\beta)\right]$ cancel out. It remains to deal with the excess intersection components along the diagonals $Y_{\{s=t\}}$ and $Y_{\{s=t\}}^{\prime}$. We introduce the locus

$$
\begin{array}{r}
Z=\left\{\left(\xi, \underline{x}, \xi^{\prime \prime}, \underline{z}, s, t\right) \text { in } X^{[n] \times[n-i+j] \times[1] \times[1]} \text { such that } s=t, \xi_{\mid p}=\xi_{\mid p}^{\prime \prime}\right. \\
\text { for } p \neq s \quad \text { and } \quad \Gamma\left(\xi^{\prime \prime}\right)=\Gamma(\xi)+(j-i) s \text { if } j \geq i \\
\left.\Gamma(\xi)=\Gamma\left(\xi^{\prime \prime}\right)+(i-j) s \text { if } j \leq i\right\}
\end{array}
$$

Then $Z$ contains $u(A \cap B)$ and $v\left(A^{\prime} \cap B^{\prime}\right)$. As before, the dimension count can be done as in the integrable case: if $i \neq j, \operatorname{dim} Z<2(2 n-i+j+2)$ and if $i=j, Z$ contains a $2(2 n+2)$-dimensional component, namely $\Delta_{X^{[n]}} \times \Delta_{X}$. All other components have lower dimensions. Thus, if $i \neq j, p_{1345 *}\left(\iota_{*} R\right)$ and $p_{1345 *}\left(\iota_{*}^{\prime} R^{\prime}\right)$ vanish since these two homology classes are supported in $Z$ and their degree is $2(2 n-i+j+2)$. In the case $i=j$, then $p_{1345 *}\left(\iota_{*} R\right)$ and $p_{1345 *}\left(\iota_{*}^{\prime} R^{\prime}\right)$ are proportional to the fundamental homology class of $\Delta_{X^{[n]}} \times \Delta_{X}$.
 identity $\left[\mathfrak{q}_{-i}(\alpha), \mathfrak{q}_{i}(\beta)\right]=\mu \int_{X} \alpha \beta$. id where $\mu$ is a rational number. The computation of the multiplicity $\mu$ is a local problem on $X$ which is solved in [12], [7]; it turns out that $\mu=-i$.
Remark 4. The proof remains quite similar for $i>0, j>0$. There is no excess term in this case. Indeed,

$$
Y=X^{[n] \times[n+i] \times[n+i+j] \times[1] \times[1]}, Z=X^{[n+i+j, n]} \subseteq X^{[n] \times[n+i] \times[n+i+j] \times[1] \times[1]}
$$

and $\operatorname{dim} Z=2(2 n+i+j+1)<2(2 n+i+j+2)$.

Theorem 4 gives a representation in $\mathbb{H}=\bigoplus H^{*}\left(X^{[n]}, \mathbb{Q}\right)$ of the Heisenberg super-algebra $\mathcal{H}\left(H^{*}(X, \mathbb{Q})\right)$ of $H^{*}(X, \mathbb{Q}) .{ }^{n \in \mathbb{N}}$

Proposition 4. $\mathbb{H}$ is an irreducible $\mathcal{H}\left(H^{*}(X, \mathbb{Q})\right)$-module with highest weight vector 1 .

This a consequence of Theorem 4 and Göttsche's formula (Theorem 3), as shown by Nakajima [16].

## 5. Tautological bundles

### 5.1. Construction of the tautological bundles

Our aim in this section is to associate to any complex vector bundle $E$ on an almost-complex compact four-manifold $X$ a collection of complex vector bundles $E^{[n]}$ on $X^{[n]}$ which generalize the tautological bundles already known in the algebraic context.

Let $(X, J)$ be an almost-complex compact four-manifold, $Z_{n} \subseteq X^{(n)} \times X$ the incidence locus, $W$ a small neighbourhood of $Z_{n}$ in $X^{(n)} \times X$ and $J_{n}^{\text {rel }}$ a relative integrable structure on $W$. The fibers of $\mathrm{pr}_{1}: W \longrightarrow X^{(n)}$ are smooth analytic sets. We endow $W$ with the sheaf $\mathcal{A}_{W}$ of continuous functions which are smooth on the fibers of $\mathrm{pr}_{1}$. We can consider the sheaf $\mathcal{A}_{W, \text { rel }}^{0,1}$ of relative $(0,1)$-forms on $W$. There exists a relative $\bar{\partial}$-operator $\bar{\partial}^{\text {rel }}: \mathcal{A}_{W} \xrightarrow{\longrightarrow} \mathcal{A}_{W, \text { rel }}^{0,1}$ which induces for each $\frac{x}{\in} \in X^{(n)}$ the usual operator $\bar{\partial}: \mathcal{A}_{W_{\underline{x}}} \longrightarrow \mathcal{A}_{W_{\underline{x}}}^{0,1}$ given by the complex
structure structure $\overline{J_{n, x}^{\mathrm{rel}}}$ on $W_{x}$.

Definition 7. Let $E$ be a complex vector bundle on $X$.
(i) $A$ relative connection $\bar{\partial}_{E}^{\text {rel }}$ on $E$ compatible with $J_{n}^{\text {rel }}$ is a $\mathbb{C}$-linear morphism of sheaves $\bar{\partial}_{E}: \mathcal{A}_{W}\left(\mathrm{pr}_{2}^{*} E\right) \longrightarrow \mathcal{A}_{W}^{0,1}\left(\mathrm{pr}_{2}^{*} E\right)$ satisfying a relative Leibniz rule: $\bar{\partial}_{E}^{\mathrm{rel}}(\varphi s)=\varphi \bar{\partial}_{E}^{\mathrm{rel}} s+\bar{\partial}^{\mathrm{rel}} \varphi \otimes s$ for all sections $\varphi$ and s of $\mathcal{A}_{W}\left(\mathrm{pr}_{2}^{*} E\right)$ and $\mathcal{A}_{W}$ respectively.
(ii) A relative connection $\bar{\partial}_{E}^{\mathrm{rel}}$ on $E$ is integrable if $\left(\bar{\partial}_{E}^{\mathrm{rel}}\right)^{2}=0$.

If $\bar{\partial}_{E}^{\text {rel }}$ is an integrable connection on $E$ compatible with $J_{n}^{\text {rel }}$, we can apply the Koszul-Malgrange integrability theorem with continuous parameters in $X^{(n)}$ (see [21]). Thus, for every $\underline{x} \in X^{(n)}, E_{\mid W_{\underline{x}}}$ is endowed with the structure of a holomorphic vector bundle over $\left(W_{\underline{x}}, J_{n, \underline{x}}^{\text {rel }}\right)$ and this structure varies continuously with $\underline{x}$. Furthermore, $\operatorname{ker} \bar{\partial}_{E}^{\text {rel }}$ is the sheaf of relative holomorphic sections of $E$. Therefore, there is no difference between relative integrable connections on $E$ compatible with $J_{n}^{\text {rel }}$ and relative holomorphic structures on $E$ compatible with $J_{n}^{\text {rel }}$.

Taking relative holomorphic coordinates for $J_{n}^{\text {rel }}$, we can see that relative integrable connections exist on $W$ over small open sets of $X^{(n)}$. By a partition of unity on $X^{(n)}$, it is possible to build global ones. Besides, the space of holomorphic structures on a complex vector bundle over a ball in $\mathbb{C}^{2}$ is contractible, so
that the space of relative holomorphic structures on $E$ compatible with $J_{n}^{\text {rel }}$ is also contractible.

We proceed now to the construction of the tautological bundle $E^{[n]}$ on $X_{J_{n}^{\text {rel }}}^{[n]}$. Let $\bar{\partial}_{E}^{\text {rel }}$ be a relative holomorphic structure on $E$ adapted to $J_{n}^{\text {rel }}$. Taking relative holomorphic coordinates, we get a vector bundle $E_{\text {rel }}^{[n]}$ over $W_{\text {rel }}^{[n]}$ satisfying the following property: for each $\underline{x}$ in $X_{-\mathrm{rel}}^{(n)}, E_{\text {rel } \mid W_{\underline{x}}^{[n]}}^{[n]}=E_{\mid W_{\underline{x}}}^{[n]}$, where $E_{\mid W_{\underline{x}}}$ is endowed with the holomorphic structure $\bar{\partial}_{E, \underline{x}}^{\text {rel }}$.
Definition 8. Let $i: X_{J_{n}^{\text {rel }}}^{[n]} \longrightarrow W_{\text {rel }}^{[n]}$ be the canonical injection. The complex vector bundle $\left(E^{[n]}, J_{n}^{\text {rel }}, \bar{\partial}_{E}^{\mathrm{rel}}\right)$ on $X_{J_{n}^{\text {rel }}}^{[n]}$ is defined by $E^{[n]}=i^{*} E_{\mathrm{rel}}^{[n]}$.
In the sequel, we consider the class of $E^{[n]}$ in $K\left(X^{[n]}\right)$, which we prove below to be independent of the structures used in the construction.
Proposition 5. The class of $E^{[n]}$ in $K\left(X^{[n]}\right)$ is independent of $\left(J_{n}^{\mathrm{rel}}, \bar{\partial}_{E}^{\mathrm{rel}}\right)$.
Proof. Let $\left(J_{0, n}^{\mathrm{rel}}, \bar{\partial}_{E, 0}^{\mathrm{rel}}\right)$ and $\left(J_{1, n}^{\mathrm{rel}}, \bar{\partial}_{E, 1}^{\mathrm{rel}}\right)$ be two relative holomorphic structures on $E,\left(J_{t, n}^{\mathrm{rel}}, \bar{\partial}_{E, t}^{\mathrm{rel}}\right)$ be a smooth path between them, and $W_{\text {rel }}^{[n]}$ be the relative Hilbert scheme over $X^{(n)} \times[0,1]$ for the family $\left(J_{t, n}^{\mathrm{rel}}\right)_{0 \leq t \leq 1}$. There exists a vector bundle $\left(\widetilde{E}_{\text {rel }}^{[n]},\left\{J_{t, n}^{\mathrm{rel}}\right\}_{0 \leq t \leq 1},\left\{\bar{\partial}_{E, t}^{\mathrm{rel}}\right\}_{0 \leq t \leq 1}\right)$ over $W_{\text {rel }}^{[n]}$ such that for all $t$ in $[0,1]$, $\widetilde{E}_{\text {rel } \mid W_{\text {rel }, t}^{[n]}}^{[n]}=\left(E_{\text {rel }}^{[n]}, J_{t, n}^{\text {rel }}, \bar{\partial}_{E, t}^{\text {rel }}\right)$. If $\mathscr{X}=\left(X^{[n]},\left\{J_{t, n}^{\text {rel }}\right\}_{0 \leq t \leq 1}\right) \subseteq W_{\text {rel }}^{[n]}$ is the relative Hilbert scheme over $[0,1]$, then $\widetilde{E}_{\text {rel } \mid \mathfrak{X}}^{[n]}$ is a complex vector bundle on $\mathfrak{X}$ whose restriction to $\mathfrak{X}_{t}$ is $\left(E^{[n]}, J_{t, n}^{\mathrm{rel}}, \bar{\partial}_{E, t}^{\mathrm{rel}}\right)$. Now $\mathfrak{X}$ is topologically trivial over $[0,1]$ by Proposition 2 . Since $K\left(\mathfrak{X}_{0} \times[0,1]\right) \simeq K\left(\mathfrak{X}_{0}\right)$, we get the result.

Let us give an important example. If $\mathbb{T}=X \times \mathbb{C}$ is the trivial complex line bundle on $X$, the tautological bundles $\mathbb{T}^{[n]}$ already convey geometric information on $X^{[n]}$. To see this, let $\partial X^{[n]} \subseteq X^{[n]}$ be the inverse image of the big diagonal of $\dot{X}^{(n)}$ by the Hilbert-Chow morphism. We have $\operatorname{dim} \partial X^{[n]}=4 n-2$ and $H_{4 n-2}\left(\partial X^{[n]}, \mathbb{Z}\right) \simeq \mathbb{Z}($ this can be proved as in Lemma 1).
Lemma 3. $c_{1}\left(\mathbb{T}^{[n]}\right)=-\frac{1}{2} P D^{-1}\left(\left[\partial X^{[n]}\right]\right)$ in $H^{2}\left(X^{[n]}, \mathbb{Q}\right)$.
Proof. Let $U=\left\{\left(x_{1}, \ldots, x_{n}\right)\right.$ in $X^{[n]}$ such that for $\left.i \neq j, x_{i} \neq x_{j}\right\}$. Then $X^{[n]} \backslash \partial X^{[n]}$ is canonically isomorphic to $U / \mathfrak{S}_{n}$. If $\sigma: U \longrightarrow X^{[n]} \backslash \partial X^{[n]}$ is the associated quotient map, $\sigma^{*} \mathbb{T}^{[n]} \simeq \bigoplus_{i=1}^{n} \operatorname{pr}_{i}^{*} \mathbb{T}$, so that $\sigma^{*} \mathbb{T}^{[n]}$ is trivial. Since $\sigma$ is a finite covering map, $c_{1}\left(\mathbb{T}^{[n]}\right){ }_{\mid X^{[n]} \backslash \partial X^{[n]}}$ is a torsion class, so it is zero in $H^{2}\left(X^{[n]} \backslash \partial X^{[n]}, \mathbb{Q}\right)$. This implies that $c_{1}\left(\mathbb{T}^{[n]}\right)$ is Poincaré dual to a rational multiple of $\left[\partial X^{[n]}\right]$. To compute the proportionality coefficient $\mu$, we argue locally on $X^{(n)}$ around a point in the stratum

$$
S=\left\{\underline{x} \in X^{(n)} \text { such that } x_{i} \neq x_{j} \text { except for one pair }\{i, j\}\right\}
$$

This reduces the computation to the case $n=2$. For any open subset $U$ of $X$ endowed with an integrable complex structure, if $\Delta$ is the diagonal of $U$, then $U^{[2]}=B l_{\Delta}(U \times U) / \mathbb{Z}_{2}$. Besides, if $E \subseteq B l_{\Delta}(U \times U)$ is the exceptional divisor and $\pi$ is the projection from $B l_{\Delta}(U \times \bar{U}) / \mathbb{Z}_{2}$ to $U^{[2]}$, then $\pi^{*}\left(\left[\partial U^{[2]}\right]\right)=2[E]$. Thus we obtain:

$$
\pi^{*} c_{1}\left(\mathbb{T}^{[2]}\right)=c_{1}\left(\pi^{*} \mathbb{T}^{[2]}\right)=c_{1}(\mathcal{O}(-E))=-[E] \quad \text { in } \quad H^{2}\left(B l_{\Delta}(U \times U), \mathbb{Z}\right)
$$

This gives the value $\mu=-1 / 2$.

### 5.2. Tautological bundles and incidence varieties

We want to compare the tautological bundles $E^{[n]}$ and $E^{[n+1]}$ through the incidence variety $X^{[n+1, n]}$. In the integrable case, $X^{[n+1, n]}$ is smooth. If $D$ denotes the divisor $\bar{Z}_{1}$ in $X^{[n+i, n]}$ (see (1)), we have an exact sequence (see [4], [15]):

$$
0 \longrightarrow \rho^{*} E \otimes \mathcal{O}_{X^{[n+1, n]}}(-D) \longrightarrow \nu^{*} E^{[n+1]} \longrightarrow \lambda^{*} E^{[n]} \longrightarrow 0
$$

where $\lambda: X^{[n+1, n]} \longrightarrow X^{[n]}, \nu: X^{[n+1, n]} \longrightarrow X^{[n+1]}$ and $\rho: X^{[n+1, n]} \longrightarrow X$ are the two natural projections and the residual map.

In the almost-complex case, $X^{[n+1, n]}$ is a topological manifold of dimension $4 n+4$ (if we choose a relative integrable structure $J_{n+1}^{\text {rel }}$ with additional properties as given in [19], $X^{[n+1, n]}$ can be endowed with a differentiable structure, but we will not need it here).

Let $J_{n}^{\text {rel }}$ and $J_{n+1}^{\text {rel }}$ be two relative integrable structures in small neighbourhoods of $Z_{n}$ and $Z_{n+1}$. We extend them to relative integrable complex structures $\breve{J}_{n \times(n+1)}^{1, \text { rel }}$ and $\breve{J}_{n \times(n+1)}^{2, \text { rel }}$ in small neighbourhoods of the incidence set $Z_{n \times(n+1)}$. Then $\left(X^{[n] \times[n+1]}, \check{J}_{n \times(n+1)}^{1, \text { rel }}, \check{J}_{n \times(n+1)}^{2 \text {, rel }}\right)=X_{J_{n}^{\text {rel }}}^{[n]} \times X_{J_{n+1}^{\text {rel }}}^{[n+1]}$. If $J_{n \times(n+1)}^{\text {rel }}$ is a relative integrable structure in a small neighbourhood of $Z_{n \times(n+1)}^{+1}$ and $J_{n \times 1}^{\text {rel }}$ is defined for all $(\underline{x}, p)$ in $X^{(n)} \times X$ by $J_{n \times 1, \underline{x}, p}^{\mathrm{rel}}=J_{n \times(n+1), \underline{x}, \underline{x} \cup p}^{\mathrm{rel}}$, then we have a commutative diagram in the homotopy category:

where $\Phi$ is a homeomorphism whose homotopy class is canonical. Let us denote by $D$ the inverse image of the incidence locus $Z_{n}$ in $X^{(n)} \times X$ by the map $X^{[n+1, n]} \longmapsto X^{(n)} \times X$, so that $D=\bar{Z}_{1}$ where $Z_{1}$ is defined by (1). The cycle $D$ has a fundamental homology class in $H_{4 n+2}\left(X^{[n+1, n]}, \mathbb{Z}\right)$, and this last homology group is in fact isomorphic to $\mathbb{Z}$ (see the proof of Lemma 1). Furthermore, there exists a unique complex line bundle $F$ on $X^{[n+1, n]}$ such that $P D^{-1}\left(c_{1}(F)\right)=-[D]$.
Proposition 6. The identity $\nu^{*} E^{[n+1]}=\lambda^{*} E^{[n]}+\rho^{*} E \otimes F$ holds in $K\left(X^{[n+1, n]}\right)$.
Proof. Let $\bar{\partial}_{E, n \times 1}^{\mathrm{rel}}, \bar{\partial}_{E, n}^{\mathrm{rel}}$ and $\bar{\partial}_{E, n+1}^{\mathrm{rel}}$ be relative holomorphic structures on $E$ compatible with $J_{n \times 1}^{\mathrm{rel}}, J_{n}^{\text {rel }}$ and $J_{n+1}^{\mathrm{rel}}$. For each $(\underline{x}, p)$ in $X^{(n)} \times X$, we consider the exact sequence (3) on $\left(W_{\underline{x}, p}, J_{n \times 1, \underline{x}, p}^{\text {rel }}\right)$ for the holomorphic vector bundle $\left(E_{\mid W_{x, p}}, \bar{\partial}_{E, n \times 1, \underline{x}, p}^{\text {ret }}\right)$. Putting these exact sequences in family over $X^{(n)} \times X$, and taking the restriction to $X^{[n+1, n]}$, we get an exact sequence

$$
0 \longrightarrow \rho^{*} E \otimes G \longrightarrow A \longrightarrow B \longrightarrow 0
$$

where $G$ is a complex line bundle on $X^{[n+1, n]}$ and $A$ and $B$ are two vector bundles on $X^{[n+1, n]}$ such that for all $(\underline{x}, p)$ in $X^{(n)} \times X$ :

$$
\left\{\begin{array}{l}
A_{\mid \xi, \xi^{\prime}, \underline{x}, p}=\left(E_{\mid \xi^{\prime}}^{[n+1]}, \bar{\partial}_{E, n \times 1, \underline{x}, p}^{\mathrm{rel}}, J_{n \times 1, \underline{x}, p}^{\mathrm{rel}}\right)  \tag{4}\\
B_{\mid \xi, \xi^{\prime}, \underline{x}, p}=\left(E_{\mid \xi}^{[n]}, \bar{\partial}_{E, n \times 1, \underline{x}, p}^{\mathrm{rel}}, J_{n \times 1, \underline{x}, p}^{\mathrm{rel}}\right)
\end{array}\right.
$$

Let us write $\Phi\left(\xi, \xi^{\prime}, \underline{u}, \underline{v}\right)=\left(\phi_{\underline{u}, \underline{v} *} \xi, \psi_{\underline{u}, \underline{v} *} \xi^{\prime}, \phi_{\underline{u}, \underline{v}}^{(n)}(\underline{u}), \psi_{\underline{u}, \underline{v}}^{(n+1)}(\underline{v})\right)$ where, for $(\underline{u}, \underline{v})$ in $X^{(n)} \times X^{(n+1)}$, the map $\phi_{\underline{u}, \underline{v}}$ (resp. $\psi_{\underline{u}, \underline{v})}$ is a biholomorphism between a neighbourhood of $\operatorname{supp}(\underline{u} \cup \underline{v})$ endowed with the complex structure $J_{n \times(n+1), \underline{u}, \underline{v}}^{\mathrm{rel}}$ and its image in $X$ endowed with the structure $\check{J}_{n \times(n+1), \phi_{\underline{u}, \underline{v}}^{(n)} \underline{(u), \phi_{\underline{u}, \underline{v}}^{(n+1)}(\underline{v})}}^{1, \text { rel }}$ (resp. $\left.\check{J}_{n \times(n+1), \psi_{\underline{u}, \underline{v}}^{(n)}(\underline{u}), \psi_{\underline{u}, \underline{v}}^{(n+1)}(\underline{v})}^{2, \text { rel }}\right)$. Then

$$
\begin{aligned}
& \nu^{*} E_{\mid \xi, \xi^{\prime}, \underline{x, p}}^{[n+1]}=\left(E_{\mid \psi_{\underline{x}, \underline{x} \cup p *}^{[n+1]}}^{[n}, \bar{\partial}_{E, n+1, \psi_{\underline{x}, \underline{x} \cup p}^{(n+1)}(\underline{x} \cup p)}^{\mathrm{rel}}, J_{n+1, \psi_{\underline{x}, \underline{x} \cup p}^{(x+1)}(\mathrm{xel})}^{\mathrm{rel}}\right), \\
& \lambda^{*} E_{\mid \xi, \xi^{\prime}, \underline{x}, p}^{[n]}=\left(E_{\mid \phi_{\underline{x}, \underline{x} \cup p *}}^{[n]}, \overline{\left.\partial_{E, n, \phi_{\underline{x}, \underline{x} \cup p}(\underline{x})}^{(n)}, J_{n, \phi_{\underline{x}, \underline{x} \cup p}^{(n)}(\underline{x})}^{\mathrm{rel}}\right) .}\right.
\end{aligned}
$$

As in Proposition 5, the classes $A$ and $B$ in $K\left(X^{[n+1, n]}\right)$ are independent of the relative holomorphic structures used to define them.

- If $J_{n \times(n+1)}^{\text {rel }}=\breve{J}_{n \times(n+1)}^{2, \text { rel }}$ and if for all $(\underline{x}, p)$ in $X^{(n)} \times X, \bar{\partial}_{E, n \times 1, \underline{x}, p}^{\text {rel }}$ and $\bar{\partial}_{E, n+1, \underline{x} \cup p}^{\text {rel }}$ are equal, we can assume that $\psi_{\underline{u, v}}=$ id in a neighbourhood of $\operatorname{supp}(\underline{v})$. Thus $A=\nu^{*} E^{[n+1]}$.
- On the other way, if $J_{n \times(n+1)}^{\mathrm{rel}}=\check{J}_{n \times(n+1)}^{1 \text {, rel }}$ and for all $(\underline{x}, p)$ in $X^{(n)} \times X$, $\bar{\partial}_{E, n \times 1, \underline{x}, p}^{\mathrm{rel}}=\bar{\partial}_{E, n, \underline{x}}^{\text {rel }}$ in a neighbourhood of $\operatorname{supp}(\underline{x})$, we can take $\phi_{\underline{u}, \underline{v}}=$ id in a neighbourhood of $\operatorname{supp}(\underline{u})$. Thus $B=\lambda^{*} E^{[n]}$.

This proves that $\nu^{*} E^{[n+1]}-\lambda^{*} E^{[n]}=\rho^{*} E \otimes G$ in $K\left(X^{[n+1, n]}\right)$. If $\mathbb{T}$ is the trivial complex line bundle on $X, \nu^{*} \mathbb{T}^{[n+1]} \simeq \lambda^{*} \mathbb{T}^{[n]} \oplus \rho^{*} \mathbb{T}$ on $X^{[n+1, n]} \backslash D$. Thus $G$ is trivial outside $D$. This yields $P D\left(c_{1}(G)\right)=\mu[D]$, where $\mu$ is rational. The computation of $\mu$ is local, as in Lemma 3. Thus, using the exact sequence (3), we get $\mu=-1$.
If $X$ is a projective surface, the subring of $H^{*}\left(X^{[n]}, \mathbb{Q}\right)$ generated by the classes $\operatorname{ch}_{k}\left(E^{[n]}\right.$ ) (where $E$ runs through all the algebraic vector bundles on $X$ ) is called the ring of algebraic classes of $X^{[n]}$. If $(X, J)$ is an almost-complex compact four-manifold, we can in the same manner consider the subring of $H^{*}\left(X^{[n]}, \mathbb{Q}\right)$ generated by the classes $\operatorname{ch}_{k}\left(E^{[n]}\right)$, where $E$ runs through all the complex vector bundles on $X$. If $X$ is projective, this ring is much bigger than the ring of the algebraic classes. In a forthcoming paper, we will show that it is indeed equal to $H^{*}\left(X^{[n]}, \mathbb{Q}\right)$ if $X$ is a symplectic compact four-manifold satisfying $b_{1}(X)=0$, and we will describe the ring structure of $H^{*}\left(X^{[n]}, \mathbb{Q}\right)$.

## 6. Appendix: the decomposition theorem for semi-small maps

In this appendix, we provide Le Potier's unpublished proof of the decomposition theorem for semi-small maps (Theorem 2). For the formalism of the six operations in the derived category of constructible sheaves, we refer the reader to [5] and [13].

Let $Z$ be a complex irreducible quasi-projective variety endowed with a stratification $Z_{\nu}$. For any positive integer $k$, we define $U_{k}=\bigsqcup_{\operatorname{codim}\left(Z_{\nu}\right) \geq k} Z_{\nu}$. The $U_{k}$ 's form an increasing family of open sets in $Z$. For any constructible complex $C^{\bullet}$ on $Z$, we denote the complex $C_{\mid U_{k}}^{\bullet}$ by $C_{k}^{\bullet}$.

Let us recall briefly (mainly to fix the notations) the definition and the basic properties about intersection cohomology needed for the proof of the decomposition theorem. They can be found in [9].

Definition 9. Let $\mathcal{L}$ be a local system of $\mathbb{Q}$-vector spaces on $U_{0}$. The intersection complex $I C(\mathcal{L})$ associated to $\mathcal{L}$ with the middle perversity is a bounded constructible complex on $Z$ satisfying the following conditions:
(i) $I C(\mathcal{L})_{0} \simeq \mathcal{L}$,
(ii) $\mathcal{H}^{i}\left(\operatorname{IC}(\mathcal{L})_{0}\right)=0$ if $i>0$,
(iii) If $j \geq 1, k \geq 0$ and $j \geq k, \mathcal{H}^{j}\left(\operatorname{IC}(\mathcal{L})_{k}\right)=0$,
(iv) If $k \geq 1$ and if $i: U_{k} \longrightarrow U_{k+1}$ is the canonical injection, then the adjunction morphism $I C(\mathcal{L})_{k+1} \longrightarrow R i_{*} i^{-1} I C(\mathcal{L})_{k+1}=R i_{*} I C(\mathcal{L})_{k}$ is a quasi-isomorphism in degrees at most $k$.

In the bounded derived category of $\mathbb{Q}$-constructible sheaves on $Z, I C(\mathcal{L})$ is unique up to a unique isomorphism.

For any stratum $S$ of codimension $k$ in $Z$, let $j_{S}: S \longrightarrow Z$ be the corresponding inclusion. If $i: U_{k-1} \longrightarrow U_{k}$ is the canonical injection, we have the adjunction triangle

$$
\bigoplus_{S, \operatorname{codim} S=k} j_{S *} j_{S}^{!} I C(\mathcal{L}) \longrightarrow I C(\mathcal{L})_{k} \longrightarrow R i_{*} I C(\mathcal{L})_{k-1} \longrightarrow
$$

The conditions (iii) and (iv) imply that $\mathcal{H}^{i}\left(j_{S}^{!} I C(\mathcal{L})\right)=0$ if $i \leq k$.
The main ingredient in Le Potier's proof is the following lifting lemma:
Lemma 4. Let $D$ be the derived category of an abelian category $\mathcal{C}, A^{\bullet}, B^{\bullet}$ and $C^{\bullet}$ be three complexes in $\mathcal{C}$ and $f: B^{\bullet} \longrightarrow C^{\bullet}$ be a morphism of complexes such that:
(i) $A^{\bullet}$ is concentrated in degrees at most $k$,
(ii) $f$ induces in cohomology a morphism which is bijective in degrees at most $k-1$, and injective in degree $k$.
Then:
(i) The morphism $\phi_{f}: \operatorname{Hom}_{D}\left(A^{\bullet}, B^{\bullet}\right) \longrightarrow \operatorname{Hom}_{D}\left(A^{\bullet}, C^{\bullet}\right)$ induced by $f$ is injective,
(ii) The image of $\phi_{f}$ consists of morphisms $g: A^{\bullet} \longrightarrow C$ in $D$ such that the induced morphism $\mathcal{H}^{k}\left(A^{\bullet}\right) \longmapsto \mathcal{H}^{k}\left(C^{\bullet}\right)$ factors through $\mathcal{H}^{k}\left(B^{\bullet}\right)$.

Remark 5. When $f$ induces in cohomology a bijective morphism in degrees at most $k$, Lemma 4 is proved in [9, p. 95].

Proof. Let $M^{\bullet}$ be the mapping cone of $f$. Then we have a distinguished triangle $B^{\bullet} \longrightarrow C^{\bullet} \longrightarrow M^{\bullet} \xrightarrow[+1]{ }$ and the hypotheses imply that $\mathcal{H}^{q}\left(M^{\bullet}\right)$ vanishes for $q \leq k-1$. Therefore $\operatorname{Hom}_{D}\left(A^{\bullet}, M^{\bullet}[-1]\right)=0$. Now, the distinguished triangle $\operatorname{RHom}_{D}\left(A^{\bullet}, B^{\bullet}\right) \longrightarrow \operatorname{RHom}_{D}\left(A^{\bullet}, C^{\bullet}\right) \longrightarrow \operatorname{RHom}_{D}\left(A^{\bullet}, M^{\bullet}\right) \underset{+1}{\longrightarrow}$ yields a long exact sequence
$\operatorname{Hom}_{D}\left(A^{\bullet}, M^{\bullet}[-1]\right) \longrightarrow \operatorname{Hom}_{D}\left(A^{\bullet}, B^{\bullet}\right) \xrightarrow{\phi_{f}} \operatorname{Hom}_{D}\left(A^{\bullet}, C^{\bullet}\right) \longrightarrow \operatorname{Hom}_{D}\left(A^{\bullet}, M^{\bullet}\right)$ which proves (i).

For (ii), remark that $M^{\bullet}\left(\right.$ resp. $\left.A^{\bullet}\right)$ is concentrated in degrees at least $k$ (resp. at most $k$ ), so that $\operatorname{Hom}_{D}\left(A^{\bullet}, M^{\bullet}\right) \simeq \operatorname{Hom}_{D}\left(\mathcal{H}^{k}\left(A^{\bullet}\right), \mathcal{H}^{k}\left(M^{\bullet}\right)\right)$. Thus $\operatorname{Im} \phi_{f}$ consists of the elements $g$ in $\operatorname{Hom}_{D}\left(A^{\bullet}, C^{\bullet}\right)$ such that the induced morphism $\mathcal{H}^{k}\left(A^{\bullet}\right) \longrightarrow \mathcal{H}^{k}\left(M^{\bullet}\right)$ vanishes. The result follows from the exact sequence $0 \longrightarrow \mathcal{H}^{k}\left(B^{\bullet}\right) \longrightarrow \mathcal{H}^{k}\left(C^{\bullet}\right) \longrightarrow \mathcal{H}^{k}\left(M^{\bullet}\right)$.

We now turn to the proof of the decomposition theorem.

Proof (of Theorem 2). We construct the quasi-isomorphism between $R f_{*} \mathbb{Q}_{Y}$ and $\bigoplus_{\text {relevant }} j_{\nu *} I C_{\bar{Z}_{\nu}}\left(\mathcal{L}_{\nu}\right)\left[-d_{\nu}\right]$ by induction on the increasing family of open sets $U_{i}$ associated to the stratification on $Z$.

On $U_{0}$, the quasi-isomorphism $R f_{0 *} \mathbb{Q}_{Y_{0}} \simeq \mathcal{L}_{0}$ holds by definition of $\mathcal{L}_{0}$. If $k$ is a positive integer, assume that we have constructed a quasi-isomorphism

$$
\lambda_{k-1}:\left(R f_{*} \mathbb{Q}_{Y}\right)_{k-1} \xrightarrow{\sim} \bigoplus_{\substack{\nu \text { relevant } \\ d_{\nu} \leq k-1}} j_{\nu *} I C_{\bar{Z}_{\nu}}\left(\mathcal{L}_{\nu}\right)\left[-d_{\nu}\right] \text {. Let us introduce the }
$$ following notations:

(i) $\mathcal{S}=\bigoplus_{\substack{\nu \text { relevant } \\ d_{\nu} \leq k-1}} j_{\nu *} I C_{\bar{Z}_{\nu}}\left(\mathcal{L}_{\nu}\right)\left[-d_{\nu}\right]$,
(ii) $i: U_{k-1} \longrightarrow U_{k}$ is the injection,
(iii) $A^{\bullet}=\left(R f_{*} \mathbb{Q}_{Y}\right)_{k}, \quad B^{\bullet}=\mathcal{S}_{k}, \quad C^{\bullet}=R i_{*} \mathcal{S}_{k-1}$,
(iv) $f: B^{\bullet} \longrightarrow C^{\bullet}$ is the adjunction morphism $\mathcal{S}_{k} \longrightarrow R i_{*} i^{-1} \mathcal{S}_{k}=R i_{*} \mathcal{S}_{k-1}$.

We have a natural morphism $g: A^{\bullet} \longrightarrow C^{\bullet}$ given by the chain of morphisms

$$
\left(R f_{*} \mathbb{Q}_{Y}\right)_{k} \longrightarrow R i_{*} i^{-1}\left(R f_{*} \mathbb{Q}_{Y}\right)_{k}=R i_{*}\left(R f_{*} \mathbb{Q}_{Y}\right)_{k-1} \xrightarrow{R i_{*} \lambda_{k-1}} R i_{*} \mathcal{S}_{k-1}
$$

We now check the hypotheses of Lemma 4.

- The complex $\left(R f_{*} \mathbb{Q}_{Y}\right)_{k}$ is concentrated in degrees at most $k$. Indeed, the fibers of $f$ over $U_{k}$ have real dimension at most $k$, and for every element $x$ of $Z$, $\left(R f_{*} \mathbb{Q}_{Y}\right)_{x}=R \Gamma\left(f^{-1}(x), \mathbb{Q}\right)$ by proper base change [5, Th. 2.3.26].
- Let $S$ be a stratum of codimension $k$ in $Z$ and $Z_{\nu}$ be a relevant stratum such that $d_{\nu} \leq k-1$. Then $S \neq Z_{\nu}$ and we have either $S \nsubseteq Z_{\nu}$ or $S \cap Z_{\nu}=\emptyset$ (which is irrelevant to the question). Let $j_{S}: S \longrightarrow Z$ be the injection of the stratum $S$ in $Z$ and $j_{S, \nu}: S \longrightarrow \bar{Z}_{\nu}$ be the injection of $S$ in $\bar{Z}_{\nu}$. Using the cartesian diagram

we obtain that $j_{S}^{!} j_{\nu *} I C_{\bar{Z}_{\nu}}\left(\mathcal{L}_{\nu}\right)\left[-d_{\nu}\right]=j_{S, \nu}^{!} I C_{\bar{Z}_{\nu}}\left(\mathcal{L}_{\nu}\right)\left[-d_{\nu}\right]$. The cohomology sheaf $\mathcal{H}^{q}\left(j_{S, \nu}^{!} I C_{\bar{Z}_{\nu}}\left(\mathcal{L}_{\nu}\right)\left[-d_{\nu}\right]\right)$ vanishes if $q-d_{\nu} \leq \operatorname{codim}_{\bar{Z}_{\nu}} S=k-d_{\nu}$, i.e. if $q \leq k$. Thus $\mathcal{H}^{q}\left(j_{S}^{!} \mathcal{S}\right)=0$ for $q \leq k$. Let us now write the adjunction triangle

$$
j_{S *} j_{S}^{!} \mathcal{S}_{k} \longrightarrow \mathcal{S}_{k} \xrightarrow{f} R i_{S *} i_{S}^{-1} \mathcal{S}_{k} \xrightarrow[+1]{ }
$$

The previous result proves that $f$ is a quasi-isomorphism in degrees at most $k-1$ on $S$, and then on $U_{k}$. In degree $k$, since $\mathcal{H}^{k}\left(j_{S *} j_{S}^{!} \mathcal{S}_{k}\right)=0$, the induced map $\mathcal{H}^{k}(f)$ is injective. We can also remark that $\mathcal{H}^{k}\left(\mathcal{S}_{k}\right)$ vanishes. Indeed, on $U_{k} \cap \bar{Z}_{\nu}$, all strata have codimension at most $k-d_{\nu}$, so that $\mathcal{H}^{j}\left(I C_{\bar{Z}_{\nu}}\left(\mathcal{L}_{\nu}\right)_{\mid U_{k} \cap \bar{Z}_{\nu}}\right)$ vanishes if $j \geq k-d_{\nu}$.

- Let us prove that $g$ can be lifted to a morphism $\widetilde{\lambda}_{k}: A^{\bullet} \longrightarrow B^{\bullet}$. Since $\mathcal{H}^{k}\left(B^{\bullet}\right)$ vanishes, the condition (ii) of Lemma 4 means that the map $\mathcal{H}^{k}(g)$ is identically zero. We will prove a slightly stronger result, namely that the map $\theta:\left(R^{k} f_{*} \mathbb{Q}_{Y}\right)_{k} \longrightarrow R^{k} i_{*}\left(R f_{*} \mathbb{Q}_{Y}\right)_{k-1}$ vanishes. Let $F_{k}=U_{k} \backslash U_{k-1}$ be the closed set consisting of all $k$-codimensional strata in $Z$ and let $j: F_{k} \longrightarrow U_{k}$ be the inclusion. The vanishing of $\theta$ is equivalent to the surjectivity of the map $\psi: \mathcal{H}^{k}\left(j_{*} j^{!} R f_{*} \mathbb{Q}_{Y}\right) \longrightarrow \mathcal{H}^{k}\left(R f_{*} \mathbb{Q}_{Y}\right)_{k}$. Let $Z_{\nu}$ be a stratum in $F_{k}$. We consider the following cartesian diagram:

If $D$ is the Verdier duality functor, since $Y$ (resp. $Z_{\nu}$ ) is rationally smooth (resp. smooth), we get:

$$
\begin{aligned}
j_{\nu}^{!} R f_{*} \mathbb{Q}_{Y} & =R f_{\nu *} i_{\nu}^{!} \mathbb{Q}_{Y}=R f_{\nu *} i_{\nu}^{!} \omega_{Y}[-2 \operatorname{dim} Y] \\
& =R f_{\nu *} \omega_{Y_{\nu}}[-2 \operatorname{dim} Y]=D\left(R f_{\nu *} \mathbb{Q}_{Y_{\nu}}\right)[-2 \operatorname{dim} Y] \\
& =\mathcal{R H o m} \mathbb{Q}_{Z_{\nu}}\left(R f_{\nu *} \mathbb{Q}_{Y_{\nu}}, \mathbb{Q}_{Z_{\nu}}\right)\left[2 \operatorname{dim} Z_{\nu}-2 \operatorname{dim} Y\right] .
\end{aligned}
$$

Now we have $\mathcal{H}^{k}\left(j_{\nu}^{!} R f_{*} \mathbb{Q}_{Y}\right)=\mathcal{H o m}_{\mathbb{Q}^{( }}\left(R^{2 \operatorname{dim} Y-2 \operatorname{dim} Z_{\nu}-k} f_{\nu *} \mathbb{Q}_{Y_{\nu}}, \mathbb{Q}_{Z_{\nu}}\right)$ and
since $k=\operatorname{dim} Z-\operatorname{dim} Z_{\nu}$, we obtain $Z_{Z_{\nu}}$

$$
\mathcal{H}^{k}\left(j_{\nu}^{!} R f_{*} \mathbb{Q}_{Y}\right)=\mathcal{H o m}_{\mathbb{Q}_{Z_{\nu}}}\left(R^{k} f_{\nu *} \mathbb{Q}_{Y_{\nu}}, \mathbb{Q}_{Z_{\nu}}\right)= \begin{cases}\mathcal{L}_{\nu}^{*} & \text { if } Z_{\nu} \text { is relevant } \\ 0 & \text { otherwise }\end{cases}
$$

Remark that the fibers of $f_{\nu}$ are complex projective varieties, so that $\mathcal{L}_{\nu} \simeq \mathcal{L}_{\nu}^{*}$. Thus

$$
\mathcal{H}^{k}\left(j_{*} j^{!} R f_{*} \mathbb{Q}_{Y}\right) \simeq \bigoplus_{\substack{\nu \text { relevant } \\ \operatorname{codim}\left(Z_{\nu}\right)=k}} j_{\nu *} \mathcal{L}_{\nu}
$$

This isomorphism can be interpreted in the following way: if we consider the canonical morphism from $\left(R f_{*} \mathbb{Q}_{Y}\right)_{k}$ to $\left(R^{k} f_{*} \mathbb{Q}_{Y}\right)_{k}[-k]$, then the associated morphism from $\mathcal{H}_{F_{k}}^{k}\left(R f_{*} \mathbb{Q}_{Y}\right)_{k}$ to $\mathcal{H}_{F_{k}}^{k}\left(R^{k} f_{*} \mathbb{Q}_{Y}[-k]\right)_{k}$ is a quasi-isomorphism.

Therefore, in the following diagram

the map $\psi$ is an isomorphism; in particular $\psi$ is surjective. This implies that $\theta$ vanishes.

The hypotheses of lemma 4 being fulfilled, there exists a canonical morphism $\widetilde{\lambda}_{k}:\left(R f_{*} \mathbb{Q}_{Y}\right)_{k} \longrightarrow \mathcal{S}_{k}$ such that the diagram

commutes. We look now at the following morphism of distinguished triangles

where $c_{\nu}=\operatorname{codim}_{Z}\left(Z_{\nu}\right)$.

- Since $j_{\nu}^{!}\left(R f_{*} \mathbb{Q}_{Y}\right)_{k} \simeq \mathcal{R} \mathcal{H} \operatorname{Hom}_{\mathbb{Q}_{Z_{\nu}}}\left(R f_{*} \mathbb{Q}_{Y_{\nu}}, \mathbb{Q}_{Z_{\nu}}\right)[-2 k], j_{\nu}^{!}\left(R f_{*} \mathbb{Q}_{Y}\right)_{k}$ is concentrated in degrees at least $2 k-d_{\nu}$. Besides, $d_{\nu} \leq c_{\nu}=k$. Thus, the complex $j_{\nu}^{!}\left(R f_{*} \mathbb{Q}_{Y}\right)_{k}$ is concentrated in degrees at least $k$.
- The complex $j_{\nu}^{!} \mathcal{S}_{k}$ is concentrated in degrees at least $k+1$. This shows that $\widetilde{\lambda}_{k}$ is a quasi-isomorphism in degrees at most $k-2$.

If we denote by $A \longrightarrow B \longrightarrow C \xrightarrow{+1}$ and $A^{\prime} \longrightarrow B^{\prime} \longrightarrow C^{\prime} \xrightarrow{+1}$ the two distinguished triangles corresponding to the two lines of the previous diagram, we write down the long cohomology exact sequences and we get another diagram:

We have seen that the map $\mathcal{H}^{k}(A) \longrightarrow \mathcal{H}^{k}(B)$ is a quasi-isomorphism. This implies that $\mathcal{H}^{k-1}(B)$ and $\mathcal{H}^{k-1}(C)$ are isomorphic and proves that $\widehat{\lambda}_{k}$ is a quasiisomorphism in degree $k-1$.

If $\mu_{k}$ denotes the natural morphism from $\left(R f_{*} \mathbb{Q}_{Y}\right)_{k}$ to $\left(R^{k} f_{*} \mathbb{Q}_{Y}\right)_{k}[-k]$, let us define $\lambda_{k}=\left(\widetilde{\lambda}_{k}, \mu_{k}\right)$. Since $\left(R^{k} f_{*} \mathbb{Q}_{Y}\right)_{k}[-k]=\underset{\substack{\text { relevant } \\ d_{\nu}=k}}{ } j_{\nu *} \mathcal{L}_{\nu}[-k], \lambda_{k}$ is a morphism from $\left(R f_{*} \mathbb{Q}_{Y}\right)_{k}$ to $\underset{\substack{\nu \text { relevant } \\ d_{\nu} \leq k}}{ } j_{\nu *} \mathcal{L}_{\nu}[-k]$ which is a quasi-isomorphism in degrees at most $k-1$ and also in degree $k$. It is zero in degrees at least $k$. Therefore $\lambda_{k}$ is a quasi isomorphism and the induction step is completed. This finishes the proof of the decomposition theorem.
