Abstract. We study here the propagation of long waves in the presence of vorticity. In the irrotational framework, the Green-Naghdi equations (also called Serre or fully nonlinear Boussinesq equations) are the standard model for the propagation of such waves. These equations couple the surface elevation to the vertically averaged horizontal velocity and are therefore independent of the vertical variable. In the presence of vorticity, the dependence on the vertical variable cannot be removed from the vorticity equation but it was however shown in [9] that the motion of the waves could be described using an extended Green-Naghdi system. In this paper we propose an analysis of these equations, and show that they can be used to get some new insight into wave-current interactions. We show in particular that solitary waves may have a drastically different behavior in the presence of vorticity and show the existence of solitary waves of maximal amplitude with a peak at their crest, whose angle depends on the vorticity. We also propose a robust and simple numerical scheme validated on several examples. Finally, we give some examples of wave-current interactions with a non trivial vorticity field and topography effects.

Keywords. Water waves, shallow water, Green-Naghdi, Boussinesq, nonlinear dispersive equations, vorticity, solitary waves, Finite-Volume discretization.

1. Introduction

1.1. General setting

Several models have been derived for the description of nearshore dynamics. One of the most widely spread is certainly the Nonlinear Shallow Water (NSW) model which is a nonlinear hyperbolic system coupling the time evolution of the surface elevation ζ to the vertically averaged horizontal component of the velocity \bar{v} . This system is derived from the free surface Euler equations by averaging in the vertical direction and neglecting all the terms of order $O(\mu)$, where the *shallowness parameter* μ is defined as

$$\mu = \frac{H_0^2}{L^2} = \frac{(\text{typical depth})^2}{(\text{horizontal length scale})^2}.$$

The NSW equations are however not fully satisfactory since they neglect all the dispersive effects that play a very important role in many situations, and in particular during the shoaling phase. These dispersive terms are of order $O(\mu)$ and are therefore neglected by the NSW equations. Keeping them in the equations, and neglecting only the $O(\mu^2)$ terms, one obtains a more accurate – but mathematically and numerically more complicated – set of equations known as the Serre [45, 52], or Green-Naghdi [21, 27], or fully nonlinear Boussinesq [55] equations. We shall refer to these models here

FIGURE 1. Main notations.

as the Green-Naghdi (GN) equations. Contrary to the weakly nonlinear Boussinesq models that go back to Boussinesq himself, no smallness assumption is made on the size of the surface perturbations. We refer to [30] for a rigorous derivation and a mathematical justification (in the sense that their solutions remain close to the exact solution of the free surface Euler equations) of all these models. If the numerical approximation of various Boussinesq-type equations has attracted a lot of attention for the last 20 years (see for instance among the recent studies [6, 17, 18, 23, 25, 38, 44, 49, 51]), it is mostly recently that discrete formulations for the GN equations have been proposed. Denoting by d the horizontal dimension, we can refer for instance, in the case $d = 1$, to [4, 5, 10] for hybrid Finite-Volume (FV) and Finite-Difference (FD) discretizations, [16, 33, 40] for discontinuous-Galerkin (dG) formulations, [13] for a compact FV approach, [35] for a Finite-Element (FE) approach on flat bottom or [39] for an hybrid FV-FE formulation. There is even less studies in the case $d = 2$, see [31, 32, 48]. These equations have also been adapted to handle wave breaking by adding an artificial viscous term to the momentum equation (see for instance [11, 14, 26, 46]) or by locally switching to the NSW equations in the vicinity of broken waves and using shock capturing schemes [24, 53, 54]. We refer to [4] for a recent review on these aspects.

The Green-Naghdi and more generally most of the Boussinesq-type models rely on the assumption that the flow is irrotational or almost irrotational. Such an assumption is satisfied in most configurations but may fail in the surf zone where wave breaking can create vorticity currents (rip currents) or in presence of some underlying current. The difficulty to describe wave motion in the presence of vorticity is that the dynamics of the flow is in general genuinely $(d + 1)$ -dimensional while in the irrotational framework the dynamics is only d -dimensional (vertical averaging has been used to remove the vertical variable).

It is shown in [12] that the GN equations can describe rotational flows with purely vertical vorticity. In horizontal dimension $d = 1$, it is shown in [36] that vorticity is responsible for the presence of an additional term in the momentum equation, which is coupled to the standard vorticity equation (see also [29, 28] for a related approach).

Following the original approach by Green and Naghdi [21], several authors [19, 50, 60] assumed a polynomial structure of the velocity profile and solved the mass and momentum equations projected on such a basis of functions. This approach is compatible with the presence of vorticity. An interesting and recent refinement for a better treatment of the surf zone consists in coupling this approach with shallow water asymptotics [58].

We follow in this paper another approach initially developed in [9] where it is shown that additional terms are necessary in the momentum equation in the presence of vorticity. Contrary to other approaches, these additional terms are determined through the resolution of d -dimensional evolution

equations and do not require the resolution of the $(d + 1)$ -dimensional vorticity equation. The procedure is reminiscent of turbulence theory with the difference that no artificial closure is needed here: based on the controls on the solutions of the full Euler equations established in [8], one can show that the cascade of equations is finite at the precision of the model (we also point out the related work [43] where a physical modeling of the closure is used instead to handle turbulent bores). The resulting equations are an extended GN system with additional advection-like equations for the vorticity related terms.

This paper is concerned with the horizontal one dimensional case $d = 1$. Its first goal is to show that this approach can be used to get some new insight into wave-current interactions; we show for instance that the behavior of solitary waves can be drastically different in the presence of vorticity, leading to extremal peaked solitary waves with an angle at the crest that depends on the vorticity. The second goal of this paper is to propose a simple and robust numerical scheme to numerically solve these extended GN equations and to highlight that despite the fact that these equations of motion are purely d -dimensional, they can be used to reconstruct the internal velocity field, even in the presence of non trivial vorticity and topography.

1.2. The models

In the case where the horizontal dimension d is equal to one and following [5], the irrotational GN equations can be formulated as

$$\begin{cases} \partial_t h + \partial_x \cdot (h\bar{v}) = 0, \\ (I + \mathbb{T})[\partial_t(h\bar{v}) + \partial_x(h\bar{v}^2)] + gh\partial_x\zeta + h\mathcal{Q}_1(\bar{v}) = 0, \end{cases} \quad (1.1)$$

where we recall that ζ is the elevation of the wave with respect to the rest level and that \bar{v} is the vertically averaged horizontal velocity, while g stands for the acceleration of gravity and h is the total water height

$$h = H_0 + \zeta - b,$$

where $\{z = H_0 - b(x)\}$ is a parametrization of the bottom (see Figure 1). Finally, the linear operator $\mathbb{T} = \mathbb{T}[h, b]$ and the quadratic form $\mathcal{Q}_1(\cdot) = \mathcal{Q}_1[h, b](\cdot)$ are defined by

$$\mathbb{T}[h, b]W = h\mathcal{T}[h, b]\left(\frac{1}{h}W\right) \quad (1.2)$$

$$\mathcal{T}[h, b]W = \mathcal{R}_1[h, b](\partial_x W) + \mathcal{R}_2[h, b](\partial_x b)W \quad (1.3)$$

$$\mathcal{Q}_1[h, b](V) = -2\mathcal{R}_1[h, b](\partial_x \bar{v})^2 + \mathcal{R}_2[h, b](V^2 \partial_x^2 b). \quad (1.4)$$

with,

$$\mathcal{R}_1[h, b]w = -\frac{1}{3h}\partial_x(h^3w) - \frac{h}{2}w\partial_x b, \quad (1.5)$$

$$\mathcal{R}_2[h, b]w = \frac{1}{2h}\partial_x(h^2w) + w\partial_x b. \quad (1.6)$$

This formulation does not require the computation of any third-order derivative, allowing for more robust numerical computations, especially when the waves become steeper. Note also that if one removes the operator \mathbb{T} and the nonlinearity \mathcal{Q}_1 from the second equation in (1.1), the model reduces to the standard NSW equations; these two terms accounts therefore for the $O(\mu)$ dispersive and nonlinear terms specific to the GN equations.

One of the main features of the Green-Naghdi model is that it allows the description of $d + 1$ dimensional waves (d being the horizontal dimension) by a set of d -dimensional equations (independent on the vertical variable z), hereby leading to considerable gains in mathematical simplicity and computational time. The d -dimensional nature of the flow is due to the fact that the flow is assumed to

be *irrotational*; indeed, the velocity field \mathbf{U} in the fluid domain then derives from a scalar velocity potential Φ (i.e. $\mathbf{U} = \nabla_{X,z}\Phi$) and as remarked by Zakharov [57] and Craig-Sulem [15] the free surface $d+1$ -dimensional Euler equations can then be reduced to an Hamiltonian system coupling the surface elevation ζ to ψ , the trace at the surface of the velocity potential. Both ζ and ψ depend only on time and on the (d -dimensional) horizontal variable X . The Green-Naghdi equation being obtained by an asymptotic expansion in terms of the shallowness parameter μ of the free surface Euler equations (see [1, 30] for a full mathematical justification of this approximation), it is no surprise that they are also d dimensional.

In presence of vorticity, the situation is drastically different since the dynamics of the vorticity $\omega = \text{curl } \mathbf{U}$ is in general fully $(d+1)$ -dimensional. The Zakharov-Craig-Sulem formulation has recently been generalized in [8] to the rotational case; this generalization, also formally hamiltonian, couples the evolution of ζ and ψ as in the irrotational case¹, but this evolution is now also coupled to the evolution of the vorticity field which depends in general on all the space variables. One should therefore expect that generalizations of the Green-Naghdi equations in presence of vorticity have a full $(d+1)$ -dimensional dependence in the space variables, hereby implying a considerable increase of computational time. It has been shown recently in [9] that this is not the case. In the case of a constant vorticity, that is, when

$$\text{curl } \mathbf{U} = (0, \omega, 0)^T \quad \text{with} \quad \omega(t, x, z) = \omega_0 = \text{cst},$$

this is not surprising because there is no z dependence coming from the equation on the vorticity. The vorticity field however induces a shear which, together with the dispersive effects, make the horizontal velocity depart from its vertical average. Because of this effect, the Green-Naghdi equations (1.1) must be replaced by

$$\begin{cases} \partial_t h + \partial_x(h\bar{v}) = 0, \\ (1 + \mathbb{T})[\partial_t(h\bar{v}) + \partial_x(h\bar{v}^2)] + gh\partial_x\zeta + h\mathcal{Q}_1(\bar{v}) \\ \quad + \partial_x(\frac{1}{12}h^3\omega_0^2) + h\mathcal{C}(\omega_0h, \bar{v}) + h\mathcal{C}_b(\omega_0h, \bar{v}) = 0. \end{cases} \quad (1.7)$$

with $\mathcal{C}(\omega_0h, \bar{v})$ and $\mathcal{C}_b(\omega_0h, \bar{v})$ are obtained by taking $v^\sharp = \omega_0h$ in the following expressions

$$\mathcal{C}(v^\sharp, \bar{v}) = -\frac{1}{6h}\partial_x\left(2h^3v^\sharp\partial_x^2\bar{v} + \partial_x(h^3v^\sharp)\partial_x\bar{v}\right), \quad (1.8)$$

$$\mathcal{C}_b(v^\sharp, \bar{v}) = \frac{1}{3h}\left(\partial_x(h^2v^\sharp\partial_x^2b\bar{v}) + h^2v^\sharp\partial_x^2b\partial_x\bar{v}\right). \quad (1.9)$$

$$(1.10)$$

For the case of a general vorticity, that is, when (in horizontal dimension $d=1$),

$$\text{curl } \mathbf{U} = (0, \omega, 0)^T \quad \text{with} \quad \omega(t, x, z) = \partial_z u - \partial_x w$$

(and $\mathbf{U} = (u, 0, w)^T$), the vorticity ω satisfies the transport equation

$$\partial_t\omega + (u\partial_x + w\partial_z)\omega = 0, \quad (1.11)$$

in which the z dependence cannot be removed. The fact that one can however derive z -independent Green-Naghdi type models in this framework is therefore more surprising. Making for the sake of simplicity a rather weak smallness assumption on the size of the bottom variations², the one-dimensional

¹Note however that in presence of vorticity, the velocity field \mathbf{U} does not derive from a scalar potential, and that an alternative definition is needed for ψ . Namely, it is defined such that $\nabla\psi$ is the projection onto (horizontal) gradient vector field of the horizontal component of the tangential velocity at the surface.

²It is assumed that $\varepsilon\beta\mu^{3/2} = O(\mu^2)$, where

$$\varepsilon = \frac{a_{\text{surf}}}{H_0} = \frac{\text{Amplitude of the waves}}{\text{typical depth}}, \quad \beta = \frac{a_{\text{bott}}}{H_0} = \frac{\text{Amplitude of the bottom variations}}{\text{typical depth}}.$$

GN system in the presence of a general vorticity is given by

$$\begin{cases} \partial_t h + \partial_x(h\bar{v}) = 0, \\ (1 + \mathbb{T})[\partial_t(h\bar{v}) + \partial_x(h\bar{v}^2)] + gh\partial_x\zeta + h\mathcal{Q}_1(\bar{v}) + \partial_x E + h\mathcal{C}(\bar{v}, v^\sharp) = 0, \\ \partial_t v^\sharp + \bar{v}\partial_x v^\sharp + v^\sharp\partial_x \bar{v} = 0, \\ \partial_t E + \bar{v}\partial_x E + 3E\partial_x \bar{v} + \partial_x F = 0, \\ \partial_t F + \bar{v}\partial_x F + 4F\partial_x \bar{v} = 0. \end{cases} \quad (1.12)$$

Let us briefly comment on this model. In these equations, the term $h\mathcal{C}(\bar{v}, v^\sharp)$ describes the interaction of the dispersive terms with the vorticity induced shear and is given by (1.8). The difference with the case of a constant vorticity is that v^\sharp is now defined as a second order momentum of the vorticity induced shear velocity,

$$v^\sharp = \frac{12}{h^3} \int_{-H_0+b}^{\zeta} (z + H_0 - b)^2 v_{\text{sh}}^* \quad \text{with} \quad v_{\text{sh}}^* = - \int_z^{\zeta} \omega + \frac{1}{h} \int_{-H_0+b}^{\zeta} \omega. \quad (1.13)$$

Even though v^\sharp is defined in terms of ω , it is not necessary to solve the (1 + 1)-dimensional vorticity equation (1.11) to compute it; indeed, it is shown in [9] that it can be determined from its initial value by solving the third equation of (1.12).

Similarly, the term $\partial_x(\frac{1}{12}h^3\omega_0^2)$ that appears in (1.7) is now replaced by $\partial_x E$, where E is a second order tensor describing the self quadratic interaction of the vorticity induced shear,

$$E = \int_{-H_0+b}^{\zeta} (v_{\text{sh}}^*)^2. \quad (1.14)$$

Here again, one wants to be able to compute E without appealing to the vorticity equation (1.11). The strategy adopted in [9] is inspired by an analogy with turbulence theory and recent works on roll waves and hydraulic jumps [41, 42]. The tensor E is viewed as a ‘‘Reynolds’’ tensor where the ‘‘averaging’’ is in the present case the vertical integration. Looking for an equation on E one obtains a cascade of equations involving tensors of increasing order; but unlike turbulence theory, there is no need for an artificial closure of the cascade. Indeed it can be proved that the contribution of the fourth order and higher tensors are below the overall $O(\mu^2)$ precision of the model and can therefore be neglected. The last two equations in (1.12) furnish this finite cascade of equations on the second order tensor E and the third order tensor F defined as

$$F = \int_{-H_0+b}^{\zeta} (v_{\text{sh}}^*)^3. \quad (1.15)$$

The generalization of (1.12) to two-dimensional surfaces is also given in [9] but our focus is here on the analysis of some properties of (1.12) as well as the development of a numerical code to compute its solutions.

Remark 1.1. As explained above, the model (1.12) is precise up to $O(\mu^2)$ terms; lowering the precision to $O(\mu^{3/2})$, one can work with the simpler model

$$\begin{cases} \partial_t h + \partial_x(h\bar{v}) = 0, \\ (1 + \mathbb{T})[\partial_t(h\bar{v}) + \partial_x(h\bar{v}^2)] + gh\partial_x\zeta + h\mathcal{Q}_1(\bar{v}) + \partial_x E = 0, \\ \partial_t E + \bar{v}\partial_x E + 3E\partial_x \bar{v} = 0. \end{cases} \quad (1.16)$$

Remark 1.2. Keeping the precision $O(\mu^2)$, a simplified model can also be obtained in the situation where F is initially almost equal to zero (this is the case when the vorticity is constant or in the

Under this assumption, the term $C_b(\omega_0 h, \bar{v})$ could be neglected in (1.7), see [9].

situation considered in §5.5 for instance). Removing F from (1.12) one then obtains the reduced model

$$\begin{cases} \partial_t h + \partial_x(h\bar{v}) = 0, \\ (1 + \mathbb{T})[\partial_t(h\bar{v}) + \partial_x(h\bar{v}^2)] + gh\partial_x\zeta + h\mathcal{Q}_1(\bar{v}) + \partial_x E + h\mathcal{C}(\bar{v}, v^\sharp) = 0, \\ \partial_t v^\sharp + \bar{v}\partial_x v^\sharp + v^\sharp\partial_x \bar{v} = 0, \\ \partial_t E + \bar{v}\partial_x E + 3E\partial_x \bar{v} = 0. \end{cases} \quad (1.17)$$

1.3. Organization of the paper

In Section 2, we study the existence of solitary waves for the GN system with vorticity (1.12). We show in §2.1 that the existence of smooth solitary waves can be reformulated as an ODE problem. The existence of solutions is then established in §2.2 where we also comment on the qualitative differences with the irrotational case. For instance, while there are solitary waves of arbitrary amplitude for the standard GN equations, there are configurations with non trivial vorticities for which solitary waves cannot exceed a critical amplitude. Solitary waves of critical amplitude are then studied in §2.3 where we show that these extremal solitary waves have a peak at their crest, whose angle depends on the vorticity.

We then present in Section 3 the numerical scheme we propose to solve (1.12). After a simple renormalisation of the system using the mass conservation equation, we present in §3.1 a simple splitting scheme inspired by previous works on the standard GN equations. This splitting involves a conservative propagation step and a dispersive correction step. The conservative step is studied in §3.2; as in the irrotational case, it is of hyperbolic type but because of the extra unknowns due to the vorticity, its structure is more complicated. In particular, there are now three wave speeds (instead of two in the irrotational case). A corresponding finite volume scheme is proposed, for which robustness is proved and higher order extensions constructed. The study of the dispersive step being similar to the irrotational case, we just briefly recall the main points in §3.3.

Section 4 is then devoted to the numerical validation of this scheme. The different kinds of smooth solitary waves predicted in Section 2 are numerically observed in §4.1 and used to evaluate the convergence rate. We also observe numerically in §4.2 the existence of the extremal peaked solitary waves exhibited in §2.3. We provide in §4.3 a numerical simulation involving a non-flat topography; we use this example to show that the vorticity may play a considerable role on the shoaling of waves.

Finally, we detail in Section 5 how the system of equations (1.12) can be used to describe the dynamics of the $(d + 1)$ velocity field $\mathbf{U} = (u, w)^T$ at any time, up to a $O(\mu^{\frac{3}{2}})$ accuracy, and show how the previous discrete formulation of Section 3 may be simply modified to numerically perform the corresponding velocity reconstructions. This process is illustrated by two prospective examples of wave-current interactions, involving a non trivial vorticity field and topography effects.

2. Solitary waves

We investigate here the existence of solitary waves for the Green-Naghdi equations with vorticity (1.12). We show in §2.1 that smooth solitary waves must satisfy a second order ODE. This ODE is solved in §2.1, while extremal peaked solutions are studied in §2.3.

2.1. Derivation of the ODE for the shape of the solitary waves

Our purpose here is to show that smooth solitary waves, if they exist, must satisfy a second order ODE. We consider here flat bottoms (i.e. $b = 0$), and the system (1.12) can therefore be written

$$\begin{cases} \zeta_t + (h\bar{v})_x = 0, \\ \bar{v}_t + g\partial_x\zeta + \bar{v}\partial_x\bar{v} + \frac{1}{h}E_x - \frac{1}{6h}[2h^3v^\sharp\bar{v}_{xx} + (h^3v^\sharp)_x\bar{v}_x]_x = \frac{1}{3}\frac{1}{h}[h^3(\bar{v}_{xt} + \bar{v}\bar{v}_{xx} - \bar{v}_x^2)]_x \\ v_t^\sharp + (\bar{v}v^\sharp)_x = 0, \\ \left(\frac{E}{h^3}\right)_t + \bar{v}\left(\frac{E}{h^3}\right)_x + \frac{1}{h^3}F_x = 0, \\ \left(\frac{F}{h^4}\right)_t + \bar{v}\left(\frac{F}{h^4}\right)_x = 0, \end{cases} \quad (2.1)$$

with $h = H_0 + \zeta$. We look for solitary waves solutions to (2.1), i.e. solutions of the form

$$(\zeta, \bar{v}, v^\sharp, E, F)(t, x) = (\underline{\zeta}, \underline{\bar{v}}, \underline{v}^\sharp, \underline{E}, \underline{F})(x - ct),$$

for some constant $c \in \mathbb{R}$, and with $\underline{\zeta}$ and \underline{v} vanishing at infinity, over a current that might not vanish at infinity, that is, we assume that

$$\lim_{\pm\infty}(\underline{\zeta}, \underline{v}) = 0 \quad \text{and} \quad \lim_{\pm\infty}(\underline{v}^\sharp, \underline{E}, \underline{F}) = (v_\infty^\sharp, E_\infty, F_\infty)$$

for some constants $E_\infty, F_\infty, v_\infty^\sharp$. Such solutions should satisfy (for the sake of clarity, we do not underline the functions in the expressions below)

$$\begin{cases} [-(c - \bar{v})h]_x = 0, \\ -(c - \bar{v})\bar{v}_x + g\partial_x\zeta + \frac{1}{h}E_x - \frac{1}{6h}[2h^3v^\sharp\bar{v}_{xx} + (h^3v^\sharp)_x\bar{v}_x]_x = -\frac{1}{3}\frac{1}{h}[h^3((c - \bar{v})\bar{v}_{xx} + \bar{v}_x^2)]_x \\ [(c - \bar{v})v^\sharp]_x = 0, \\ -(c - \bar{v})\left(\frac{E}{h^3}\right)_x + \frac{1}{h^3}F_x = 0, \\ (c - \bar{v})\left(\frac{F}{h^4}\right)_x = 0. \end{cases} \quad (2.2)$$

Integrating the first equation, and using the fact that ζ and \bar{v} vanish at infinity, one readily deduces

$$(c - \bar{v})h = cH_0. \quad (2.3)$$

Multiplying the second equation by h and integrating in x , we therefore get

$$-cH_0\bar{v} + \frac{g}{2}(h^2 - H_0^2) + (E - E_\infty) - \frac{1}{6}(2h^3v^\sharp\bar{v}_{xx} + (h^3v^\sharp)_x\bar{v}_x) = -\frac{1}{3}(h^2cH_0\bar{v}_{xx} + h^3\bar{v}_x^2), \quad (2.4)$$

and we need to determine v^\sharp and E . Let us proceed first with v^\sharp . From the third equation in (2.2), we have

$$(c - \bar{v})v^\sharp = cv_\infty^\sharp,$$

which, together with (2.3), yields

$$v^\sharp = \frac{h}{H_0}v_\infty^\sharp. \quad (2.5)$$

We now turn to derive an expression for E . From the last equation, we get that

$$F = \frac{h^4}{H_0^4}F_\infty. \quad (2.6)$$

Together with (2.3), this allows one to rewrite the fourth equation as

$$-cH_0\left(\frac{E}{h^3}\right)_x + 4\frac{F_\infty}{H_0^4}hh_x = 0,$$

and therefore

$$E = E_\infty + \left(\frac{h^3}{H_0^3} - 1\right)E_\infty + 2\frac{F_\infty}{c} \frac{(h^2 - H_0^2)h^3}{H_0^5}. \quad (2.7)$$

Plugging (2.5) and (2.7) into (2.4) we obtain

$$-cH_0\bar{v} + \frac{g}{2}(h^2 - H_0^2) + \left(\frac{h^3}{H_0^3} - 1\right)E_\infty + 2\frac{F_\infty}{c} \frac{(h^2 - H_0^2)h^3}{H_0^5} - \frac{h^2}{3H_0}v_\infty^\sharp[h^2\bar{v}_x]_x = -\frac{1}{3}(h^2cH_0\bar{v}_{xx} + h^3\bar{v}_x^2).$$

Since (2.3) implies that $h^2v_x = cH_0h_x$ and $v = c\frac{h-H_0}{h}$, we deduce further that

$$-c^2H_0\frac{h-H_0}{h} + \frac{g}{2}(h^2 - H_0^2) + \left(\frac{h^3}{H_0^3} - 1\right)E_\infty + 2\frac{F_\infty}{c} \frac{(h^2 - H_0^2)h^3}{H_0^5} - \frac{1}{3}cv_\infty^\sharp h^2h_{xx} = -\frac{c^2}{3}H_0^2h\left[\frac{1}{h}h_x\right]_x.$$

This leads us to the following definition of a (smooth) solitary wave.

Definition 2.1. A solitary wave of speed c for (2.1) is a mapping

$$(t, x) \in \mathbb{R}^2 \mapsto (\underline{\zeta}, \underline{v}, \underline{v}^\sharp, \underline{E}, \underline{F})(x - ct)$$

such that there exists $h \in C^2(\mathbb{R})$ and $E_\infty > 0$, $v_\infty^\sharp \in \mathbb{R}$ and $F_\infty \in \mathbb{R}$ such that

$$\underline{\zeta} = h - H_0, \quad \underline{v} = c\frac{h - H_0}{h}, \quad \underline{v}^\sharp = \frac{h}{H_0}v_\infty^\sharp, \quad \underline{E} = \frac{h^3}{H_0^3}E_\infty + 2\frac{F_\infty}{c} \frac{(h^2 - H_0^2)h^3}{H_0^5}, \quad \underline{F} = \frac{h^4}{H_0^4}F_\infty$$

and h solves the ODE

$$\frac{1}{3}c(cH_0^2 - v_\infty^\sharp h^2)h_{xx} = \frac{h - H_0}{2h}(2c^2H_0 - gh(h + H_0)) - \left(\frac{h^3}{H_0^3} - 1\right)E_\infty - 2\frac{F_\infty}{c} \frac{(h^2 - H_0^2)h^3}{H_0^5} + \frac{c^2}{3}H_0^2\frac{h_x^2}{h} \quad (2.8)$$

on \mathbb{R} and satisfies $\lim_{\pm\infty} h = H_0$. The function h is called the *profile* of the solitary wave.

2.2. Existence of smooth solitary waves

We first consider here the case where $F_\infty = 0$ and prove the existence of solitary waves in the sense of Definition 2.1.

Proposition 2.2. *Let $E_\infty > 0$, $v_\infty^\sharp \in \mathbb{R}$ and $F_\infty = 0$. Let also $h_{\max} > H_0$.*

i. *Up to translations, there can be at most two solitary waves of maximal height h_{\max} for (2.1); if they exist, they have opposite speed $\pm \underline{c}$, with*

$$\underline{c} = \left(gh_{\max} + \frac{h_{\max}(h_{\max} + 2H_0)}{H_0^3}E_\infty\right)^{1/2}.$$

ii. *The solitary wave of speed \underline{c} (resp. $-\underline{c}$) exists if and only if the following condition holds*

$$\underline{c}(\underline{c}H_0^2 - v_\infty^\sharp h_{\max}^2) > 0 \quad (\text{resp. } -\underline{c}(-\underline{c}H_0^2 - v_\infty^\sharp h_{\max}^2) > 0).$$

The profile of the solitary wave then attains its maximal value at a unique point x_{\max} and it is symmetric with respect to the axis $x = x_{\max}$ and decaying on the half-line $x > x_{\max}$.

Proof. Step 1. We derive here an expression for h_x^2 in terms of h . For later investigations, we deal with the general case $F_\infty \in \mathbb{R}$ here. Multiplying the differential equation (2.8) by h_x and dividing by h^2 , we get

$$\begin{aligned} -\frac{c^2}{3}H_0^2\frac{h_x^3}{h^3} + \frac{1}{3}c^2H_0^2\frac{1}{h^2}h_{xx}h_x - \frac{1}{3}cv_\infty^\sharp h_{xx}h_x &= \frac{h - H_0}{2h^3}(2c^2H_0 - gh(h + H_0))h_x \\ &\quad - \left(\frac{h^3}{H_0^3} - 1\right)\frac{h_x}{h^2}E_\infty - 2\frac{F_\infty}{c} \frac{(h^2 - H_0^2)}{H_0^5}hh_x. \end{aligned}$$

After integrating in x , this yields

$$\begin{aligned} \frac{1}{6}c(cH_0^2 - v_\infty^\sharp h^2) \frac{h_x^2}{h^2} &= \frac{c^2}{2} \frac{1}{h^2} (h - H_0)^2 - \frac{1}{2}g \frac{1}{h} (h - H_0)^2 \\ &\quad - \frac{1}{2H_0^3} \frac{1}{h} (h - H_0)^2 (h + 2H_0) E_\infty - \frac{F_\infty}{2c} \frac{(h^2 - H_0^2)^2}{H_0^5} \end{aligned}$$

(the integration constant has been chosen in order to respect the constraint that ζ and its derivatives vanish at infinity), or equivalently

$$\frac{c}{3}(cH_0^2 - v_\infty^\sharp h^2) h_x^2 = (h - H_0)^2 \left(c^2 - gh - \frac{h(h + 2H_0)}{H_0^3} E_\infty - \frac{h^2(h + H_0)^2}{H_0^5} \frac{F_\infty}{c} \right). \quad (2.9)$$

Step 2. Expressions for the velocity and qualitative analysis. By definition, if h is the profile of a solitary wave then it is a C^2 -function and its derivative must vanish at its maximum. The formula (2.9) then provides directly the only two (recall that F_∞ is assumed to be zero here) possible values for the speed c .

Since the function $h \mapsto gh + \frac{h(h+2H_0)}{H_0^3}$ is strictly increasing on \mathbb{R}^+ , we also deduce from (2.9) that h_x cannot vanish at another point, and therefore that the maximum of h is attained at a unique point x_{\max} , and further, that h has to be monotonous on both sides of x_{\max} . The fact that it is decaying on $x > x_{\max}$ follows from the condition that $h \rightarrow H_0 < h_{\max}$ at infinity. Finally, the fact that h is symmetric with respect to x_{\max} follows from the simple observation that if h solves (2.8) for $x \geq x_{\max}$ with boundary conditions $h(x_{\max}) = h_{\max}$ and $h_x(x_{\max}) = 0$ then $x \mapsto h(2x_{\max} - x)$ furnishes a solution for $x \leq x_{\max}$.

Step 3. Existence of a solitary wave of speed $c = \underline{c}$ or $c = -\underline{c}$. If $cH_0^2 - v_\infty^\sharp h_{\max}^2 \neq 0$, then the Cauchy-Lipschitz theorem furnishes a local solution with boundary condition $h(x_{\max}) = h_{\max}$ and $h_x(x_{\max}) = 0$. If moreover $c(cH_0^2 - v_\infty^\sharp h_{\max}^2) > 0$, then it is easy to deduce from (2.8) that this local solution satisfies $h''(x_{\max}) < 0$ and therefore that the solution attains a local maximum at x_{\max} . Proceeding as in Step 2, one gets that this local solution is symmetric with respect to x_{\max} and decaying on $x > x_{\max}$. Moreover, one always has $h > H_0$; indeed, if one had $h(x_0) = H_0$ for some $x_0 \in \mathbb{R}$, then one would have $h_x(x_0) = 0$ by (2.9), and by uniqueness, one would have $h \equiv H_0$, which is absurd. Therefore h decays to some limit as $x \rightarrow \infty$, and this limit is necessarily H_0 by (2.9). The identity (2.9) also shows that h_x remains bounded, so that no blow up of h nor h_x can occur and the solution of the ODE (2.8) is global.

Step 4. Non existence of a solitary wave of speed $c = \underline{c}$ or $c = -\underline{c}$. If $c(cH_0^2 - v_\infty^\sharp h_{\max}^2) < 0$, then it is easy to deduce from (2.9) that no solitary wave can exist. The only case left to investigate is therefore the critical case $cH_0^2 - v_\infty^\sharp h_{\max}^2 = 0$. In this case, one gets from (2.8) that

$$\begin{aligned} \frac{c^2}{3} H_0^2 \frac{h'(x_{\max})}{h(x_{\max})} &= \frac{h_{\max} - H_0}{2h_{\max}} (gh_{\max}(h_{\max} + H_0) - 2c^2 H_0) + \left(\frac{h_{\max}^3}{H_0^3} - 1 \right) E_\infty \\ &> 0 \end{aligned}$$

which contradicts the assumption that h is a C^1 -function attaining its maximum at x_{\max} . \blacksquare

Remark 2.3. If in addition to the assumption $F_\infty = 0$ we take $E_\infty = v_\infty^\sharp = 0$ in the statement of Proposition 2.2, then one has $\underline{v}^\sharp = \underline{E} = \underline{F} = 0$ in Definition 2.1 so that the solitary waves are the same as in the irrotational setting for which it is well known that explicit solitary waves exist. More precisely, for *any* maximal amplitude $h_{\max} > H_0$, there exists two (up to translations) solitary waves

FIGURE 2. Influence of E_∞ on the solitary wave profile for $H_0 = 1\text{ m}$, $h_{\max} = 2\text{ m}$, $v_\infty^\sharp = 0$, $F_\infty = 0$.

of speed $c = \pm\sqrt{gh_{\max}}$ and with the same profile $h_+ = h_-$ given by the resolution of (2.8) and which can in this particular case be computed explicitly,

$$h(x) = H_0 + \varepsilon H_0 \left(\operatorname{sech}\left(\frac{x}{\lambda}\right)\right)^2 \quad \text{with} \quad \lambda = \frac{2}{\sqrt{3}} \sqrt{\frac{1+\varepsilon}{\varepsilon}} H_0,$$

and where we denoted $h_{\max} = H_0(1+\varepsilon)$.

Remark 2.4. If in addition to the assumption $F_\infty = 0$ we take $v_\infty^\sharp = 0$ but consider the case $E_\infty > 0$, the situation is qualitatively the same as in Remark 2.3: for *any* maximal amplitude $h_{\max} = H_0(1+\varepsilon) > H_0$, there exists two solitary waves of same shape and of opposite speed $c = \pm \underline{c}$. The only difference is that the speed \underline{c} is larger than in the irrotational case,

$$\underline{c} = \left(gh_{\max} + \frac{h_{\max}(h_{\max} + 2H_0)}{H_0^3} E_\infty \right)^{1/2}, \quad (2.10)$$

and that the solitary waves becomes narrower as E_∞ increases (this follows easily from the comparison principle for ODEs); see Fig. 2.

Remark 2.5. If we assume that $F_\infty = 0$ but $E_\infty > 0$ and $v_\infty^\sharp > 0$ (the case $v_\infty^\sharp < 0$ can be treated in a similar way) in the statement of Proposition 2.2 then there are two major qualitative changes with respect to the situation considered in Remark 2.4. The first one is that right going solitary waves do not exist for any maximal amplitude $h_{\max} > H_0$. Indeed, the criterion given in the second point of the proposition is always satisfied for the left-going solitary wave, but requires for the right-going one that

$$\underline{c}H_0^2 - v_\infty^\sharp h_{\max}^2 > 0.$$

or equivalently, using the explicit expression of \underline{c} given in Proposition 2.2,

$$\left(gH_0 + (\tilde{h} + 2) \frac{E_\infty}{H_0} \right) > (v_\infty^\sharp)^2 \tilde{h}^3 \quad \text{with} \quad \tilde{h} = \frac{h_{\max}}{H_0}.$$

In the case where $v_\infty^\sharp > 0$, the criterion given in the statement of Proposition 2.2 for the existence of solitary waves can therefore be restated as: left-going solitary waves always exist, but right-going solitary waves exist if and only if $h_{\max} < h_{\text{crit}}$ where the critical height h_{crit} is given by $h_{\text{crit}} = H_0 \tilde{h}_{\text{crit}}$ with \tilde{h}_{crit} the only positive root of the polynomial

$$P(X) = (v_\infty^\sharp)^2 X^3 - \left(gH_0 + (X + 2) \frac{E_\infty}{H_0} \right).$$

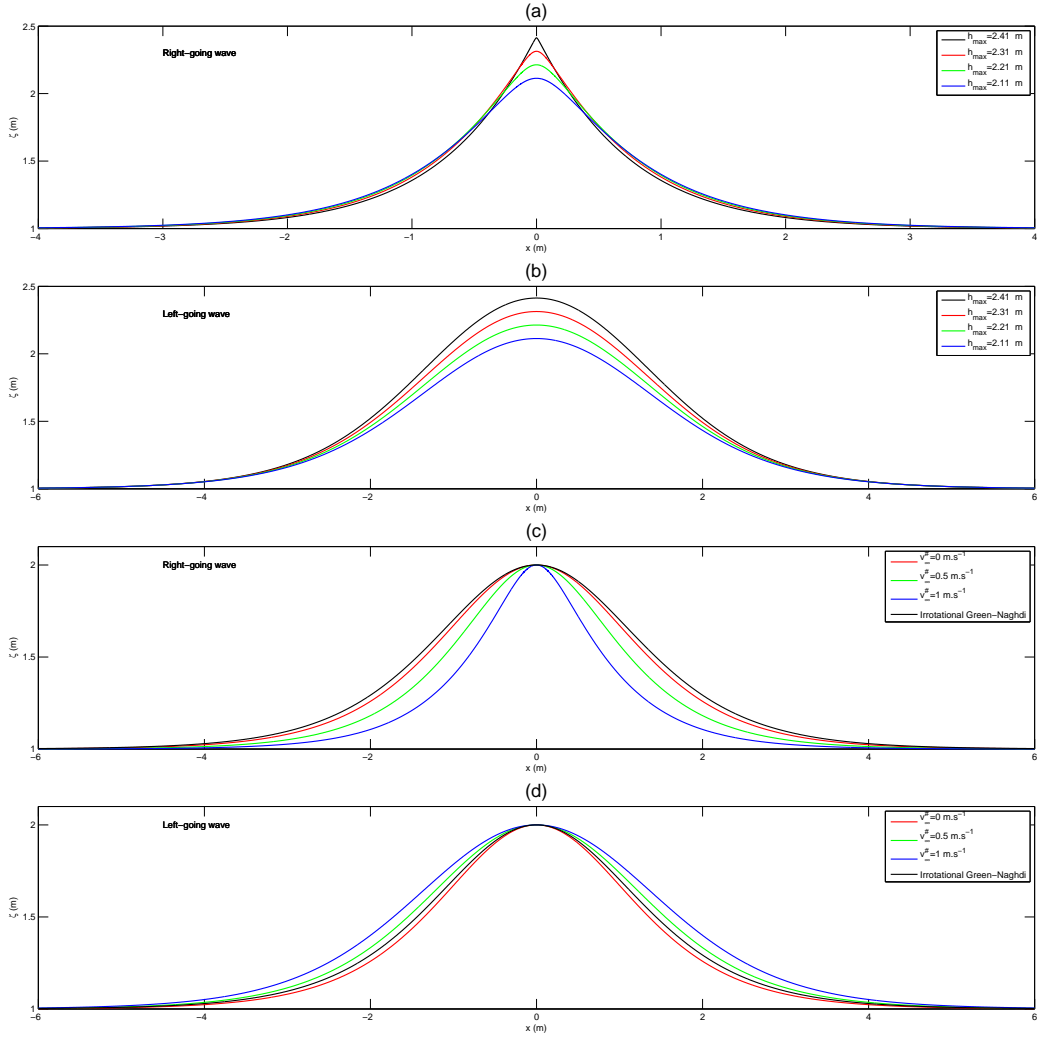

FIGURE 3. Influence of $v_{\infty}^{\sharp} > 0$ on the profiles for $H_0 = 1 m$, $E_{\infty} = 1 m^3 \cdot s^{-2}$ and $F_{\infty} = 0$. (a) Right-going solitary waves of nearly critical amplitudes for $v_{\infty}^{\sharp} = 1 m \cdot s^{-1}$ and therefore $h_{\text{crit}} \approx 2.42 m$. (b) Left going solitary waves for the same amplitudes. (c) Right-going solitary waves for $h_{\text{max}} = 2 m$ and increasing values of v_{∞}^{\sharp} . (d) Left-going solitary waves for $h_{\text{max}} = 2 m$ and increasing values of v_{∞}^{\sharp} .

The second qualitative change with respect to the situation previously considered is that the shape of the two solitary waves of speed $c = \pm \underline{c}$ are not the same since the ODE in Definition 2.1 does no longer depend on c through c^2 only. We refer to Fig. 3 for an illustration of this behavior, in which we show the right and left-going waves profiles for increasing values of h_{max} in the vicinity of h_{crit} , for $v_{\infty}^{\sharp} = 1 m \cdot s^{-1}$. We also highlight the influence of increasing values of v_{∞}^{\sharp} on the left-going waves profiles for a given value of h_{max} .

We recall that we assumed in Proposition 2.2 that $F_{\infty} = 0$. Let us now give a brief discussion about the general case $E_{\infty} > 0$, $v_{\infty}^{\sharp} > 0$ and $F_{\infty} > 0$ (one can treat the case $v_{\infty}^{\sharp} < 0$ and/or $F_{\infty} < 0$ in a similar way). The presence of $F_{\infty} \neq 0$ implies that the possible speeds for solitary waves of maximal

amplitude h_{\max} are found by solving the *third* order polynomial

$$X^3 + pX + q \quad \text{with} \quad p = -(gh_{\max} + h_{\max}(h_{\max} + 2H_0)\frac{E_{\infty}}{H_0^3}) \quad q = -h_{\max}^2(h_{\max} + H_0)^2\frac{F_{\infty}}{H_0^5}, \quad (2.11)$$

(this is a simple consequence of (2.9)). Defining as previously ε by

$$\frac{h_{\max}}{H_0} = 1 + \varepsilon$$

the discriminant $\Delta = -(4p^3 + 27q^2)$ of this polynomial is always positive provided that the following smallness condition holds for F_{∞}

$$F_{\infty}^2 < \frac{27}{4} \frac{H_0^5}{(1 + \varepsilon)(2 + \varepsilon)^4} \left(g + (3 + \varepsilon)\frac{E_{\infty}}{H_0^2}\right)^3 \quad (2.12)$$

(this condition is satisfied for all realistic configurations). The polynomial (2.11) has then three distinct roots. Since the coefficient of X^2 is equal to zero, the sum of the three roots is necessarily equal to zero; moreover, their product has the sign of $-q$, and therefore the sign of F_{∞} . If $F_{\infty} > 0$, then one has one positive root $0 < c_+$ and two negative roots $-c_{-,2} < -c_{-,1} < 0$. There are therefore possibly two left going solitary waves, and a right going one. The right-going wave is subject to the same constraint $h_{\max} < h_{\text{crit}}$ as in the case $E_{\infty} > 0$, $v_{\infty}^{\sharp} > 0$ and $F_{\infty} = 0$. In addition, (2.9) shows that the function

$$\varphi_c : h \mapsto c^2 - h - \varepsilon^2 \mu h(h + 2)E_{\infty} - \varepsilon^3 \mu^{3/2} h^2 (h + 1)^2 \frac{F_{\infty}}{c} \quad (2.13)$$

must be positive for all $H_0 \leq h < h_{\max}$. We can now state the following proposition where for the sake of simplicity, we considered only the case $v_{\infty}^{\sharp} > 0$ and $F_{\infty} > 0$. The cases where these quantities are negative can be treated similarly.

Proposition 2.6. *Let $E_{\infty} > 0$, $v_{\infty}^{\sharp} > 0$ and $F_{\infty} > 0$. Let also $h_{\max} = H_0(1 + \varepsilon)$ with $\varepsilon > 0$ and assume that (2.12) is satisfied.*

- i. *Up to translations, there can be at most three solitary waves of maximal height h_{\max} for (2.1) and corresponding speeds $-c_{-,2} < -c_{-,1} < 0 < c_+$ given by the roots of (2.11).*
- ii. *The solitary wave of speed c_+ exists if and only if the following conditions hold*

$$c_+ H_0^2 - v_{\infty}^{\sharp} h_{\max}^2 > 0 \quad \text{and} \quad \forall h \in [H_0, h_{\max}), \quad \varphi_{c_+}(h) > 0, \quad (2.14)$$

where φ_c is as defined in (2.13).

- iii. *The solitary wave of speed $c_{-,j}$ ($j = 1, 2$) exists if and only $\varphi_{-c_{-,j}} > 0$ on $[H_0, h_{\max})$.*

Remark 2.7. Though there could be in principle a third solitary wave arising in the case $F_{\infty} > 0$, we could not exhibit any configuration where this is the case because the condition $\varphi_{-c_{-,1}} > 0$ on $[H_0, h_{\max})$ is never fulfilled. In practice, there are as in the case $F_{\infty} = 0$ one left going and one right going solitary wave, of different shape and of respective speed $-c_{-,2}$ and c_+ . The profiles of the corresponding solitary waves are shown on Fig. 4. Note that smaller values of F_{∞} have to be taken to obtain the profiles of the left-going waves (Fig. 4 (b)) in order to fulfill the condition $\varphi_{-c_{-,2}} > 0$ on $[H_0, h_{\max})$. Note also that additional solitary waves profiles can be observed, for both the constant vorticity model (1.7) and the general model (1.12), in §4.

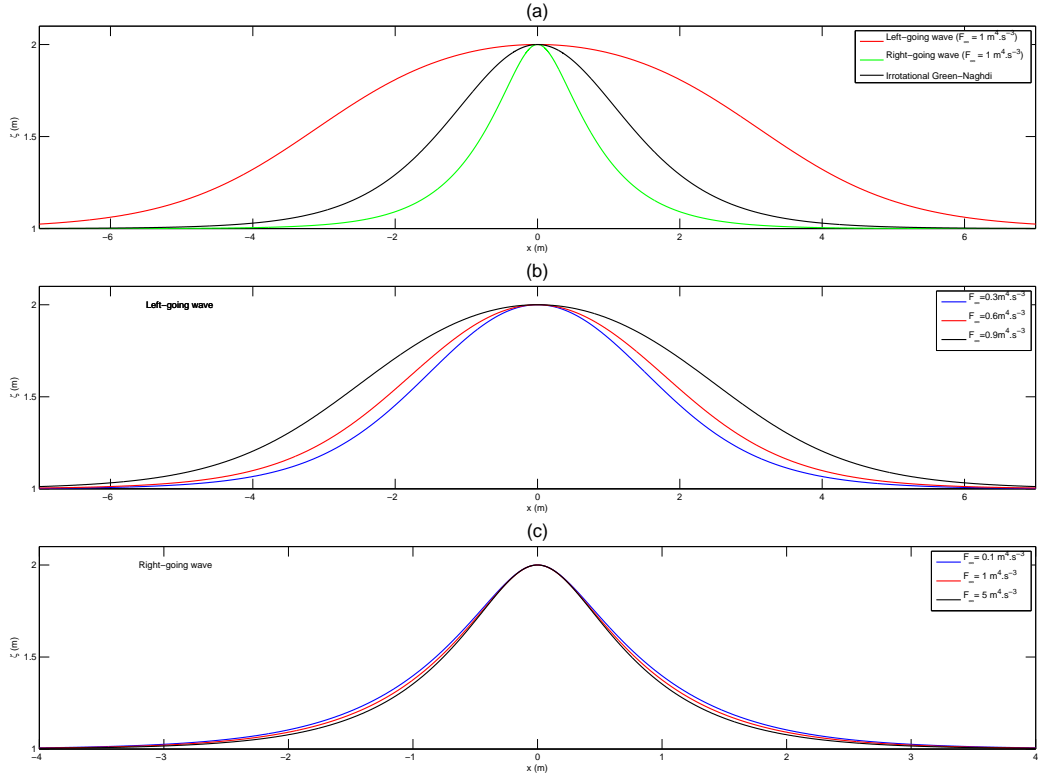

FIGURE 4. Influence of F_∞ on the solitary waves profiles. (a) Shape of the left and right going solitary waves, and comparison with the usual Green-Naghdi solitary wave, for $H_0 = 1 \text{ m}$, $h_{\max} = 2 \text{ m}$, $E_\infty = 1 \text{ m}^3 \cdot \text{s}^{-2}$, $v_\infty = 1 \text{ m} \cdot \text{s}^{-1}$, $F_\infty = 1 \text{ m}^4 \cdot \text{s}^{-3}$. (b) Influence of the value of F_∞ on the left-going wave's profile. (c) Influence of the value of F_∞ on the right-going wave's profile.

2.3. Existence of peaked solitary waves

As seen in the previous section, when $E_\infty > 0$, $v_\infty^\sharp > 0$ and $F_\infty = 0$, solitary waves have speed $\pm \underline{c}$, with

$$\underline{c} = \underline{c}(h_{\max}) = \left(gh_{\max} + \frac{h_{\max}(h_{\max} + 2H_0)}{H_0^3} E_\infty \right)^{1/2}$$

and the maximal amplitude h_{\max} of the right-going solitary wave cannot exceed a critical value h_{crit} corresponding to the only positive root of the equation

$$\underline{c}(h_{\text{crit}})H_0^2 - v_\infty^\sharp h_{\text{crit}}^2 = 0.$$

Figure 3 suggests that the shape of the solitary waves tend to form an angle at their crest as their amplitude become close to the maximal amplitude. A byproduct of the analysis of the previous section is that there cannot exist any *smooth* solitary wave of maximal amplitude h_{crit} . However, we show here that it is possible to obtain a *peaked* solitary wave of maximal amplitude in the following sense.

Definition 2.8. A *peaked* solitary wave of speed c , centered at $x_0 \in \mathbb{R}$, for (2.1), is a mapping

$$(t, x) \in \mathbb{R}^2 \mapsto (\underline{\zeta}, \underline{v}, \underline{v}^\sharp, \underline{E}, \underline{F})(x - ct - x_0)$$

such that there exists $h \in C(\mathbb{R})$, with $h|_{\mathbb{R}^+} \in C^2([0, \infty))$, $h|_{\mathbb{R}^-} \in C^2((-\infty, 0])$, and $E_\infty > 0$, $v_\infty^\sharp \in \mathbb{R}$ and $F_\infty \in \mathbb{R}$ such that

$$\underline{c} = h - H_0, \quad \bar{v} = c \frac{h - H_0}{h}, \quad \underline{v}^\sharp = \frac{h}{H_0} v_\infty^\sharp, \quad \underline{E} = \frac{h^3}{H_0^3} E_\infty + 2 \frac{F_\infty}{c} \frac{(h^2 - H_0^2) h^3}{H_0^5}, \quad \underline{F} = \frac{h^4}{H_0^4} F_\infty,$$

and such that h solves the ODE (2.8) on \mathbb{R}^+ and \mathbb{R}^- , and satisfies $\lim_{\pm\infty} h = H_0$.

The proposition below proves the existence of peaked solitary waves in the case $F_\infty = 0$. Such a property could also be established for $F_\infty \neq 0$ (according to Proposition 2.6 there is also a critical maximal wave in some cases when $F_\infty \neq 0$), but the proof would be more technical and since no new phenomena arises in this case, we decide not to treat it. Some examples of peaked solitary waves are plotted on Fig. 5, on which we highlight the influence of the value of $v_\infty^\sharp > 0$ on the critical amplitude h_{crit} .

Proposition 2.9. *Let $E_\infty > 0$, $v_\infty^\sharp > 0$ and $F_\infty = 0$. For all $x_0 \in \mathbb{R}$, there exists a unique peaked solitary wave centered at x_0 of critical maximal amplitude h_{crit} and speed $\underline{c} = \underline{c}(h_{\text{crit}})$. It is even, decaying on both sides of the crest, and its angle at the crest is 2θ , with*

$$\tan \theta = \left(\frac{3}{2} \frac{E_\infty}{\underline{c} H_0^3 v_\infty^\sharp} (h_{\text{crit}} - H_0)^2 \left(1 + \frac{(v_\infty^\sharp)^2 h_{\text{crit}}^2}{E_\infty H_0} \right) \right)^{-1/2}.$$

Proof. We focus here on the case $x \geq 0$; the case of negative values of x can be treated similarly. Without loss of generality, we also assume that $x_0 = 0$. By definition of h_{crit} , one can write, for all h ,

$$\underline{c} H_0^2 - v_\infty^\sharp h^2 = -v_\infty^\sharp (h - h_{\text{crit}})(h + h_{\text{crit}})$$

and

$$\underline{c}^2 - gh - \frac{h(h + 2H_0)}{H_0^3} E_\infty = -\frac{E_\infty}{H_0^3} (h - h_{\text{crit}}) \left(h + \frac{(v_\infty^\sharp)^2 h_{\text{crit}}^3}{E_\infty H_0} \right).$$

One can therefore rewrite (2.9) under the form

$$\frac{\underline{c}}{3} v_\infty^\sharp (h - h_{\text{crit}})(h + h_{\text{crit}}) h_x^2 = \frac{E_\infty}{H_0^3} (h - H_0)^2 (h - h_{\text{crit}}) \left(h + \frac{(v_\infty^\sharp)^2 h_{\text{crit}}^3}{E_\infty H_0} \right)$$

or equivalently

$$\frac{\underline{c}}{3} v_\infty^\sharp (h + h_{\text{crit}}) h_x^2 = \frac{E_\infty}{H_0^3} (h - H_0)^2 \left(h + \frac{(v_\infty^\sharp)^2 h_{\text{crit}}^3}{E_\infty H_0} \right).$$

Since h_{crit} is by definition the maximal value of h and since h cannot reach the value H_0 (otherwise it would be identically equal to H_0), this ODE is equivalent to

$$h_x = - \left(3 \frac{E_\infty}{\underline{c} H_0^3 v_\infty^\sharp} (h - H_0)^2 \frac{h + \frac{(v_\infty^\sharp)^2 h_{\text{crit}}^3}{E_\infty H_0}}{h + h_{\text{crit}}} \right)^{1/2}.$$

Existence of a local solution is therefore given by the standard Cauchy-Lipschitz theorem; the fact that the solution is global and tends to H_0 at infinity is then easily established as in Step 3 of the proof of Proposition 2.2. When evaluated at the origin (i.e replacing h by h_{crit}) in the above formula

■

FIGURE 5. Influence of $v_{\infty}^{\#} > 0$ on the peaked solitary waves profiles for $H_0 = 1 \text{ m}$, $E_{\infty} = 1 \text{ m}^3 \cdot \text{s}^{-2}$ and $F_{\infty} = 0$.

3. Numerical method

We introduce now a simple numerical method to approximate the solutions of system (1.12) and illustrate the propagation of some of the various wave profiles exhibited in section 2. This approach is inspired by some of our previous works [5, 10, 31], and we mostly detail the new ingredients introduced to account for the specificities of (1.12).

3.1. Splitting

To build our numerical method, denoting $E = h^2 \tilde{E}$ et $F = h^3 \tilde{F}$ and using the mass conservation equation, we rewrite system (1.12) in the equivalent form:

$$\left\{ \begin{array}{l} h_t + (h\bar{v})_x = 0, \\ (1 + \mathbb{T}) \left((h\bar{v})_t + (h\bar{v}^2)_x \right) + gh\zeta_x + (h^2 \tilde{E})_x + h\mathcal{Q}_1(\bar{v}) + h\mathcal{C}(\bar{v}, v^{\#}) = 0, \\ v_t^{\#} + (\bar{v}v^{\#})_x = 0, \\ \tilde{E}_t + (\bar{v}\tilde{E})_x + 3\tilde{F}h_x + h\tilde{F}_x = 0, \\ \tilde{F}_t + (\bar{v}\tilde{F})_x = 0. \end{array} \right. \quad (3.1)$$

Then, in the spirit of [5, 10, 31], we decompose the solution operator $S(\cdot)$ associated to the formulation (3.1), at each time step by the second order splitting scheme

$$S(\delta_t) = S_1(\delta_t/2)S_2(\delta_t)S_1(\delta_t/2), \quad (3.2)$$

where S_1 and S_2 are respectively associated to the transport part and dispersive perturbation of the Green-Naghdi equations (3.1). More precisely:

- $S_1(t)$ is the solution operator associated to the conservative *propagation* step

$$\left\{ \begin{array}{l} h_t + (h\bar{v})_x \\ (h\bar{v})_t + (h\bar{v}^2)_x + gh\zeta_x + (h^2 \tilde{E})_x \\ v_t^{\#} + (\bar{v}v^{\#})_x \\ \tilde{E}_t + (\bar{v}\tilde{E})_x \\ \tilde{F}_t + (\bar{v}\tilde{F})_x \end{array} \right. = 0, \quad (3.3)$$

- $S_2(t)$ is the solution operator associated to the *dispersive correction*,

$$\begin{cases} h_t = 0, \\ (h\bar{v})_t - gh\zeta_x - (h^2\tilde{E})_x + (1 + \mathbb{T})^{-1}[gh\zeta_x + (h^2\tilde{E})_x + h\mathcal{Q}_1(\bar{v}) + h\mathcal{C}(\bar{v}, v^\sharp)] = 0, \\ v_t^\sharp = 0, \\ \tilde{E}_t + 3\tilde{F}h_x + h\tilde{F}_x = 0, \\ \tilde{F}_t = 0. \end{cases} \quad (3.4)$$

As detailed in the next subsection, $S_1(t)$ is discretized using a finite-volume approach. As far as the operator $S_2(t)$ is concerned, we use a finite-difference approach, briefly detailed in §3.3.

Remark 3.1. Even if the terms $3\tilde{F}h_x + h\tilde{F}_x$ occurring in the evolution equation for \tilde{E} are of first order, we choose not to include them in S_1 . Indeed, this would lead to a non-conservative equation for \tilde{E} and introduce additional difficulties. As shown in the following, the study of the hyperbolicity of system (3.3) is straightforward and the computation of the associated algebra lead to simple expressions for the system's eigenvalues. On the contrary, there is no closed expressions for the eigenvalues of the system obtained considering the equation on \tilde{E} with the non-conservative terms.

Actually, approximated eigenvalues for this non-conservative system have been computed, up to the $\mathcal{O}(\mu^2)$ model's accuracy, and some numerical investigations have been performed to compare both numerical approaches, without highlighting noticeable differences on the numerical results. Note however that further investigations are needed on these issues, especially considering the study of possibly breaking waves, in the spirit of [53].

We use the following notations in the following:

- the numerical one-dimensional domain Ω is uniformly divided into N_x cells $(\mathcal{C}_i)_{1 \leq i \leq N_x}$ such that $\mathcal{C}_i = [x_{i-\frac{1}{2}}, x_{i+\frac{1}{2}}]$, where $(x_{i+\frac{1}{2}})_{0 \leq i \leq N_x}$ are the $N_x + 1$ nodes of the regular grid. We denote by x_i the center of \mathcal{C}_i ,
- we denote by δ_x the cell size (constant in this work) and by δ_t the chosen time step (to be specified according to a relevant CFL-like condition),
- we denote by \bar{w}_i^n the averaged value of an arbitrary quantity w on the i^{th} cell \mathcal{C}_i at time $t_n = n\delta_t$.

3.2. Discretization of the conservative step

We focus on the discretization of system (3.3) which can be written in compact form as follows

$$\partial_t \mathcal{W} + \partial_x \mathbb{F}(\mathcal{W}) = \mathbb{S}(\mathcal{W}, b), \quad (3.5)$$

with $\mathcal{W} = (h, h\bar{v}, v^\sharp, \tilde{E}, \tilde{F})$ and

$$\mathbb{F}(\mathcal{W}) = \begin{pmatrix} h\bar{v} \\ h\bar{v}^2 + p(h, \tilde{E}) \\ \bar{v}v^\sharp \\ \bar{v}\tilde{E} \\ \bar{v}\tilde{F} \end{pmatrix}, \quad \mathbb{S}(\mathcal{W}, b) = \begin{pmatrix} 0 \\ -ghb_x \\ 0 \\ 0 \\ 0 \end{pmatrix}, \quad (3.6)$$

with $p(h, \tilde{E}) = \frac{g}{2}h^2 + h^2\tilde{E}$. The state vector \mathcal{W} is assumed to take values in a convex and open set \mathcal{U} defined as

$$\mathcal{U} = \{(h, h\bar{v}, v^\sharp, \tilde{E}, \tilde{F}) \in \mathbb{R}^5, h \geq 0, \tilde{E} \geq 0\}. \quad (3.7)$$

Neglecting the bottom variations, the study of the associated algebra shows that the system is hyperbolic with the following eigenvalues:

$$\lambda_1 = \bar{v} - \sqrt{gh + \frac{3E}{h}}, \quad \lambda_2 = \bar{v} + \sqrt{gh + \frac{3E}{h}}, \quad \lambda_3 = \lambda_4 = \lambda_5 = \bar{v}. \quad (3.8)$$

3.2.1. 1st-order FV discretization of the homogeneous system

We first study a first order conservative spatial discretization of the homogeneous system associated with (3.5):

$$\bar{\mathcal{W}}_i^{n+1} - \bar{\mathcal{W}}_i^n + \frac{\delta t}{\delta x} \left(\mathcal{F}(\bar{\mathcal{W}}_i^n, \bar{\mathcal{W}}_{i+1}^n) - \mathcal{F}(\bar{\mathcal{W}}_{i-1}^n, \bar{\mathcal{W}}_i^n) \right) = 0 \quad (3.9)$$

where $(u, v) \mapsto \mathcal{F}(u, v)$ is a numerical flux function consistent with the physical flux $w \mapsto \mathbb{F}(w)$. For the numerical validations shown in §4, we have implemented a simple HLLC-type Riemann solver, see for instance [3, 7]. We consider an approximate Riemann solver consisting of 2 finite external wave-speeds λ_L , λ_R and an additional intermediate wave λ^\diamond . We denote by \mathcal{W}_L^\diamond and \mathcal{W}_R^\diamond the intermediate states to the left and to the right of the wave λ^\diamond respectively. The 3 wave speeds are therefore separating 4 constant states \mathcal{W}_L , \mathcal{W}_L^\diamond , \mathcal{W}_R^\diamond and \mathcal{W}_R , leading to the following approximate solver:

$$\hat{\mathcal{W}}\left(\frac{x}{t}, \mathcal{W}_L, \mathcal{W}_R\right) = \begin{cases} \mathcal{W}_L & \text{if } \frac{x}{t} \leq \lambda_L, \\ \mathcal{W}_L^\diamond & \text{if } \lambda_L \leq \frac{x}{t} \leq \lambda^\diamond, \\ \mathcal{W}_R^\diamond & \text{if } \lambda^\diamond \leq \frac{x}{t} \leq \lambda_R, \\ \mathcal{W}_R & \text{if } \lambda_R \leq \frac{x}{t}. \end{cases} \quad (3.10)$$

Assuming that λ_L and λ_R are given by some estimates, we need to define the 10 components of the 2 unknown intermediate states \mathcal{W}_L^\diamond and \mathcal{W}_R^\diamond , and the intermediate wave speed λ^\diamond . To achieve this, we use the consistency condition for the discharge $h\bar{v}$, with the notation $\Delta p_{LR} = p(h_R, \tilde{E}_R) - p(h_L, \tilde{E}_L)$, together with the jump conditions across each wave for the variables h, v^\sharp, \tilde{E} and \tilde{F} , leading to the following system:

$$\begin{cases} \lambda_L(h_L^\diamond - h_L) = h_L^\diamond \bar{v}_L^\diamond - h_L \bar{v}_L, & \lambda^\diamond(h_R^\diamond - h_L^\diamond) = h_R^\diamond \bar{v}_R^\diamond - h_L^\diamond \bar{v}_L^\diamond, & \lambda_R(h_R - h_R^\diamond) = h_R \bar{v}_R - h_R^\diamond \bar{v}_R^\diamond, \\ \lambda_L((h\bar{v})_L^\diamond - (h\bar{v})_L) + \lambda^\diamond((h\bar{v})_R^\diamond - (h\bar{v})_L^\diamond) + \lambda_R((h\bar{v})_R - (h\bar{v})_R^\diamond) = h_R \bar{v}_R^2 - h_L \bar{v}_L^2 + \Delta p_{LR}, \\ \lambda_L(v_L^{\sharp, \diamond} - v_L^\sharp) = \bar{v}_L^\diamond v_L^{\sharp, \diamond} - \bar{v}_L v_L^\sharp, & \lambda^\diamond(v_R^{\sharp, \diamond} - v_L^{\sharp, \diamond}) = \bar{v}_R^\diamond v_R^{\sharp, \diamond} - \bar{v}_L^\diamond v_L^{\sharp, \diamond}, & \lambda_R(v_R^\sharp - v_R^{\sharp, \diamond}) = \bar{v}_R v_R^\sharp - \bar{v}_R^\diamond v_R^{\sharp, \diamond}, \\ \lambda_L(\tilde{E}_L^\diamond - \tilde{E}_L) = \bar{v}_L^\diamond \tilde{E}_L^\diamond - \bar{v}_L \tilde{E}_L, & \lambda^\diamond(\tilde{E}_R^\diamond - \tilde{E}_L^\diamond) = \bar{v}_R^\diamond \tilde{E}_R^\diamond - \bar{v}_L^\diamond \tilde{E}_L^\diamond, & \lambda_R(\tilde{E}_R - \tilde{E}_R^\diamond) = \bar{v}_R \tilde{E}_R - \bar{v}_R^\diamond \tilde{E}_R^\diamond, \\ \lambda_L(\tilde{F}_L^\diamond - \tilde{F}_L) = \bar{v}_L^\diamond \tilde{F}_L^\diamond - \bar{v}_L \tilde{F}_L, & \lambda^\diamond(\tilde{F}_R^\diamond - \tilde{F}_L^\diamond) = \bar{v}_R^\diamond \tilde{F}_R^\diamond - \bar{v}_L^\diamond \tilde{F}_L^\diamond, & \lambda_R(\tilde{F}_R - \tilde{F}_R^\diamond) = \bar{v}_R \tilde{F}_R - \bar{v}_R^\diamond \tilde{F}_R^\diamond, \end{cases}$$

whose solution is given by

$$\lambda^\diamond = \frac{h_L \bar{v}_L (\lambda_L - \bar{v}_L) - h_R \bar{v}_R (\lambda_R - \bar{v}_R) + \Delta p_{LR}}{h_L (\lambda_L - \bar{v}_L) - h_R (\lambda_R - \bar{v}_R)}, \quad (3.11)$$

$$\bar{v}_L^\diamond = \bar{v}_R^\diamond = \lambda^\diamond, \quad (3.12)$$

$$h_L^\diamond = \frac{h_L (\lambda_L - \bar{v}_L)}{\lambda_L - \lambda^\diamond}, \quad h_R^\diamond = \frac{h_R (\lambda_R - \bar{v}_R)}{\lambda_R - \lambda^\diamond}, \quad (3.13)$$

$$v_L^{\sharp, \diamond} = v_L^\sharp, \quad v_R^{\sharp, \diamond} = v_R^\sharp, \quad (3.14)$$

$$\tilde{E}_L^\diamond = \tilde{E}_L, \quad \tilde{E}_R^\diamond = \tilde{E}_R, \quad (3.15)$$

$$\tilde{F}_L^\diamond = \tilde{F}_L, \quad \tilde{F}_R^\diamond = \tilde{F}_R. \quad (3.16)$$

Once the intermediate states are known, the corresponding fluxes can be computed as usual

$$\mathcal{F}(\mathcal{W}_L, \mathcal{W}_R) = \begin{cases} \mathbb{F}(\mathcal{W}_L) & \text{if } \frac{x}{t} \leq \lambda_L, \\ \mathbb{F}(\mathcal{W}_L) + \lambda_L (\mathcal{W}_L^\diamond - \mathcal{W}_L) & \text{if } \lambda_L \leq \frac{x}{t} \leq \lambda^\diamond, \\ \mathbb{F}(\mathcal{W}_R) + \lambda_R (\mathcal{W}_R^\diamond - \mathcal{W}_R) & \text{if } \lambda^\diamond \leq \frac{x}{t} \leq \lambda_R, \\ \mathbb{F}(\mathcal{W}_R) & \text{if } \lambda_R \leq \frac{x}{t}. \end{cases} \quad (3.17)$$

Remark 3.2. Introducing the following wave speed estimates:

$$\lambda_L = \bar{v}_L - \frac{s_L}{h_L}, \quad \lambda_R = \bar{v}_R + \frac{s_R}{h_R}, \quad (3.18)$$

where s_L and s_R are 2 positive values which definition is temporarily postponed to §3.2.3, (3.11)-(3.13) may be reformulated as follows:

$$\lambda^\diamond = \frac{s_L \bar{v}_L + s_R \bar{v}_R - \Delta p_{LR}}{s_L + s_R}, \quad (3.19)$$

$$\frac{1}{h_L^\diamond} = \frac{1}{h_L} + \frac{s_R (\bar{v}_R - \bar{v}_L) - \Delta p_{LR}}{s_L (s_L + s_R)}, \quad \frac{1}{h_R^\diamond} = \frac{1}{h_R} + \frac{s_L (\bar{v}_R - \bar{v}_L) + \Delta p_{LR}}{s_R (s_L + s_R)}. \quad (3.20)$$

3.2.2. Discretization of the topography

The discretization of the topography source term occurring in (3.5) is done following the well-balanced approach for the Saint-Venant equations described in [2], allowing to preserve the motionless steady states corresponding to

$$\zeta = 0, \quad \bar{v} = 0, \quad v^\sharp = 0, \quad E = 0, \quad F = 0. \quad (3.21)$$

We choose not to recall the details of this reconstruction as it has been extensively applied and validated in recent years, including some variants like the reconstructions proposed in [34] relying on a pre-balanced formulation. We just recall that one of the main properties of this approach is that whenever the initial solver satisfies some classical stability properties, it yields a simple and fast well-balanced scheme that preserves the positivity of the water height and satisfies a semi-discrete entropy inequality.

3.2.3. Robustness

We show here that a suitable choice of the external wave speed estimates λ_L and λ_R ensures that the intermediate water heights h_L^\diamond and h_R^\diamond remains positive.

Proposition 3.3. *The numerical scheme (3.9) based on the Riemann solver (3.10) and the definitions (3.12)-(3.20) with s_L and s_R defined as follows:*

$$\text{if } \Delta p_{LR} \geq 0, \quad \begin{cases} \frac{s_L}{h_L} = \sqrt{h_L(g + 2\tilde{E}_L)} + \frac{3}{2} \left(\frac{\Delta p_{LR}}{h_R \sqrt{h_R(g + 2\tilde{E}_R)}} + \bar{v}_L - \bar{v}_R \right)_+, \\ \frac{s_R}{h_R} = \sqrt{h_R(g + 2\tilde{E}_R)} + \frac{3}{2} \left(\frac{-\Delta p_{LR}}{s_L} + \bar{v}_L - \bar{v}_R \right)_+. \end{cases} \quad (3.22)$$

$$\text{if } \Delta p_{LR} \leq 0, \quad \begin{cases} \frac{s_R}{h_R} = \sqrt{h_R(g + 2\tilde{E}_R)} + \frac{3}{2} \left(\frac{-\Delta p_{LR}}{h_L \sqrt{h_L(g + 2\tilde{E}_L)}} + \bar{v}_L - \bar{v}_R \right)_+, \\ \frac{s_L}{h_L} = \sqrt{h_L(g + 2\tilde{E}_L)} + \frac{3}{2} \left(\frac{\Delta p_{LR}}{s_R} + \bar{v}_L - \bar{v}_R \right)_+. \end{cases} \quad (3.23)$$

preserves the positivity of h .

Proof. We adapt the ideas of [7], initially introduced for the Suliciu relaxation schemes.

Step 1. We remark first that $(h, \tilde{E}) \rightarrow p(h, \tilde{E}) = \frac{g}{2}h^2 + h^2\tilde{E}$ satisfies the following properties:

$$\forall h, \tilde{E} > 0, \quad \partial_h(h\sqrt{\partial_h p(h, \tilde{E})}) > 0, \quad (3.24)$$

$$h\sqrt{\partial_h p(h, \tilde{E})} \xrightarrow{h \rightarrow \infty} \infty, \quad (3.25)$$

$$\partial_h(h\sqrt{\partial_h p(h, \tilde{E})}) \leq \frac{3}{2}\sqrt{\partial_h p(h, \tilde{E})}, \quad (3.26)$$

ensuring that there exists, for each value of \tilde{E} , an inverse function $\psi(\cdot, \tilde{E}) : (0, \infty) \rightarrow (0, \infty)$ such that

$$h\sqrt{\partial_h p(h, \tilde{E})} = s \Leftrightarrow h = \psi(s, \tilde{E}).$$

Note also that (3.26) entails $\partial_s \psi(s, \tilde{E}) \geq \frac{2\psi(s, \tilde{E})}{3s}$, and as $\partial_s(\psi(s, \tilde{E})s^{-\frac{2}{3}}) \geq 0$, we have:

$$\psi(\lambda s; \tilde{E}) \geq \lambda^{\frac{2}{3}}\psi(s, \tilde{E}), \quad \forall \lambda \geq 1. \quad (3.27)$$

Step 2. We show in this step that for any given $s_R > 0$, the choice

$$\frac{s_L}{h_L} = \sqrt{\partial_h p(h_L, \tilde{E}_L)} + \frac{3}{2} \left(\frac{\Delta p_{LR}}{s_R} + \bar{v}_L - \bar{v}_R \right)_+,$$

ensures that

$$\frac{1}{h_L^2} = \frac{1}{h_L} + \frac{s_R(\bar{v}_R - \bar{v}_L) - \Delta p_{LR}}{s_L(s_L + s_R)} \geq \frac{1}{\psi(s_L, \tilde{E}_L)} > 0.$$

Indeed, if $s_R(\bar{v}_R - \bar{v}_L) - \Delta p_{LR} \geq 0$, we have $s_L = h_L\sqrt{\partial_h p(h_L, \tilde{E}_L)}$ and $h_L = \psi(s_L, \tilde{E}_L)$, giving the expected result. If $s_R(\bar{v}_R - \bar{v}_L) - \Delta p_{LR} < 0$, it is equivalent to show that

$$1 - \frac{s_R}{s_L + s_R} \frac{X}{\sqrt{\partial_h p(h_L, \tilde{E}_L)} + \frac{3}{2}X} \geq \frac{h_L}{\psi(s_L, \tilde{E}_L)},$$

with $X = \frac{\Delta p_{LR}}{s_R} + \bar{v}_L - \bar{v}_R$. Introducing $\theta = \frac{\sqrt{\partial_h p(h_L, \tilde{E}_L)}}{\sqrt{\partial_h p(h_L, \tilde{E}_L)} + \frac{3}{2}X}$, a sufficient condition is

$$1 - \frac{2(1-\theta)}{3} - \frac{h_L}{\psi\left(h_L(\sqrt{\partial_h p(h_L, \tilde{E}_L)} + \frac{3}{2}X), \tilde{E}_L\right)} \geq 0. \quad (3.28)$$

Using (3.27), we see that (3.28) holds if we have $1 - \frac{2(1-\theta)}{3} - \theta^{\frac{2}{3}} \geq 0$, which is always true for $0 < \theta \leq 1$.

Note that the symmetric result holds: for all $s_L > 0$, the choice

$$\frac{s_R}{h_R} = \sqrt{\partial_h p(h_R, \tilde{E}_R)} + \frac{3}{2} \left(\frac{-\Delta p_{LR}}{s_L} + \bar{v}_L - \bar{v}_R \right)_+,$$

ensures that

$$\frac{1}{h_R^\circ} = \frac{1}{h_R} + \frac{s_L(\bar{v}_R - \bar{v}_L) + \Delta p_{LR}}{s_L(s_L + s_R)} \geq \frac{1}{\psi(s_R, \tilde{E}_R)} > 0,$$

Step 3. Let us assume in this step $\Delta p_{LR} \geq 0$ and define s_L, s_L following (3.22). As $s_L \geq 0$, the symmetric result of the previous step directly ensures that $1/h_R^\circ > 0$. Additionally, if $s_R(\bar{v}_R - \bar{v}_L) - \Delta p_{LR} \geq 0$, we obviously have

$$\frac{1}{h_L^\circ} = \frac{1}{h_L} + \frac{s_R(\bar{v}_R - \bar{v}_L) - \Delta p_{LR}}{s_L(s_L + s_R)} \geq \frac{1}{h_L} > 0.$$

Now, if $s_R(\bar{v}_R - \bar{v}_L) - \Delta p_{LR} \leq 0$, as $s_R \geq h_R \sqrt{\partial_h p(h_R, \tilde{E}_R)}$, we have $s_L \geq \tilde{s}_L$, with

$$\frac{\tilde{s}_L}{h_L} = \sqrt{\partial_h p(h_L, \tilde{E}_L)} + \frac{3}{2} \left(\frac{\Delta p_{LR}}{s_R} + \bar{v}_L - \bar{v}_R \right)_+.$$

Using **Step 2**, we obtain

$$\frac{1}{h_L} + \frac{s_R(\bar{v}_R - \bar{v}_L) - \Delta p_{LR}}{\tilde{s}_L(\tilde{s}_L + s_R)} \geq \frac{1}{\psi(\tilde{s}_L, \tilde{E}_L)}.$$

As $\frac{-1}{s(s+s_R)}$ is an increasing function of $s > 0$, we show that

$$\frac{1}{h_L^\circ} = \frac{1}{h_L} + \frac{s_R(\bar{v}_R - \bar{v}_L) - \Delta p_{LR}}{s_L(s_L + s_R)} \geq \frac{1}{h_L} + \frac{s_R(\bar{v}_R - \bar{v}_L) - \Delta p_{LR}}{\tilde{s}_L(\tilde{s}_L + s_R)} \geq \frac{1}{\psi(\tilde{s}_L, \tilde{E}_L)} > 0.$$

Step 4. Assuming that $\bar{\mathcal{W}}_i^n \in \mathcal{U}$ for each cell \mathcal{C}_i , the previous step ensures that the associated approximate Riemann solver (3.10) satisfies at each interface $x_{i+\frac{1}{2}}$:

$$\forall (t, x) \in (t^n, t^{n+1}] \times (x_i, x_{i+1}), \quad \hat{\mathcal{W}}\left(\frac{x - x_{i+\frac{1}{2}}}{t - t^n}, \bar{\mathcal{W}}_i^n, \bar{\mathcal{W}}_{i+1}^n\right) \in \mathcal{U}.$$

Then, it is a classical result to show that $\bar{\mathcal{W}}_i^{n+1} \in \mathcal{U}$ for each cell \mathcal{C}_i under the CFL-like condition

$$\frac{\delta t}{\delta x} \max_i \max \left(|\lambda_{i+\frac{1}{2},L}|, |\lambda_{i+\frac{1}{2},R}| \right) \leq \frac{1}{2},$$

in which $\lambda_{i+\frac{1}{2},L}$ and $\lambda_{i+\frac{1}{2},R}$ are the speed estimates obtained from (3.18)-(3.22)-(3.23) at the interface $x_{i+\frac{1}{2}}$. This final result is based on the fact that the numerical scheme (3.9) updates values from a convex averaging of the states that appear in the approximate Riemann problem, see for instance [3, 7]. \blacksquare

Remark 3.4. The previous positivity result can be straightforwardly extended from equations (3.3) to the *constant vorticity* model (1.7), the *medium amplitude* model (1.16) and the *reduced model with $F = 0$* (1.17). Indeed, adapting the splitting approach (3.3)-(3.4) to these simplified models, we observe that the positivity preservation property on h and \tilde{E} obtained in Proposition 3.3 for $\mathcal{S}_1(\delta t/2)$ is preserved by the dispersive step $\mathcal{S}_2(\delta t)$.

However, showing that $\mathcal{S}_2(\delta t)$ preserves the positivity of \tilde{E} for the *general vorticity* model (3.1) is a non trivial task, due to the occurrence of source terms in the equation on \tilde{E} . However, in practice, we did not observe any loss of positivity for \tilde{E} in our numerical investigations. Indeed, coming back to the non-dimensionalized equations as introduced in [9], we can observe that the scaling of the additional terms $3\tilde{F}h_x + h\tilde{F}_x$ is $\varepsilon\sqrt{\mu}$. Consequently, these terms may usually be small enough to preserve the robustness of the whole method. Some practical examples of the orders of magnitude for these various quantities can be observed in §5, on Fig. 24 and Fig. 26.

3.2.4. High-order extension

As shown in previous studies [10, 5, 16, 31], the use of high-order schemes is mandatory for the study of dispersive water waves, to avoid as much as possible to pollute the dispersive properties of the model with some dispersive truncation errors associated with 2^{nd} order schemes. Based on discrete finite-volume cell averaging $\bar{\mathcal{W}}_i^n$ at time $t^n = n\delta t$ we use in this work 3^{rd} and 5^{th} -order accuracy WENO reconstructions, following [22], together with the weight splitting method [47]. Considering a cell \mathcal{C}_i , this approach provides, for all t^n , interpolated quantities $\bar{\mathcal{W}}_{i,l}$, and $\bar{\mathcal{W}}_{i,r}$, respectively at the left and right boundaries of the cell. Classically, for well-balancing requirements when the topography is not flat, we also build reconstruction for the additional quantity $h + b$ and deduce reconstructed values for the topography $b_{i,l}$ and $b_{i,r}$. Again, we chose not to develop the details of this classical step as no further difficulties are introduced when considering the new models with vorticity. We rather refer to our previous studies [10, 5, 16, 31] for implementation details.

Note that the positivity result issued from Proposition 3.3 can be extended to the high-order schemes using the recent WENO polynomials limitations from [59, 56], with a more restricting CFL-like condition. We also refer to [31] for some details concerning the implementation for the Green-Naghdi equations.

Note also that when the topography is not flat, we use the quadrature rule of [37] for the topography source term discretization, which leads to a high-order well-balanced scheme for the motionless steady states (3.21) and relies on additional high-order WENO reconstructed values $\bar{\mathcal{W}}_{i,c}$ at each cell centers.

3.3. Spatial discretization of $\mathcal{S}_2(\cdot)$, time discretization and boundary conditions

Following the approach developed in [5], system (3.4) is discretized using 4^{th} finite-differences. The resulting matrix, for the discretization of the linear operator \mathbb{T} is the same as in [5].

As far as time discretization is concerned, we choose to use explicit methods. The systems corresponding to \mathcal{S}_1 and \mathcal{S}_2 are integrated in time using third or fourth-order *SSP-Runge-Kutta* scheme [20]. For the sake of simplicity, we only use periodic and Neumann boundary conditions here, adapting the ghost-cells methods detailed in [5].

Remark 3.5. The whole numerical strategy described here can be straightforwardly applied to the *constant vorticity* model (1.7), the *medium amplitude* equations (1.16) and the reduced model with $F = 0$ (1.17), adapting the approximate Riemann solvers to the corresponding hyperbolic part.

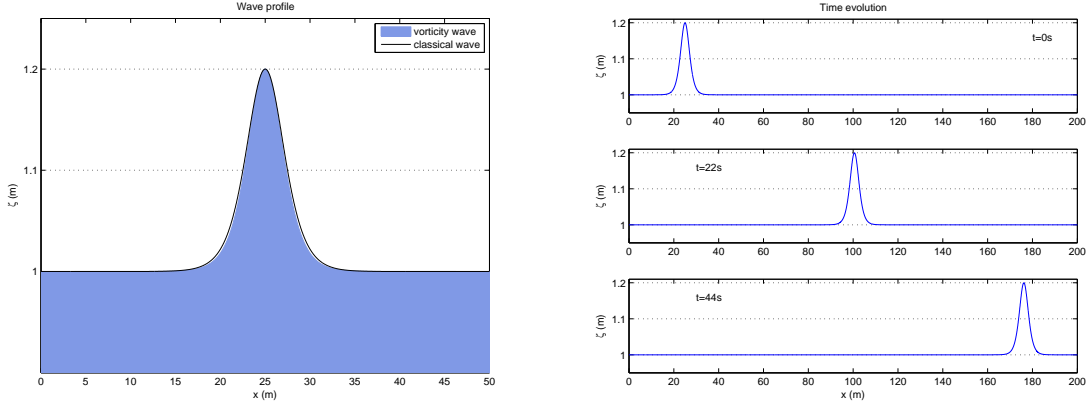

FIGURE 6. Propagation of a right-going solitary wave solution for the constant vorticity model - $\varepsilon = 0.2$ and $\omega_0 = 0.3 \text{ s}^{-1}$. Initial profile (on the left) and snapshots at different locations along the channel (on the right). The solitary wave solution of the classical Green-Naghdi equations is plotted in black solid line at $t = 0 \text{ s}$.

4. Numerical validation

In this section, we use the analysis of solitary waves performed in Section 2 to validate our numerical scheme. All the various kinds of smooth solitary waves exhibited in Section 2 are numerically observed in §4.1 and used to evaluate the convergence rate. As shown in §4.2, our code is accurate enough to capture also the extremal peaked solitary waves exhibited in §2.3. We then treat in §4.3 an example with a non trivial topography which allows us to show that vorticity may have a considerable influence on the shoaling phase.

4.1. Solitary waves propagation

A common test for Green-Naghdi models is the propagation of solitary waves in a long, frictionless channel of constant depth. The numerical model must handle the equilibrium between amplitude and frequency dispersion to propagate the wave profile at constant shape and speed. Typical problems during propagation involve trailing edge dispersion consequently causing reduction in wave height and celerity. Those phenomena arise generally from a combination of numerical errors from poorly balanced schemes and truncation of numerical approximations.

In the next test cases of these section, we consider $H_0 = 1$ and we compute the propagation of several solitary waves in a computational domain of 200 m long. We consider several set of values for the wave amplitude εH_0 and the triplet $(E_\infty, v_\infty^\sharp, F_\infty)$, allowing to cover the various configurations detailed in §2. Unless stated otherwise, we use WENO3 reconstructions, a SSP-RK3 scheme and we set the CFL number to 0.8.

4.1.1. Constant vorticity model

We consider here the Green-Naghdi model (1.7) with constant vorticity. We consequently have

$$\text{curl } \mathbf{U} = (0, \omega, 0)^T \quad \text{with} \quad \omega(t, x, z) = \omega_0 = \text{cst.}$$

The analysis of the existence of solitary waves solutions for the constant vorticity equations (1.7) is provided in Proposition 2.2. Indeed, we recall that in the case of flat bottom, the Green-Naghdi

N_x	ζ	$h\bar{v}$
6 400	$4.58 \cdot 10^{-7}$	$1.38 \cdot 10^{-5}$
3 200	$4.81 \cdot 10^{-6}$	$1.47 \cdot 10^{-4}$
1 600	$4.79 \cdot 10^{-5}$	$1.48 \cdot 10^{-3}$
800	$4.01 \cdot 10^{-4}$	$1.31 \cdot 10^{-2}$
400	$1.87 \cdot 10^{-3}$	$6.64 \cdot 10^{-2}$

FIGURE 7. Propagation of a right-going solitary wave solution for the constant vorticity model - $\varepsilon = 0.2$ and $\omega_0 = 0.3 \text{ s}^{-1}$. Convergence curves in logarithmic scales on the left and L^2 error values at $t = 3 \text{ s}$ for ζ and $h\bar{v}$ on the right.

model with constant vorticity can be obtained from the general equations (1.12), setting $E = \frac{1}{12}h^3\omega_0^2$, $v^\sharp = h\omega_0$, $F = 0$, and consequently neglecting the equations on \tilde{E} and v^\sharp which are equivalent to the continuity equation. Solitary wave solutions for (1.7) belong to the situation depicted in Remark 2.5. In the present test case, we first set $\omega_0 = 0.3 \text{ s}^{-1}$ and we study the propagation of a solitary wave of relative amplitude $\varepsilon = 0.2$, initially centred at $x_0 = 25 \text{ m}$. The initial water height $h^0(x) = h(0, x)$ is computed as a solution of equation (2.9) and the corresponding velocity is initialized as

$$\bar{v}^0(x) = \underline{c} \left(1 - \frac{H_0}{h^0(x)} \right),$$

where \underline{c} is obtained from (2.10):

$$\underline{c}^2 = gh_{\max} + \frac{h_{\max}(h_{\max} + 2H_0)}{12}\omega_0^2. \quad (4.1)$$

Remark 4.1. From Proposition 2.2, we observe that with the choice $\omega_0 > 0$, we have existence of right-going solitary waves (propagating at speed $\underline{c} > 0$) for all amplitudes a . On the contrary, the existence of left-going waves is ruled by the additional compatibility condition

$$\underline{c}H_0 - \omega_0 h_{\max}^2 > 0.$$

We only focus here on the right-going wave, and we show on Fig. 6 the corresponding profile h^0 , together with the usual profile for the classical Green-Naghdi equations. We also compute the propagation of this solitary wave on the time interval $]0, T]$, with $T = 50 \text{ s}$ and show the corresponding profiles at several locations along the channel. For these pictures, we set $\delta x = 0.125 \text{ m}$.

In order to perform some numerical convergence analysis, we compute L^2 errors at $T = 3 \text{ s}$ for ζ and $h\bar{v}$ on a sequence of refined meshes. The results are reported on Fig. 7, where we observe mean orders of convergence, obtained with linear regressions, of 3.26 and 3.3 respectively for ζ and $h\bar{v}$.

In a second time, we increase the wave amplitude, together with the magnitude of the vorticity field. We set $\varepsilon = 0.3$ and $\omega_0 = 1 \text{ s}^{-1}$. The influence of the increased vorticity on the wave profile can be observed on the left side of Fig. 8. The propagating wave shown on the right side is obtained setting $\delta x = 0.07 \text{ m}$. The convergence study results are reported on Fig. 9, and we can observe similar magnitudes for the numerical errors, but very slightly decreased convergence rates.

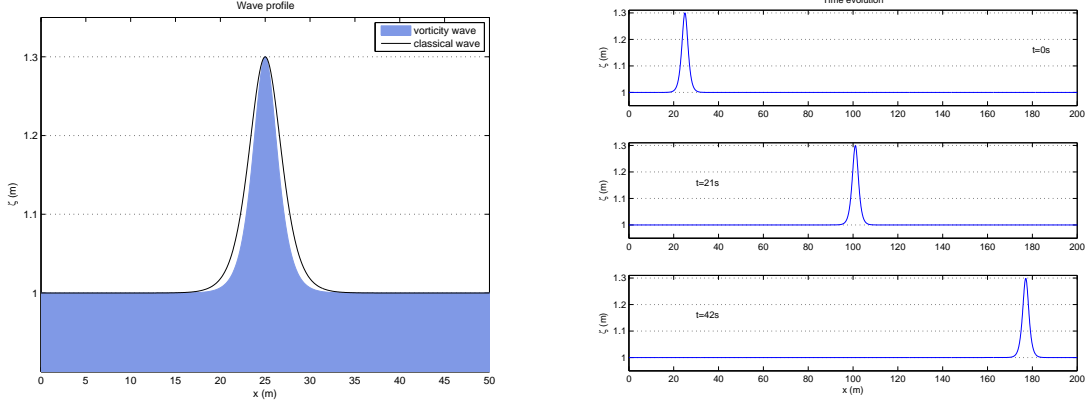

FIGURE 8. Propagation of a right-going solitary wave solution for the constant vorticity model - $\varepsilon = 0.3$ and $\omega_0 = 1 \text{ s}^{-1}$. Initial profile (on the left) and snapshots at different locations along the channel (on the right). The solitary wave solution of the classical Green-Naghdi equations is plotted in black solid line at $t = 0 \text{ s}$.

FIGURE 9. Propagation of a right-going solitary wave solution for the constant vorticity model - $\varepsilon = 0.3$ and $\omega_0 = 1 \text{ s}^{-1}$. Convergence curves in logarithmic scales on the left and L^2 error values at $t = 3 \text{ s}$ for ζ and $h\bar{v}$ on the right.

4.1.2. General vorticity model - Case $E_\infty > 0$, $v_\infty^\sharp > 0$, $F_\infty = 0$

In this second case, we consider the propagation of a solitary wave for non-constant vorticity in the case $F_\infty = 0$. The third order tensor F remains uniformly equal to 0 during the propagation, and we can therefore consider the reduced model (1.17). The existence of solitary waves solutions is still ruled by Proposition 2.2. There are 2 solitary waves of opposite velocities given by (2.10), but with different profiles. We choose here $E_\infty = 0.2 \text{ m}^3 \cdot \text{s}^{-2}$, $v_\infty^\sharp = 1.6 \text{ m} \cdot \text{s}^{-1}$ and again, we set successively $\varepsilon = 0.2$ and $\varepsilon = 0.3$. Such choices ensure the existence of both left and right-going waves, leading to

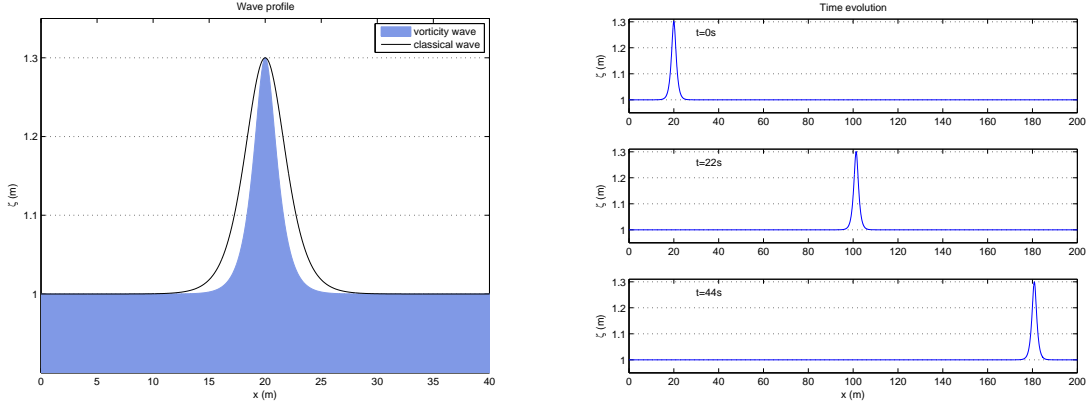

FIGURE 10. Case $E_\infty > 0$, $v_\infty > 0$, $F_\infty = 0$ - Right-going wave with $\varepsilon = 0.3$. Initial profile (on the left) and snapshots at different locations along the channel (on the right).

the profiles shown on the left of Fig.10 and Fig.11 respectively for the right-going and the left-going waves in the case $\varepsilon = 0.3$. The right-going wave is initially centred at $x = 20\text{ m}$ and the left-going wave at $x = 170\text{ m}$. Again, we also plot the classical solitary wave profile of same amplitude for comparison purpose. The time evolutions of both right and left going waves are shown on the right of Fig.10 and Fig.11. For these computations, we have set $\delta x = 0.07\text{ m}$. We observe the preservation of the initial profiles, together with a very low numerical dissipation for the considered time interval.

Again, we perform a numerical convergence analysis on a sequence of refined meshes for both cases. The L^2 numerical errors obtained at $t = 3\text{ s}$ for h , $h\bar{v}$, \tilde{E} and v^\sharp in the cases $\varepsilon = 0.2$ and $\varepsilon = 0.3$ are reported on Fig. 12-right and Fig. 13-right respectively. The corresponding convergence curves are shown on Fig. 12-left and Fig. 13-left respectively. In the case $\varepsilon = 0.2$, we observe some convergence rates of 2.9 for $h\bar{v}$ and 2.88 for ζ , \tilde{E} and v^\sharp . Similar results are obtained in the case $\varepsilon = 0.3$, with convergence rates of 2.88 for $h\bar{v}$ and 2.87 for ζ , \tilde{E} and v^\sharp . Note that the obtained L^2 errors for \tilde{E} and v^\sharp are almost identical to the one on ζ and are therefore not plotted. Although not reported here, we obtain a very similar behavior for the left going wave.

4.1.3. General vorticity model - Case $E_\infty > 0$, $v_\infty^\sharp > 0$, $F_\infty > 0$

Let us now focus on the case $F_\infty > 0$ and consider the *general vorticity* model (1.12). The existence of solitary wave solutions is now ruled by Proposition 2.6 and we have existence of 2 solitary waves, provided that conditions (2.14) are fulfilled. We also recall that the waves speeds are now obtained as the minimum and maximum roots of the 3^{rd} order polynomial (2.11). We consider the following set of parameters $E_\infty = 1/12\text{ m}^3.\text{s}^{-2}$, $v_\infty^\sharp = 1\text{ m}.\text{s}^{-1}$, $F_\infty = 1/12\text{ m}^4.\text{s}^{-3}$ and $\varepsilon = 0.5$, ensuring the existence of both left and right going waves and leading to the following wave speeds:

$$\underline{c}^- \approx -3.852\text{ m}.\text{s}^{-1} \quad \text{and} \quad \underline{c}^+ \approx 3.93\text{ m}.\text{s}^{-1}.$$

The corresponding profiles for ζ are shown on Fig.14 and Fig.15, together with some snapshots of the corresponding time evolutions. For these computations, we set $\delta x = 0.05\text{ m}$. The corresponding convergence analysis is provided in Fig.16. The L^2 errors for ζ , $h\bar{v}$, \tilde{E} , v^\sharp and \tilde{F} obtained at $t = 3\text{ s}$ are

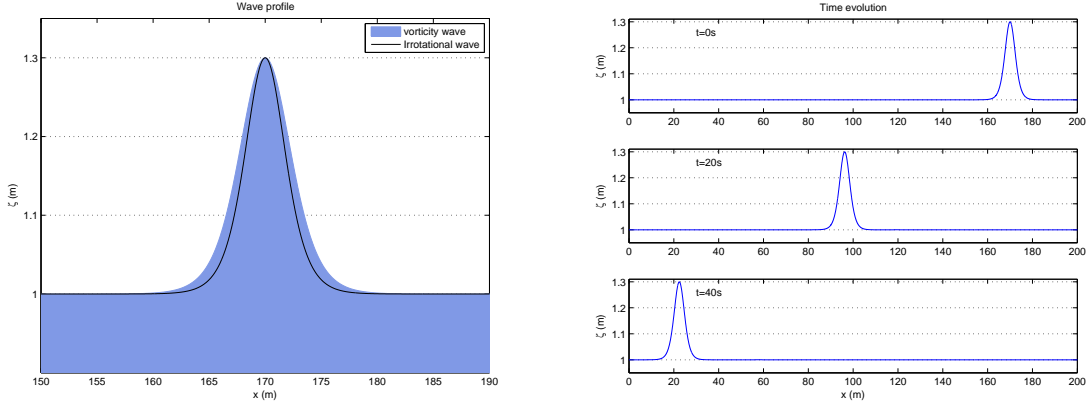

FIGURE 11. Case $E_\infty > 0$, $v_\infty > 0$, $F_\infty = 0$ - Left-going wave with $\varepsilon = 0.3$. Initial profile (on the left) and snapshots at different locations along the channel (on the right).

FIGURE 12. Case $E_\infty > 0$, $v_\infty > 0$, $F_\infty = 0$ - Right-going wave with $\varepsilon = 0.2$. Convergence curves in logarithmic scales for ζ and $h\bar{v}$ on the left and L^2 error values at $t = 3$ s for ζ , $h\bar{v}$, v^\sharp and \tilde{E} on the right.

reported on Table 1, and the corresponding convergence curves are plotted on Fig.16. Note that when $F_\infty \neq 0$, we observe a slight increase of the L^2 -errors for \tilde{E} when compared with those obtained for v^\sharp , \tilde{F} and ζ . However the convergence rates obtained for both v^\sharp , \tilde{F} , \tilde{E} and ζ are almost identical. Note also that as the L^2 -errors computed for both v^\sharp and \tilde{F} are similar to those obtained for ζ , we only show the convergence curves for ζ , $h\bar{v}$ and \tilde{E} . We obtain the same behavior for the left going wave.

FIGURE 13. Case $E_\infty > 0$, $v_\infty > 0$, $F_\infty = 0$ - Right-going wave with $\varepsilon = 0.3$. Convergence curves in logarithmic scales for ζ and $h\bar{v}$ on the left and L^2 error values at $t = 3$ s for ζ , $h\bar{v}$, v^\sharp and \tilde{E} on the right.

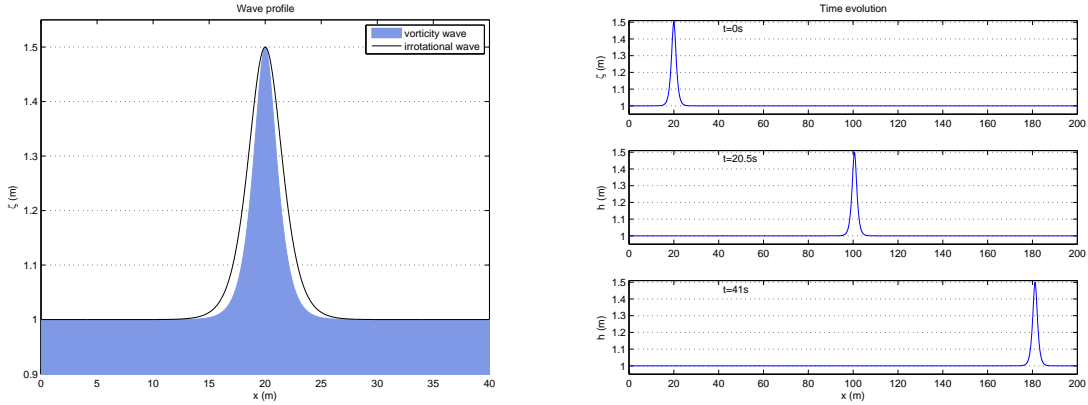

FIGURE 14. Case $E_\infty > 0$, $v_\infty > 0$, $F_\infty > 0$ - Right-going wave with $\varepsilon = 0.5$. Initial profile (on the left) and snapshots at different locations along the channel (on the right).

4.2. Peaked solitary waves

Let us now briefly illustrate the propagation of *peaked* solitary waves, exhibited in Proposition 2.9. The numerical simulation of such waves with singularities is a difficult problem as the solution is not smooth. Indeed, the damping introduced by the numerical methods rapidly smooth out the peak and thereby deform and delay the wave. These issues may be avoided by locally refining the mesh (h -adaptivity) or increasing the scheme order (p -adaptivity) in the vicinity of the waves crest. However, our goal here is not to extensively study the dynamic and interactions of peaked waves, but simply to numerically confirm their existence and stability. The development of a more involved discrete formulation allowing for h/p -adaptivity, based on the recently introduced discontinuous-Galerkin method for the Green-Naghdi equations [16], is left for future work.

FIGURE 17. Case $E_\infty > 0$, $v_\infty > 0$, $F_\infty = 0$ - Right-going peaked wave with $\varepsilon = 0.1044$. We also show in black solid line the shape of the solitary wave for the irrotational Green-Naghdi equations.

To achieve this, we consider the simplified case $F_\infty = 0$, neglecting the third order tensor F , and still set $H_0 = 1 m$. Choosing the following values $v_\infty^\# = 3 m.s^{-1}$ and $E_\infty = 9/12 m^3.s^{-2}$, we set the relative amplitude in order to be very close to the critical case. In this particular configuration, we have existence of a right-propagating wave only for $h_{max} < h_{crit} = 1.1045 m$. Consequently, we consider here a wave of amplitude $0.1044 m$, initially centered at $x = 11 m$. We show the corresponding initial profile on the left side of Fig.17. The corresponding propagation is shown on the right side. For this simulation, in order to minimize the numerical diffusion in the vicinity of the singularity we increase the numerical resolution, setting $\delta x = 2.5 \cdot 10^{-3} m$ and use WENO5 reconstructions with a SSP-RK4 time marching scheme.

4.3. Influence of vorticity on wave shoaling

In the following test case, we assess the topography terms discretization, and aim at giving a brief insight into the important study of the impact of the vorticity on wave shoaling. We still consider a $200 m$ channel with $H_0 = 1 m$ but now, we the topography is varying and defined as follows:

$$b(x) = \frac{H_0}{10} \left(1 + \tanh \left(\frac{x - x_1}{\lambda} \right) \right),$$

with $\lambda = 20 m$, and $x_1 = 100 m$. We follow successively the propagation of 3 solitary waves over this uneven bottom. The first one is a classical solitary wave ($E_\infty = v_\infty^\# = F_\infty = 0$) associated with the irrotational Green-Naghdi equations. In this case, the model (3.1) and the associated numerical approach reduces to the extensively validated framework of [5, 10, 4]. This wave may therefore be used as a reference solution to highlight the influence of the additional vorticity terms.

The second and third ones are solitary wave solutions of (3.1) defined with $F_\infty = 0$ and $(E_\infty, v_\infty^\#)$ respectively set to $(8.33 \cdot 10^{-2}, -1)$ and $(0.18, -1.5)$. The corresponding celerities are given by $c_0 \approx 3.43 m.s^{-1}$ for the irrotational wave and respectively $c_0 \approx 3.47 m.s^{-1}$ and $c_0 \approx 3.53 m.s^{-1}$ for the second and third vorticity waves. The corresponding initial profiles are shown on Fig. 18-left. We also show on Fig. 19 some snapshots of the waves evolution along the channel, and particularly as the waves propagates over the smooth step located in the vicinity of x_1 . The computation is performed with $\delta x = 0.1 m$. We can observe the increasing influence of the vorticity on the waves shoaling

FIGURE 18. Influence of vorticity on wave shoaling: initial wave profiles ($t = 0$ s) on the left and propagated profiles at $t = 35$ s on the right. In the legend, 'Wave 1' refers to the irrotational solitary wave, while 'Wave 2' and 'Wave 3' respectively refers to the cases ($E_\infty = 8.33 \cdot 10^{-2}$, $v_\infty^\# = -1$) and ($E_\infty = 0.18$, $v_\infty^\# = -1.5$)

processes, as the waves amplitude increase with respect to the vorticity magnitude, as well as on the stretching area at the rear of the waves and on the mean level at the front. A zoom on the profiles at $t = 35$ s is shown on Fig. 19-right. Of course, extensive studies are still needed to systematically analyze and accurately quantify this influence.

5. Evolution of the velocity field inside the fluid domain

In the previous numerical computations we computed the surface elevation ζ , the average velocity \bar{v} as well as $v^\#$, E and F from their initial value through the resolution of the *one*-dimensional equations (1.12). We show here how this system of equations can be used to describe the dynamics of the (1+1)-dimensional velocity field $U = (v, w)$ and of the surface elevation in terms of their initial value U^0 and ζ^0 .

5.1. The initial condition

Denoting by \bar{v}^0 the vertical average of the horizontal velocity at $t = 0$ and by $v^{*,0}$ its fluctuation, one can write

$$\begin{cases} v^0 = \bar{v}^0 + v^{*,0}, \\ w^0 = -\partial_x((H_0 + z - b)\bar{v}^0) - \partial_x \int_{-H_0+b}^z v^{*,0}; \end{cases} \quad (5.1)$$

the expression for w^0 is deduced from the expression for v^0 thanks to the incompressibility condition and the non penetration condition at the bottom. We also recall that the initial vorticity ω^0 is defined as

$$\omega^0 = \partial_z u^0 - \partial_x w^0.$$

We shall consider here initial conditions that correspond to shallow water configurations (i.e. $\mu = H_0^2/L^2 \ll 1$). Denoting by v_{sh}^0 the shear velocity induced by the vorticity field ω^0 and by $v_{\text{sh}}^{*,0}$ its

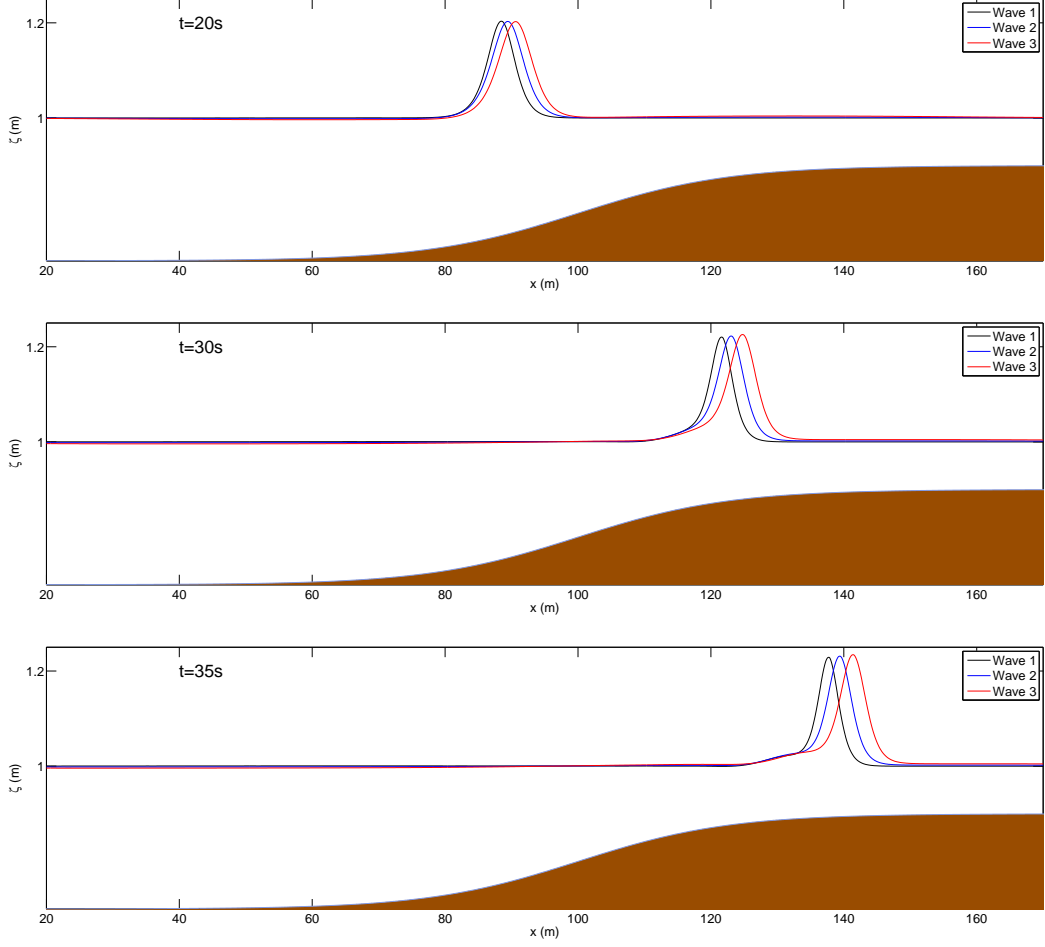

FIGURE 19. Influence of vorticity on wave shoaling: evolution of the waves profiles along the channel at times $t = 20, 30$ and 35 s.

fluctuation around its vertical mean value,

$$v_{\text{sh}}^{*,0} = - \int_z^{\zeta^0} \omega^0 + \frac{1}{h^0} \int_{-H_0+b}^{\zeta^0} \int_z^{\zeta^0} \omega^0 \quad (h^0 = H_0 + \zeta^0 - b), \quad (5.2)$$

it is shown in [9], Eq. (2.30), that up to $O(\mu^{3/2})$ terms, one has

$$v^{*,0} = v_{\text{sh}}^{*,0} + T^* \bar{v}^0 \quad (5.3)$$

where $T^* \bar{v}^0$ accounts for the fluctuations due to dispersion and is given by

$$T^* \bar{v}^0 = -\frac{1}{2}((z + H_0 - b)^2 - \frac{1}{3}(h^0)^2) \partial_x^2 \bar{v} + (z - \zeta^0 + \frac{1}{2}h^0) (\partial_x b \partial_x \bar{v}^0 + \partial_x (v^0 \partial_x b)).$$

Since our main goal here is to comment on the effects of the vorticity on the propagation of waves, it is convenient to consider an initial vorticity field ω^0 and to construct the corresponding approximate velocity field U^0 given by (5.1), (5.2) and (5.3).

5.2. Reconstruction methodology

Let us now briefly recall the procedure described in [9] to recover U at all times from ζ^0 and U^0 . It is of course sufficient to compute U on each level line $\theta \in [0, 1]$, that is,

$$\begin{aligned} v_\theta(t, x) &= v(t, x, -H_0 + b(x) + \theta h(t, x)), \\ w_\theta(t, x) &= w(t, x, -H_0 + b(x) + \theta h(t, x)). \end{aligned}$$

Remark 5.1. One can also define the vorticity on the level lines by $\omega_\theta(t, x) = \omega(t, x, -H_0 + b(x) + \theta h(t, x))$. It can be computed in terms of v_θ and w_θ by the formula

$$\omega_\theta = \frac{1}{h} \partial_\theta v_\theta - \partial_x w_\theta + \frac{\partial_x(b + \theta h)}{h} \partial_\theta w_\theta.$$

It is shown in [9] that the velocity fields conserves its initial structure (5.1)-(5.3) and that one has

$$v_\theta = \bar{v} + v_{\text{sh},\theta}^* + T_\theta^* \bar{v} \tag{5.4}$$

$$w_\theta = -\partial_x(h(\theta \bar{v} + Q_\theta + \int_0^\theta T_{\theta'}^* \bar{v} d\theta')) + \partial_x(-H_0 + b + \theta h)v_\theta. \tag{5.5}$$

with

$$T_\theta^* \bar{v} = -\frac{1}{2}(\theta^2 - \frac{1}{3})h^2 \partial_x^2 \bar{v} + (\theta - \frac{1}{2})h(\partial_x b \partial_x \bar{v} + \partial_x(\partial_x b \bar{v})).$$

The computation of the different quantities involved in these expressions must be performed as follows:

- (1) From the initial datas ζ^0 , \bar{v}^0 and $v_{\text{sh}}^{*,0}$ compute the initial values E^0 , F^0 and $v^{\#,0}$ from their definitions (1.13), (1.14) and (1.15).
- (2) Compute ζ , \bar{v} , v^\sharp , E and F on the time interval $[0, T]$ by solving the Green-Naghdi equations (1.12).
- (3) Compute the quantities q_θ and Q_θ on the same time interval by solving

$$\partial_t q_\theta + \partial_x(\bar{v} q_\theta) = 0, \quad \partial_t Q_\theta + \partial_x(\bar{v} Q_\theta) = 0$$

with initial conditions $q_\theta^0 = \partial_\theta v_{\text{sh},\theta}^{*,0}$ and $Q_\theta^0(x) = \int_0^\theta v_{\text{sh},\theta'}^{*,0} d\theta'$, where we use the notation $v_{\text{sh},\theta}^{*,0}(x) = v_{\text{sh}}^{*,0}(t, x, -H_0 + b(x) + \theta h^0(t, x))$.

- (4) Compute $v_{\text{sh},\theta}^*$ by solving on $[0, T]$ the equation

$$\partial_t v_{\text{sh},\theta}^* + \partial_x(v_{\text{sh},\theta}^*(\bar{v} + \frac{1}{2}v_{\text{sh},\theta}^*)) = \frac{1}{h} \partial_x E + \frac{q_\theta}{h} \partial_x(hQ_\theta),$$

with initial data $v_{\text{sh},\theta}^{*,0}$.

- (5) Use (5.4) and (5.5) to get v_θ and w_θ .

5.3. Implementation hints

From a practical point of view, we aim at computing the velocity field U on some given N_z level lines along the vertical layer of fluid. We introduce the discrete increments

$$\theta_j = \frac{\delta z + (j-1)\delta z}{H_0}, \quad 1 \leq j \leq N_z, \quad \text{with} \quad \delta z = \frac{H_0}{N_z},$$

FIGURE 20. An example of a curvilinear mesh generated from $N_z = 12$ level lines and $N_x = 100$ horizontal cells.

such that, for some given time t and horizontal coordinate x , the j^{th} level line is located at the vertical coordinate $z = -H_0 + b(x) + \theta_j h(t, x)$. An example of the resulting $2d$ meshes is plotted on Fig. 20. To compute the velocity field on each of these level lines, we supplement the Green-Naghdi model with general vorticity (3.1) with a set of equations describing the time evolution of the auxiliary quantities q_{θ_j} , Q_{θ_j} and $v_{\theta_j}^*$:

$$\left\{ \begin{array}{l} \partial_t h + \partial_x(h\bar{v}) = 0, \\ (1 + \mathbb{T})[\partial_t(h\bar{v}) + \partial_x(h\bar{v}^2)] + gh\partial_x\zeta + h\mathcal{Q}_1(\bar{v}) + \partial_x(h^2\tilde{E}) + h\mathcal{C}(\bar{v}, v^\#) = 0, \\ \partial_t v^\# + \partial_x(\bar{v}v^\#) = 0, \\ \partial_t\tilde{E} + (\bar{v}\tilde{E})_x + 3\tilde{F}\partial_x h + h\partial_x\tilde{F} = 0, \\ \partial_t\tilde{F} + \partial_x(\bar{v}\tilde{F}) = 0, \\ \partial_t q_{\theta_j} + \partial_x(\bar{v}q_{\theta_j}) = 0, \quad 1 \leq j \leq N_z, \\ \partial_t Q_{\theta_j} + \partial_x(\bar{v}Q_{\theta_j}) = 0, \quad 1 \leq j \leq N_z, \\ \partial_t v_{\theta_j}^* + \partial_x(v_{\theta_j}^*(\bar{v} + \frac{1}{2}v_{\theta_j}^*)) = \frac{1}{h}\partial_x(h^2\tilde{E}) + \frac{q_{\theta_j}}{h}\partial_x(hQ_{\theta_j}), \quad 1 \leq j \leq N_z. \end{array} \right. \quad (5.6)$$

Considering the numerical method introduced in §3, the easiest way to account for these additional equations, from a discrete point of view, is to incorporate the auxiliary quantities q_{θ_j} , Q_{θ_j} and $v_{\theta_j}^*$ into our splitting approach, and into the approximate Riemann solver for the transport part of the equations.

Remark 5.2. As these new equations are decoupled from the equations on mass and momentum, we choose to keep the simple 3 waves structure of the approximate solver (3.10). Such a choice may appear as surprising for the quantities $v_{\theta_j}^*$, considering the particular form of the associated non-linear evolution equations. However, our numerical investigations have shown that considering each scalar equations separately, the corresponding wave speeds associated with the values of $\bar{v} + \frac{1}{2}v_{\theta_j}^*$ at interfaces are very close to \bar{v} (which is in accordance with the vorticity scaling studied here, see [9]), and always lie between the external wave speed estimates (3.18).

To simplify the notations, let us consider the case of one level line, located at the vertical coordinate $z = -H_0 + b(x) + \theta h(t, x)$, with $\theta \in]0, 1]$, and denote by q_θ , Q_θ and v_θ^* the associated quantities. The splitting scheme (3.3)-(3.4) is modified as follows:

- $S_1(t)$ is the solution operator associated to the conservative *propagation* step, which may be written in the following conservative form

$$\partial_t \mathcal{W}_\theta + \partial_x \mathbb{F}(\mathcal{W}_\theta) = \mathbb{S}(\mathcal{W}_\theta, b), \quad (5.7)$$

with $\mathcal{W}_\theta = (h, h\bar{v}, v^\sharp, \tilde{E}, \tilde{F}, q_\theta, Q_\theta, v_\theta^*)$ and

$$\mathbb{F}(\mathcal{W}_\theta) = \begin{pmatrix} h\bar{v} \\ h\bar{v}^2 + p(h, \tilde{E}) \\ \bar{v}v^\sharp \\ \bar{v}\tilde{E} \\ \bar{v}\tilde{F} \\ \bar{v}q_\theta \\ \bar{v}Q_\theta \\ v_\theta^*(\bar{v} + \frac{1}{2}v_\theta^*) \end{pmatrix}, \quad \mathbb{S}(\mathcal{W}_\theta, b) = \begin{pmatrix} 0 \\ -ghb_x \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{pmatrix}. \quad (5.8)$$

The associated semi-discrete conservative scheme now reads

$$\frac{d}{dt}(\bar{\mathcal{W}}_\theta)_i(t) + \frac{1}{\delta_x} \left(\mathcal{F}((\bar{\mathcal{W}}_\theta)_i, (\bar{\mathcal{W}}_\theta)_{i+1}) - \mathcal{F}((\bar{\mathcal{W}}_\theta)_{i-1}, (\bar{\mathcal{W}}_\theta)_i) \right) = 0, \quad (5.9)$$

with

$$\mathcal{F}((\mathcal{W}_\theta)_L, (\mathcal{W}_\theta)_R) = \begin{cases} \mathbb{F}((\mathcal{W}_\theta)_L) & \text{if } \frac{x}{t} \leq \lambda_L, \\ \mathbb{F}((\mathcal{W}_\theta)_L) + \lambda_L((\mathcal{W}_\theta)_L^\diamond - (\mathcal{W}_\theta)_L) & \text{if } \lambda_L \leq \frac{x}{t} \leq \lambda^\diamond, \\ \mathbb{F}((\mathcal{W}_\theta)_R) + \lambda_R((\mathcal{W}_\theta)_R^\diamond - (\mathcal{W}_\theta)_R) & \text{if } \lambda^\diamond \leq \frac{x}{t} \leq \lambda_R, \\ \mathbb{F}((\mathcal{W}_\theta)_R) & \text{if } \lambda_R \leq \frac{x}{t}, \end{cases} \quad (5.10)$$

with λ_L , λ_R and λ^\diamond defined with (3.22), (3.23) and (3.19) and the 2 intermediate states $(\mathcal{W}_\theta)_L^\diamond$ and $(\mathcal{W}_\theta)_R^\diamond$ defined with formulae (3.11)-(3.16), supplemented with

$$(q_\theta)_L^\diamond = (q_\theta)_L, \quad (q_\theta)_R^\diamond = (q_\theta)_R, \quad (5.11)$$

$$(Q_\theta)_L^\diamond = (Q_\theta)_L, \quad (Q_\theta)_R^\diamond = (Q_\theta)_R, \quad (5.12)$$

$$(v_\theta^*)_L^\diamond = (v_\theta^*)_R^\diamond = \frac{1}{\lambda_R - \lambda_L} \left(\lambda_R (v_\theta^*)_R - \lambda_L (v_\theta^*)_L \right) \quad (5.13)$$

$$- (v_\theta^*)_R (\bar{v}_R + \frac{1}{2}(v_\theta^*)_R) + (v_\theta^*)_L (\bar{v}_L + \frac{1}{2}(v_\theta^*)_L), \quad (5.14)$$

trading the facts that q_θ and Q_θ are essentially transported at speed \bar{v} , and that we use a HLL average to obtain the intermediate state for v_θ^* . Note that the high-order WENO reconstructions of §3.2.4 are also used for the auxiliary variables q_θ , Q_θ and v_θ^* , providing 3^{rd} -order reconstructed values at each element face.

- $S_2(t)$ is the solution operator associated to the *non-conservative and dispersive correction*,

$$\left\{ \begin{array}{l} \partial_t h = 0, \\ \partial_t(h\bar{v}) - gh\partial_x\zeta - \partial_x(h^2\tilde{E}) + (1 + \mathbb{T})^{-1} [gh\partial_x\zeta + \partial_x(h^2\tilde{E}) + h\mathcal{Q}_1(\bar{v}) + h\mathcal{C}(\bar{v}, v^\sharp)] = 0, \\ \partial_t v^\sharp = 0, \\ \partial_t \tilde{E} + 3\tilde{F}\partial_x h + h\partial_x \tilde{F} = 0, \\ \partial_t \tilde{F} = 0, \\ \partial_t q_\theta = 0, \\ \partial_t Q_\theta = 0, \\ \partial_t v_\theta^* - \frac{1}{h}\partial_x(h^2\tilde{E}) - \frac{q_\theta}{h}\partial_x(hQ_\theta) = 0. \end{array} \right. \quad (5.15)$$

Note that when compared with (3.4), the second step is only modified with the introduction of a source term in the equation on v_θ^* .

Remark 5.3. Embedding this splitting approach into a Runge-Kutta scheme and coming back to the general case of N_z level lines, the quantities

$$((\overline{q_{\theta_j}})_i^n, (\overline{Q_{\theta_j}})_i^n, (\overline{v_{\theta_j}^*})_i^n)_{1 \leq i \leq N_x},$$

which stand for some averaged approximations of $(q_{\theta_j}, Q_{\theta_j}, v_{\theta_j}^*)$ on cell \mathcal{C}_i at the discrete time t_n , are used to post-process, at each time step, some approximations

$$((v_{\theta_j})_i^n, (w_{\theta_j})_i^n)_{1 \leq i \leq N_x}$$

of the velocity field v_{θ_j} and w_{θ_j} following the method given in the previous section. The resulting discrete velocity $U_{\theta_j}^n = ((v_{\theta_j})_i^n, (w_{\theta_j})_i^n)$ is an approximated value of $U(t^n, x_i, -H_0 + b + \theta_j h)$.

5.4. A solitary wave propagating in a constant vorticity field

To illustrate the previous reconstructions, we show here the velocity fields associated with some of the new solitary wave solutions exhibited in §2.1. We choose the simplest case of a constant vorticity field, described by model (1.7) and we set

$$\text{curl } \mathbf{U} = (0, \omega, 0)^T \quad \text{with} \quad \omega(t, x, z) = \omega_0.$$

Using (5.2), we obtain the initial horizontal shear velocity field

$$v_{\text{sh}}^{*,0}(x, z) = -\omega_0(\zeta^0 - z) + \frac{\omega_0}{2}h^0,$$

and the initial velocity field v_θ^0 et w_θ^0 are obtained with straightforward computations using (5.4) and (5.5). This initial velocity field is shown on Fig. 21 for the values $\omega_0 = 0.3 \text{ s}^{-1}$ and $\omega_0 = 1.5 \text{ s}^{-1}$. For comparison purpose, we also show the velocity field corresponding to the irrotational solitary wave of similar amplitude. We can observe the vertical decreasing of the velocity's horizontal component magnitude for the rotational solitary wave, while this is left unchanged for the irrotational wave.

5.5. A solitary wave arriving in a vorticity region

We consider now an initial vorticity field with vertical and horizontal dependencies, defined as follows:

$$\omega^0(x, z) = -2\pi\underline{\omega} \cos\left(2\pi\frac{\zeta - z}{H_0}\right) \exp\left(-\frac{(x - x_1)^2}{\lambda^2}\right) \quad (5.16)$$

with $\underline{\omega} = \frac{\varepsilon\sqrt{gH_0}}{\lambda}$ (this scaling of the vorticity corresponds to the regime studied in [8, 9] where the Green-Naghdi models with vorticity have been derived and justified).

With this definition, we observe that the vorticity vanishes as $x \rightarrow \pm\infty$. Additionally, its strongest variations of amplitude along the horizontal dimension are located near some point of abscissa x_1 (see Fig. 22).

In the following, we aim at qualitatively observing the behavior of an irrotational solitary wave arriving from afar (where the vorticity is therefore negligible). We consider a channel of 50 m long, set $H_0 = 1 \text{ m}$, $x_1 = 25 \text{ m}$ and take as initial surface elevation the profile of an irrotational solitary wave centred at $x_0 = 12.5 \text{ m}$, namely

$$\zeta^0(x) = \varepsilon H_0 \left(\text{sech}\left(\frac{x - x_0}{\lambda}\right)\right)^2 \quad \text{with} \quad \lambda = \frac{2}{\sqrt{3}} \sqrt{\frac{1 + \varepsilon}{\varepsilon}} H_0$$

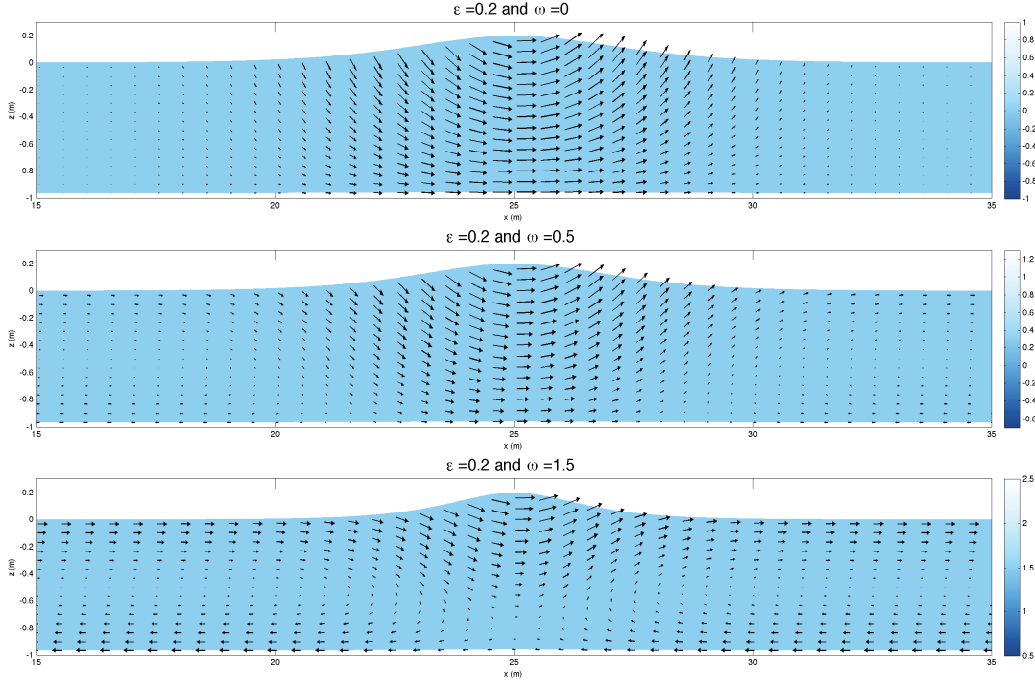

FIGURE 21. Velocity fields in solitary waves with constant vorticity: influence of the vorticity magnitude.

with $\varepsilon = 0.25$, and we correspondingly take for the initial value of the mean velocity

$$\bar{v}^0(x) = c \frac{\zeta^0}{H_0 + \zeta^0(x)} \quad \text{with} \quad c = \sqrt{gH_0(1 + \varepsilon)}.$$

We highlight that x_0 is chosen far enough from x_1 to ensure that the vorticity is initially negligible in the vicinity of the solitary wave. The choice (5.16) for the initial vorticity field leads to the following initial horizontal shear velocity

$$v_{\text{sh}}^{*,0}(x, z) = \underline{\omega} H_0 \left[\sin \left(2\pi \frac{\zeta^0 - z}{H_0} \right) - \frac{H_0}{2\pi} \frac{1 - \cos \left(2\pi \frac{h^0}{H_0} \right)}{h^0} \right] \exp \left(- \frac{(x - x_1)^2}{\lambda^2} \right)$$

so that the full initial velocity field can again be constructed³ through (5.1) (see Figure 23). This initial shear velocity field's structure is also plotted on Fig. 22.

³The two integrals in the expression for w^0 can be computed explicitly,

$$\int_{-H_0}^z v_{\text{sh}}^{*,0} = \frac{\underline{\omega} H_0^2}{6\pi} \left[\cos \left(2\pi \frac{\zeta - z}{H_0} \right) - \cos \left(2\pi \frac{h^0}{H_0} \right) - \frac{z + H_0}{h^0} (1 - \cos \left(2\pi \frac{h^0}{H_0} \right)) \right] \exp \left(- \frac{(x - x_1)^2}{\lambda^2} \right)$$

$$\int_{-H_0}^z T^* \bar{v}^0 = -\frac{1}{6} (z + H_0) ((z + H_0)^2 - (h^0)^2) \partial_x^2 \bar{v}^0.$$

FIGURE 22. A solitary wave arriving on a vorticity region: snapshot of the free surface profile at times $t = 0$, with the corresponding fluctuation velocity field $v_{\text{sh}}^{*,0}$ plotted with black arrows. The corresponding initial vorticity is shown according to the left colorbar.

We now follow the procedure described in the previous sections. From simple computations, one gets

$$\begin{aligned}
 v^{\#,0} &= \frac{2H_0^2\omega}{\pi^3(h^0)^3} [(h^0)^2\pi^2(1+2\underline{c}^2) - 3H_0^2\underline{s}^2] \exp\left(-\frac{(x-x_1)^2}{\lambda^2}\right) \\
 E^0 &= \frac{3H_0^2\omega^2}{2\pi^2h^0} [H_0h^0\pi(\underline{s}^2 - \underline{c}^2)\underline{s}\underline{c} - 2H_0^2\underline{s}^4 + \pi^2(h^0)^2] \exp\left(-2\frac{(x-x_1)^2}{\lambda^2}\right) \\
 F^0 &= \frac{3H_0^4\omega^3}{2\pi^3(h^0)^2}\underline{s}^2 [4\pi^2(h^0)^2(1-2\underline{c}^2)\underline{c}^2 - 9\pi H_0h^0(1-2\underline{c}^2)\underline{c}\underline{s} \\
 &\quad + 12H_0^2(1-\underline{c}^2)^2 - 5\pi^2(h^0)^2] \exp\left(-3\frac{(x-x_1)^2}{\lambda^2}\right)
 \end{aligned}$$

where we used the notations $\underline{s} = \sin(\pi\frac{z^0}{H_0})$ and $\underline{c} = \cos(\pi\frac{z^0}{H_0})$. These functions are shown on Figure 24. Note in particular that the function F almost identically vanishes (its sup norm does not exceed 2.10^{-9}), and it is therefore possible to work with the reduced model (1.17).

For the computation, we set $N_x = 500$, leading to $\delta x = 0.1 \text{ m}$, and $N_z = 30$. The corresponding results are shown on Fig. 23, where we plot the free surfaces at several times during the propagation, together with the reconstructed velocity fields and the corresponding vorticity. We can observe the impact of the current on the initial velocity field and the free surface profile, and that the initial vorticity area is slightly dragged along and stretched as the wave propagates.

5.6. Influence of vorticity on shoaling

We consider here the same configuration as in §5.5 but with the vorticity region now located in an area where the topography varies. More precisely, instead of a flat bottom ($b = 0$) we now consider a bottom parametrized by $z = -H_0 + b(x)$, with

$$b(x) = \frac{H_0}{6} \left(1 + \tanh\left(\frac{x-x_1}{\lambda}\right)\right).$$

One could derive as in §5.5 explicit expressions for the initial values of E , F and v^\sharp , but they can also easily be numerically computed; they are represented in Figure 26. Note that in this configuration, F is still small (of order 10^{-3}) but not as much as in the previous configuration with a flat bottom. For this kind of configurations, it is therefore suitable to work with the full system (1.12). We show the corresponding results for the velocity fields on Fig. 25.

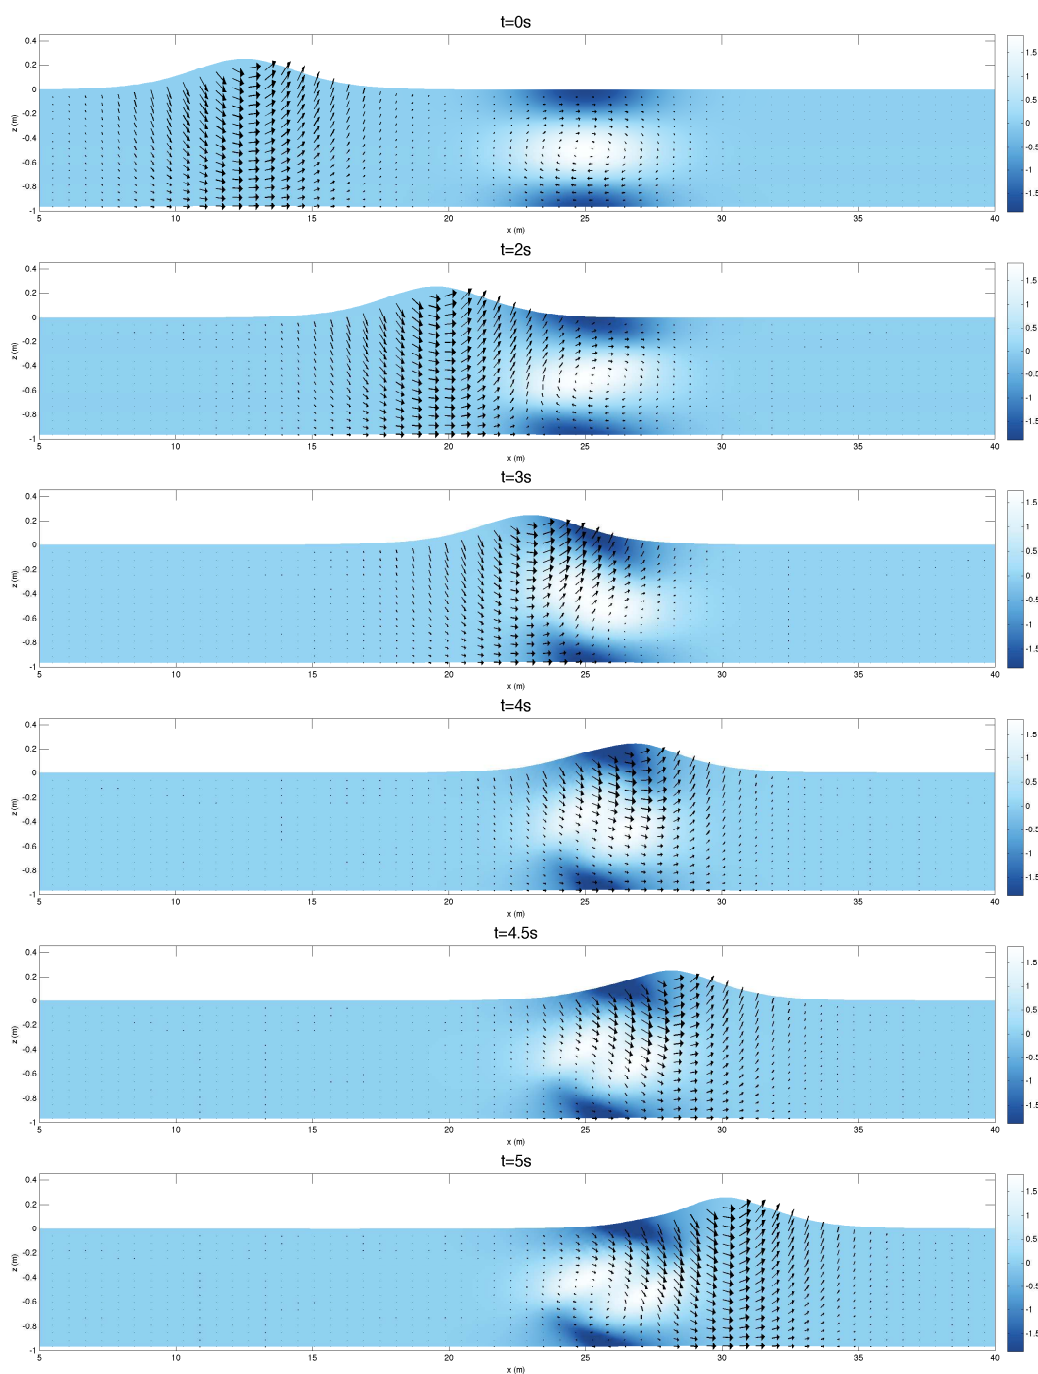

FIGURE 23. A solitary wave arriving on a vorticity region: snapshot of the free surface profile at times $t = 0, 2, 3, 4, 4.5$ and 5 s. The velocity fields structures are plotted with black arrows and the corresponding vorticity is shown according to the left colorbar.
