# CONVERGENCE OF THE MAC SCHEME FOR THE COMPRESSIBLE STATIONARY NAVIER-STOKES EQUATIONS 

T. GALLOUËT, R. HERBIN, J.-C. LATCHÉ, AND D. MALTESE

#### Abstract

We prove in this paper the convergence of the Marker and Cell (MAC) scheme for the discretization of the steady state compressible and isentropic Navier-Stokes equations on two or three-dimensional Cartesian grids. Existence of a solution to the scheme is proven, followed by estimates on approximate solutions, which yield the convergence of the approximate solutions, up to a subsequence, and in an appropriate sense. We then prove that the limit of the approximate solutions satisfies the mass and momentum balance equations, as well as the equation of state, which is the main difficulty of this study.

## 1. Introduction

The aim of this paper is to prove the convergence of the marker-and-cell (MAC) scheme for the discretization of the stationary and isentropic compressible Navier-Stokes system. These equations are posed on a bounded domain $\Omega$ of $\mathbb{R}^{d}$, compatible with a MAC grid (see section 3 ), $d=2,3$, and read:

$$
\begin{align*}
& \operatorname{div}(\varrho \boldsymbol{u})=0 \text { in } \Omega  \tag{1.1a}\\
& \operatorname{div}(\varrho \boldsymbol{u} \otimes \boldsymbol{u})-\mu \Delta \boldsymbol{u}-(\mu+\lambda) \nabla \operatorname{div} \boldsymbol{u}+\nabla p=\boldsymbol{f} \text { in } \Omega  \tag{1.1b}\\
& p=\varrho^{\gamma} \text { in } \Omega, \varrho \geq 0 \text { in } \Omega, \int_{\Omega} \varrho \mathrm{d} \boldsymbol{x}=M \tag{1.1c}
\end{align*}
$$

supplemented by the boundary condition

$$
\begin{equation*}
\boldsymbol{u}_{\mid \partial \Omega}=0 \tag{1.2}
\end{equation*}
$$

In the above equations, the unknown functions are the scalar density and pressure fields, denoted by $\varrho(\boldsymbol{x}) \geq 0$ and $p(\boldsymbol{x})$ respectively, and the vector velocity field $\boldsymbol{u}=\left(u_{1}, \ldots, u_{d}\right)(\boldsymbol{x})$, where $\boldsymbol{x} \in \Omega$ denotes the space variable. The viscosity coefficients $\mu$ and $\lambda$ are such that (see [10])

$$
\begin{equation*}
\mu>0, \quad \lambda+\frac{2}{d} \mu \geq 0 \tag{1.3}
\end{equation*}
$$

The function $f \in L^{2}(\Omega)^{d}$ represents the resultant of the exterior forces acting on the fluid while the constant $M>0$ stands for the total mass of the fluid. In the compressible barotropic Navier-Stokes equations, the pressure is a given function of the density. Here we assume that the fluid is a perfect gas obeying Boyle's law:

$$
\begin{equation*}
p=a \varrho^{\gamma} \text { in } \Omega, \tag{1.4}
\end{equation*}
$$

[^0]where $a>0$ and where $\gamma>1$ is termed the adiabatic constant. Typical values of $\gamma$ range from a maximum $5 / 3$ for monoatomic gases, through $7 / 5$ for diatomic gases incuding air, to lower values close to 1 for polyatomic gases at high temperature. For the sake of simplicity, the constant $a$ will be taken equal to 1 . Unfortunately, for purely technical reasons, we will be forced to require that $\gamma>3$ if $d=3$ to prove the convergence of the MAC scheme. There is no restriction if $d=2$ in the sense that we can choose $\gamma>1$.

Remark 1 (Forcing term involving the density). Instead of taking a given function $\boldsymbol{f}$ in (1.1b), it is possible, in order to take the gravity effects into account, to take $\boldsymbol{f}=\varrho \boldsymbol{g}$ with $\boldsymbol{g} \in L^{\infty}(\Omega)^{d}$.

The mathematical analysis of numerical schemes for the discretization of the steady and/or timedependent compressible Navier-Stokes and/or compressible Stokes equations has been the object of some recent works. The convergence of the discrete solutions to the weak solutions of the compressible stationary Stokes problem was shown for a finite volume- non conforming P1 finite element $[9,12,14]$ and for the wellknown MAC scheme (see [8]) which was introduced in [20] and is widely used in computational fluid dynamics. The unsteady Stokes problem was also discretized using a FV-FE scheme (Finite Volumes and Finite Elements) on a reformulation of the problem, which were proven to be convergent [26]. The unsteady barotropic Navier-Stokes equations was also recently tackled in [27], with a FV-FE scheme, albeit only in the case $\gamma>3$ (there is a real difficulty in the realistic case $\gamma \leq 3$ arising from the treatment of the non linear convection term). Some error estimates have been derived for this FV-FE scheme in [17].
Since the very beginning of the introduction of the Marker-and-Cell (MAC) scheme [20], it is claimed that this discretization is suitable for both incompressible and compressible flow problems (see [18, 19] for the seminal papers, [1-3, 23-25, 32-36] for subsequent developments and [37] for a review). The use of the MAC scheme in the incompressible case is now standard, and the convergence in this case has been recently tackled in [16].
The paper is organized as follows. After recalling the fundamental setting of the problem in the continuous case in Section 2, we present a simple way (which adapts to the discrete setting) to prove a known preliminary result, namely the convergence (up to a subsequence) of the weak solution of Problem (1.1)-(1.4) with $\boldsymbol{f}_{n}$ and $M_{n}$ (instead of $\boldsymbol{f}$ and $M$ ) towards a weak solution of Problem (1.1)-(1.4) (with $M_{n} \rightarrow M$ and $f_{n} \rightarrow f$ weakly in $L^{2}(\Omega)^{d}$ as $\left.n \rightarrow+\infty\right)$. Then we proceed in Section 3 to the discretization: we introduce the discrete functional spaces and the definition of the numerical scheme, and state an existence result for this numerical scheme, the proof of which is given in Appendix A. The main result of this paper, that is the convergence theorem, is stated in Theorem 4. The remaining sections are devoted to the proof of Theorem 4. In Section 6, we derive estimates satisfied by the solutions of the scheme. In Section 7, we prove the convergence of the numerical scheme in the sense of Theorem 4 toward a weak solution of Problem (1.1)-(1.4).

## 2. The continuous problem

2.1. Definition of weak solution. In the sequel we explain what we mean by weak solution of Problem (1.1)-(1.4). Briefly, if $d=2$ and $\gamma>1$, it is possible to obtain a weak solution $(\boldsymbol{u}, p, \varrho)$ of (1.1)-(1.4) in the space $\left(H_{0}^{1}(\Omega)\right)^{2} \times L^{2}(\Omega) \times L^{2 \gamma}(\Omega)$ and to prove the convergence of a sequence of approximate solutions (up to a subsequence) towards a weak solution in the sense of Definition 1. If $d=3$, the problem is much more difficult. For any $\gamma>3 / 2$, a weak solution $(\boldsymbol{u}, p, \varrho)$ may be defined (with the extra hypothesis that $\boldsymbol{f}$ satisfies curl $\boldsymbol{f}=\mathbf{0}$ in the case $\left.\gamma \in\left(\frac{3}{2}, \frac{5}{3}\right]\right)$. However, this weak solution belongs to a functional space which depends on $\gamma$. Indeed, the function $\boldsymbol{u}$ always belongs to $H_{0}^{1}(\Omega)^{3}$, but the function $p$ belongs to $L^{2}(\Omega)$ only if $\gamma \geq 3$ (and the function $\varrho$ belongs to
$L^{2}(\Omega)$ only if $\left.\gamma \geq 5 / 3\right)$. More precisely, for $d=3$ and $\gamma<3$, we only get an estimate on $p$ in $L^{\delta}(\Omega)$, and an estimate on $\varrho$ in $L^{\gamma \delta}(\Omega)$, with $\delta=\frac{3(\gamma-1)}{\gamma}$. Note that for $\gamma=\frac{3}{2}$, one has $\delta=\frac{3(\gamma-1)}{\gamma}=1$, and $\gamma \delta=3(\gamma-1)=\frac{3}{2}$, so that the natural spaces are $p \in L^{1}(\Omega)$ and $\varrho \in L^{\frac{3}{2}}(\Omega)$. Note that in the case of the compressible Stokes equations, an $L^{2}$ estimate on the pressure and an $L^{2 \gamma}$ estimate on the density are obtained for $d=2$ or 3 and there is no restriction on $\gamma$ in the sense that we can take $\gamma>1$ (see for instance [9] and [8]).
To be in accordance with the main theorem of this article (see Theorem 4), we then define the notion of weak solution only for the case $\gamma>3$ if $d=3$ and $\gamma>1$ if $d=2$. We refer the reader to [29] and [30] for further informations about the notion of weak solutions and their existence. We recall that a bounded Lipschitz domain of $\mathbb{R}^{d}$ is a bounded connected open subset of $\mathbb{R}^{d}$ with a Lipschitz boundary.
In the whole paper, we define the $L^{p}$ vector norm by: $\|\cdot\|_{L^{p}(\Omega)^{d}}=\| \| \cdot \mid \|_{L^{p}(\Omega)}$, where $|\cdot|$ denotes the Euclidean norm in $\mathbb{R}^{d}$.
Definition 1. Let $d=2$ or $3, \Omega$ be a bounded Lipschitz domain of $\mathbb{R}^{d}$ and let $\boldsymbol{f} \in L^{2}(\Omega)^{d}, M>0$. Let $\gamma>3$ if $d=3$ or $\gamma>1$ if $d=2$. A weak solution of Problem (1.1)-(1.4) is a function $(\boldsymbol{u}, p, \varrho) \in\left(H_{0}^{1}(\Omega)\right)^{d} \times L^{2}(\Omega) \times L^{2 \gamma}(\Omega)$ satisfying the equations of (1.1)-(1.4) in the following weak sense:

$$
\begin{gather*}
\int_{\Omega} \varrho \boldsymbol{u} \cdot \nabla \varphi \mathrm{d} \boldsymbol{x}=0, \forall \varphi \in W^{1, \infty}(\Omega) .  \tag{2.1a}\\
-\int_{\Omega} \varrho \boldsymbol{u} \otimes \boldsymbol{u}: \nabla \boldsymbol{v} \mathrm{d} \boldsymbol{x}+\mu \int_{\Omega} \nabla \boldsymbol{u}: \nabla \boldsymbol{v} \mathrm{d} \boldsymbol{x}+(\mu+\lambda) \int_{\Omega} \operatorname{div} \boldsymbol{u} \operatorname{div} \boldsymbol{v} \mathrm{d} \boldsymbol{x}  \tag{2.1b}\\
-\int_{\Omega} p \operatorname{div} \boldsymbol{v} \mathrm{~d} \boldsymbol{x}=\int_{\Omega} \boldsymbol{f} \cdot \boldsymbol{v} \mathrm{d} \boldsymbol{x}, \forall \boldsymbol{v} \in C_{c}^{\infty}(\Omega)^{d} . \\
\varrho \geq 0 \text { a.e. in } \Omega, \int_{\Omega} \varrho \mathrm{d} \boldsymbol{x}=M \text { and } p=\varrho^{\gamma} \text { a.e in } \Omega . \tag{2.1c}
\end{gather*}
$$

Remark 2. Let $(\boldsymbol{u}, p, \varrho)$ be a weak solution in the sense of Definition 1. Then:
(1) $(\boldsymbol{u}, p, \varrho)$ satisfies the following inequality (see Step 1 of the proof of Theorem 1)

$$
\begin{equation*}
\int_{\Omega}\left(\mu|\nabla \boldsymbol{u}|^{2}+(\mu+\lambda)|\operatorname{div} \boldsymbol{u}|^{2}\right) \mathrm{d} \boldsymbol{x} \mathrm{dt} \leq \int_{\Omega} \boldsymbol{f} \cdot \boldsymbol{u} \mathrm{d} \boldsymbol{x} \tag{2.2}
\end{equation*}
$$

(2) By a density argument, using $\gamma \geq 3$, one can take $\boldsymbol{v} \in H_{0}^{1}(\Omega)^{d}$ in (2.1b).
2.2. Passage to the limit with approximate data. In order to understand our strategy in the discrete case, we first prove here the following result (which states the continuity, up to a subsequence, of the weak solution of (1.1)-(1.4) with respect to the data). In the following, we set

$$
q(d)=\left\{\begin{array}{l}
+\infty \text { if } d=2 \\
6 \text { if } d=3
\end{array}\right.
$$

Theorem 1. Let $\Omega$ be a bounded Lipschitz domain of $\mathbb{R}^{d}, d=2$ or 3 . Let $\gamma>1$ if $d=2$ and $\gamma>3$ if $d=3$. Let $\boldsymbol{f} \in L^{2}(\Omega)^{d}, M>0$ and $\left(\boldsymbol{f}_{n}\right)_{n \in \mathbb{N}} \subset L^{2}(\Omega)^{d},\left(M_{n}\right)_{n \in \mathbb{N}} \subset \mathbb{R}_{+}^{\star}$ be some sequences satisfying $\boldsymbol{f}_{n} \rightarrow \boldsymbol{f}$ weakly in $\left(L^{2}(\Omega)\right)^{d}$ and $M_{n} \rightarrow M$. For $n \in \mathbb{N}$, let $\left(\boldsymbol{u}_{n}, p_{n}, \varrho_{n}\right)$ be a weak solution of (1.1)-(1.4), in the sense of Definition 1, with $\boldsymbol{f}_{n}$ and $M_{n}$ instead of $\boldsymbol{f}$ and $M$.

Then, there exists $(\boldsymbol{u}, p, \varrho) \in\left(H_{0}^{1}(\Omega)\right)^{d} \times L^{2}(\Omega) \times L^{2 \gamma}(\Omega)$ such that, up to a subsequence, as $n \rightarrow+\infty$,

- $\boldsymbol{u}_{n} \rightarrow \boldsymbol{u}$ in $\left(L^{q}(\Omega)\right)^{d}$ for $1 \leq q<q(d)$ and weakly in $H_{0}^{1}(\Omega)^{d}$,
- $p_{n} \rightarrow p$ in $L^{q}(\Omega)$ for $1 \leq q<2$ and weakly in $L^{2}(\Omega)$,
- $\varrho_{n} \rightarrow \varrho$ in $L^{q}(\Omega)$ for $1 \leq q<2 \gamma$ and weakly in $L^{2 \gamma}(\Omega)$,
and $(\boldsymbol{u}, p, \varrho)$ is a weak solution of (1.1)-(1.4).
Proof. For the sake of simplicity, we will perform the proof for $\gamma>3$ and $d=3$. The case $d=2$ and $\gamma>1$ is simpler, and the modifications to be done to adapt the proof to the two-dimensional case are mostly due to the fact that Sobolev embeddings differ.
Let $\left(\boldsymbol{u}_{n}, p_{n}, \varrho_{n}\right)$ be a weak solution of Problem (1.1)-(1.4) with $f_{n}$ and $M_{n}$ instead of $f$ and $M$. The proof consists in 4 steps. In Step 1, we obtain some estimates on $\left(\boldsymbol{u}_{n}, p_{n}, \varrho_{n}\right)$. These estimates imply the convergence, in an appropriate sense, of $\left(\boldsymbol{u}_{n}, p_{n}, \varrho_{n}\right)$ to some ( $\left.\boldsymbol{u}, p, \varrho\right)$, up to a subsequence. Then, it is quite easy to prove that $(\boldsymbol{u}, p, \varrho)$ satisfies (2.1a), (2.1b) and a part of (2.1c) (this is Step 2) but it is not easy to prove that $p=\varrho^{\gamma}$ since, using the estimates of Step 1 , the convergence of $p_{n}$ and $\varrho_{n}$ is only weak (and $\gamma \neq 1$ ). In Step 3, we prove the convergence of the integral of $p_{n} \varrho_{n}$ to the integral of $p \varrho$. This allows in Step 4 to obtain the "strong" convergence of $\varrho_{n}$ (or $p_{n}$ ) and to conclude the proof.
We recall Lemma 2.1 of [9], which is crucial for Steps 1 and 3 of the proof. This lemma states that if $\varrho \in L^{2 \gamma}(\Omega), \gamma>1, \varrho \geq 0$ a.e. in $\Omega, \boldsymbol{u} \in\left(H_{0}^{1}(\Omega)\right)^{3}$ and ( $\left.\varrho, \boldsymbol{u}\right)$ satisfies (2.1a), then we have:

$$
\begin{equation*}
\int_{\Omega} \varrho \operatorname{div} \boldsymbol{u} \mathrm{d} \boldsymbol{x}=0 \tag{2.3}
\end{equation*}
$$

and

$$
\begin{equation*}
\int_{\Omega} \varrho^{\gamma} \operatorname{div} \boldsymbol{u} \mathrm{d} \boldsymbol{x}=0 \tag{2.4}
\end{equation*}
$$

This result is in fact also true for $\gamma=1$ [12, Lemma B1]. In Step 1 below, we use (2.4) (in fact, we only need $\int_{\Omega} \varrho^{\gamma} \operatorname{div} \boldsymbol{u} \mathrm{d} \boldsymbol{x} \leq 0$ and it is this weaker result which will be adapted and used for the approximate solution obtained by a numerical scheme). In Step 3, we use (2.3).

Step 1. Estimates. We recall that $\left(\boldsymbol{u}_{n}, p_{n}, \varrho_{n}\right)$ satisfies (2.1) with $f_{n}$ and $M_{n}$.
1.a Estimate on the velocity. Taking $\boldsymbol{u}_{n}$ as a test function in (2.1b), we get:

$$
\begin{aligned}
\mu \int_{\Omega} \nabla \boldsymbol{u}_{n}: \nabla \boldsymbol{u}_{n} \mathrm{~d} \boldsymbol{x}+(\mu+\lambda) \int_{\Omega}\left(\operatorname{div} \boldsymbol{u}_{n}\right)^{2} \mathrm{~d} \boldsymbol{x}-\int_{\Omega} \varrho_{n} \boldsymbol{u}_{n} \otimes & \boldsymbol{u}_{n}: \nabla \boldsymbol{u}_{n} \mathrm{~d} \boldsymbol{x} \\
& -\int_{\Omega} p_{n} \operatorname{div} \boldsymbol{u}_{n} \mathrm{~d} \boldsymbol{x}=\int_{\Omega} \boldsymbol{f}_{n} \cdot \boldsymbol{u}_{n} \mathrm{~d} \boldsymbol{x}
\end{aligned}
$$

Note that, since $\gamma>3$, we have $\varrho_{n} \boldsymbol{u}_{n} \otimes \boldsymbol{u}_{n} \in L^{2}(\Omega)^{3 \times 3}$, and, by density of $C_{c}^{\infty}(\Omega)^{d}$ in $L^{2}(\Omega)^{d}, \boldsymbol{u}_{n}$ is indeed an admissible test function. But $p_{n}=\varrho_{n}^{\gamma}$ a.e. in $\Omega$ and $\operatorname{div}\left(\varrho_{n} \boldsymbol{u}_{n}\right)=0$ (in the sense of (2.1a)), then using (2.4) (with $\varrho_{n}$ and $\boldsymbol{u}_{n}$ )

$$
\int_{\Omega} p_{n} \operatorname{div} \boldsymbol{u}_{n} \mathrm{~d} \boldsymbol{x}=0
$$

Again thanks to the mass equation (2.1a), and to the fact that $\varrho_{n} \in L^{2 \gamma}(\Omega) \subset L^{6}(\Omega)$ a straightforward computation gives

$$
\int_{\Omega} \varrho_{n} \boldsymbol{u}_{n} \otimes \boldsymbol{u}_{n}: \nabla \boldsymbol{u}_{n} \mathrm{~d} \boldsymbol{x}=0
$$

Hence, there exists $C_{1}$, only depending on the $L^{2}$-bound of $\left(\boldsymbol{f}_{n}\right)_{n \in \mathbb{N}}$, on $\Omega$ and on $\mu$, such that:

$$
\begin{equation*}
\left\|\boldsymbol{u}_{n}\right\|_{\left(H_{0}^{1}(\Omega)\right)^{3}} \leq C_{1} \tag{2.5}
\end{equation*}
$$

1.b Estimate on the pressure. In order to obtain an estimate on $p_{n}$ in $L^{2}(\Omega)$, we now use the two following lemmas. The first one is due to Bogovski, see e.g. [30, Section 3.3] or [11, Theorem 10.1] for a proof.

Lemma 1. Let $\Omega$ be a bounded Lipschitz domain of $\mathbb{R}^{d}(d \geq 1)$. Let $r \in(1,+\infty)$. Let $q \in L^{r}(\Omega)$ such that $\int_{\Omega} q \mathrm{~d} \boldsymbol{x}=0$. Then, there exists $\boldsymbol{v} \in\left(W_{0}^{1, r}(\Omega)\right)^{d}$ such that $\operatorname{div} \boldsymbol{v}=q$ a.e. in $\Omega$ and $\|\boldsymbol{v}\|_{\left(W_{0}^{1, r}(\Omega)\right)^{d}} \leq C_{2}\|q\|_{L^{r}(\Omega)}$ with $C_{2}$ depending only on $\Omega$ and $r$.

The following lemma is a straightforward consequence of [13, Lemma 5.4].
Lemma 2. Let $\Omega$ be a bounded Lipschitz domain of $\mathbb{R}^{d}(d \geq 1)$ and $p \in L^{2}(\Omega)$ such that $p \geq 0$ a.e in $\Omega$. We assume that there exist $a>0, b, c \in \mathbb{R}$ and $r \in(0,1)$ such that

$$
\left\{\begin{array}{l}
\|p-m(p)\|_{L^{2}(\Omega)} \leq a\|p\|_{L^{2}(\Omega)}^{r}+b \\
\int_{\Omega} p^{r} \mathrm{~d} \boldsymbol{x} \leq c
\end{array}\right.
$$

where $m(p)=\frac{1}{|\Omega|} \int_{\Omega} p \mathrm{~d} \boldsymbol{x}$ is the mean value of $p$. Then, there exists $C$ only depending on $\Omega, a, b, c$ and $r$ such that $\|p\|_{L^{2}(\Omega)} \leq C$.

Let $m_{n}=\frac{1}{|\Omega|} \int_{\Omega} p_{n} \mathrm{~d} \boldsymbol{x}$; thanks to Lemma 1 with $r=2$, there exists $\boldsymbol{v}_{n} \in H_{0}^{1}(\Omega)^{3}$ such that $\operatorname{div} \boldsymbol{v}_{n}=p_{n}-m_{n}$ and

$$
\begin{equation*}
\left\|\boldsymbol{v}_{n}\right\|_{\left(H_{0}^{1}(\Omega)\right)^{3}} \leq C_{2}\left\|p_{n}-m_{n}\right\|_{L^{2}(\Omega)} \tag{2.6}
\end{equation*}
$$

Taking $\boldsymbol{v}_{n}$ as a test function in (2.1b) yields:

$$
\begin{align*}
& \mu \int_{\Omega} \nabla \boldsymbol{u}_{n}: \nabla \boldsymbol{v}_{n} \mathrm{~d} \boldsymbol{x}+(\mu+\lambda) \int_{\Omega} \operatorname{div} \boldsymbol{u}_{n} \operatorname{div} \boldsymbol{v}_{n} \mathrm{~d} \boldsymbol{x}-\int_{\Omega} \varrho_{n} \boldsymbol{u}_{n} \otimes \boldsymbol{u}_{n}: \nabla \boldsymbol{v}_{n} \mathrm{~d} \boldsymbol{x}  \tag{2.7}\\
&-\int_{\Omega} p_{n} \operatorname{div} \boldsymbol{v}_{n} \mathrm{~d} \boldsymbol{x}=\int_{\Omega} \boldsymbol{f}_{n} \cdot \boldsymbol{v}_{n} \mathrm{~d} \boldsymbol{x}
\end{align*}
$$

Since $\int_{\Omega} \operatorname{div} \boldsymbol{u}_{n} \mathrm{~d} \boldsymbol{x}=\int_{\Omega} \operatorname{div} \boldsymbol{v}_{n} \mathrm{~d} \boldsymbol{x}=0$, we get:

$$
\int_{\Omega}\left(p_{n}-m_{n}\right)^{2} \mathrm{~d} \boldsymbol{x}=\int_{\Omega}\left(-\boldsymbol{f}_{n} \cdot \boldsymbol{v}_{n}+\mu \nabla \boldsymbol{u}_{n}: \nabla \boldsymbol{v}_{n}+(\mu+\lambda) p_{n} \operatorname{div} \boldsymbol{u}_{n}-\varrho_{n} \boldsymbol{u}_{n} \otimes \boldsymbol{u}_{n}: \nabla \boldsymbol{v}_{n}\right) \mathrm{d} \boldsymbol{x}
$$

Since $\left\|\boldsymbol{u}_{n}\right\|_{\left(H_{0}^{1}(\Omega)\right)^{3}} \leq C_{1}$ and $H_{0}^{1}(\Omega)$ is continuously embedded in $L^{6}(\Omega)$, we get that:

$$
\begin{equation*}
\int_{\Omega} \varrho_{n} \boldsymbol{u}_{n} \otimes \boldsymbol{u}_{n}: \nabla v_{n} \mathrm{~d} \boldsymbol{x} \leq\left\|\varrho_{n}\right\|_{L^{6}(\Omega)}\left\|\boldsymbol{u}_{n}\right\|_{L^{6}(\Omega)^{3}}^{2}\left\|\boldsymbol{v}_{n}\right\|_{\left(H^{1}(\Omega)\right)^{3}} . \tag{2.8}
\end{equation*}
$$

From (2.7), (2.8) and (2.6), since $2 \gamma \geq 6$ and $p_{n}=\varrho_{n}^{\gamma}$, we get:

$$
\left\|p_{n}-m_{n}\right\|_{L^{2}(\Omega)} \leq C_{3}\left(1+\left\|\varrho_{n}\right\|_{L^{6}(\Omega)}\right) \leq C_{4}\left(1+\left\|\varrho_{n}\right\|_{L^{2 \gamma}(\Omega)}\right) \leq C_{4}\left(1+\left\|p_{n}\right\|_{L^{2}(\Omega)}^{1 / \gamma}\right)
$$

Since $\int_{\Omega} p_{n}^{1 / \gamma} \mathrm{d} \boldsymbol{x}=\int_{\Omega} \varrho_{n} \mathrm{~d} \boldsymbol{x} \leq \sup \left\{M_{k}, k \in \mathbb{N}\right\}$, we get from Lemma 2 that $\left\|p_{n}\right\|_{L^{2}(\Omega)} \leq C_{5}$, where $C_{5}$ depends only on the $L^{2}$-bound on $\left(\boldsymbol{f}_{n}\right)_{n \in \mathbb{N}}$, the bound on $\left(M_{n}\right)_{n \in \mathbb{N}}, \gamma, \mu, \lambda$ and $\Omega$. Thanks to the equation of state, we have $p_{n}=\varrho_{n}^{\gamma}$ a.e. in $\Omega$, and therefore $\left\|\varrho_{n}\right\|_{L^{2 \gamma}(\Omega)} \leq C_{6}=C_{5}^{1 / \gamma}$.

Step 2. Passing to the limit on the equations (2.1a), (2.1b) and a part of (2.1c).
The estimates obtained in Step 1 yield that, up to a subsequence, as $n \rightarrow+\infty$ :

$$
\begin{aligned}
& \boldsymbol{u}_{n} \rightarrow u \text { in } L^{q}(\Omega)^{3} \text { for any } 1 \leq q<6 \text { and weakly in } H_{0}^{1}(\Omega)^{3}, \\
& p_{n} \rightarrow p \text { weakly in } L^{2}(\Omega), \\
& \varrho_{n} \rightarrow \varrho \text { weakly in } L^{2 \gamma}(\Omega) .
\end{aligned}
$$

Since $\varrho_{n} \rightarrow \varrho$ weakly in $L^{2 \gamma}(\Omega)$, with $2 \gamma>6>\frac{3}{2}$, and $\boldsymbol{u}_{n} \rightarrow \boldsymbol{u}$ in $L^{q}(\Omega)$ for all $q<6$ (and $\frac{2}{3}+\frac{1}{6}+\frac{1}{6}=1$ ), we have that $\varrho_{n} \boldsymbol{u}_{n} \otimes \boldsymbol{u}_{n} \rightarrow \varrho \boldsymbol{u} \otimes \boldsymbol{u}$ weakly in $L^{1}(\Omega)$. Moreover, $\nabla \boldsymbol{u}_{n} \rightarrow \nabla \boldsymbol{u}$ weakly in $L^{2}(\Omega)^{3}, p_{n} \rightarrow p$ weakly in $L^{2}(\Omega)$ and $\boldsymbol{f}_{n} \rightarrow \boldsymbol{f}$ weakly in $L^{2}(\Omega)^{3}$. Therefore, passing to the limit in (2.1b) (the weak momentum equation) for $\left(\boldsymbol{u}_{n}, p_{n}, \varrho_{n}\right)$, we obtain (2.1b) for $(\boldsymbol{u}, p, \varrho)$.
Since $\varrho_{n} \rightarrow \varrho$ weakly in $L^{2 \gamma}(\Omega)$, with $2 \gamma>\frac{6}{5}$ and $\boldsymbol{u}_{n} \rightarrow \boldsymbol{u}$ in $L^{q}(\Omega)$ for all $q<6$, we get that $\varrho_{n} \boldsymbol{u}_{n} \rightarrow \varrho \boldsymbol{u}$ weakly in $L^{1}(\Omega)$. Then passing to the limit on (2.1a) (the weak mass balance) for $\left(\boldsymbol{u}_{n}, \varrho_{n}\right)$, we obtain (2.1a) for $(\boldsymbol{u}, \varrho)$.
The weak convergence of $\varrho_{n}$ to $\varrho$ and the fact that $\varrho_{n} \geq 0$ a.e. in $\Omega$ gives that $\varrho \geq 0$ a.e. in $\Omega$ (indeed, taking $\psi=1_{\varrho<0}$ as test function gives $\int_{\Omega} \varrho \psi \mathrm{d} \boldsymbol{x}=\lim _{n \rightarrow+\infty} \int_{\Omega} \varrho_{n} \psi \mathrm{~d} \boldsymbol{x} \geq 0$, which proves that $\varrho \psi=0$ a.e.). The weak convergence of $\varrho_{n}$ to $\varrho$ also gives (taking $\psi=1$ as test function) that $\int_{\Omega} \varrho \mathrm{d} \boldsymbol{x}=M$. Therefore, $(\boldsymbol{u}, p, \varrho)$ is a weak solution of the momentum equation and of the mass balance equation satisfying $\varrho \geq 0$ a.e in $\Omega$ and $\int_{\Omega} \varrho \mathrm{d} \boldsymbol{x}=M$. Hence Theorem 1 is proved except for the fact that $p=\varrho^{\gamma}$ a.e. in $\Omega$. This is the objective of the last two steps, where we also prove a "strong" convergence of $\varrho_{n}$ and $p_{n}$. We need to prove that $p=\varrho^{\gamma}$ in $\Omega$, even though we only have a weak convergence of $p_{n}$ and $\varrho_{n}$, and $\gamma>1$. The idea (for $d=2$ or $d=3, \gamma>3$ ) is to prove $\int_{\Omega} p_{n} \varrho_{n} \rightarrow \int_{\Omega} p \varrho$ and deduce the a.e. convergence (of $p_{n}$ and $\varrho_{n}$ ) and $p=\varrho^{\gamma}$.
Step 3. Proving the convergence of the effective viscous flux and $\int_{\Omega} \varrho_{n} p_{n} \mathrm{~d} \boldsymbol{x} \rightarrow \int_{\Omega} \varrho p \mathrm{~d} \boldsymbol{x}$. Since the sequence $\left(\varrho_{n}\right)_{n \in \mathbb{N}}$ is bounded in $L^{2}(\Omega)$, The result of [9, Lemma B.8] gives the existence of a bounded sequence $\left(\boldsymbol{v}_{n}\right)_{n \in \mathbb{N}}$ in $H^{1}(\Omega)^{3}$ such that $\operatorname{div} \boldsymbol{v}_{n}=\varrho_{n}$ and $\operatorname{curl} \boldsymbol{v}_{n}=0$. It is possible to assume (up to a subsequence) that $\boldsymbol{v}_{n} \rightarrow v$ in $L^{2}(\Omega)^{3}$ and weakly in $H^{1}(\Omega)^{3}$. Passing to the limit in the preceding equations gives $\operatorname{div} \boldsymbol{v}=\varrho$ and $\operatorname{curl} \boldsymbol{v}=0$.
Let $\varphi \in C_{c}^{\infty}(\Omega)$ (so that $\left.\varphi \boldsymbol{v}_{n} \in H_{0}^{1}(\Omega)^{3}\right)$. Taking $\boldsymbol{v}=\varphi \boldsymbol{v}_{n}$ in the weak momentum equation (2.1b) written for $\left.\left(\boldsymbol{u}_{n}, p_{n}, \varrho_{n}\right)\right)$ leads to:

$$
\begin{align*}
\mu \int_{\Omega} \nabla \boldsymbol{u}_{n}: \nabla\left(\varphi \boldsymbol{v}_{n}\right) \mathrm{d} \boldsymbol{x}+(\mu+\lambda) \int_{\Omega} \operatorname{div} & \boldsymbol{u}_{n} \operatorname{div}\left(\varphi \boldsymbol{v}_{n}\right) \mathrm{d} \boldsymbol{x}-\int_{\Omega} p_{n} \operatorname{div}\left(\varphi \boldsymbol{v}_{n}\right) \mathrm{d} \boldsymbol{x}  \tag{2.9}\\
& =\int_{\Omega} \varrho_{n} \boldsymbol{u}_{n} \otimes \boldsymbol{u}_{n}: \nabla\left(\varphi \boldsymbol{v}_{n}\right) \mathrm{d} \boldsymbol{x}+\int_{\Omega} \boldsymbol{f}_{n} \cdot\left(\varphi \boldsymbol{v}_{n}\right) \mathrm{d} \boldsymbol{x}
\end{align*}
$$

The choice of $\boldsymbol{v}_{n}$ gives $\operatorname{div}\left(\varphi \boldsymbol{v}_{n}\right)=\varphi \varrho_{n}+\boldsymbol{v}_{n} \cdot \nabla \varphi$ and $\operatorname{curl} \varphi \boldsymbol{v}_{n}=L(\varphi) \boldsymbol{v}_{n}$, where $L(\varphi)$ is a matrix with entries involving the first order derivatives of $\varphi$. Noting that

$$
\begin{equation*}
\int_{\Omega} \nabla \overline{\boldsymbol{u}}: \nabla \overline{\boldsymbol{v}} \mathrm{d} \boldsymbol{x}=\int_{\Omega} \operatorname{div} \overline{\boldsymbol{u}} \operatorname{div} \overline{\boldsymbol{v}} \mathrm{d} \boldsymbol{x}+\int_{\Omega} \operatorname{curl} \overline{\boldsymbol{u}} \cdot \operatorname{curl} \overline{\boldsymbol{v}} \mathrm{d} \boldsymbol{x}, \text { for all }(\overline{\boldsymbol{u}}, \overline{\boldsymbol{v}}) \in H_{0}^{1}(\Omega)^{3}, \tag{2.10}
\end{equation*}
$$

the equality (2.9) leads to:

$$
\begin{aligned}
& \int_{\Omega}\left((2 \mu+\lambda) \operatorname{div} \boldsymbol{u}_{n}-p_{n}\right) \varrho_{n} \varphi \mathrm{~d} \boldsymbol{x}+\int_{\Omega}\left((2 \mu+\lambda) \operatorname{div} \boldsymbol{u}_{n}-p_{n}\right) \boldsymbol{v}_{n} \cdot \nabla \varphi \mathrm{~d} \boldsymbol{x} \\
&+\mu \int \operatorname{curl} \boldsymbol{u}_{n} \cdot L(\varphi) \boldsymbol{v}_{n} \mathrm{~d} \boldsymbol{x}=\int_{\Omega} \varrho_{n} \boldsymbol{u}_{n} \otimes \boldsymbol{u}_{n}: \nabla\left(\varphi \boldsymbol{v}_{n}\right) \mathrm{d} \boldsymbol{x}+\int_{\Omega} \boldsymbol{f}_{n} \cdot\left(\varphi \boldsymbol{v}_{n}\right) \mathrm{d} \boldsymbol{x}
\end{aligned}
$$

Thanks to the weak convergence of $\boldsymbol{u}_{n}$ in $H_{0}^{1}(\Omega)^{d}$ to $\boldsymbol{u}$, the weak convergence of $p_{n}$ in $L^{2}(\Omega)$ to $p$, the weak convergence of $\boldsymbol{f}_{n}$ in $L^{2}(\Omega)$ to $\boldsymbol{f}$ and the convergence of $\boldsymbol{v}_{n}$ in $L^{2}(\Omega)^{d}$ to $\boldsymbol{v}$, we obtain:

$$
\begin{align*}
\lim _{n \rightarrow+\infty} \int_{\Omega}( & \left.\left((2 \mu+\lambda) \operatorname{div} \boldsymbol{u}_{n}-p_{n}\right) \varrho_{n} \varphi-\varrho_{n} \boldsymbol{u}_{n} \otimes \boldsymbol{u}_{n}: \nabla\left(\varphi v_{n}\right)\right) \mathrm{d} \boldsymbol{x}=  \tag{2.11}\\
& \int_{\Omega} \boldsymbol{f} \cdot(\varphi \boldsymbol{v}) \mathrm{d} \boldsymbol{x}+\int_{\Omega}(p-(2 \mu+\lambda) \operatorname{div} \boldsymbol{u}) \boldsymbol{v} \cdot \nabla \varphi \mathrm{d} \boldsymbol{x}-\mu \int_{\Omega)} \operatorname{curl} \boldsymbol{u} \cdot L(\varphi) \boldsymbol{v} \mathrm{d} \boldsymbol{x}
\end{align*}
$$

But, thanks to the weak momentum equation (2.1b) for $(\boldsymbol{u}, p, \varrho)$, we have

$$
\begin{aligned}
\mu \int_{\Omega} \nabla \boldsymbol{u}: \nabla(\varphi \boldsymbol{v}) \mathrm{d} \boldsymbol{x}+(\mu+\lambda) \int_{\Omega} \operatorname{div} \boldsymbol{u} \operatorname{div}(\varphi \boldsymbol{v}) \mathrm{d} \boldsymbol{x} & -\int_{\Omega} p \operatorname{div}(\varphi \boldsymbol{v}) \mathrm{d} \boldsymbol{x} \\
& =\int_{\Omega} \varrho \boldsymbol{u} \otimes \boldsymbol{u}: \nabla(\varphi \boldsymbol{v}) \mathrm{d} \boldsymbol{x}+\int_{\Omega} \boldsymbol{f} \cdot(\varphi \boldsymbol{v}) \mathrm{d} \boldsymbol{x}
\end{aligned}
$$

or equivalently, thanks to (2.10):

$$
\begin{aligned}
\int_{\Omega}((2 \mu+\lambda) \operatorname{div} \boldsymbol{u}-p) \operatorname{div}(\varphi \boldsymbol{v}) \mathrm{d} \boldsymbol{x}+\mu \int_{\Omega} \operatorname{curl} \boldsymbol{u} \cdot & \operatorname{curl}(\varphi \boldsymbol{v}) \mathrm{d} \boldsymbol{x} \\
& =\int_{\Omega} \varrho \boldsymbol{u} \otimes \boldsymbol{u}: \nabla(\varphi \boldsymbol{v}) \mathrm{d} \boldsymbol{x}+\int_{\Omega} f \cdot(\varphi \boldsymbol{v}) \mathrm{d} \boldsymbol{x}
\end{aligned}
$$

Since $\operatorname{div} \boldsymbol{v}=\varrho$ and $\operatorname{curl} \boldsymbol{v}=0$, we obtain:

$$
\begin{aligned}
& \int_{\Omega}((2 \mu+\lambda) \operatorname{div} \boldsymbol{u}-p) \varrho \varphi \mathrm{d} \boldsymbol{x}-\int_{\Omega} \varrho \boldsymbol{u} \otimes \boldsymbol{u}: \nabla(\varphi \boldsymbol{v}) \mathrm{d} \boldsymbol{x}= \\
& \qquad \int_{\Omega} \boldsymbol{f} \cdot(\varphi \boldsymbol{v}) \mathrm{d} \boldsymbol{x}+\int_{\Omega}(p-(2 \mu+\lambda) \operatorname{div} \boldsymbol{u}) \boldsymbol{v} \cdot \nabla \varphi \mathrm{d} \boldsymbol{x}-\mu \int_{\Omega} \operatorname{curl} \boldsymbol{u} \cdot L(\varphi) \boldsymbol{v} \mathrm{d} \boldsymbol{x}
\end{aligned}
$$

Let us assume momentarily that:

$$
\begin{equation*}
\int_{\Omega} \varrho_{n} \boldsymbol{u}_{n} \otimes \boldsymbol{u}_{n}: \nabla\left(\varphi \boldsymbol{v}_{n}\right) \mathrm{d} \boldsymbol{x} \rightarrow \int_{\Omega} \varrho \boldsymbol{u} \otimes \boldsymbol{u}: \nabla(\varphi \boldsymbol{v}) \mathrm{d} \boldsymbol{x} \text { as } n \rightarrow+\infty \tag{2.12}
\end{equation*}
$$

We then obtain thanks to (2.11):

$$
\begin{equation*}
\lim _{n \rightarrow+\infty} \int_{\Omega}\left(p_{n}-(2 \mu+\lambda) \operatorname{div} \boldsymbol{u}_{n}\right) \varrho_{n} \varphi \mathrm{~d} \boldsymbol{x}=\int_{\Omega}(p-(2 \mu+\lambda) \operatorname{div} \boldsymbol{u}) \varrho \varphi \mathrm{d} \boldsymbol{x} \tag{2.13}
\end{equation*}
$$

The quantity $p-(\lambda+2 \mu) \operatorname{div} \boldsymbol{u}$ is usually called the effective viscous flux. This quantity enjoys many remarkable properties for which we refer to Hoff [22], Lions [28], or Serre [31]. Note that this quantity is the amplitude of the normal viscous stress augmented by the hydrostatic pressure $p$, that is, the "real" pressure acting on a volume element of the fluid. In (2.13), the function $\varphi$ is an arbitrary element of $C_{c}^{\infty}(\Omega)$. Then as in [9], we remark that it is possible to take $\varphi=1$ in (2.13), thanks to the fact that $\left(p_{n}-(2 \mu+\lambda) \operatorname{div} \boldsymbol{u}_{n}\right) \varrho_{n} \in L^{r}(\Omega)$ for some $r>1$ (see [9, Lemma B.2]).
Using (2.3), which holds by [9, Lemma 2.1] thanks to the fact that $\operatorname{div}\left(\varrho_{n} \boldsymbol{u}_{n}\right)=\operatorname{div}(\varrho \boldsymbol{u})=0$ (in the sense of (2.1a)), we have $\int_{\Omega} \varrho_{n} \operatorname{div} \boldsymbol{u}_{n} \mathrm{~d} \boldsymbol{x}=\int_{\Omega} \varrho \operatorname{div} \boldsymbol{u} \mathrm{d} \boldsymbol{x}=0$. Therefore, (2.13) yields:

$$
\begin{equation*}
\lim _{n \rightarrow+\infty} \int_{\Omega} p_{n} \varrho_{n} \mathrm{~d} \boldsymbol{x}=\int_{\Omega} p \varrho \mathrm{~d} \boldsymbol{x} \tag{2.14}
\end{equation*}
$$

Remark 3. The equality in (2.14) is not necessary in Step 4; in fact, it is sufficient to have $\liminf _{n \rightarrow+\infty} \int_{\Omega} p_{n} \varrho_{n} \mathrm{~d} \boldsymbol{x} \leq \int_{\Omega} p \varrho \mathrm{~d} \boldsymbol{x}$. Then, instead of $\int_{\Omega} \varrho_{n} \operatorname{div} \boldsymbol{u}_{n} \mathrm{~d} \boldsymbol{x}=0$, it is sufficient to have
$\liminf _{n \rightarrow+\infty} \int_{\Omega} \varrho_{n} \operatorname{div} \boldsymbol{u}_{n} \mathrm{~d} \boldsymbol{x} \leq 0$. This will be the case in the framework of an approximation by a numerical scheme.

In order to conclude Step 3, it remains to show (2.12).
We remark that, since $\operatorname{div}\left(\varrho_{n} \boldsymbol{u}_{n}\right)=0$ and $\left(\varrho_{n}, \boldsymbol{u}_{n}\right) \in L^{6}(\Omega) \times H_{0}^{1}(\Omega)^{3}$,

$$
\begin{equation*}
\int_{\Omega} \varrho_{n} \boldsymbol{u}_{n} \otimes \boldsymbol{u}_{n}: \nabla\left(\varphi \boldsymbol{v}_{n}\right) \mathrm{d} \boldsymbol{x}=-\int_{\Omega}\left(\varrho_{n} \boldsymbol{u}_{n} \cdot \nabla\right) \boldsymbol{u}_{n} \cdot\left(\varphi \boldsymbol{v}_{n}\right) \mathrm{d} \boldsymbol{x} \tag{2.15}
\end{equation*}
$$

The sequence $\left(\left(\varrho_{n} \boldsymbol{u}_{n} \cdot \nabla\right) \boldsymbol{u}_{n}\right)_{n \in \mathbb{N}}$ is bounded in $L^{r}(\Omega)^{3}$, with $\frac{1}{r}=\frac{1}{2}+\frac{1}{6}+\frac{1}{2 \gamma}$. Since $\gamma>3$, we have $r>\frac{6}{5}$. Then, up to a subsequence, $\left(\varrho_{n} \boldsymbol{u}_{n} \cdot \nabla\right) \boldsymbol{u}_{n}$ tends to some function $G$ weakly in $L^{r}(\Omega)^{3}$. Since $\boldsymbol{v}_{n} \rightarrow \boldsymbol{v}$ in $L^{s}(\Omega)^{3}$ for all $s<6$ and therefore for $s=\frac{r}{r-1}$, we deduce that:

$$
\int_{\Omega}\left(\varrho_{n} \boldsymbol{u}_{n} \cdot \nabla\right) \boldsymbol{u}_{n} \cdot\left(\varphi \boldsymbol{v}_{n}\right) \mathrm{d} \boldsymbol{x} \rightarrow \int_{\Omega} G \cdot(\varphi \boldsymbol{v}) \mathrm{d} \boldsymbol{x}
$$

Moreover, for a fixed $\boldsymbol{w} \in H_{0}^{1}(\Omega)^{3}$,

$$
\int_{\Omega}\left(\varrho_{n} \boldsymbol{u}_{n} \cdot \nabla\right) \boldsymbol{u}_{n} \cdot \boldsymbol{w} \mathrm{~d} \boldsymbol{x}=-\int_{\Omega} \varrho_{n} \boldsymbol{u}_{n} \otimes \boldsymbol{u}_{n}: \nabla \boldsymbol{w} \mathrm{d} \boldsymbol{x} \rightarrow-\int_{\Omega} \varrho \boldsymbol{u} \otimes \boldsymbol{u}: \nabla \boldsymbol{w} \mathrm{d} \boldsymbol{x}
$$

But, since $\operatorname{div}(\varrho u)=0$ and $(\varrho, \boldsymbol{u}) \in L^{6}(\Omega) \times H_{0}^{1}(\Omega)^{3}$, we have

$$
-\int_{\Omega} \varrho \boldsymbol{u} \otimes \boldsymbol{u}: \nabla \boldsymbol{w} \mathrm{d} \boldsymbol{x}=\int_{\Omega}(\varrho \boldsymbol{u} \cdot \nabla) \boldsymbol{u} \cdot \boldsymbol{w} \mathrm{d} \boldsymbol{x}
$$

We thus get that $G=(\varrho \boldsymbol{u} \cdot \nabla) \boldsymbol{u}$, which concludes the proof of (2.12).
Step 4. Passing to the limit on the EOS and "strong" convergence of $\varrho_{n}$ and $p_{n}$. The end of the proof is exactly the same as Step 4 of [9, Proof of Theorem 2.2]; it is reproduced here for the sake of completeness. For $n \in \mathbb{N}$, let $G_{n}=\left(\varrho_{n}^{\gamma}-\varrho^{\gamma}\right)\left(\varrho_{n}-\varrho\right)$. For all $n \in \mathbb{N}$, the function $G_{n}$ belongs to $L^{1}(\Omega)$ and $G_{n} \geq 0$ a.e. in $\Omega$. Futhermore $G_{n}=\left(p_{n}-\varrho^{\gamma}\right)\left(\varrho_{n}-\varrho\right)=p_{n} \varrho_{n}-p_{n} \varrho-\varrho^{\gamma} \varrho_{n}+\varrho^{\gamma} \varrho$ and $\int_{\Omega} G_{n} \mathrm{~d} \boldsymbol{x}=\int_{\Omega} p_{n} \varrho_{n} \mathrm{~d} \boldsymbol{x}-\int_{\Omega} p_{n} \varrho \mathrm{~d} \boldsymbol{x}-\int_{\Omega} \varrho^{\gamma} \varrho_{n} \mathrm{~d} \boldsymbol{x}+\int_{\Omega} \varrho^{\gamma} \varrho \mathrm{d} \boldsymbol{x}$.
Using the weak convergence in $L^{2}(\Omega)$ of $p_{n}$ to $p$ and of $\varrho_{n}$ to $\varrho$, the fact that $\varrho, \varrho^{\gamma} \in L^{2}(\Omega)$ and (2.14) gives $\lim _{n \rightarrow+\infty} \int_{\Omega} G_{n} \mathrm{~d} \boldsymbol{x}=0$, that is $G_{n} \rightarrow 0$ in $L^{1}(\Omega)$. Then, up to a subsequence, we have $G_{n} \rightarrow 0$ a.e. in $\Omega$. Since $y \mapsto y^{\gamma}$ is an increasing function on $\mathbb{R}_{+}$, we deduce that $\varrho_{n} \rightarrow \varrho$ a.e., as $n \rightarrow+\infty$. Then, we also have $p_{n}=\varrho_{n}^{\gamma} \rightarrow \varrho^{\gamma}$ a.e.. Since $\left(\varrho_{n}\right)_{n \in \mathbb{N}}$ is bounded in $L^{2 \gamma}(\Omega)$ and $\left(p_{n}\right)_{n \in \mathbb{N}}$ is bounded in $L^{2}(\Omega)$, we obtain, as $n \rightarrow+\infty$ :

$$
\begin{aligned}
& \varrho_{n} \rightarrow \varrho \text { in } L^{q}(\Omega) \text { for all } 1 \leq q<2 \gamma, \\
& p_{n} \rightarrow \varrho^{\gamma} \text { in } L^{q}(\Omega) \text { for all } 1 \leq q<2 .
\end{aligned}
$$

Since we already know that $p_{n} \rightarrow p$ weakly in $L^{2}(\Omega)$, we necessarily have (by uniqueness of the weak limit in $\left.L^{q}(\Omega)\right)$ that $p=\varrho^{\gamma}$ a.e. in $\Omega$. The proof of Theorem 1 is now complete.

## 3. The numerical scheme

3.1. Mesh and discrete spaces. We will now assume that the bounded domain $\Omega$ is $M A C$ compatible in the sense that $\bar{\Omega}$ is a finite union of (closed) rectangles $(d=2)$ or (closed) orthogonal parallelepipeds $(d=3)$ and, without loss of generality, we assume that the edges (or faces) of these rectangles (or parallelepipeds) are orthogonal to the canonical basis vectors, denoted by $\left(\boldsymbol{e}_{1}, \ldots, \boldsymbol{e}_{d}\right)$.

Definition 2 (MAC grid). A discretization of a MAC compatible bounded domain $\Omega$ with a MAC grid is defined by $\mathcal{D}=(\mathcal{M}, \mathcal{E})$, where:

- $\mathcal{M}$ stands for the primal grid, and consists in a regular structured partition of $\Omega$ in possibly non uniform rectangles $(d=2)$ or rectangular parallelepipeds $(d=3)$. A generic cell of this grid is denoted by $K$, and its mass center by $\boldsymbol{x}_{K}$. The scalar unknowns, namely the density and the pressure, are associated to this mesh, and $\mathcal{M}$ is also sometimes referred as "the pressure mesh".
- The set of all faces of the mesh is denoted by $\mathcal{E}$; we have $\mathcal{E}=\mathcal{E}_{\text {int }} \cup \mathcal{E}_{\text {ext }}$, where $\mathcal{E}_{\text {int }}$ (resp. $\mathcal{E}_{\text {ext }}$ ) are the edges of $\mathcal{E}$ that lie in the interior (resp. on the boundary) of the domain. The set of faces that are orthogonal to the $i^{\text {th }}$ unit vector $\boldsymbol{e}_{i}$ of the canonical basis of $\mathbb{R}^{d}$ is denoted by $\mathcal{E}^{(i)}$, for $i=1, \ldots$, d. We then have $\mathcal{E}^{(i)}=\mathcal{E}_{\text {int }}^{(i)} \cup \mathcal{E}_{\text {ext }}^{(i)}$, where $\mathcal{E}_{\text {int }}^{(i)}$ (resp. $\left.\mathcal{E}_{\text {ext }}^{(i)}\right)$ are the edges of $\mathcal{E}^{(i)}$ that lie in the interior (resp. on the boundary) of the domain.

For each $\sigma \in \mathcal{E}$, we write that $\sigma=K \mid L$ if $\sigma=\partial K \cap \partial L$. A dual cell $D_{\sigma}$ associated to $a$ face $\sigma \in \mathcal{E}$ is defined as follows:

* if $\sigma=K \mid L \in \mathcal{E}_{\text {int }}$ then $D_{\sigma}=D_{K, \sigma} \cup D_{L, \sigma}$, where $D_{K, \sigma}$ (resp. $D_{L, \sigma}$ ) is the half-part of $K$ (resp. L) adjacent to $\sigma$ (see Fig. 1 for the two-dimensional case) ;
* if $\sigma \in \mathcal{E}_{\text {ext }}$ is adjacent to the cell $K$, then $D_{\sigma}=D_{K, \sigma}$.

We obtain d partitions of the computational domain $\Omega$ as follows:

$$
\Omega=\cup_{\sigma \in \mathcal{E}^{(i)}} D_{\sigma}, \quad 1 \leq i \leq d
$$

and the $i^{\text {th }}$ of these partitions is called $i^{\text {th }}$ dual mesh, and is associated to the $i^{\text {th }}$ velocity component, in a sense which is precised below. The set of the faces of the $i^{\text {th }}$ dual mesh is denoted by $\widetilde{\mathcal{E}}^{(i)}$ and is decomposed into the internal and boundary edges: $\widetilde{\mathcal{E}}^{(i)}=\widetilde{\mathcal{E}}_{\text {int }}^{(i)} \cup \widetilde{\mathcal{E}}_{\mathrm{ext}}^{(i)}$. The dual face separating two dual cells $D_{\sigma}$ and $D_{\sigma^{\prime}}$ is denoted by $\epsilon=\sigma \mid \sigma^{\prime}$.

To define the scheme, we need some additional notations. The set of faces of a primal cell $K$ and a dual cell $D_{\sigma}$ are denoted by $\mathcal{E}(K)$ and $\widetilde{\mathcal{E}}\left(D_{\sigma}\right)$ respectively. For $\sigma \in \mathcal{E}$, we denote by $\boldsymbol{x}_{\sigma}$ the mass center of $\sigma$.
In some cases, we need to specify the orientation of a geometrical quantity with respect to the axis:

- a primal cell $K$ will be denoted $K=\left[\overrightarrow{\sigma \sigma^{\prime}}\right]$ if there exists $i \in[1, d]$ and $\sigma, \sigma^{\prime} \in \mathcal{E}^{(i)} \cap \mathcal{E}(K)$ such that $\left(\boldsymbol{x}_{\sigma^{\prime}}-\boldsymbol{x}_{\sigma}\right) \cdot \boldsymbol{e}_{i}>0$;
- we write $\sigma=\overrightarrow{K \mid L}$ if $\sigma \in \mathcal{E}^{(i)}$ and $\overrightarrow{\boldsymbol{x}_{K} \boldsymbol{x}_{L}} \cdot \boldsymbol{e}_{i}>0$ for some $i \in[1, d]$;
- the dual face $\epsilon$ separating $D_{\sigma}$ and $D_{\sigma^{\prime}}$ is written $\epsilon=\overrightarrow{\sigma \sigma^{\prime}}$ if $\overrightarrow{\boldsymbol{x}_{\sigma} \boldsymbol{x}_{\sigma^{\prime}}} \cdot \boldsymbol{e}_{i}>0$ for some $i \in[1, d]$. For the definition of the discrete momentum diffusion operator, we associate to any dual face $\epsilon$ a distance $d_{\epsilon}$ as sketched in Figure 1. For a dual face $\epsilon \in \widetilde{\mathcal{E}}\left(D_{\sigma}\right), \sigma \in \mathcal{E}^{(i)}, i \in[1, d]$, the distance $d_{\epsilon}$ is defined by:

$$
d_{\epsilon}= \begin{cases}d\left(\boldsymbol{x}_{\sigma}, \boldsymbol{x}_{\sigma^{\prime}}\right) & \text { if } \epsilon=\sigma \sigma^{\prime} \in \widetilde{\mathcal{E}}_{\text {int }}^{(i)}  \tag{3.1}\\ d\left(\boldsymbol{x}_{\sigma}, \epsilon\right) & \text { if } \epsilon \in \widetilde{\mathcal{E}}_{\mathrm{ext}}^{(i)} \cap \tilde{\mathcal{E}}\left(D_{\sigma}\right)\end{cases}
$$

where $d(\cdot, \cdot)$ denotes the Euclidean distance in $\mathbb{R}^{d}$. We also define the size of the mesh by $h_{\mathcal{M}}=$ $\max \{\operatorname{diam}(K), K \in \mathcal{M}\}$. The regularity of $\eta_{\mathcal{M}}$ of the mesh is defined by

$$
\begin{equation*}
\eta_{\mathcal{M}}=\frac{1}{h_{\mathcal{M}}} \min _{K \in \mathcal{M}} \min _{1 \leq i \leq d}\left\{d\left(\boldsymbol{x}_{\sigma}, \boldsymbol{x}_{\sigma^{\prime}}\right), \sigma, \sigma^{\prime} \in \mathcal{E}^{(i)}(K)\right\} \tag{3.2}
\end{equation*}
$$

In other words, $\eta_{\mathcal{M}}$ is such that

$$
\eta_{\mathcal{M}} h_{\mathcal{M}} \leq d\left(\boldsymbol{x}_{\sigma}, \boldsymbol{x}_{\sigma^{\prime}}\right) \leq h_{\mathcal{M}}, \forall \sigma, \sigma^{\prime} \in \mathcal{E}^{(i)}(K), \forall i=1, \ldots, d, \forall K \in \mathcal{M}
$$

Figure 1. Notations for control volumes and dual cells (for the second component of the velocity).

The discrete velocity unknowns are associated to the velocity cells and are denoted by $\left(u_{\sigma}\right)_{\sigma \in \mathcal{E}^{(i)}}$ for each component $u_{i}$ of the discrete velocity, $1 \leq i \leq d$, while the discrete density and pressure unknowns are associated to the primal cells and are respectively denoted by $\left(\varrho_{K}\right)_{K \in \mathcal{M}}$ and $\left(p_{K}\right)_{K \in \mathcal{M}}$.
Definition 3 (Discrete spaces). Let $\mathcal{D}=(\mathcal{M}, \mathcal{E})$ be a MAC grid in the sense of Definition 2. The discrete density and pressure space $L_{\mathcal{M}}$ is the set of piecewise constant functions over the grid cells $K$ of $\mathcal{M}$, and the discrete $i^{\text {th }}$ velocity space $H_{\mathcal{E}}^{(i)}$ is the set of piecewise constant functions over the grid cells $D_{\sigma}, \sigma \in \mathcal{E}^{(i)}$. The Dirichlet boundary conditions (1.2) are partly incorporated in the definition of the velocity spaces by introducing

$$
H_{\mathcal{E}, 0}^{(i)}=\left\{u \in H_{\mathcal{E}}^{(i)}, u(\boldsymbol{x})=0 \forall \boldsymbol{x} \in D_{\sigma}, \sigma \in \mathcal{E}_{\mathrm{ext}}^{(i)}\right\} \subset H_{\mathcal{E}}^{(i)}, i=1, \ldots, d
$$

We then set $\mathbf{H}_{\mathcal{E}, 0}=\prod_{i=1}^{d} H_{\mathcal{E}, 0}^{(i)}$. Since we are dealing with piecewise constant functions, it is useful to introduce the characteristic functions $\mathbb{1}_{K}$, for $K \in \mathcal{M}$, and $\mathbb{1}_{D_{\sigma}}$, for $\sigma \in \mathcal{E}$, defined by

$$
\mathbb{1}_{K}(\boldsymbol{x})=\left\{\begin{array}{l}
1 \text { if } \boldsymbol{x} \in K, \\
0 \text { if } \boldsymbol{x} \notin K,
\end{array} \quad \mathbb{1}_{D_{\sigma}}(\boldsymbol{x})=\left\{\begin{array}{l}
1 \text { if } \boldsymbol{x} \in D_{\sigma} \\
0 \text { if } \boldsymbol{x} \notin D_{\sigma}
\end{array}\right.\right.
$$

We can then write the functions $\boldsymbol{u} \in \mathbf{H}_{\mathcal{E}, 0}$ and $p, \varrho \in L_{\mathcal{M}}$ as

$$
\boldsymbol{u}=\left(u_{1}, \ldots, u_{d}\right) \text { with } u_{i}=\sum_{\sigma \in \mathcal{E}_{\mathrm{int}}^{(i)}} u_{\sigma} \mathbb{1}_{D_{\sigma}}, \text { for } i \in[1, d], \quad p=\sum_{K \in \mathcal{M}} p_{K} \mathbb{1}_{K}, \varrho=\sum_{K \in \mathcal{M}} \varrho_{K} \mathbb{1}_{K}
$$

3.2. The numerical scheme. Let $\mathcal{D}=(\mathcal{M}, \mathcal{E})$ be a MAC grid of the computational domain $\Omega \subset \mathbb{R}^{d}$. Let $h_{\mathcal{M}}$ be the size of the mesh. Let $\alpha>1$ and $C_{s}>0$ be given. Let $\boldsymbol{f} \in L^{2}(\Omega)^{d}$ and $M>0$, and let $\varrho^{\star}=M /|\Omega|$. We consider the following numerical scheme:

Find $(\boldsymbol{u}, p, \varrho) \in \mathbf{H}_{\mathcal{E}, 0} \times L_{\mathcal{M}} \times L_{\mathcal{M}}$ such that, a.e in $\Omega$,

$$
\begin{align*}
& \operatorname{div}_{\mathcal{M}}^{\operatorname{up}}(\varrho \boldsymbol{u})+C_{s} h_{\mathcal{M}}^{\alpha}\left(\varrho-\varrho^{\star}\right)=0  \tag{3.3a}\\
& \operatorname{div}_{\tilde{\mathcal{E}}}(\varrho \boldsymbol{u} \otimes \boldsymbol{u})+\nabla_{\mathcal{E}} p-\mu \Delta_{\mathcal{E}} \boldsymbol{u}-(\mu+\lambda) \nabla_{\mathcal{E}} \operatorname{div}_{\mathcal{M}} \boldsymbol{u}=\mathcal{P}_{\mathcal{E}} \boldsymbol{f}  \tag{3.3b}\\
& p=\varrho^{\gamma}, \varrho \geq 0 \tag{3.3c}
\end{align*}
$$

where the discrete operators are defined hereafter for each equation.
3.2.1. The mass balance equation. Equation (3.3a) is a finite volume discretization of the mass balance $(1.1 a)$ over the primal mesh. The discrete function $\operatorname{div}_{\mathcal{M}}^{\text {up }}(\varrho \boldsymbol{u}) \in L_{\mathcal{M}}$ is defined by

$$
\operatorname{div}_{\mathcal{M}}^{\mathrm{up}}(\varrho \boldsymbol{u})(\boldsymbol{x})=\frac{1}{|K|} \sum_{\sigma \in \mathcal{E}(K)} F_{K, \sigma}, \forall \boldsymbol{x} \in K
$$

where $F_{K, \sigma}$ stands for the upwind mass flux across $\sigma$ outward $K$, which reads:

$$
\forall \sigma \in \mathcal{E}(K), \quad F_{K, \sigma}=|\sigma| \varrho_{\sigma}^{\text {up }} u_{K, \sigma} \quad \text { with } \varrho_{\sigma}^{\text {up }}=\left\lvert\, \begin{array}{ll}
\varrho_{K} & \text { if } u_{K, \sigma} \geq 0  \tag{3.4}\\
\varrho_{L} & \text { otherwise }
\end{array}\right.
$$

and where $u_{K, \sigma}$ is an approximation of the normal velocity to the face $\sigma$ outward $K$, defined by:

$$
\begin{equation*}
u_{K, \sigma}=u_{\sigma} \boldsymbol{e}_{i} \cdot \boldsymbol{n}_{K, \sigma} \text { for } \sigma \in \mathcal{E}^{(i)} \cap \mathcal{E}(K), \tag{3.5}
\end{equation*}
$$

where $\boldsymbol{n}_{K, \sigma}$ denotes the unit normal vector to $\sigma$ outward $K$. Thanks to the boundary conditions, $u_{K, \sigma}$ vanishes for any external face $\sigma$, and so does $F_{K, \sigma}$. Any solution $(\varrho, \boldsymbol{u}) \in L_{\mathcal{M}} \times \mathbf{H}_{\mathcal{E}, 0}$ to (3.3a) satisfies $\varrho_{K}>0$ for all $K \in \mathcal{M}$ so that in particular (3.3c) makes sense: the positivity of the density $\varrho$ in $(3.3 a)$ is not enforced in the scheme but results from the above upwind choice. Indeed, for any velocity field, the upwinding ensures that the discrete mass balance (3.3a) is a linear system for $\varrho$ whose matrix is invertible and has a non negative inverse [12, Lemma C.3] and this gives $\varrho_{K}>0$ for all $K \in \mathcal{M}$ (thanks to $\varrho^{\star}>0$ ).
Note also that we have the usual finite volume property of local conservativity of the mass flux through a primal face $\sigma=K \mid L$ (i.e. $F_{K, \sigma}=-F_{L, \sigma}$ ). For $\sigma=\overrightarrow{K \mid L} \in \mathcal{E}_{\text {int }}$, we also define

$$
\begin{equation*}
[\varrho]_{\sigma}=\varrho_{L}-\varrho_{K} \tag{3.6}
\end{equation*}
$$

The artificial term $C_{s} h_{\mathcal{M}}^{\alpha}\left(\varrho-\varrho^{\star}\right)$ guarantees that the integral of the density over the computational domain is always $M$. Indeed, summing (3.3a) over $K \in \mathcal{M}$, and using the conservativity of the flux through a primal face, immediately yields the total conservation of mass, which reads:

$$
\begin{equation*}
\int_{\Omega} \varrho \mathrm{d} \boldsymbol{x}=M . \tag{3.7}
\end{equation*}
$$

The constant $C_{s}$ is chosen so that a uniform (with respect to the mesh) bound holds on the solutions to (3.3); these bounds are stated in Proposition 1. The proof of this proposition shows that $C_{s}$ can be chosen sufficiently small with respect to the data (see (6.11)). However, in practice, $C_{s}$ may be set to 1 , in which case, the uniform bounds stated in Proposition 1 hold for $h_{\mathcal{M}}$ sufficiently small.
3.2.2. The momentum balance equation. We now turn to the discrete momentum balances (3.3b), which are obtained by discretizing the momentum balance equation (1.1b) on the dual cells associated to the faces of the mesh. In the right hand side of $(3.3 \mathrm{~b}), \mathcal{P}_{\mathcal{E}}$ denotes the cell mean-value operator defined for $\boldsymbol{v}=\left(v_{1}, \ldots, v_{d}\right) \in L^{2}(\Omega)^{d}$ by

$$
\begin{align*}
\mathcal{P}_{\mathcal{E}} \boldsymbol{v}= & \left(\mathcal{P}_{\mathcal{E}}^{(1)} v_{1}, \cdots, \mathcal{P}_{\mathcal{E}}^{(d)} v_{d}\right) \in H_{\mathcal{E}, 0}^{(1)} \times \cdots \times H_{\mathcal{E}, 0}^{(d)}, \text { where, for } i=1, \ldots d, \\
\mathcal{P}_{\mathcal{E}}^{(i)}: & L^{2}(\Omega) \longrightarrow H_{\mathcal{E}, 0}^{(i)} \\
& v_{i} \longmapsto \mathcal{P}_{\mathcal{E}}^{(i)} v_{i}=\sum_{\sigma \in \mathcal{E}_{\text {int }}^{(i)}}\left(\frac{1}{\left|D_{\sigma}\right|} \int_{D_{\sigma}} v_{i}(\boldsymbol{x}) \mathrm{d} \boldsymbol{x}\right) \mathbb{1}_{D_{\sigma}} . \tag{3.8}
\end{align*}
$$

The discrete convective operator - The discrete divergence of $\varrho \boldsymbol{u} \otimes \boldsymbol{u}$ is defined by

$$
\begin{equation*}
\operatorname{div}_{\widetilde{\mathcal{E}}}(\varrho \boldsymbol{u} \otimes \boldsymbol{u})=\left(\operatorname{div}_{\widetilde{\mathcal{E}}}^{(1)}\left(\varrho \boldsymbol{u} u_{1}\right), \ldots, \operatorname{div}_{\widetilde{\mathcal{E}}}^{(d)}\left(\varrho \boldsymbol{u} u_{d}\right)\right) \in \mathbf{H}_{\mathcal{E}, 0} \tag{3.9}
\end{equation*}
$$

where the $i^{t h}$ component of the above operator reads:

$$
\operatorname{div}_{\tilde{\mathcal{E}}}^{(i)}\left(\varrho \boldsymbol{u} u_{i}\right)(\boldsymbol{x})=\frac{1}{\left|D_{\sigma}\right|} \sum_{\epsilon \in \widetilde{\mathcal{E}}\left(D_{\sigma}\right)} F_{\sigma, \epsilon} u_{\epsilon}, \forall \boldsymbol{x} \in D_{\sigma}, \sigma \in \mathcal{E}_{\mathrm{int}}^{(i)}
$$

The expression $F_{\sigma, \epsilon}$ stands for the mass flux through the dual face $\epsilon$, and $u_{\epsilon}$ is an approximation of $i^{\text {th }}$ component of the velocity over $\epsilon$.
Let us consider the momentum balance equation for the $i^{\text {th }}$ component of the velocity, and $\sigma \in \mathcal{E}_{\text {int }}^{(i)}$, $\sigma=K \mid L$. We have to distinguish two cases (see Figure 3.2.2):

- First case - The vector $\boldsymbol{e}_{i}$ is normal to $\epsilon$, in which case $\epsilon$ is included in a primal cell $K$; we then denote by $\sigma^{\prime}$ the second face of $K$ which is also normal to $\boldsymbol{e}_{i}$. We thus have $\epsilon=D_{\sigma} \mid D_{\sigma^{\prime}}$. Then the mass flux through $\epsilon$ is given by:

$$
\begin{equation*}
F_{\sigma, \epsilon}=\frac{1}{2}\left[F_{K, \sigma} \boldsymbol{n}_{K, \sigma}+F_{K, \sigma^{\prime}} \boldsymbol{n}_{K, \sigma^{\prime}}\right] \cdot \boldsymbol{n}_{D_{\sigma}, \epsilon} \tag{3.10}
\end{equation*}
$$

where $\boldsymbol{n}_{D_{\sigma}, \epsilon}$ stands for the unit normal vector to $\epsilon$ outward $D_{\sigma}$.

- Second case - The vector $\boldsymbol{e}_{i}$ is tangent to $\epsilon$, and $\epsilon$ is the union of the halves of two primal faces $\tau$ and $\tau^{\prime}$ such that $\tau \in \mathcal{E}(K)$ and $\tau^{\prime} \in \mathcal{E}(L)$. The mass flux through $\epsilon$ is then given by:

$$
\begin{equation*}
F_{\sigma, \epsilon}=\frac{1}{2}\left[F_{K, \tau}+F_{L, \tau^{\prime}}\right] \tag{3.11}
\end{equation*}
$$

Figure 2. Notations for the dual fluxes of the first component of the velocity.
Note that we have the usual finite volume property of local conservativity of the mass flux through a dual face $D_{\sigma} \mid D_{\sigma^{\prime}}$ (i.e. $\left.F_{\sigma, \epsilon}=-F_{\sigma^{\prime}, \epsilon}\right)$, and that the flux through a dual face included in the boundary still vanishes.

The density on a dual cell is given by:

$$
\begin{array}{ll}
\text { for } \sigma \in \mathcal{E}_{\mathrm{int}}, \sigma=K \mid L & \left|D_{\sigma}\right| \varrho_{D_{\sigma}}=\left|D_{K, \sigma}\right| \varrho_{K}+\left|D_{L, \sigma}\right| \varrho_{L} \\
\text { for } \sigma \in \mathcal{E}_{\mathrm{ext}}, \sigma \in \mathcal{E}(K), & \varrho_{D_{\sigma}}=\varrho_{K} \tag{3.12}
\end{array}
$$

These definitions of the dual mass fluxes and the dual densities ensure that a finite volume discretization of the mass balance equation over the diamond cells holds:

$$
\begin{equation*}
\text { for } 1 \leq i \leq d, \forall \sigma \in \mathcal{E}_{\text {int }}^{(i)}, \quad \frac{1}{\left|D_{\sigma}\right|} \sum_{\epsilon \in \widetilde{\mathcal{E}}\left(D_{\sigma}\right)} F_{\sigma, \epsilon}+C_{s} h_{\mathcal{M}}^{\alpha}\left(\varrho_{D_{\sigma}}-\varrho^{\star}\right)=0 \tag{3.13}
\end{equation*}
$$

This condition is essential to derive a discrete kinetic energy balance in Proposition 1 below.
Since the flux across a dual face lying on the boundary is zero, the values $u_{\epsilon}$ are only needed at the internal dual faces; they are chosen centered i.e.,

$$
\text { for } \epsilon=D_{\sigma} \mid D_{\sigma^{\prime}} \in \widetilde{\mathcal{E}}_{\text {int }}^{(i)}, \quad u_{\epsilon}=\frac{u_{\sigma}+u_{\sigma^{\prime}}}{2} .
$$

Discrete divergence and gradient - The discrete divergence operator $\operatorname{div}_{\mathcal{M}}$ is defined by:

$$
\begin{array}{l|l}
\operatorname{div}_{\mathcal{M}}: & \mathbf{H}_{\mathcal{E}} \longrightarrow L_{\mathcal{M}}  \tag{3.14}\\
& \boldsymbol{u} \longmapsto \operatorname{div}_{\mathcal{M}} \boldsymbol{u}=\sum_{K \in \mathcal{M}} \frac{1}{|K|} \sum_{\sigma \in \mathcal{E}(K)}|\sigma| u_{K, \sigma} \mathbb{1}_{K}
\end{array}
$$

where $u_{K, \sigma}$ is defined in (3.5). Once again, we have the usual finite volume property of local conservativity of the flux through an interface $\sigma=K \mid L$ between the cells $K, L \in \mathcal{M}$, i.e. $u_{K, \sigma}=$ $-u_{L, \sigma}, \quad \forall \sigma=K \mid L \in \mathcal{E}_{\text {int }}$. The discrete divergence of $\boldsymbol{u}=\left(u_{1}, \ldots, u_{d}\right) \in \mathbf{H}_{\mathcal{E}, 0}$ may also be written as

$$
\begin{equation*}
\operatorname{div}_{\mathcal{M}} \boldsymbol{u}=\sum_{i=1}^{d} \sum_{K \in \mathcal{M}}\left(\check{\partial}_{i} u_{i}\right)_{K} \mathbb{1}_{K} \tag{3.15}
\end{equation*}
$$

where the discrete derivative $\left(\partial_{i} u_{i}\right)_{K}$ of $u_{i}$ on $K$ is defined by

$$
\begin{equation*}
\left(\check{\partial}_{i} u_{i}\right)_{K}=\frac{|\sigma|}{|K|}\left(u_{\sigma^{\prime}}-u_{\sigma}\right) \text { with } K=\left[\overrightarrow{\sigma \sigma^{\prime}}\right], \sigma, \sigma^{\prime} \in \mathcal{E}^{(i)} \tag{3.16}
\end{equation*}
$$

The pressure gradient in the discrete momentum balance is defined as follows:

$$
\begin{array}{l|l}
\nabla_{\mathcal{E}}: & L_{\mathcal{M}} \longrightarrow \mathbf{H}_{\mathcal{E}, 0}  \tag{3.17}\\
& p \longmapsto \nabla_{\mathcal{E}} p=\left(\check{\partial}_{1} p, \ldots, \partial_{d} p\right)^{t}
\end{array}
$$

where $\partial_{i} p \in H_{\mathcal{E}, 0}^{(i)}$ is the discrete derivative of $p$ in the $i^{t h}$ direction, defined by:

$$
\begin{equation*}
\searrow_{i} p(\boldsymbol{x})=\frac{|\sigma|}{\left|D_{\sigma}\right|}\left(p_{L}-p_{K}\right) \quad \forall \boldsymbol{x} \in D_{\sigma}, \text { for } \sigma=\overrightarrow{K \mid L} \in \mathcal{E}_{\mathrm{int}}^{(i)}, i=1, \ldots, d \tag{3.18}
\end{equation*}
$$

Note that, in fact, the discrete gradient of a function of $L_{\mathcal{M}}$ should only be defined on the internal faces, and does not need to be defined on the external faces; we set it here in $\mathbf{H}_{\mathcal{E}, 0}$ (that is zero on the external faces) in order to be coherent with (3.3b). This gradient is built as the dual operator of the discrete divergence, which means:

Lemma 3 (Discrete div $-\nabla$ duality). Let $\Omega$ be a MAC-compatible bounded domain of $\mathbb{R}^{d}$, $d=2$ or $d=3$. Let $q \in L_{\mathcal{M}}$ and $\boldsymbol{v} \in \mathbf{H}_{\mathcal{E}, 0}$. Then we have:

$$
\begin{equation*}
\int_{\Omega} q \operatorname{div}_{\mathcal{M}} \boldsymbol{v} \mathrm{d} \boldsymbol{x}+\int_{\Omega} \nabla_{\mathcal{E}} q \cdot \boldsymbol{v} \mathrm{~d} \boldsymbol{x}=0 \tag{3.19}
\end{equation*}
$$

Discrete Laplace operator - For $i=1 \ldots, d$, we classically define the discrete Laplace operator on the $i^{\text {th }}$ velocity grid by:

$$
\begin{align*}
-\Delta_{\mathcal{E}}^{(i)}: \mid & H_{\mathcal{E}, 0}^{(i)} \longrightarrow H_{\mathcal{E}, 0}^{(i)} \\
& u_{i} \longmapsto-\Delta_{\mathcal{E}}^{(i)} u_{i}  \tag{3.20}\\
-\Delta_{\mathcal{E}}^{(i)} u_{i}(\boldsymbol{x})= & \frac{1}{\left|D_{\sigma}\right|} \sum_{\epsilon \in \tilde{\mathcal{E}}\left(D_{\sigma}\right)} \phi_{\sigma, \epsilon}, \quad \forall \boldsymbol{x} \in D_{\sigma}, \quad \text { for } \sigma \in \mathcal{E}_{\mathrm{int}}^{(i)}
\end{align*}
$$

where

$$
\phi_{\sigma, \epsilon}= \begin{cases}\frac{|\epsilon|}{d_{\epsilon}}\left(u_{\sigma}-u_{\sigma^{\prime}}\right) & \text { if } \epsilon=\sigma \sigma^{\prime} \in \widetilde{\mathcal{E}}_{\mathrm{int}}^{(i)}  \tag{3.21}\\ \frac{|\epsilon|}{d_{\epsilon}} u_{\sigma} & \text { if } \epsilon \in \widetilde{\mathcal{E}}_{\mathrm{ext}}^{(i)} \cap \tilde{\mathcal{E}}\left(D_{\sigma}\right)\end{cases}
$$

with $d_{\epsilon}$ given by (3.1). The fluxes $\phi_{\sigma, \epsilon}$ satisfy the local conservativity property:

$$
\begin{equation*}
\phi_{\sigma, \epsilon}=-\phi_{\sigma^{\prime}, \epsilon}, \quad \forall \epsilon=\sigma \mid \sigma^{\prime} \in \widetilde{\mathcal{E}}_{\mathrm{int}}^{(i)} \tag{3.22}
\end{equation*}
$$

Then the discrete Laplace operator of the full velocity vector is defined by

$$
\begin{align*}
-\Delta_{\mathcal{E}}: & \mathbf{H}_{\mathcal{E}, 0} \longrightarrow \mathbf{H}_{\mathcal{E}, 0} \\
& \boldsymbol{u} \mapsto-\Delta_{\mathcal{E}} \boldsymbol{u}=\left(-\Delta_{\mathcal{E}}^{(1)} u_{1}, \ldots,-\Delta_{\mathcal{E}}^{(d)} u_{d}\right)^{t} \tag{3.23}
\end{align*}
$$

Let us now recall the definition of the discrete $H_{0}^{1}$ inner product [6]; it is obtained by taking the inner product of the discrete Laplace operator and a test function $\boldsymbol{v} \in \mathbf{H}_{\mathcal{E}, 0}$ and integrating over the computational domain. A simple reordering of the sums (which may be seen as a discrete integration by parts) yields, thanks to the conservativity of the diffusion flux (3.22):

$$
\begin{align*}
& \forall(\boldsymbol{u}, \boldsymbol{v}) \in \mathbf{H}_{\mathcal{E}, 0}^{2}, \quad \int_{\Omega}-\Delta_{\mathcal{E}} \boldsymbol{u} \cdot \boldsymbol{v} \mathrm{d} \boldsymbol{x}=[\boldsymbol{u}, \boldsymbol{v}]_{1, \mathcal{E}, 0}=\sum_{i=1}^{d}\left[u_{i}, v_{i}\right]_{1, \mathcal{E}}{ }^{(i), 0} \\
& \text { with }\left[u_{i}, v_{i}\right]_{1, \mathcal{E}^{(i)}, 0}=\sum_{\substack{\epsilon \in \widetilde{\mathcal{E}}_{\text {int }}^{(i)} \\
\epsilon=\overline{\sigma \sigma^{\prime}}}} \frac{|\epsilon|}{d_{\epsilon}}\left(u_{\sigma}-u_{\sigma^{\prime}}\right)\left(v_{\sigma}-v_{\sigma^{\prime}}\right)+\sum_{\substack{\epsilon \in \widetilde{\mathcal{E}}_{\text {ext }}^{(i)} \\
\epsilon \in \tilde{\mathcal{E}}\left(D_{\sigma}\right)}} \frac{|\epsilon|}{d_{\epsilon}} u_{\sigma} v_{\sigma} \tag{3.24}
\end{align*}
$$

The bilinear forms $\left\lvert\, \begin{aligned} & H_{\mathcal{E}, 0}^{(i)} \times H_{\mathcal{E}, 0}^{(i)} \rightarrow \mathbb{R} \\ & (u, v) \mapsto\left[u_{i}, v_{i}\right]_{1, \mathcal{E}^{(i)}, 0}\end{aligned} \quad\right.$ and $\left\lvert\, \begin{aligned} & \mathbf{H}_{\mathcal{E}, 0} \times \mathbf{H}_{\mathcal{E}, 0} \rightarrow \mathbb{R} \\ & (\boldsymbol{u}, \boldsymbol{v}) \mapsto[\boldsymbol{u}, \boldsymbol{v}]_{1, \mathcal{E}, 0}\end{aligned}\right.$ are inner products on $H_{\mathcal{E}, 0}^{(i)}$, for $i=1, \ldots, d$, and on $\mathbf{H}_{\mathcal{E}, 0}$ respectively, which induce the following discrete $H_{0}^{1}$ norms:

$$
\begin{align*}
& \left\|u_{i}\right\|_{1, \mathcal{E}^{(i)}, 0}^{2}=\left[u_{i}, u_{i}\right]_{1, \mathcal{E}^{(i)}, 0}=\sum_{\substack{\epsilon \in \tilde{\mathcal{E}}_{\text {int }}^{(i)} \\
\epsilon=\sigma \sigma^{\prime}}} \frac{|\epsilon|}{d_{\epsilon}}\left(u_{\sigma}-u_{\sigma^{\prime}}\right)^{2}+\sum_{\substack{\epsilon \in \tilde{\mathcal{E}}_{\text {ext }}^{(i)} \\
\epsilon \in \mathcal{\mathcal { E }}\left(D_{\sigma}\right)}} \frac{|\epsilon|}{d_{\epsilon}} u_{\sigma}^{2}  \tag{3.25a}\\
& \|\boldsymbol{u}\|_{1, \mathcal{E}, 0}^{2}=[\boldsymbol{u}, \boldsymbol{u}]_{1, \mathcal{E}, 0}=\sum_{i=1}^{d}\left\|u_{i}\right\|_{1, \mathcal{E}^{(i)}, 0}^{2} . \tag{3.25b}
\end{align*}
$$

| M | $\sigma^{\prime}$ |  | $N$ |
| :---: | :---: | :---: | :---: |
|  | $\epsilon=\sigma \mid \sigma^{\prime}$ |  |  |
| K | $\pm$ |  | $L$ |
|  | 11 <br> 0 | $D_{\sigma}$ |  |

Figure 3. Full grid for the definition of the derivative of the velocity.

Since we are working on Cartesian grids, this inner product may be formulated as the $L^{2}$ inner product of discrete gradients. Indeed, we define the following discrete gradient of each velocity component $u_{i}$

$$
\begin{equation*}
\nabla_{\widetilde{\mathcal{E}}^{(i)}} u_{i}=\left(\check{\partial}_{1} u_{i}, \ldots, \partial_{d} u_{i}\right) \text { with } \check{\partial}_{j} u_{i}=\sum_{\substack{\epsilon \in \widetilde{\mathcal{E}}_{\text {int }}^{(i)} \\ \epsilon \perp \boldsymbol{e}_{j}}}\left(\check{\partial}_{j} u_{i}\right)_{D_{\epsilon}} \mathbb{1}_{D_{\epsilon}}+\sum_{\epsilon \in \tilde{\mathcal{E}}_{\text {ext }}^{(i)}}\left(\check{\partial}_{j} u_{i}\right)_{D_{\epsilon}} \mathbb{1}_{D_{\epsilon}}, \tag{3.26}
\end{equation*}
$$

where $\left(\check{\partial}_{j} u_{i}\right)_{D_{\epsilon}}=\frac{u_{\sigma^{\prime}}-u_{\sigma}}{d_{\epsilon}}$ with $\epsilon=\overrightarrow{\sigma \mid \sigma^{\prime}}$, and $D_{\epsilon}=\epsilon \times \boldsymbol{x}_{\sigma} \boldsymbol{x}_{\sigma^{\prime}}$ (see Figure 3, note also that $u_{\sigma}=0$ if $\left.\sigma \in \mathcal{E}_{\text {ext }}^{(i)}\right)$. This definition is compatible with the definition of the discrete derivative $\left(\partial_{i} u_{i}\right)_{K}$ given by (3.16), since, if $\epsilon \subset K$, then $D_{\epsilon}=K$. If $\epsilon \in \widetilde{\mathcal{E}}_{\text {ext }}^{(i)} \cap \tilde{\mathcal{E}}\left(D_{\sigma}\right)$, we set $\left(\check{\partial}_{j} u_{i}\right)_{D_{\epsilon}}=\frac{-u_{\sigma}}{d_{\epsilon}} \boldsymbol{n}_{D_{\sigma}, \epsilon} \cdot e_{j}$ with $D_{\epsilon}=\epsilon \times \boldsymbol{x}_{\sigma} \boldsymbol{x}_{\sigma, b}$, where $\boldsymbol{x}_{\sigma, b}=\sigma \cap \partial \Omega$. With this definition, it is easily seen that

$$
\begin{equation*}
\int_{\Omega} \nabla_{\widetilde{\mathcal{E}}^{(i)}} u \cdot \nabla_{\widetilde{\mathcal{E}}^{(i)}} v \mathrm{~d} \boldsymbol{x}=[u, v]_{1, \mathcal{E}^{(i)}, 0}, \quad \forall u, v \in H_{\mathcal{E}, 0}^{(i)}, \text { for } i=1, \ldots, d \tag{3.27}
\end{equation*}
$$

where $[u, v]_{1, \mathcal{E}}{ }^{(i), 0}$ is the discrete $H_{0}^{1}$ inner product defined by (3.24). We may then define $\nabla_{\widetilde{\mathcal{E}}} \boldsymbol{u}=$
 discrete momentum balance (3.3b) reads:

$$
\begin{array}{rl}
\int_{\Omega} \operatorname{div}_{\widetilde{\mathcal{E}}}(\varrho \boldsymbol{u} \otimes \boldsymbol{u}) \cdot \boldsymbol{v} \mathrm{d} \boldsymbol{x}+\mu \int_{\Omega} \nabla_{\widetilde{\mathcal{E}}} \boldsymbol{u}: \nabla_{\widetilde{\mathcal{E}}} \boldsymbol{v} & \mathrm{d} \boldsymbol{x}+(\mu+\lambda) \int_{\Omega} \operatorname{div}_{\mathcal{M}} \boldsymbol{u} \operatorname{div}_{\mathcal{M}} \boldsymbol{v} \mathrm{d} \boldsymbol{x}  \tag{3.28}\\
& -\int_{\Omega} p \operatorname{div}_{\mathcal{M}} \boldsymbol{v} \mathrm{d} \boldsymbol{x}=\int_{\Omega} \mathcal{P}_{\mathcal{E}} \boldsymbol{f} \cdot \boldsymbol{v} \mathrm{d} \boldsymbol{x}, \forall \boldsymbol{v} \in \mathbf{H}_{\mathcal{E}, 0}
\end{array}
$$

## 4. Some analysis Results for Discrete functions

In the theory developed in this paper, we will need discrete Sobolev inequalites for the discrete approximations. The following result is proved in [6, Lemma 9.5].

Theorem 2 (Discrete Sobolev inequalities). Let $\Omega$ be a MAC compatible bounded domain of $\mathbb{R}^{d}$, $d=2$ or $d=3$. Let $q<+\infty$ if $d=2$ and $q=6$ if $d=3$. Then there exists $C=C\left(q, \Omega, \eta_{\mathcal{M}}\right)$, non increasing with respect to $\eta_{\mathcal{M}}$, such that, for all $\boldsymbol{u} \in \mathbf{H}_{\mathcal{E}, 0}$,

$$
\|\boldsymbol{u}\|_{L^{q}(\Omega)} \leq C\|\boldsymbol{u}\|_{1, \mathcal{E}, 0}
$$

The following compactness theorem is a consequence of [6, Theorem 9.1 and Lemma 9.5] and [7, Lemma 5.7].
Theorem 3. Let $\Omega$ be a MAC compatible bounded domain of $\mathbb{R}^{d}, d=2$ or $d=3$. Consider $a$ sequence of MAC grids $\left(\mathcal{M}_{n}, \mathcal{E}_{n}\right)_{n \in \mathbb{N}}$, with step size $h_{\mathcal{M}_{n}}$ tending to zero as $n \rightarrow+\infty$. Let $\left(\boldsymbol{u}_{n}\right)_{n \in \mathbb{N}}$ be a sequence of discrete functions such that each element of the sequence belongs to $\mathbf{H}_{\mathcal{E}_{n}, 0}$ and such that the sequence $\left(\left\|\boldsymbol{u}_{n}\right\|_{1, \mathcal{E}_{n}, 0}\right)_{n \in \mathbb{N}}$ is bounded. Then, up to the extraction of a subsequence, the sequence $\left(\boldsymbol{u}_{n}\right)_{n \in \mathbb{N}}$ converges in $L^{2}(\Omega)^{d}$ to a limit $\boldsymbol{u}$ and this limit satisfies $\boldsymbol{u} \in\left(\mathrm{H}_{0}^{1}(\Omega)\right)^{d}$. Furthermore, one has $\nabla_{\widetilde{\mathcal{E}}_{n}} \boldsymbol{u}_{n} \rightarrow \nabla \boldsymbol{u}$ weakly in $L^{2}(\Omega)^{d \times d}$ as $n \rightarrow+\infty$. If $\eta_{\mathcal{M}_{n}} \geq \eta>0$, one has also $\boldsymbol{u}_{n} \rightarrow \boldsymbol{u}$ in $L^{q}(\Omega)$ for all $q<q(d)$.
We now recall a discrete analogue of the identity (2.10) linking the gradient, divergence and curl operators, which is proved in [8]. First of all, we modify the definition of the discrete gradient $\left(\nabla_{\mathcal{E}}\right)$ of an element of $L_{\mathcal{M}}$ in some dual cells near the boundary, in order to take into account a null boundary condition at the external faces. It reads:

$$
\begin{array}{l|l}
\bar{\nabla}_{\mathcal{E}}: & \begin{array}{l}
L_{\mathcal{M}} \longrightarrow \mathbf{H}_{\mathcal{E}} \\
\end{array}  \tag{4.1}\\
w \longmapsto \bar{\nabla}_{\mathcal{E}} w=\left(\bar{\partial}_{1} w, \ldots, \bar{\partial}_{d} w\right)^{t},
\end{array}
$$

where $\bar{ठ}_{i} w \in H_{\mathcal{E}}^{(i)}$ is the discrete derivative of $w$ in the $i^{t h}$ direction, defined, for $i=1, \ldots, d$, by:

$$
\bar{ð}_{i} w(\boldsymbol{x})= \begin{cases}\check{ð}_{i} w(\boldsymbol{x})=\frac{|\sigma|}{\left|D_{\sigma}\right|}\left(w_{L}-w_{K}\right), & \forall \boldsymbol{x} \in D_{\sigma}, \text { for } \sigma=\overrightarrow{K \mid L} \in \mathcal{E}_{\mathrm{int}}^{(i)}  \tag{4.2}\\ -\frac{|\sigma|}{\left|D_{\sigma}\right|} w_{K} \boldsymbol{n}_{\sigma, K} \cdot \boldsymbol{e}_{i}, & \forall \boldsymbol{x} \in D_{\sigma}, \text { for } \sigma \in \mathcal{E}(K) \cap \mathcal{E}_{\mathrm{ext}}^{(i)}\end{cases}
$$

In order to define the discrete curl operator of a function $\boldsymbol{v}=\left(v_{1}, \ldots, v_{d}\right) \in \mathbf{H}_{\mathcal{E}}$, we use the functions $\left(\check{\partial}_{j} u_{i}\right)_{1 \leq i, j \leq d}$ defined in (3.26). This definition is the same for $\boldsymbol{v} \in \mathbf{H}_{\mathcal{E}, 0}$ and $\boldsymbol{v} \in \mathbf{H}_{\mathcal{E}}$, the only difference is that we may have $u_{\sigma} \neq 0$ if $\sigma \in \mathcal{E}_{\text {ext }}^{(i)}$ and $\boldsymbol{v} \in \mathbf{H}_{\mathcal{E}}$. Then, the discrete curl operator of a function $\boldsymbol{v}=\left(v_{1}, \ldots, v_{d}\right) \in \mathbf{H}_{\mathcal{E}}$ is defined by

$$
\operatorname{curl}_{\mathcal{M}} \boldsymbol{v}= \begin{cases}\partial_{1} v_{2}-\check{\partial}_{2} v_{1} & \text { if } d=2  \tag{4.3}\\ \left(\check{\partial}_{2} v_{3}-\partial_{3} v_{2}, \partial_{3} v_{1}-\check{\partial}_{1} v_{3}, \partial_{1} v_{2}-\partial_{2} v_{1}\right) & \text { if } d=3\end{cases}
$$

The following algebraic identity is a discrete version of (2.10), which is exact in the case of the MAC scheme, contrary to the case of the non conforming P1 finite element scheme, see [9].
Lemma 4. Let $\Omega$ be a MAC compatbile bounded domain of $\mathbb{R}^{d}$, $d=2$ or $d=3$ and let $\mathcal{M}$ be a MAC grid and $(\boldsymbol{v}, \boldsymbol{w}) \in\left(\mathbf{H}_{\mathcal{E}, 0}\right)^{2}$. Then the following discrete identity holds:

$$
\begin{equation*}
\int_{\Omega} \nabla_{\widetilde{\mathcal{E}}} \boldsymbol{v}: \nabla_{\widetilde{\mathcal{E}}} \boldsymbol{w} \mathrm{d} \boldsymbol{x}=\int_{\Omega} \operatorname{div}_{\mathcal{M}} \boldsymbol{v} \operatorname{div}_{\mathcal{M}} \boldsymbol{w} \mathrm{d} \boldsymbol{x}+\int_{\Omega} \operatorname{curl}_{\mathcal{M}} \boldsymbol{v} \cdot \operatorname{curl}_{\mathcal{M}} \boldsymbol{w} \mathrm{d} \boldsymbol{x} \tag{4.4}
\end{equation*}
$$

We finish this section by introducing a discrete construction of the test function used in Step 3 of the proof of Theorem 1 to obtain the convergence of the so-called effective viscous flux. We recall that this test function is the product of a scalar regular function with a velocity field whose divergence is the density; we need here to show the existence, at the discrete level, of such a velocity field, and then some regularity estimates for the resulting test function. To this goal, we first introduce the discrete Laplace operator on the primal mesh. For $\sigma \in \mathcal{E}_{\text {int }}, \sigma=K \mid L$, let $d_{\sigma}$ be defined as the distance between the mass center of $K$ and $L$, i.e. $d_{\sigma}=d\left(\boldsymbol{x}_{K}, \boldsymbol{x}_{L}\right)$; for an external face
$\sigma \in \mathcal{E}_{\text {ext }}$ adjacent to the primal cell $K$, let $d_{\sigma}=d\left(\boldsymbol{x}_{K}, \sigma\right)$. Then, with this notation, we obtain a discretization of the Laplace operator wih homogeneous Dirichet boundary conditions on the primal mesh by:

$$
\begin{array}{l|l}
-\Delta_{\mathcal{M}}: \mid & L_{\mathcal{M}} \longrightarrow L_{\mathcal{M}} \\
& w \longmapsto-\Delta_{\mathcal{M} w}  \tag{4.5}\\
-\Delta_{\mathcal{M}} w(\boldsymbol{x})= & \frac{1}{|K|} \sum_{\sigma \in \mathcal{E}(K)} \phi_{K, \sigma}, \quad \forall \boldsymbol{x} \in K, \quad \text { for } K \in \mathcal{M}
\end{array}
$$

where

$$
\phi_{K, \sigma}= \begin{cases}\frac{|\sigma|}{d_{\sigma}}\left(w_{K}-w_{L}\right) & \text { if } \sigma=K \mid L \in \mathcal{E}_{\mathrm{int}}  \tag{4.6}\\ \frac{|\sigma|}{d_{\sigma}} w_{K} & \text { if } \sigma \in \mathcal{E}_{\mathrm{ext}} \cap \mathcal{E}(K)\end{cases}
$$

The following lemma [8] clarifies the relations between this Laplace operator and the already defined gradient divergence and curl operators.

Lemma 5. Let $\Omega$ be a MAC compatible bounded domain of $\mathbb{R}^{d}$, $d=2$ or $d=3$. Let $w \in L_{\mathcal{M}}$. Let $\boldsymbol{v}=-\bar{\nabla}_{\mathcal{E}} w \in \mathbf{H}_{\mathcal{E}}$ be defined by (4.1). Then, with the discrete curl operator defined by (4.3), we have $\operatorname{curl}_{\mathcal{M}} \boldsymbol{v}=0$. Furthermore, for any $\varrho \in L_{\mathcal{M}}$, there exists one and only one $w$ in $L_{\mathcal{M}}$ such that $-\Delta_{\mathcal{M}} w=\varrho$, and, in this case, $\operatorname{div}_{\mathcal{M}} \boldsymbol{v}=\varrho$.

Now, to any regular function $\varphi \in \mathrm{C}_{c}^{\infty}(\Omega)$, we associate an interpolant $\varphi_{\mathcal{M}} \in L_{\mathcal{M}}$ defined by:

$$
\begin{equation*}
\varphi_{\mathcal{M}}(\boldsymbol{x})=\varphi\left(\boldsymbol{x}_{K}\right) \text { for all } \boldsymbol{x} \in K, \forall K \in \mathcal{M} \tag{4.7}
\end{equation*}
$$

We are now in position to state the following discrete regularity result (see [8] for a proof).
Lemma 6. Let $\Omega$ be a MAC compatible bounded domain of $\mathbb{R}^{d}$, $d=2$ or $d=3$. Let $\mathcal{D}=(\mathcal{M}, \mathcal{E})$ be a MAC grid. Let $\varrho \in L_{\mathcal{M}}$ and $w \in L_{\mathcal{M}}$ be defined by

$$
\begin{equation*}
-\Delta_{\mathcal{M}} w=\varrho \tag{4.8}
\end{equation*}
$$

Let $\varphi \in \mathrm{C}_{c}^{\infty}(\Omega)$ and $\bar{\nabla}\left(w \varphi_{\mathcal{M}}\right)$ be the gradient of the function $w \varphi_{\mathcal{M}}$ as defined in (4.1). Then there exists $C_{\varphi}$ only depending on $\varphi, \Omega$ and on $\eta_{\mathcal{M}}$ in a non increasing way such that $\left.\| \bar{\nabla}_{\mathcal{E}}\left(w \varphi_{\mathcal{M}}\right)\right) \|_{1, \mathcal{E}, 0} \leq$ $C_{\varphi}\|\varrho\|_{L^{2}(\Omega)}$, where $\|\cdot\|_{1, \mathcal{E}, 0}$ is defined in (3.25b).

## 5. Main theorem

Now, we are ready to state the main result of this paper. We recall the notation:

$$
q(d)=\left\{\begin{array}{l}
+\infty \text { if } d=2 \\
6 \text { if } d=3
\end{array}\right.
$$

Theorem 4. Let $\Omega$ be a MAC compatible bounded domain of $\mathbb{R}^{d}, d=2$ or $d=3$. Let $\boldsymbol{f} \in$ $\left(L^{2}(\Omega)\right)^{d}, M>0$, and $\alpha>1$. Let $\gamma>3$ if $d=3$ and $\gamma>1$ if $d=2$. Consider a sequence of $M A C$ grids $\left(\mathcal{D}_{n}=\left(\mathcal{M}_{n}, \mathcal{E}_{n}\right)\right)_{n \in \mathbb{N}}$, with step size $h_{\mathcal{M}_{n}}$ going to zero as $n \rightarrow+\infty$. Assume that there exists $\eta>0$ such that $\eta \leq \eta_{\mathcal{M}_{n}}$ for all $n \in \mathbb{N}$, where $\eta_{\mathcal{M}_{n}}$ is defined by (3.2). For a value of the constant $C_{s}$ independent of $n \in \mathbb{N}$ and sufficiently small with respect to the data, there exists a solution $\left(\boldsymbol{u}_{n}, p_{n}, \varrho_{n}\right) \in \mathbf{H}_{\mathcal{E}_{n}, 0} \times L_{\mathcal{M}_{n}}(\Omega) \times L_{\mathcal{M}_{n}}(\Omega)$ to the scheme (3.3) with any of the MAC discretizations $\mathcal{D}_{n}$; in addition, the obtained density and pressure are positive a.e. in $\Omega$. Furthermore, up to a subsequence:

- the sequence $\left(\boldsymbol{u}_{n}\right)_{n \in \mathbb{N}}$ converges in $\left(L^{q}(\Omega)\right)^{d}$ for any $q \in[1, q(d))$ to a function $\boldsymbol{u} \in \mathrm{H}_{0}^{1}(\Omega)^{d}$, and $\left(\nabla_{\mathcal{E}_{n}} \boldsymbol{u}_{n}\right)_{n \in \mathbb{N}}$ converges weakly to $\nabla \boldsymbol{u}$ in $L^{2}(\Omega)^{d \times d}$,
- the sequence $\left(\varrho_{n}\right)_{n \in \mathbb{N}}$ converges in $L^{p}(\Omega)$ for any $p$ such that $1 \leq p<2 \gamma$ and weakly in $L^{2 \gamma}(\Omega)$ to a function $\varrho$ of $L^{2 \gamma}(\Omega)$,
- the sequence $\left(p_{n}\right)_{n \in \mathbb{N}}$ converges in $L^{p}(\Omega)$ for any $p$ such that $1 \leq p<2$ and weakly in $L^{2}(\Omega)$ to a function $p$ of $L^{2}(\Omega)$,
- $(\boldsymbol{u}, p, \varrho)$ is a weak solution of Problem (1.1)-(1.4) in the sense of Definition 1.

The convergence part of Theorem 4 remains true with a fixed value of $C_{s}$ (for instance, $C_{s}=1$ ). The only difference is that the estimates on the approximated solutions are valid only for $h_{\mathcal{M}}$ small enough with respect to the data. The following sections are devoted to the proof of Theorem 4. For the sake of clarity, we shall perform the proofs only in the three-dimensional case (and then $\gamma>3$ ). The modifications to be done for the two-dimensional case, which is in fact simpler, are mostly due to the different Sobolev embeddings and are left to the interested reader. Throughout the proof of this theorem, we adapt to the discrete case the strategy followed to prove Theorem 1.

## 6. Mesh independent estimates

6.1. Notations. From now on, we assume that $\Omega$ is a MAC compatible bounded domain of $\mathbb{R}^{d}$, $d=2$ or $d=3$, and that all the considered meshes satisfy $\eta \leq \eta_{\mathcal{M}}$, for a given $\eta>0$ and with $\eta_{\mathcal{M}}$ defined by (3.2). The letter $C$ denotes positive real numbers that may tacitly depend on $|\Omega|$, $\operatorname{diam}(\Omega), \gamma, \lambda, \mu, M, f, \alpha, \eta$ and on other parameters; the dependency on these other parameters (if any) is always explicitly indicated. These numbers can take different values, even in the same formula. They are always independent of the size of the discretisation $h_{\mathcal{M}}$.
6.2. Existence. Let us now state that the discrete problem (3.3) admits at least one solution. This existence result follows from a the topological degree argument (see [4] for the theory, [5] for the first application to a nonlinear numerical scheme and Appendix A for the proof).
Theorem 5. There exists a solution $(\boldsymbol{u}, p, \varrho) \in \mathbf{H}_{\mathcal{E}, 0} \times L_{\mathcal{M}} \times L_{\mathcal{M}}$ to Problem (3.3). Moreover any solution is such that $\varrho>0$ a.e in $\Omega$ (in the sense that $\varrho_{K}>0, \forall K \in \mathcal{M}$ ).
6.3. Energy Inequality. Let us now turn to stability issues: in order to prove the convergence of the scheme, we wish to obtain some uniform (with respect to the mesh) bounds on the solutions to (3.3), see Proposition 1 below. We begin by a technical lemma [8, Lemma 5.4] which is useful not only for stability issues, but also for the three following reasons. First, it allows an estimate on $\boldsymbol{u}$ in a dicrete $\mathrm{H}_{0}^{1}$ norm (Proposition 1), as in [8, Proposition 5.5]. Second, it yields a so called weak BV estimate, which depend on the mesh and does not give a direct compactness result on the sequence of approximate solutions; however it is useful in the passage to the limit in the mass equation, in the discrete convective term and in the equation of state. Third, Lemma 7 gives (with $\beta=1$ ) a crucial inequality which is also used in order to pass to the limit in the equation of state.
Lemma 7. Let $\varrho \in L_{\mathcal{M}}$ and $\boldsymbol{u} \in \mathbf{H}_{\mathcal{E}, 0}$ satisfy (3.3a). Then, for any $\beta \geq 1$ :

$$
\int_{\Omega} \varrho^{\beta} \operatorname{div}_{\mathcal{M}} \boldsymbol{u} \mathrm{d} \boldsymbol{x}+\frac{1}{2} \sum_{\sigma \in \mathcal{E}_{\mathrm{int}}} \beta|\sigma| \varrho_{\sigma, \beta}\left|u_{\sigma}\right|[\varrho]_{\sigma}^{2} \leq C C_{s} h_{\mathcal{M}}^{\alpha}
$$

where $C$ depends only on $M, \beta, \mu, \alpha, \Omega$ and $\eta$, and, for any $\sigma \in \mathcal{E}_{\text {int }}, \sigma=K \mid L$,

$$
\begin{equation*}
\varrho_{\sigma, \beta}=\min \left(\varrho_{K}^{\beta-2}, \varrho_{L}^{\beta-2}\right) \tag{6.1}
\end{equation*}
$$

In order to obtain an estimate on the pressure, we need to introduce a so-called Fortin interpolation operator, i.e. an operator which maps velocity functions to discrete functions and preserves the divergence. The following lemma is given in [15, Theorem 1], and we repeat it here with our notations for the sake of clarity. We will use this Lemma later on with $p=2$.

Lemma 8 (Fortin interpolation operator). Let $\mathcal{D}=(\mathcal{M}, \mathcal{E})$ be a MAC grid of $\Omega$. Let $1 \leq p<\infty$. For $\boldsymbol{v}=\left(v_{1}, \ldots, v_{d}\right) \in\left(W_{0}^{1, p}(\Omega)\right)^{d}$ we define $\widetilde{\mathcal{P}}_{\mathcal{E}} \boldsymbol{v}$ by

$$
\begin{align*}
\widetilde{\mathcal{P}}_{\mathcal{E}} \boldsymbol{v}= & \left(\widetilde{\mathcal{P}}_{\mathcal{E}}^{(1)} v_{1}, \cdots, \widetilde{\mathcal{P}}_{\mathcal{E}}^{(1)} v_{d}\right) \in \mathbf{H}_{\mathcal{E}, 0}, \text { where for } i=1, \ldots d \\
\widetilde{\mathcal{P}}_{\mathcal{E}}^{(i)}: & W_{0}^{1, p}(\Omega) \longrightarrow H_{\mathcal{E}, 0}^{(i)} \\
& v_{i} \longmapsto \widetilde{\mathcal{P}}_{\mathcal{E}} v_{i} \text { defined by }  \tag{6.2}\\
& \widetilde{\mathcal{P}}_{\mathcal{E}}^{(i)} v_{i}(\boldsymbol{x})=\left(\widetilde{\mathcal{P}}_{\mathcal{E}}^{(i)} v_{i}\right)_{\sigma}=\frac{1}{|\sigma|} \int_{\sigma} v_{i}(\boldsymbol{x}) \mathrm{d} \gamma(\boldsymbol{x}), \forall \boldsymbol{x} \in D_{\sigma}, \sigma \in \mathcal{E}^{(i)} .
\end{align*}
$$

Then $\widetilde{\mathcal{P}}_{\mathcal{E}}$ satisfies:

$$
\begin{equation*}
\left\|\widetilde{\mathcal{P}}_{\mathcal{E}} \varphi-\varphi\right\|_{L^{\infty}(\Omega)} \leq C_{\varphi} h_{\mathcal{M}}, \forall \varphi \in C_{c}^{\infty}(\Omega)^{d} \tag{6.3}
\end{equation*}
$$

For $q \in L^{1}(\Omega)$, we define $\mathcal{P}_{\mathcal{M}} q \in L_{\mathcal{M}}$ by:

$$
\begin{equation*}
\mathcal{P}_{\mathcal{M}} q(\boldsymbol{x})=\frac{1}{|K|} \int_{K} q(\boldsymbol{x}) \mathrm{d} \boldsymbol{x} \tag{6.4}
\end{equation*}
$$

Let $\eta_{\mathcal{M}}>0$ be defined by (3.2). Then, for $\boldsymbol{\varphi} \in\left(W_{0}^{1, p}(\Omega)\right)^{d}$,

$$
\begin{align*}
& \operatorname{div}_{\mathcal{M}}\left(\widetilde{\mathcal{P}}_{\mathcal{E}} \varphi\right)=\mathcal{P}_{\mathcal{M}}(\operatorname{div} \varphi)  \tag{6.5a}\\
& \left\|\nabla_{\tilde{\mathcal{E}}^{\mathcal{P}}} \widetilde{\mathcal{E}}\right\|_{\left(L^{p}(\Omega)^{d \times d}\right)} \leq C_{\eta_{\mathcal{M}}}\|\nabla \boldsymbol{\varphi}\|_{\left(L^{p}(\Omega)\right)^{d}} \tag{6.5b}
\end{align*}
$$

where $C_{\eta_{\mathcal{M}}}$ depends only on $\Omega, p$ and on $\eta_{\mathcal{M}}$ in a decreasing way.
We can now state and prove the estimates on a discrete solution that we are seeking. These estimates may be seen as an equivalent for the discrete case of Step 1 of the proof of Theorem 1.

Proposition 1. Let $(\boldsymbol{u}, p, \varrho) \in \mathbf{H}_{\mathcal{E}, 0} \times L_{\mathcal{M}} \times L_{\mathcal{M}}$ be a solution to the scheme, i.e. system (3.3). Taking $C_{s}$ small enough with respect to the data (namely $\mu, M, \Omega, \alpha, \eta$ ) there exists $C_{1}$ depending only on $\boldsymbol{f}, \mu, M, \Omega, \gamma, \alpha$ and on $\eta$ such that:

$$
\begin{equation*}
\|\boldsymbol{u}\|_{1, \mathcal{E}, 0}+\|p\|_{L^{2}(\Omega)}+\|\varrho\|_{L^{2 \gamma}(\Omega)} \leq C_{1} \tag{6.6}
\end{equation*}
$$

Moreover, for any $\beta \in[1, \gamma]$, there exists $C_{2}$ depending only on $\boldsymbol{f}, M, \Omega, \gamma, \mu, \alpha, \beta$ and $\eta$ such that

$$
\begin{equation*}
\sum_{\sigma \in \mathcal{E}_{\text {int }}}|\sigma| \varrho_{\sigma, \beta}\left|u_{\sigma}\right|[\varrho]_{\sigma}^{2} \leq C_{2} \tag{6.7}
\end{equation*}
$$

where $\varrho_{\sigma, \beta}$ is defined in (6.1). In particular, since $\gamma>3$, we get by taking $\beta=2$ in (6.7):

$$
\begin{equation*}
\sum_{\sigma \in \mathcal{E}_{\text {int }}}|\sigma|\left|u_{\sigma}\right|\left[\varrho \varrho_{\sigma}^{2} \leq C_{2} .\right. \tag{6.8}
\end{equation*}
$$

Proof. In order to prove Proposition 1, we proceed in several steps. We follow the proof established in the continuous case to obtain uniform bounds of the approximate solutions.

Step 1 : Estimates on $\|\boldsymbol{u}\|_{1, \mathcal{E}, 0}$ and inequality (6.7).
Taking $\boldsymbol{u}$ as a test function in (3.28), using the Holdër's inequality and thanks to the fact that the discrete $\mathrm{H}^{1}$ norm controls the $L^{2}$ norm (see Theorem 2), we have:

$$
\begin{align*}
& \frac{\mu}{2}\|\boldsymbol{u}\|_{1, \mathcal{E}, 0}^{2}+(\mu+\lambda)\left\|\operatorname{div}_{\mathcal{M}} \boldsymbol{u}\right\|_{L^{2}(\Omega)}^{2}-\int_{\Omega} p \operatorname{div}_{\mathcal{M}} \boldsymbol{u} \mathrm{d} \boldsymbol{x}  \tag{6.9}\\
& \quad+\sum_{i=1}^{3} \sum_{\substack{\epsilon \in \tilde{\mathcal{I}}_{\text {int }}^{(i)}, \epsilon=D_{\sigma} \mid D_{\sigma^{\prime}}}} \frac{1}{2} F_{\sigma, \epsilon}\left(u_{\sigma}+u_{\sigma^{\prime}}\right)\left(u_{\sigma}-u_{\sigma^{\prime}}\right) \leq C
\end{align*}
$$

where $C$ depends only on $\boldsymbol{f}$ and $\Omega$. Moreover, by virtue of (3.13),

$$
\begin{aligned}
& \sum_{i=1}^{3} \sum_{\substack{\epsilon \in \widetilde{\mathcal{E}}_{\text {int }}^{(i)}, \epsilon=D_{\sigma} \mid D_{\sigma^{\prime}}}} \frac{1}{2} F_{\sigma, \epsilon}\left(u_{\sigma}+u_{\sigma^{\prime}}\right)\left(u_{\sigma}-u_{\sigma^{\prime}}\right)=\sum_{i=1}^{3} \sum_{\substack{\epsilon \in \widetilde{\mathcal{E}}^{(i)}, \epsilon=D_{\sigma} \mid D_{\sigma^{\prime}}}} \frac{1}{2} F_{\sigma, \epsilon}\left(\left(u_{\sigma}\right)^{2}-\left(u_{\sigma^{\prime}}\right)^{2}\right) \\
&=\sum_{i=1}^{3} \sum_{\sigma \in \mathcal{E}_{\text {int }}^{(i)}} \frac{\left(u_{\sigma}\right)^{2}}{2} \sum_{\epsilon \in \widetilde{\mathcal{E}}\left(D_{\sigma}\right)} F_{\sigma, \epsilon}=-\frac{1}{2} C_{s} h_{\mathcal{M}}^{\alpha}\left(\int_{\Omega} \varrho\|\boldsymbol{u}\|^{2} \mathrm{~d} \boldsymbol{x}-\varrho^{\star} \int_{\Omega}\|\boldsymbol{u}\|^{2} \mathrm{~d} \boldsymbol{x}\right)
\end{aligned}
$$

Lemma 7 with $\beta=\gamma$ yields, since $p=\varrho^{\gamma}$ :

$$
\int_{\Omega} p \operatorname{div}_{\mathcal{M}} \boldsymbol{u} \mathrm{d} \boldsymbol{x}+\frac{1}{2} \sum_{\sigma \in \mathcal{E}_{\mathrm{int}}} \gamma|\sigma| \varrho_{\sigma, \gamma}\left|u_{\sigma}\right|[\varrho]_{\sigma}^{2} \leq C
$$

where $C$ depends only on $M, \gamma, \alpha, \mu, \Omega$ and $\eta$.
Consequently

$$
\frac{\mu}{2}\|\boldsymbol{u}\|_{1, \mathcal{E}, 0}^{2}+\frac{1}{2} \sum_{\sigma \in \mathcal{E}_{\text {int }}} \gamma|\sigma| \varrho_{\sigma, \gamma}\left|u_{\sigma}\right|[\varrho]_{\sigma}^{2} \leq \frac{1}{2} C_{s} M h^{\alpha}\||\boldsymbol{u}|\|_{L^{\infty}(\Omega)}^{2}+C
$$

By virtue of Theorem 2 we have $h_{\mathcal{M}}^{3}\|\boldsymbol{u}\|_{L^{\infty}(\Omega)^{3}}^{6} \leq C(\eta)\|\boldsymbol{u}\|_{L^{6}(\Omega)^{3}}^{6} \leq C(\eta)\|\boldsymbol{u}\|_{1, \mathcal{E}, 0}^{6}$ and therefore

$$
\|\boldsymbol{u}\|_{L^{\infty}(\Omega)^{3}} \leq C(\eta) \frac{1}{\sqrt{h_{\mathcal{M}}}}\|\boldsymbol{u}\|_{1, \mathcal{E}, 0}
$$

Summing these two relations, we thus obtain:

$$
\begin{equation*}
\frac{\mu}{2}\|\boldsymbol{u}\|_{1, \mathcal{E}, 0}^{2}+\frac{1}{2} \sum_{\sigma \in \mathcal{E}_{\text {int }}} \gamma|\sigma| \varrho_{\sigma, \gamma}\left|u_{\sigma}\right|[\varrho]_{\sigma}^{2} \leq C+\frac{1}{2} C(\eta) C_{s} M h_{\mathcal{M}}^{\alpha-1}\|\boldsymbol{u}\|_{1, \mathcal{E}, 0}^{2} \tag{6.10}
\end{equation*}
$$

and consequently, since $\alpha>1$,

$$
\frac{1}{2}\left(\mu-C(\eta) C_{s} M \operatorname{diam}(\Omega)^{\alpha-1}\right)\|\boldsymbol{u}\|_{1, \mathcal{E}, 0}^{2}+\frac{1}{2} \sum_{\sigma \in \mathcal{E}_{\mathrm{int}}} \gamma|\sigma| \varrho_{\sigma, \gamma}\left|u_{\sigma}\right|[\varrho]_{\sigma}^{2} \leq C
$$

Let us choose $C_{s}$ such that $0<C_{s}<\frac{\mu}{C(\eta) M \operatorname{diam}(\Omega)^{\alpha-1}}$; a possible choice is:

$$
\begin{equation*}
0<C_{s}<\frac{\mu \eta^{6}}{M \operatorname{diam}(\Omega)^{\alpha-1}} \tag{6.11}
\end{equation*}
$$

Then

$$
\|\boldsymbol{u}\|_{1, \mathcal{E}, 0}+\frac{1}{2} \sum_{\sigma \in \mathcal{E}_{\mathrm{int}}} \gamma|\sigma| \varrho_{\sigma, \gamma}\left|u_{\sigma}\right|[\varrho]_{\sigma}^{2} \leq C
$$

Step 2: Estimate on $\|p\|_{L^{2}(\Omega)}$.
Let $m(p)$ stand for the mean value of $p$. By Lemma 1 , there exists $\boldsymbol{v}=\left(v_{1}, v_{2}, v_{3}\right) \in H_{0}^{1}(\Omega)^{3}$ such that

$$
\left\{\begin{array}{l}
\operatorname{div} \boldsymbol{v}=p-m(p) \\
\|\boldsymbol{v}\|_{H_{0}^{1}(\Omega)^{3}} \leq C(\Omega)\|p-m(p)\|_{L^{2}(\Omega)}
\end{array}\right.
$$

Multiplying (3.3b) by $\widetilde{\mathcal{P}}_{\mathcal{E}} \boldsymbol{v}$ (where $\widetilde{\mathcal{P}}_{\mathcal{E}}$ is defined in Lemma 8 ) and integrating over $\Omega$ we have:

$$
\|p-m(p)\|_{L^{2}(\Omega)}^{2} \leq C\|p-m(p)\|_{L^{2}(\Omega)}+\sum_{i=1}^{3} \sum_{\substack{\epsilon \in \widetilde{\mathcal{E}}_{\text {int }}^{(i)}, \epsilon=D_{\sigma} \mid D_{\sigma^{\prime}}}} F_{\sigma, \epsilon} \frac{1}{2}\left(u_{\sigma}+u_{\sigma^{\prime}}\right)\left(\left(\widetilde{\mathcal{P}}_{\mathcal{E}}^{(i)} v_{i}\right)_{\sigma}-\left(\widetilde{\mathcal{P}}_{\mathcal{E}}^{(i)} v_{i}\right)_{\sigma^{\prime}}\right)
$$

where C depends on $f, \Omega, \eta, \mu, \alpha, \gamma, M$. Now keeping in mind the definition of the dual fluxes (see (3.10) and (3.11)) and the definition of $\|\cdot\|_{1, \mathcal{E}, 0}$, a technical but straightforward computation gives

$$
\begin{aligned}
\left|\sum_{i=1}^{3} \sum_{\substack{\epsilon \in \widetilde{\mathcal{E}}_{\text {int }}^{(i)}, \epsilon=D_{\sigma} \mid D_{\sigma^{\prime}}}} F_{\sigma, \epsilon} \frac{1}{2}\left(u_{\sigma}+u_{\sigma^{\prime}}\right)\left(\left(\widetilde{\mathcal{P}}_{\mathcal{E}}^{(i)} v_{i}\right)_{\sigma}-\left(\widetilde{\mathcal{P}}_{\mathcal{E}}^{(i)} v_{i}\right)_{\sigma^{\prime}}\right)\right| & \leq C\|\varrho\|_{L^{6}(\Omega)}\|\boldsymbol{u}\|_{L^{6}(\Omega)}^{2}\left\|\widetilde{\mathcal{P}}_{\mathcal{E}} \boldsymbol{v}\right\|_{1, \mathcal{E}, 0} \\
& \leq C\|p\|_{L^{2}(\Omega)}^{\frac{1}{\gamma}}\|p-m(p)\|_{L^{2}(\Omega)}
\end{aligned}
$$

where C depends on $\boldsymbol{f}, \Omega, \eta, \mu, \alpha, \gamma, M$. The last inequality is obtained thanks to the the energy inequality (6.6) to get a bound on $\|\boldsymbol{u}\|_{L^{6}(\Omega)}$ (thanks to Theorem 2) and Hölder's inequality since $2 \gamma \geq 6$ and $p=\varrho^{\gamma}$. Consequently

$$
\|p-m(p)\|_{L^{2}(\Omega)} \leq C\left(\|p\|_{L^{2}(\Omega)}^{\frac{1}{\gamma}}+1\right)
$$

where $C$ depends on $\boldsymbol{f}, \mu, M, \Omega, \gamma, \alpha$ and on $\eta$. Since $\int_{\Omega} p^{\frac{1}{\gamma}} \mathrm{~d} \boldsymbol{x}=\int_{\Omega} \varrho \mathrm{d} \boldsymbol{x}=M$, Lemma 2 gives an $L^{2}$ bound for $p$ depending only on the data. To conclude, we obtain a $L^{2 \gamma}$ bound for the density since $p=\varrho^{\gamma}$.
In order to prove (6.7) for $1 \leq \beta \leq \gamma$, let us use once again Lemma 7 , to obtain:

$$
\frac{1}{2} \sum_{\sigma \in \mathcal{E}_{\mathrm{int}}} \beta|\sigma| \varrho_{\sigma, \beta}\left|u_{\sigma}\right|[\varrho]_{\sigma}^{2} \leq-\int_{\Omega} \varrho^{\beta} \operatorname{div}_{\mathcal{M}} \boldsymbol{u} \mathrm{d} \boldsymbol{x}+C
$$

where $C$ depends on $M, \beta, \mu, \alpha, \Omega, \eta$. Since $\varrho$ is bounded in $L^{2 \beta}(\Omega)$ and $\left\|\operatorname{div}_{\mathcal{M}} \boldsymbol{u}\right\|_{L^{2}(\Omega)}$ is controlled by $\|\boldsymbol{u}\|_{1, \mathcal{E}, 0}$, this concludes the proof.

Note that if, in Proposition 1, we choose a fixed value of $C_{s}$, for instance $C_{s}=1$, There exists $\bar{h}>0$, depending of the data, such that the conclusions of Proposition 1 are true for $h_{\mathcal{M}} \leq \bar{h}$. This is easy to see with (6.10).

## 7. Convergence analysis

The aim of this section is to pass to the limit in the discrete equations (3.3a)-(3.3c). As in the continuous case, thanks to the estimates established in the previous section, taking a sequence of meshes, we can assume the convergence, up to a subsequence, of the discrete solution to some $(\boldsymbol{u}, p, \varrho)$, in a convenient sense. We will first prove that $(\boldsymbol{u}, p, \varrho)$ satisfies the weak form of Problem (1.1)-(1.2). We then prove that $p=\varrho^{\gamma}$. The first difficulty is the convergence of the discrete convective term (the second consists in passing to the limit in the equation of state). Indeed it is not easy to manipulate the discrete convective operator defined with the dual fluxes. We then
introduce velocity interpolators in order to transform the discrete convective operator. It relies on the reconstruction of each velocity component on all faces (or edges in 2D) of the mesh. Similar results are used in [16] for the incompressible case.

### 7.1. Passing to the limit in the mass and momentum balance equations.

Lemma 9 (Velocity interpolators). For a given $M A C$ grid $\mathcal{D}=(\mathcal{M}, \mathcal{E})$, we define, for $i, j=1,2,3$, the full grid velocity reconstruction operator with respect to $(i, j)$ by

$$
\begin{align*}
\mathcal{R}_{\mathcal{E}}^{(i, j)}: & H_{\mathcal{E}, 0}^{(i)} \rightarrow H_{\mathcal{E}, 0}^{(j)} \\
& v \mapsto \mathcal{R}_{\mathcal{E}}^{(i, j)} v=\sum_{\sigma \in \mathcal{E}_{\mathrm{int}}^{(j)}}\left(\mathcal{R}_{\mathcal{E}}^{(i, j)} v\right)_{\sigma} \mathbb{1}_{D_{\sigma}}, \tag{7.1}
\end{align*}
$$

where

$$
\begin{align*}
& \left(\mathcal{R}_{\mathcal{E}}^{(i, i)} v\right)_{\sigma}=v_{\sigma} \text { for } \sigma \in \mathcal{E}_{\mathrm{int}}^{(i)}  \tag{7.2}\\
& \text { and, for } \sigma=K \mid L \in \mathcal{E}_{\mathrm{int}}^{(j)}, j \neq i \\
& \left(\mathcal{R}_{\mathcal{E}}^{(i, j)} v\right)_{\sigma}=\frac{1}{4} \sum_{\sigma^{\prime} \in \mathcal{N}_{\sigma}} v_{\sigma^{\prime}}, \mathcal{N}_{\sigma}=\left\{\sigma^{\prime} \in \mathcal{E}^{(i)}, \sigma^{\prime} \in \mathcal{E}(K) \cup \mathcal{E}(L)\right\} \tag{7.3}
\end{align*}
$$

For any $i=1,2,3$, we also define a projector from $H_{\mathcal{E}}^{(i)}$ into $L_{\mathcal{M}}$ by

$$
\begin{align*}
\mathcal{R}_{\mathcal{M}}^{(i)}: & H_{\mathcal{E}}^{(i)} \rightarrow L_{\mathcal{M}} \\
& v \mapsto \mathcal{R}_{\mathcal{M}}^{(i)} v=\sum_{K \in \mathcal{M}}\left(\mathcal{R}_{\mathcal{M}}^{(i)} v\right)_{K} \mathbb{1}_{K} \tag{7.4}
\end{align*}
$$

where

$$
\begin{equation*}
\left(\mathcal{R}_{\mathcal{M}}^{(i)} v\right)_{K}=\frac{1}{2} \sum_{\sigma \in \mathcal{E}^{(i)}(K)} v_{\sigma} \tag{7.5}
\end{equation*}
$$

Then there exists $C \geq 0$, depending only on the regularity of the mesh (defined by (3.2)) in a decreasing way, such that, for any $1 \leq q<\infty$ and for any $i, j=1,2,3$,

$$
\begin{gathered}
\left\|\mathcal{R}_{\mathcal{E}}^{(i, j)} v\right\|_{L^{q}(\Omega)} \leq C\|v\|_{L^{q}(\Omega)} \text { for any } v \in H_{\mathcal{E}, 0}^{(i)} \\
\left\|\mathcal{R}_{\mathcal{M}}^{(i)} v\right\|_{L^{q}(\Omega)} \leq C\|v\|_{L^{q}(\Omega)} \text { for any } v \in H_{\mathcal{E}}^{(i)}
\end{gathered}
$$

Proof. Let us prove the bound on $\left\|\mathcal{R}_{\mathcal{E}}^{(i, j)} v\right\|_{L^{q}(\Omega)}$ for $d=2, i=1$ and $j=2$. The other cases are similar. In this case, for a given $\sigma=K \mid L \in \mathcal{E}_{\text {int }}^{(i)}$, the edge $\sigma$ belongs to $\mathcal{N}_{\sigma^{\prime}}$ for $\sigma^{\prime} \in\left\{\sigma_{K}^{t}, \sigma_{K}^{b}, \sigma_{L}^{t}, \sigma_{L}^{b}\right\}$ where $\sigma_{K}^{t}$ (resp. $\sigma_{K}^{b}$ ) denotes the top (resp. bottom) edge of $K$, as depicted in Figure 4. Let $v \in H_{\mathcal{E}, 0}^{(i)}$; by definition of $\mathcal{R}_{\mathcal{E}}^{(i, j)} v$, noting that $\left[\frac{1}{4}(a+b+c+d)\right]^{q} \leq a^{q}+b^{q}+c^{q}+d^{q}$, we have:

$$
\left\|\mathcal{R}_{\mathcal{E}}^{(i, j)} v\right\|_{L^{q}(\Omega)}^{q} \leq \sum_{\substack{\sigma \in \mathcal{E}_{\text {int }}^{(i)} \\ \sigma=K \mid L}}\left|v_{\sigma}\right|^{q}\left(\left|D_{\sigma_{K}^{t}}\right|+\left|D_{\sigma_{K}^{b}}\right|+\left|D_{\sigma_{L}^{t}}\right|+\left|D_{\sigma_{L}^{b}}\right|\right) \leq 4 \eta^{-2} \sum_{\substack{\sigma \in \mathcal{E}_{\text {int }}^{(i)} \\ \sigma=K \mid L}}\left|v_{\sigma}\right|^{q}\left|D_{\sigma}\right|
$$

which concludes the proof.

Figure 4. Full grid velocity interpolate.

Lemma 10 (Convergence of the full grid velocity interpolate). Let $\left(\mathcal{M}_{n}, \mathcal{E}_{n}\right)_{n \in \mathbb{N}}$ be a sequence of MAC meshes such that $h_{\mathcal{M}_{n}} \rightarrow 0$ as $n \rightarrow+\infty$, and, for all $n$, $\eta_{\mathcal{M}_{n}} \geq \eta>0$. Let $1 \leq q<\infty$.
Let $i, j \in\{1,2,3\}, v \in L^{q}(\Omega)$ and $\left(v_{n}\right)_{n \in \mathbb{N}}$ be such that $v_{n} \in H_{\mathcal{E}_{n}, 0}^{(i)}$ and $v_{n}$ converges to $v$ as $n \rightarrow+\infty$ in $L^{q}(\Omega)$. Let $\mathcal{R}_{\mathcal{E}_{n}}^{(i, j)}$ be the full grid velocity reconstruction operator defined by (7.1). Then $\mathcal{R}_{\mathcal{E}_{n}}^{(i, j)} v_{n} \rightarrow v$ in $L^{q}(\Omega)$ as $n \rightarrow+\infty$.
Similarly, if $\left(v_{n}\right)_{n \in \mathbb{N}}$ is such that $v_{n} \in H_{\mathcal{E}_{n}}^{(i)}$ and $v_{n}$ converges to $v$ as $n \rightarrow+\infty$ in $L^{q}(\Omega)$, then, $\mathcal{R}_{\mathcal{M}_{n}}^{(i)} v_{n} \rightarrow v$ in $L^{q}(\Omega)$ as $n \rightarrow+\infty$, where $\mathcal{R}_{\mathcal{M}_{n}}^{(i)} v$ is defined by (7.4).
Proof. We give the proof for $\mathcal{R}_{\mathcal{E}_{n}}^{(i, j)}$ (the proof is similar for $\left.\mathcal{R}_{\mathcal{M}_{n}}^{(i)}\right)$.
Let $\varphi \in C_{c}^{\infty}(\Omega)$. Denoting $\mathcal{R}_{\mathcal{E}_{n}}^{(i, j)}$ by $\mathcal{R}_{n}$ and $\mathcal{P}_{\mathcal{E}_{n}}^{(i)}$ (defined by (3.8)) by $\mathcal{P}_{n}$ for short, we have:

$$
\begin{array}{r}
\left\|\mathcal{R}_{n} v_{n}-v\right\|_{L^{q}(\Omega)} \leq\left\|\mathcal{R}_{n} v_{n}-\mathcal{R}_{n} \circ \mathcal{P}_{n} v\right\|_{L^{q}(\Omega)}+\left\|\mathcal{R}_{n} \circ \mathcal{P}_{n} v-\mathcal{R}_{n} \circ \mathcal{P}_{n} \varphi\right\|_{L^{q}(\Omega)}+ \\
\left\|\mathcal{R}_{n} \circ \mathcal{P}_{n} \varphi-\varphi\right\|_{L^{q}(\Omega)}+\|\varphi-v\|_{L^{q}(\Omega)}
\end{array}
$$

Since $\mathcal{R}_{n} v_{n}=\mathcal{R}_{n} \circ \mathcal{P}_{n} v_{n}$, and thanks to the fact that $\left\|\mathcal{R}_{n} w\right\|_{L^{q}(\Omega)} \leq C\|w\|_{L^{q}(\Omega)}$ (for some $C>0$, see Lemma 9) and that $\left\|\mathcal{P}_{n} w\right\|_{L^{q}(\Omega)} \leq\|w\|_{L^{q}(\Omega)}$, we get

$$
\left\|\mathcal{R}_{n} v_{n}-v\right\|_{L^{q}(\Omega)} \leq C\left\|v_{n}-v\right\|_{L^{q}(\Omega)}+C\|v-\varphi\|_{L^{q}(\Omega)}+\left\|\mathcal{R}_{n} \circ \mathcal{P}_{n} \varphi-\varphi\right\|_{L^{q}(\Omega)}+\|\varphi-v\|_{L^{q}(\Omega)}
$$

Let $\varepsilon>0$. Let us choose $\varphi \in C_{c}^{\infty}(\Omega)$ such that $\|\varphi-v\|_{L^{q}(\Omega)} \leq \frac{\varepsilon}{C+1}$. There exists $n_{1}$ such that $C\left\|v_{n}-v\right\|_{L^{q}(\Omega)} \leq \varepsilon$ for all $n \geq n_{1}$, and there exists $n_{2}$ such that $\left\|\mathcal{R}_{n} \circ \mathcal{P}_{n} \varphi-\varphi\right\|_{L^{q}(\Omega)} \leq \varepsilon$, for all $n \geq n_{2}$. Therefore $\left\|\mathcal{R}_{n} v_{n}-v\right\|_{L^{q}(\Omega)} \leq 3 \varepsilon$ for $n \geq \max \left(n_{1}, n_{2}\right)$, which concludes the proof.

With the above definitions the following algebraic identity holds (a similar identity is in [21]):
Lemma 11. Let $\varrho \in L_{\mathcal{M}}$ and $\boldsymbol{u}=\left(u_{1}, u_{2}, u_{3}\right) \in \mathbf{H}_{\mathcal{E}, 0}$. Let $i \in\{1,2,3\}$ and $\varphi=\left(\varphi_{\sigma}\right)_{\sigma \in \mathcal{E}_{\text {int }}^{(i)}} \in H_{\mathcal{E}, 0}^{(i)}$ be a discrete scalar function. Let the primal fluxes $F_{K, \sigma}$ be given by (3.4) and let the dual fluxes $F_{\sigma, \epsilon}$ be given by (3.10) or (3.11). Then we have

$$
\sum_{\sigma \in \mathcal{E}_{\text {int }}^{(i)}} \sum_{\epsilon \in \widetilde{\mathcal{E}}\left(D_{\sigma}\right)} F_{\sigma, \epsilon} u_{\epsilon} \varphi_{\sigma}=\sum_{j=1}^{3} S_{j},
$$

where

$$
S_{i}=\sum_{\substack{K=\underset{\left[\sigma \sigma^{\prime}\right]}{\sigma, \sigma^{\prime} \in \mathcal{E}^{(i)}}}}\left(\varrho_{\sigma}^{u p} u_{\sigma}\left|D_{K, \sigma}\right|+\varrho_{\sigma^{\prime}}^{u p} u_{\sigma^{\prime}}\left|D_{K, \sigma^{\prime}}\right|\right)\left(\mathcal{R}_{\mathcal{M}}^{(i)} u_{i}\right)_{K} \frac{\varphi_{\sigma}-\varphi_{\sigma^{\prime}}}{d\left(\boldsymbol{x}_{\sigma}, \boldsymbol{x}_{\sigma^{\prime}}\right)}
$$

and, for $j \neq i$,

$$
S_{j}=\sum_{\tau \in \mathcal{E}_{\mathrm{int}}^{(j)}}\left|D_{\tau}\right| \frac{\varrho_{\tau}^{u p} u_{\tau}}{4}\left[\left(u_{\sigma_{3}}+u_{\sigma_{1}}\right) \frac{\varphi_{\sigma_{3}}-\varphi_{\sigma_{1}}}{d\left(\boldsymbol{x}_{\sigma_{1}}, \boldsymbol{x}_{\sigma_{3}}\right)}+\left(u_{\sigma_{4}}+u_{\sigma_{2}}\right) \frac{\varphi_{\sigma_{4}}-\varphi_{\sigma_{2}}}{d\left(\boldsymbol{x}_{\sigma_{2}}, \boldsymbol{x}_{\sigma_{4}}\right)}\right]
$$

where $\left(\sigma_{k}\right)_{k=1, \ldots, 4}$ are the four faces (or edges) belonging to $\mathcal{E}^{(i)}$, neighbors of $\tau$, with $\boldsymbol{x}_{\sigma_{3}} \boldsymbol{x}_{\sigma_{1}}=$ $\boldsymbol{x}_{\sigma_{4}} \boldsymbol{x}_{\sigma_{2}}=\beta \boldsymbol{e}_{j}, \beta>0$ (see Figure 5).
Proof. We write $\sum_{\sigma \in \mathcal{E}_{\text {int }}^{(i)}} \sum_{\epsilon \in \widetilde{\mathcal{E}}\left(D_{\sigma}\right)} F_{\sigma, \epsilon} u_{\epsilon} \varphi_{\sigma}=\sum_{j=1}^{3} S_{j}$ with, using (3.10), (3.11) and the centred choice for $u_{\epsilon}$,

$$
\begin{aligned}
& S_{i}=\sum_{\substack{\sigma \in \mathcal{E}_{\text {int }}^{(i)}}} \sum_{\substack{\epsilon=\sigma \mid \sigma^{\prime} \in \widetilde{\mathcal{E}}_{\text {int }}^{(i)} \\
\epsilon \perp \boldsymbol{e}_{i}, \in \subset K}} \frac{1}{2}\left[F_{K, \sigma} \boldsymbol{n}_{K, \sigma}+F_{K, \sigma^{\prime}} \boldsymbol{n}_{K, \sigma^{\prime}}\right] \cdot \boldsymbol{n}_{D_{\sigma}, \epsilon} \frac{u_{\sigma}+u_{\sigma^{\prime}}}{2} \varphi_{\sigma} \\
& S_{j}=\sum_{\substack{\sigma \in \mathcal{E}_{\text {int }}^{(i)}}} \sum_{\substack{\epsilon=\sigma \mid \sigma^{\prime} \in \widetilde{\mathcal{E}}_{\text {int }}^{(i)} \\
\epsilon \perp \boldsymbol{e}_{j}, \epsilon \subset \tau \cup \tau^{\prime}}} \frac{1}{2}\left[F_{K, \tau}+F_{L, \tau^{\prime}}\right] \frac{u_{\sigma}+u_{\sigma^{\prime}}}{2} \varphi_{\sigma}, \text { for } j \neq i,
\end{aligned}
$$

where $\tau$ and $\tau^{\prime}$ are the faces of $\mathcal{E}^{(j)}$ such that $\epsilon \subset \tau \cup \tau^{\prime}, \tau \in \mathcal{E}(K), \tau^{\prime} \in \mathcal{E}(L)$ and $\sigma=K \mid L$. For $S_{i}$, a reordering of the summation and the fact that $\left(u_{\sigma}+u_{\sigma^{\prime}}\right) / 2=\left(\mathcal{R}_{\mathcal{M}}^{(i)} u_{i}\right)_{K}$ yield

$$
S_{i}=\sum_{\substack{K=\overline{\left[\sigma \sigma^{\prime}\right]} \\ \sigma, \sigma^{\prime} \in \mathcal{E}^{(i)}}} \frac{1}{2}\left[F_{K, \sigma^{\prime}}-F_{K, \sigma}\right]\left(\mathcal{R}_{\mathcal{M}}^{(i)} u_{i}\right)_{K}\left(\varphi_{\sigma}-\varphi_{\sigma^{\prime}}\right)
$$

Since $F_{K, \sigma}=|\sigma| \varrho_{\sigma}^{u p} u_{\sigma}$, this gives

$$
S_{i}=\sum_{\substack{K=\overline{\left[\sigma \sigma^{\prime}\right]} \\ \sigma, \sigma^{\prime} \in \mathcal{E}^{(i)}}}\left(\varrho_{\sigma}^{u p} u_{\sigma}\left|D_{K, \sigma}\right|+\varrho_{\sigma^{\prime}}^{u p} u_{\sigma^{\prime}}\left|D_{K, \sigma^{\prime}}\right|\right)\left(\mathcal{R}_{\mathcal{M}}^{(i)} u_{i}\right)_{K} \frac{\varphi_{\sigma}-\varphi_{\sigma^{\prime}}}{d\left(\boldsymbol{x}_{\sigma}, \boldsymbol{x}_{\sigma^{\prime}}\right)}
$$

For $S_{j}, j \neq i$, we have

$$
S_{j}=\sum_{\tau \in \mathcal{E}_{\mathrm{int}}^{(j)}}|\tau| \frac{\varrho_{\tau}^{u p} u_{\tau}}{4}\left[-\left(u_{\sigma_{3}}+u_{\sigma_{1}}\right) \varphi_{\sigma_{1}}-\left(u_{\sigma_{4}}+u_{\sigma_{2}}\right) \varphi_{\sigma_{2}}+\left(u_{\sigma_{1}}+u_{\sigma_{3}}\right) \varphi_{\sigma_{3}}+\left(u_{\sigma_{2}}+u_{\sigma_{4}}\right) \varphi_{\sigma_{4}}\right]
$$

where $\left(\sigma_{k}\right)_{k=1, \ldots, 4}$ are the four neighbouring faces (or edges) of $\tau$ belonging to $\mathcal{E}^{(i)}$, i.e. such that $\bar{\tau} \cap \bar{\sigma}_{k} \neq \emptyset$, see figure 5 .
Thus,

$$
\begin{aligned}
& S_{j}=\sum_{\tau \in \mathcal{E}_{\text {int }}^{(j)}}|\tau| \frac{\varrho_{\tau}^{u p} u_{\tau}}{4}\left[\left(u_{\sigma_{3}}+u_{\sigma_{1}}\right)\left(\varphi_{\sigma_{3}}-\varphi_{\sigma_{1}}\right)+\left(u_{\sigma_{4}}+u_{\sigma_{2}}\right)\left(\varphi_{\sigma_{4}}-\varphi_{\sigma_{2}}\right)\right] \\
& =\sum_{\tau \in \mathcal{E}_{\text {int }}^{(j)}}\left|D_{\tau}\right| \frac{\varrho_{\tau}^{u p} u_{\tau}}{4}\left[\left(u_{\sigma_{3}}+u_{\sigma_{1}}\right) \frac{\varphi_{\sigma_{3}}-\varphi_{\sigma_{1}}}{d\left(\boldsymbol{x}_{\sigma_{1}}, \boldsymbol{x}_{\sigma_{3}}\right)}+\left(u_{\sigma_{4}}+u_{\sigma_{2}}\right) \frac{\varphi_{\sigma_{4}}-\varphi_{\sigma_{2}}}{d\left(\boldsymbol{x}_{\sigma_{2}}, \boldsymbol{x}_{\sigma_{4}}\right)}\right]
\end{aligned}
$$

Figure 5. Neighbouring faces of $\tau$

With the uniform estimates stated in Proposition 1 and the material introduced above we are able to pass to the limit in the discrete equations (3.3a)-(3.3b).

Proposition 2. Let $\eta>0$ and $\left(\mathcal{D}_{n}=\left(\mathcal{M}_{n}, \mathcal{E}_{n}\right)\right)_{n \in \mathbb{N}}$ be a sequence of MAC grids with step size $h_{\mathcal{M}_{n}}$ tending to zero as $n \rightarrow+\infty$. Assume that $\eta \leq \eta_{\mathcal{M}_{n}}$ for all $n \in \mathbb{N}$, where $\eta_{\mathcal{M}_{n}}$ is defined by (3.2). Let $\left(\boldsymbol{u}_{n}\right)_{n \in \mathbb{N}},\left(p_{n}\right)_{n \in \mathbb{N}}$ and $\left(\varrho_{n}\right)_{n \in \mathbb{N}}$ be the corresponding sequence of solutions to (3.3). Then, up to the extraction of a subsequence:
(1) the sequence $\left(\boldsymbol{u}_{n}\right)_{n \in \mathbb{N}}$ converges in $\left(L^{q}(\Omega)\right)^{3}$ where $q \in[1,6)$ to a function $\boldsymbol{u} \in\left(H_{0}^{1}(\Omega)\right)^{3}$ and $\left(\nabla_{\mathcal{E}_{n}} \boldsymbol{u}_{n}\right)_{n \in \mathbb{N}}$ converges weakly in $L^{2}(\Omega)^{3 \times 3}$ to $\nabla \boldsymbol{u}$.
(2) the sequence $\left(\varrho_{n}\right)_{n \in \mathbb{N}}$ weakly converges to a function $\varrho$ in $L^{2 \gamma}(\Omega)$,
(3) the sequence $\left(p_{n}\right)_{n \in \mathbb{N}}$ weakly converges to a function $p$ in $L^{2}(\Omega)$,
(4) $\boldsymbol{u}$ and $\varrho$ satisfy the continuous mass balance equation (2.1a).
(5) $\boldsymbol{u}, p$ and $\varrho$ satisfy the continuous momentum balance equation (2.1b).
(6) $\varrho \geq 0$ a.e. and $\int_{\Omega} \varrho \mathrm{d} \boldsymbol{x}=M$.

Proof. The stated convergences (i.e. points (1) to (3)) are straightforward consequences of the uniform bounds for the sequence of solutions, together, for the velocity, with the compactness theorem 3 and the Sobolev inequalities stated in Theorem 2. Point (6) is an easy consequence of point (2). We refer the reader to [8] for the proof of point (4). Let us then prove point (5) i.e. that $\boldsymbol{u}, p$ and $\varrho$ satisfy (2.1b). Let $\boldsymbol{\varphi}=\left(\varphi_{1}, \varphi_{2}, \varphi_{3}\right)$ be a function of $\mathrm{C}_{c}^{\infty}(\Omega)^{3}$. Taking $\widetilde{\mathcal{P}}_{\mathcal{E}_{n}} \boldsymbol{\varphi} \in \mathbf{H}_{\mathcal{E}_{n}, 0}$ as a test function in (3.28), we infer:

$$
\begin{aligned}
& \int_{\Omega} \operatorname{div}_{\tilde{\mathcal{E}}_{n}}\left(\varrho_{n} \boldsymbol{u}_{n} \otimes \boldsymbol{u}_{n}\right) \cdot \widetilde{\mathcal{P}}_{\mathcal{E}_{n}} \boldsymbol{\varphi} \mathrm{~d} \boldsymbol{x}+\mu \int_{\Omega} \nabla_{\mathcal{E}_{n}} \boldsymbol{u}_{n}: \nabla_{\mathcal{E}_{n}} \widetilde{\mathcal{P}}_{\mathcal{E}_{n}} \boldsymbol{\varphi} \mathrm{~d} \boldsymbol{x} \\
& \quad+(\mu+\lambda) \int_{\Omega} \operatorname{div}_{\mathcal{M}_{n}} \boldsymbol{u}_{n} \operatorname{div}_{\mathcal{M}_{n}}\left(\widetilde{\mathcal{P}}_{\mathcal{E}_{n}} \boldsymbol{\varphi} \mathrm{~d} \boldsymbol{x}-\int_{\Omega} p_{n} \operatorname{div}_{\mathcal{M}_{n}} \widetilde{\mathcal{P}}_{\mathcal{E}_{n}} \boldsymbol{\varphi}\right) \mathrm{d} \boldsymbol{x}=\int_{\Omega} \mathcal{P}_{\mathcal{E}_{n}} \boldsymbol{f} \cdot \widetilde{\mathcal{P}}_{\mathcal{E}_{n}} \boldsymbol{\varphi} \mathrm{~d} \boldsymbol{x}
\end{aligned}
$$

The convergence of the diffusive term may be proven by slight modifications of a classical result [6, Chapter III]:

$$
\lim _{n \rightarrow+\infty} \int_{\Omega} \nabla_{\mathcal{E}_{n}} \boldsymbol{u}_{n}: \nabla_{\mathcal{E}_{n}}\left(\widetilde{\mathcal{P}}_{\mathcal{E}_{n}} \boldsymbol{\varphi}\right) \mathrm{d} \boldsymbol{x}=\int_{\Omega} \nabla \boldsymbol{u}: \nabla \boldsymbol{\varphi} \mathrm{d} \boldsymbol{x}
$$

By definition of $\widetilde{\mathcal{P}}_{\mathcal{E}_{n}} \varphi$ and thanks to Lemma 8 we have:

$$
\int_{\Omega} p_{n} \operatorname{div}_{\mathcal{M}_{n}}\left(\widetilde{\mathcal{P}}_{\mathcal{E}_{n}} \boldsymbol{\varphi}\right) \mathrm{d} \boldsymbol{x}=\int_{\Omega} p_{n} \operatorname{div} \boldsymbol{\varphi} \mathrm{~d} \boldsymbol{x}
$$

and therefore, thanks to the $L^{2}$ weak convergence of the pressure,

$$
\lim _{n \rightarrow+\infty} \int_{\Omega} p_{n} \operatorname{div}_{\mathcal{M}_{n}}\left(\widetilde{\mathcal{P}}_{\mathcal{E}_{n}} \boldsymbol{\varphi}\right) \mathrm{d} \boldsymbol{x}=\int_{\Omega} p \operatorname{div} \boldsymbol{\varphi} \mathrm{~d} \boldsymbol{x}
$$

By virtue of the $L^{2}$ weak convergence of $\operatorname{div}_{\mathcal{M}_{n}} \boldsymbol{u}_{n}$, we also have:

$$
\lim _{n \rightarrow+\infty} \int_{\Omega} \operatorname{div}_{\mathcal{M}_{n}} \boldsymbol{u}_{n} \operatorname{div}_{\mathcal{M}_{n}}\left(\widetilde{\mathcal{P}}_{\mathcal{E}_{n}} \boldsymbol{\varphi}\right) \mathrm{d} \boldsymbol{x}=\int_{\Omega} \operatorname{div} \boldsymbol{u} \operatorname{div} \boldsymbol{\varphi} \mathrm{d} \boldsymbol{x}
$$

From (6.3) and the strong convergence of $\mathcal{P}_{\mathcal{E}_{n}} \boldsymbol{f}$ towards $\boldsymbol{f}$, we infer that

$$
\lim _{n \rightarrow+\infty} \int_{\Omega} \mathcal{P}_{\mathcal{E}_{n}} \boldsymbol{f} \cdot \widetilde{\mathcal{P}}_{\mathcal{E}_{n}} \boldsymbol{\varphi} \mathrm{~d} \boldsymbol{x}=\int_{\Omega} \boldsymbol{f} \cdot \boldsymbol{\varphi} \mathrm{d} \boldsymbol{x}
$$

Now it remains to treat the convective term. Here again the dependency of the mesh on $n$ will be omitted for short. First of all we have

$$
\int_{\Omega} \operatorname{div}_{\widetilde{\mathcal{E}}_{n}}\left(\varrho_{n} \boldsymbol{u}_{n} \otimes \boldsymbol{u}_{n}\right) \cdot \widetilde{\mathcal{P}}_{\mathcal{E}_{n}} \boldsymbol{\varphi} \mathrm{~d} \boldsymbol{x}=\sum_{i=1}^{3} \sum_{\sigma \in \mathcal{E}_{\text {int }}^{(i)}} \sum_{\epsilon \in \widetilde{\mathcal{E}}\left(D_{\sigma}\right)} F_{\sigma, \epsilon} u_{\epsilon}\left(\widetilde{\mathcal{P}}_{\mathcal{E}_{n}}^{(i)} \varphi_{i}\right)_{\sigma}
$$

Let $1 \leq i \leq 3$. Using Lemma 11, we can write, setting $\left(\widetilde{\mathcal{P}}_{\mathcal{E}_{n}}^{(i)} \varphi_{i}\right)_{\sigma}=\psi_{\sigma}$ and using the notations of Lemma 11,

$$
\sum_{\left.\sigma \in \mathcal{E}_{\text {int }}^{(i)}\right)} \sum_{\epsilon \in \widetilde{\mathcal{E}}\left(D_{\sigma}\right)} F_{\sigma, \epsilon} u_{\epsilon}\left(\widetilde{\mathcal{P}}_{\mathcal{E}_{n}}^{(i)} \varphi_{i}\right)_{\sigma}=\sum_{j=1}^{3} S_{j}
$$

where

$$
S_{i}=\sum_{\substack{K=\overrightarrow{\left[\sigma \sigma^{\prime}\right]} \\ \sigma, \sigma^{\prime} \in \mathcal{E}^{(i)}}}\left(\varrho_{\sigma}^{u p} u_{\sigma}\left|D_{K, \sigma}\right|+\varrho_{\sigma^{\prime}}^{u p} u_{\sigma^{\prime}}\left|D_{K, \sigma^{\prime}}\right|\right)\left(\mathcal{R}_{\mathcal{M}}^{(i)} u_{i}\right)_{K} \frac{\psi_{\sigma}-\psi_{\sigma^{\prime}}}{d\left(\boldsymbol{x}_{\sigma}, \boldsymbol{x}_{\sigma^{\prime}}\right)}
$$

and, for $j \neq i$ (see Figure 5 for the definition of $\sigma_{k}, k=1, \ldots, 4$ ),

$$
S_{j}=\sum_{\tau \in \mathcal{E}_{\mathrm{int}}^{(j)}}\left|D_{\tau}\right| \frac{\varrho_{\tau}^{u p} u_{\tau}}{4}\left[\left(u_{\sigma_{3}}+u_{\sigma_{1}}\right) \frac{\varphi_{\sigma_{3}}-\varphi_{\sigma_{1}}}{d\left(\boldsymbol{x}_{\sigma_{1}}, \boldsymbol{x}_{\sigma_{3}}\right)}+\left(u_{\sigma_{4}}+u_{\sigma_{2}}\right) \frac{\varphi_{\sigma_{4}}-\varphi_{\sigma_{2}}}{d\left(\boldsymbol{x}_{\sigma_{2}}, \boldsymbol{x}_{\sigma_{4}}\right)}\right]
$$

Replacing, in $S_{i}, \varrho_{\sigma}^{u p}$ by $\varrho_{K}$, the term $S_{i}$ can be written as $S_{i}=\bar{S}_{i}+R_{i}$ with

$$
\bar{S}_{i}=\sum_{\substack{K=\overline{\left[\sigma \sigma^{\prime}\right]} \\ \sigma, \sigma^{\prime} \in \mathcal{E}^{(i)}}}\left(\varrho_{K} u_{\sigma}\left|D_{K, \sigma}\right|+\varrho_{K} u_{\sigma^{\prime}}\left|D_{K, \sigma^{\prime}}\right|\right)\left(\mathcal{R}_{\mathcal{M}}^{(i)} u_{i}\right)_{K} \frac{\psi_{\sigma}-\psi_{\sigma^{\prime}}}{d\left(\boldsymbol{x}_{\sigma}, \boldsymbol{x}_{\sigma^{\prime}}\right)}
$$

Thanks to the weak convergence of $\varrho$ in $L^{2}(\Omega)$, the convergence of $\boldsymbol{u}$ in $L^{4}(\Omega)^{3}$, Lemma 10 and the uniform convergence of the term $\frac{\psi_{\sigma}-\psi_{\sigma^{\prime}}}{d\left(\boldsymbol{x}_{\sigma}, \boldsymbol{x}_{\sigma^{\prime}}\right)}$ to $-\partial_{i} \varphi_{i}$, we obtain

$$
\lim _{n \rightarrow+\infty} \bar{S}_{i}=-\int_{\Omega} \varrho u_{i} u_{i} \partial_{i} \varphi_{i} \mathrm{~d} \boldsymbol{x}
$$

Furthermore, using Hölder's inequality and Inequality (6.8), one has $\left|R_{i}\right| \leq C \sqrt{h_{\mathcal{M}_{n}}}$ and then

$$
\lim _{n \rightarrow+\infty} S_{i}=-\int_{\Omega} \varrho u_{i} u_{i} \partial_{i} \varphi_{i} \mathrm{~d} \boldsymbol{x}
$$

For $j \neq i$ we can write $S_{j}=\bar{S}_{j}+R_{j}$ with

$$
\begin{aligned}
\bar{S}_{j}=-\sum_{\tau \in \mathcal{E}_{\mathrm{int}}^{(j)}}\left|D_{\tau}\right| \frac{\varrho_{\tau}^{u p} u_{\tau}}{4}\left[\left(u_{\sigma_{3}}+u_{\sigma_{1}}\right) \partial_{j} \varphi_{i}\left(\boldsymbol{x}_{\tau}\right)+\left(u_{\sigma_{4}}\right.\right. & \left.\left.+u_{\sigma_{2}}\right) \partial_{j} \varphi_{i}\left(\boldsymbol{x}_{\tau}\right)\right] \\
& =-\sum_{\tau \in \mathcal{E}_{\mathrm{int}}^{(j)}}\left|D_{\tau}\right| \varrho_{\tau}^{u p} u_{\tau}\left(\mathcal{R}_{\mathcal{E}_{n}}^{(i, j)} u_{i}\right)_{\tau} \partial_{j} \varphi_{i}\left(\boldsymbol{x}_{\tau}\right)
\end{aligned}
$$

and $\left|R_{j}\right| \leq C h_{\mathcal{M}_{n}}$ thanks to the $L^{2}$-bound for $\varrho$, the $L^{4}$-bound for $\boldsymbol{u}$, Lemma 9 and the regularity of $\varphi_{i}$.
Now, as for $S_{i}$, we replace $\varrho_{\tau}^{u p}$ by $\varrho_{K}$ or $\varrho_{L}($ for $\tau=K \mid L)$, the term $\bar{S}_{j}$ can be written as $\bar{S}_{j}=\tilde{S}_{j}+\tilde{R}_{j}$ with

$$
\tilde{S}_{j}=-\sum_{\tau \in \mathcal{E}_{\text {int }}^{(j)}}\left(\left|D_{K, \tau}\right| \varrho_{K}+\left|D_{L, \tau}\right| \varrho_{L}\right) u_{\tau}\left(\mathcal{R}_{\mathcal{E}_{n}}^{(i, j)} u_{i}\right)_{\tau} \partial_{j} \varphi_{i}\left(\boldsymbol{x}_{\tau}\right)
$$

As for $\bar{S}_{i}$ (weak convergence $\varrho$ in $L^{2}(\Omega)$, convergence of $\boldsymbol{u}$ in $L^{4}(\Omega)^{3}$, Lemma 10 and regularity of $\varphi_{i}$ ), we obtain

$$
\lim _{n \rightarrow+\infty} \tilde{S}_{j}=-\int_{\Omega} \varrho u_{i} u_{j} \partial_{j} \varphi_{i} \mathrm{~d} \boldsymbol{x}
$$

Furthermore, using Hölder's inequality and Inequality (6.8), one has $\left|\tilde{R}_{j}\right| \leq C \sqrt{h_{\mathcal{M}_{n}}}$ and then

$$
\lim _{n \rightarrow+\infty} S_{j}=-\int_{\Omega} \varrho u_{i} u_{j} \partial_{j} \varphi_{i} \mathrm{~d} \boldsymbol{x}
$$

Summing the limit of $S_{j}$ for $j=1,2,3$, we obtain

$$
\lim _{n \rightarrow+\infty} \sum_{\sigma \in \mathcal{E}_{\text {int }}^{(i)}} \sum_{\epsilon \in \widetilde{\mathcal{E}}\left(D_{\sigma}\right)} F_{\sigma, \epsilon} u_{\epsilon}\left(\widetilde{\mathcal{P}}_{\mathcal{E}_{n}}^{(i)} \varphi_{i}\right)_{\sigma}=-\int_{\Omega} u_{i} \varrho \boldsymbol{u} \cdot \nabla \varphi_{i} \mathrm{~d} \boldsymbol{x}
$$

Now, summing for $i \in\{1,2,3\}$ we obtain

$$
\int_{\Omega} \operatorname{div}_{\widetilde{\mathcal{E}}_{n}}\left(\varrho_{n} \boldsymbol{u}_{n} \otimes \boldsymbol{u}_{n}\right) \cdot \boldsymbol{\varphi} \mathrm{d} \boldsymbol{x} \rightarrow-\int_{\Omega} \varrho \boldsymbol{u} \otimes \boldsymbol{u}: \nabla \boldsymbol{\varphi} \mathrm{d} \boldsymbol{x} \text { as } n \rightarrow+\infty
$$

Finally $\boldsymbol{u}, p, \varrho$ satisfy point (5) and the proof of Proposition 2 is complete.
7.2. Passing to the limit in the equation of the state. The goal of this part is to pass to the limit in the nonlinear equation (3.3c). As in the continuous case, the main idea is to prove the a.e. convergence of $\varrho_{n}$ towards $\varrho$ (up to a subsequence).
7.2.1. The effective viscous flux. To overtake this difficulty in the continuous case we have proved that the sequence of approximate solution satisfy (2.13). The following proposition is nothing else than the discrete version of this identity.

Proposition 3 (Convergence of the effective viscous flux). Under the assumptions of Proposition 2 we have for all $\varphi \in \mathrm{C}_{c}^{\infty}(\Omega)$,

$$
\begin{equation*}
\lim _{n \rightarrow+\infty} \int_{\Omega}\left(p_{n}-(\lambda+2 \mu) \operatorname{div}_{\mathcal{M}_{n}} \boldsymbol{u}_{n}\right) \varrho_{n} \varphi \mathrm{~d} \boldsymbol{x}=\int_{\Omega}(p-(\lambda+2 \mu) \operatorname{div} \boldsymbol{u}) \varrho \varphi \mathrm{d} \boldsymbol{x} \tag{7.6}
\end{equation*}
$$

passing to subsequences if necessary.

Proof. The following proof can be seen as a discrete version of Step 3 of the proof of Theorem 1. Let $\varphi \in \mathrm{C}_{c}^{\infty}(\Omega)$. For a MAC grid $\mathcal{M}$, we define $\varphi_{\mathcal{M}} \in L_{\mathcal{M}}, \varphi_{\mathcal{E}}^{(i)} \in H_{\mathcal{E}, 0}^{(i)}$ by:

$$
\left\{\begin{array}{l}
\varphi_{\mathcal{M}}(\boldsymbol{x})=\varphi\left(\boldsymbol{x}_{K}\right), \forall \boldsymbol{x} \in K, \forall K \in \mathcal{M} \\
\varphi_{\mathcal{E}}^{(i)}(\boldsymbol{x})=\varphi\left(\boldsymbol{x}_{\sigma}\right), \forall \boldsymbol{x} \in D_{\sigma}, \forall \sigma \in \mathcal{E}^{(i)}
\end{array}\right.
$$

We define $w_{n}$ with (4.8) (with $\mathcal{M}_{n}$ and $\varrho_{n}$ instead of $\mathcal{M}$ and $\varrho$ ) and $\boldsymbol{v}_{n}$ with $\boldsymbol{v}_{n}=-\bar{\nabla}_{\mathcal{E}_{n}} w_{n}$. We set $\boldsymbol{V}_{n}=\left(V_{n, 1}, V_{n, 2}, V_{n, 3}\right)=\left(v_{n, 1} \varphi_{\mathcal{E}_{n}}^{(1)}, v_{n, 2} \varphi_{\mathcal{E}_{n}}^{(2)}, v_{n, 3} \varphi_{\mathcal{E}_{n}}^{(3)}\right)$.
Thanks to Lemma 6 , since $\varrho_{n}$ is bounded in $L^{2}(\Omega)$, the compactness theorem 3 gives that, up to a subsequence, as $n \rightarrow \infty, \boldsymbol{v}_{n}$ converges to some $\boldsymbol{v}=\left(v_{1}, v_{2}, v_{3}\right)$ in $L_{l o c}^{2}(\Omega)^{3}$ and that $\boldsymbol{v} \in \mathrm{H}_{l o c}^{1}(\Omega)^{3}$. As a consequence, using Theorem 2 , the sequence $\left(\boldsymbol{V}_{n}\right)_{n \in \mathbb{N}}$ converges to $\varphi \boldsymbol{v}$ in $L^{q}(\Omega)^{3}$ for any $q \in[1,6)$. As a consequence of the compactness theorem 3 we also have that $\operatorname{div}_{\mathcal{M}} \boldsymbol{u}_{n}$ and $\operatorname{curl}_{\mathcal{M}} \boldsymbol{u}_{n}$ converge weakly in $L^{2}(\Omega)$ towards $\operatorname{div} \boldsymbol{u}$ and $\operatorname{curl} \boldsymbol{u}$.
Since $\boldsymbol{V}_{n} \in \mathbf{H}_{\mathcal{E}_{n}, 0}$, it is possible to take $\boldsymbol{V}_{n}$ in (3.28) and write, using Lemma 4,

$$
\begin{align*}
& \int_{\Omega} \operatorname{div}_{\tilde{\mathcal{E}}_{n}}\left(\varrho_{n} \boldsymbol{u}_{n} \otimes \boldsymbol{u}_{n}\right) \cdot \boldsymbol{V}_{n} \mathrm{~d} \boldsymbol{x}+(\lambda+2 \mu) \int_{\Omega} \operatorname{div}_{\mathcal{M}_{n}} \boldsymbol{u}_{n} \operatorname{div}_{\mathcal{M}_{n}} \boldsymbol{V}_{n} \mathrm{~d} \boldsymbol{x}  \tag{7.7}\\
&+\mu \int_{\Omega} \operatorname{curl}_{\mathcal{M}_{n}} \boldsymbol{u}_{n} \cdot \operatorname{curl}_{\mathcal{M}_{n}} \boldsymbol{V}_{n} \mathrm{~d} \boldsymbol{x}-\int_{\Omega} p_{n} \operatorname{div}_{\mathcal{M}_{n}} \boldsymbol{V}_{n} \mathrm{~d} \boldsymbol{x}=\int_{\Omega} \mathcal{P}_{\mathcal{E}_{n}} \boldsymbol{f} \cdot \boldsymbol{V}_{n} \mathrm{~d} \boldsymbol{x} .
\end{align*}
$$

where we have used formula (4.4). We now mimick the proof given in the continuous case for the proof of (2.14). Since $\operatorname{div}_{\mathcal{M}_{n}} \boldsymbol{v}_{n}=\varrho_{n}$, we first remark that:

$$
\begin{equation*}
\int_{\Omega} \operatorname{div}_{\mathcal{M}_{n}} \boldsymbol{u}_{n} \operatorname{div}_{\mathcal{M}_{n}} \boldsymbol{V}_{n} \mathrm{~d} \boldsymbol{x}=\int_{\Omega}\left(\operatorname{div}_{\mathcal{M}_{n}} \boldsymbol{u}_{n}\right) \varrho_{n} \varphi \mathrm{~d} \boldsymbol{x}+\int_{\Omega}\left(\operatorname{div}_{\mathcal{M}_{n}} \boldsymbol{u}_{n}\right) \boldsymbol{v}_{n} \cdot \boldsymbol{\nabla} \varphi \mathrm{~d} \boldsymbol{x}+R_{1, n} \tag{7.8}
\end{equation*}
$$

where $\lim _{n \rightarrow+\infty} R_{1, n}=0$, thanks to the discrete $\mathrm{H}^{1}(\Omega)$-estimate (1) on $\boldsymbol{u}_{n}$ and the $L_{\text {loc }}^{2}(\Omega)$ estimate of Lemma 6 on $\boldsymbol{v}_{n}$. Replacing $\operatorname{div}_{\mathcal{M}_{n}} \boldsymbol{u}_{n}$ by $p_{n}$, the same computation gives:

$$
\begin{equation*}
\int_{\Omega} p_{n} \operatorname{div}_{\mathcal{M}_{n}} \boldsymbol{V}_{n} \mathrm{~d} \boldsymbol{x}=\int_{\Omega} p_{n} \varrho_{n} \varphi \mathrm{~d} \boldsymbol{x}+\int_{\Omega} p_{n} \boldsymbol{v}_{n} \cdot \boldsymbol{\nabla} \varphi \mathrm{~d} \boldsymbol{x}+R_{2, n} \tag{7.9}
\end{equation*}
$$

where $\lim _{n \rightarrow+\infty} R_{2, n}=0$. In accordance with [8], the second term of (7.7) can be transformed as follows:

$$
\begin{align*}
\int_{\Omega} \operatorname{curl}_{\mathcal{M}_{n}} \boldsymbol{u}_{n} \cdot \operatorname{curl}_{\mathcal{M}_{n}} & \boldsymbol{V}_{n} \mathrm{~d} \boldsymbol{x}=\int_{\Omega} \operatorname{curl}_{\mathcal{M}_{n}} \boldsymbol{u}_{n} \cdot \operatorname{curl}_{\mathcal{M}_{n}} \boldsymbol{v}_{n} \varphi \mathrm{~d} \boldsymbol{x}  \tag{7.10}\\
+ & \int_{\Omega} \operatorname{curl}_{\mathcal{M}_{n}} \boldsymbol{u}_{n} \cdot L(\varphi) \overline{\boldsymbol{v}}_{n} \mathrm{~d} \boldsymbol{x}+R_{3, n}
\end{align*}
$$

where $\lim _{n \rightarrow+\infty} R_{3, n}=0$ (for the same reasons as $R_{1, n}$ ), the matrix $L(\varphi)$ is the same as in the proof of (2.14) and involves the first order derivatives of $\varphi$, and $\overline{\boldsymbol{v}}_{n}$ satisfies:

$$
\begin{equation*}
\overline{\boldsymbol{v}}_{n} \rightarrow \boldsymbol{v} \text { in } L_{\mathrm{loc}}^{2}(\Omega)^{3} \text { as } n \rightarrow+\infty \tag{7.11}
\end{equation*}
$$

We refer the interested reader to [8] for an explicit expression of $\overline{\boldsymbol{v}}_{n}$ and for a proof of (7.11).
Since $\operatorname{curl}_{\mathcal{M}_{n}} \boldsymbol{v}_{n}=0,(7.10)$ leads to:

$$
\begin{equation*}
\int_{\Omega} \operatorname{curl}_{\mathcal{M}_{n}} \boldsymbol{u}_{n} \cdot \operatorname{curl}_{\mathcal{M}_{n}} \boldsymbol{V}_{n} \mathrm{~d} \boldsymbol{x}=\int_{\Omega} \operatorname{curl}_{\mathcal{M}_{n}} \boldsymbol{u}_{n} \cdot L(\varphi) \overline{\boldsymbol{v}}_{n} \mathrm{~d} \boldsymbol{x}+R_{3, n} \tag{7.12}
\end{equation*}
$$

Let us turn our attention to the convective term. For the readability, the dependency of some terms with respect to $n$ will be omitted when there are indices related to the mesh (such as $\sigma, \epsilon, \tau$ ).

One has

$$
\int_{\Omega} \operatorname{div}_{\widetilde{\mathcal{E}}_{n}}\left(\varrho_{n} \boldsymbol{u}_{n} \otimes \boldsymbol{u}_{n}\right) \cdot \boldsymbol{V}_{n} \mathrm{~d} \boldsymbol{x}=\sum_{i=1}^{3} \sum_{\sigma \in \mathcal{E}_{\text {int }}^{(i)}} \sum_{\epsilon \in \widetilde{\mathcal{E}}\left(D_{\sigma}\right)} F_{\sigma, \epsilon} u_{\epsilon} V_{\sigma}
$$

where $V_{\sigma}$ is the value of $V_{n, i}$ in $D_{\sigma}$. Let $i \in\{1,2,3\}$. Setting $Q_{n}=\sum_{\sigma \in \mathcal{E}_{\text {int }}^{(i)}} Q_{\sigma} \mathbb{1}_{D_{\sigma}}$ with $Q_{\sigma}=$ $\left(1 /\left|D_{\sigma}\right|\right) \sum_{\epsilon \in \widetilde{\mathcal{E}}\left(D_{\sigma}\right)} F_{\sigma, \epsilon} u_{\epsilon}$, one has

$$
\begin{equation*}
\sum_{\sigma \in \mathcal{E}_{\text {int }}^{(i)}} \sum_{\epsilon \in \widetilde{\mathcal{E}}\left(D_{\sigma}\right)} F_{\sigma, \epsilon} u_{\epsilon} V_{\sigma}=\int_{\Omega} Q_{n} V_{n, i} \mathrm{~d} \boldsymbol{x} \tag{7.13}
\end{equation*}
$$

We recall that $V_{n, i} \rightarrow \varphi v_{i}$ in $L^{q}(\Omega)$ for $q<6$ (as $n \rightarrow+\infty$ ). In a first step, we prove that the sequence $\left(Q_{n}\right)_{n \in \mathbb{N}}$ is bounded in $L^{p}(\Omega)$ for some $p>6 / 5$ (indeed we will have $p$ such that $1 / p=1 /(2 \gamma)+1 / 2+1 / 6$ and then $p>6 / 5$ since $\gamma>3)$. Then, up to subsequence, $Q_{n} \rightarrow Q$ weakly in $L^{p}(\Omega)$. In a second step we identify $Q$, proving that $Q=\varrho \sum_{j=1}^{3} u_{j} \partial_{j} u_{i}$.

- Estimate on $Q_{n}$. For $\sigma \in \mathcal{E}_{\text {int }}^{(i)}$, we use (3.13). It gives

$$
\begin{equation*}
Q_{\sigma}=\frac{1}{\left|D_{\sigma}\right|} \sum_{\epsilon \in \widetilde{\mathcal{E}}\left(D_{\sigma}\right)} F_{\sigma, \epsilon}\left(u_{\epsilon}-u_{\sigma}\right)-C_{s} h_{\mathcal{M}}^{\alpha}\left(\varrho_{D_{\sigma}}-\varrho^{\star}\right) u_{\sigma} \tag{7.14}
\end{equation*}
$$

Let $\epsilon \in \widetilde{\mathcal{E}}\left(D_{\sigma}\right)$ such that $\epsilon=\sigma \mid \sigma^{\prime} \in \widetilde{\mathcal{E}}_{\text {int }}^{(i)}$

- If $\epsilon \perp e_{i}, \epsilon \subset K$, then

$$
\left|F_{\sigma, \epsilon}\right| \leq \frac{1}{2}\left(\left|F_{K, \sigma}\right|+\left|F_{K, \sigma^{\prime}}\right|\right) \leq \frac{1}{2}\left(|\sigma| \varrho_{\sigma}^{u p}\left|u_{\sigma}\right|+\left|\sigma^{\prime}\right| \varrho_{\sigma^{\prime}}^{u p}\left|u_{\sigma^{\prime}}\right|\right) .
$$

- If $\epsilon \perp \boldsymbol{e}_{j}, j \neq i, \epsilon \subset \tau \cup \tau^{\prime}$, where $\tau$ and $\tau^{\prime}$ are the faces of $\mathcal{E}^{(j)}$ such that $\epsilon \subset \tau \cup \tau^{\prime}$, $\tau \in \mathcal{E}(K), \tau^{\prime} \in \mathcal{E}(L), \sigma=K \mid L$, then,

$$
\left|F_{\sigma, \epsilon}\right| \leq \frac{1}{2}\left(\left|F_{K, \tau}\right|+\mid F_{L, \tau^{\prime} \mid}\right) \leq \frac{1}{2}\left(|\tau| \varrho_{\tau}^{u p}\left|u_{\tau}\right|+\left|\tau^{\prime}\right| \varrho_{\tau^{\prime}}^{u p}\left|u_{\tau^{\prime}}\right|\right)
$$

Using the estimates on $\varrho$ in $L^{2 \gamma}(\Omega), \boldsymbol{u}$ in $L^{6}(\Omega), \nabla_{\widetilde{\mathcal{E}}} u_{i}$ in $L^{2}(\Omega)$ and the fact that $\eta_{n} \geq \eta$ for all $n$, the part of $Q$ given by the first term of (7.14) is bounded in $L^{p}(\Omega)$ with $p$ such that $1 / p=$ $1 /(2 \gamma)+1 / 2+1 / 6$. The part of $Q$ given by the second term of (7.14) tends to 0 in $L^{3 / 2}(\Omega)$ for instance (since $\varrho$ is bounded in $L^{2}(\Omega)$ and $\boldsymbol{u}$ in $\left.L^{6}(\Omega)\right)$ and then also in $L^{p}(\Omega)$. Thus, up to a subsequence, we can assume that $Q_{n} \rightarrow Q$ weakly in $L^{p}(\Omega)$ and this gives

$$
\begin{equation*}
\lim _{n \rightarrow+\infty} \int_{\Omega} Q_{n} V_{n, i} \mathrm{~d} \boldsymbol{x}=\int_{\Omega} Q \varphi v_{i} \mathrm{~d} \boldsymbol{x} . \tag{7.15}
\end{equation*}
$$

- Identification of $Q$. Let $\bar{\varphi} \in C_{c}^{\infty}(\Omega)$. For $\sigma \in \mathcal{E}_{\text {int }}^{(i)}$, let $\bar{\varphi}_{\sigma}=\left(\widetilde{\mathcal{P}}_{\mathcal{E}_{n}}^{(i)} \bar{\varphi}\right)_{\sigma}$. Then, for $h_{n}$ small enough,

$$
\int_{\Omega} Q_{n} \bar{\varphi} \mathrm{~d} \boldsymbol{x}=\sum_{\sigma \in \mathcal{E}_{\mathrm{int}}^{(i)}} \sum_{\epsilon \in \tilde{\mathcal{E}}\left(D_{\sigma}\right)} F_{\sigma, \epsilon} u_{\epsilon} \bar{\varphi}_{\sigma} .
$$

We already passed to the limit on this term in Proposition 2:

$$
\lim _{n \rightarrow+\infty} \sum_{\sigma \in \mathcal{E}_{\text {int }}^{(i)}} \sum_{\epsilon \in \widetilde{\mathcal{E}}\left(D_{\sigma}\right)} F_{\sigma, \epsilon} u_{\epsilon}\left(\widetilde{\mathcal{P}}_{\mathcal{E}_{n}}^{(i)} \bar{\varphi}\right)_{\sigma}=-\int_{\Omega} u_{i} \varrho \boldsymbol{u} \cdot \nabla \bar{\varphi} \mathrm{~d} \boldsymbol{x}
$$

Then $\int_{\Omega} Q \bar{\varphi} \mathrm{~d} \boldsymbol{x}=-\int_{\Omega} u_{i} \varrho \boldsymbol{u} \cdot \nabla \bar{\varphi} \mathrm{~d} \boldsymbol{x}$. Since we already know that $\operatorname{div}(\varrho \boldsymbol{u})=0$ we obtain (using $u_{i} \in H^{1}(\Omega)$ and $\left.\varrho \boldsymbol{u} \in L^{2}(\Omega)^{3}\right)$

$$
Q=\sum_{j=1}^{3} \varrho u_{j} \partial_{j} u_{i} .
$$

Finally, we have the limit of the convection term:

$$
\begin{equation*}
\lim _{n \rightarrow+\infty} \int_{\Omega} \operatorname{div}_{\widetilde{\mathcal{E}}_{n}}\left(\varrho_{n} \boldsymbol{u}_{n} \otimes \boldsymbol{u}_{n}\right) \cdot \boldsymbol{V}_{n} \mathrm{~d} \boldsymbol{x}=\int_{\Omega} \sum_{i=1}^{3} \sum_{j=1}^{3} \varrho u_{j}\left(\partial_{j} u_{i}\right) \varphi v_{i} \mathrm{~d} \boldsymbol{x} \tag{7.16}
\end{equation*}
$$

We recall now that $\left(\boldsymbol{V}_{n}\right)_{n \in \mathbb{N}}$ converges to $\varphi \boldsymbol{v}$ in $L^{q}(\Omega)^{3}$ for any $q \in[1,6)$ and that $\operatorname{div}_{\mathcal{M}_{n}} \boldsymbol{u}_{n}, p_{n}$ and $\operatorname{curl}_{\mathcal{M}_{n}} \boldsymbol{u}_{n}$ weakly converge respectively in $L^{2}(\Omega)$ and $L^{2}(\Omega)^{3}$ to div $\boldsymbol{u}, p$ and curl $\boldsymbol{u}$. Then, using (7.8)-(7.12), we deduce from (7.7) and (7.16):

$$
\begin{aligned}
& \lim _{n \rightarrow+\infty} \int_{\Omega}\left((\lambda+2 \mu) \operatorname{div}_{\mathcal{M}} \boldsymbol{u}_{n}-p_{n}\right) \varrho_{n} \varphi \mathrm{~d} \boldsymbol{x}=\int_{\Omega}(p-(\lambda+2 \mu) \operatorname{div} \boldsymbol{u}) \boldsymbol{v} \cdot \nabla \varphi \mathrm{d} \boldsymbol{x} \\
&-\mu \int_{\Omega} \operatorname{curl} \boldsymbol{u} \cdot(L(\varphi) \boldsymbol{v}) \mathrm{d} \boldsymbol{x}-\int_{\Omega} \varrho((\boldsymbol{u} \cdot \nabla) \boldsymbol{u}) \cdot \varphi \boldsymbol{v} \mathrm{d} \boldsymbol{x}+\int_{\Omega} \boldsymbol{f} \cdot \boldsymbol{v} \varphi \mathrm{d} \boldsymbol{x}
\end{aligned}
$$

Finally, since $p_{n}$ and $\boldsymbol{u}_{n}$ are solution of the discrete momentum balance equations, we already know, thanks to the estimates on $p_{n}$ and $\varrho_{n}$, that the limits $p$ and $\boldsymbol{u}$ are solution of the momentum balance equation; hence, since $\boldsymbol{v} \in \mathrm{H}_{l o c}^{1}(\Omega)^{3}$ and in accordance with the continuous case:

$$
\begin{aligned}
& \int_{\Omega}((2 \mu+\lambda) \operatorname{div} \boldsymbol{u}-p)(\operatorname{div} \boldsymbol{v}) \varphi \mathrm{d} \boldsymbol{x}-\int_{\Omega} \varrho \boldsymbol{u} \otimes \boldsymbol{u}: \nabla(\varphi \boldsymbol{v}) \mathrm{d} \boldsymbol{x}= \\
& \int_{\Omega}((p-(2 \mu+\lambda) \operatorname{div} \boldsymbol{u}) \boldsymbol{v} \cdot \nabla \varphi-\mu \operatorname{curl} \boldsymbol{u} \cdot(L(\varphi) \boldsymbol{v})-\mu \operatorname{curl} \boldsymbol{u} \cdot \operatorname{curl} \boldsymbol{v} \varphi+\boldsymbol{f} \cdot \boldsymbol{v} \varphi) \mathrm{d} \boldsymbol{x} .
\end{aligned}
$$

Moreover we know that $\operatorname{div}(\varrho \boldsymbol{u})=0$ and $(\varrho, \boldsymbol{u}) \in L^{6}(\Omega) \times H_{0}^{1}(\Omega)^{3}$ and consequently $\int_{\Omega} \varrho \boldsymbol{u} \otimes \boldsymbol{u}$ : $\nabla(\varphi \boldsymbol{v}) \mathrm{d} \boldsymbol{x}=-\int_{\Omega} \varrho(\boldsymbol{u} \cdot \nabla \boldsymbol{u}) \cdot \varphi \boldsymbol{v} \mathrm{d} \boldsymbol{x}$. Since $\operatorname{div}_{\mathcal{M}_{n}} \boldsymbol{v}_{n}$ and $\operatorname{curl}_{\mathcal{M}_{n}} \boldsymbol{v}_{n}$ converge weakly in $L_{l o c}^{2}(\Omega)$ towards $\operatorname{div} \boldsymbol{v}$ and $\operatorname{curl} \boldsymbol{v}$, one has $\operatorname{div} \boldsymbol{v}=\varrho$ and $\operatorname{curl} \boldsymbol{v}=0$ and therefore:

$$
\begin{aligned}
\int_{\Omega}((2 \mu+\lambda) \operatorname{div} \boldsymbol{u}-p) \varrho \varphi \mathrm{d} \boldsymbol{x}=\int_{\Omega}((p-(2 \mu+\lambda) \operatorname{div} \boldsymbol{u}) \boldsymbol{v} \cdot \nabla \varphi-\mu(\operatorname{curl} \boldsymbol{u}) \cdot L(\varphi) \boldsymbol{v}) \mathrm{d} \boldsymbol{x}
\end{aligned} \quad \begin{aligned}
& -\int_{\Omega} \varrho(\boldsymbol{u} \cdot \nabla \boldsymbol{u}) \cdot \varphi \boldsymbol{v} \mathrm{d} \boldsymbol{x}+\int_{\Omega} \boldsymbol{f} \cdot \boldsymbol{v} \varphi \mathrm{d} \boldsymbol{x}
\end{aligned}
$$

Then, we obtain the desired result, that is:

$$
\begin{equation*}
\lim _{n \rightarrow+\infty} \int_{\Omega}\left(p_{n}-(\lambda+2 \mu) \operatorname{div}_{\mathcal{M}_{n}} \boldsymbol{u}_{n}\right) \varrho_{n} \varphi \mathrm{~d} \boldsymbol{x}=\int_{\Omega}(p-(\lambda+2 \mu) \operatorname{div} \boldsymbol{u}) \varrho \varphi \mathrm{d} \boldsymbol{x} \tag{7.17}
\end{equation*}
$$

7.2.2. A.e. and strong convergence of $\varrho_{n}$ and $p_{n}$. Let us now prove the a.e. convergence of $\varrho_{n}$ and $p_{n}$. Using [9, Lemma 2.1], one can take $\varphi=1$ in (7.6), wich gives:

$$
\lim _{n \rightarrow+\infty} \int_{\Omega}\left(p_{n}-(2 \mu+\lambda) \operatorname{div}_{\mathcal{M}_{n}} \boldsymbol{u}_{n}\right) \varrho_{n} \mathrm{~d} \boldsymbol{x}=\int_{\Omega}\left(p-(2 \mu+\lambda) \operatorname{div}_{\mathcal{M}} \boldsymbol{u}\right) \varrho \mathrm{d} \boldsymbol{x}
$$

Now using Lemma 7 and (2.3) we obtain the discrete version of (2.14) that is

$$
\begin{equation*}
\limsup _{n \rightarrow+\infty} \int_{\Omega} p_{n} \varrho_{n} \mathrm{~d} \boldsymbol{x} \leq \int_{\Omega} p \varrho \mathrm{~d} \boldsymbol{x} \tag{7.18}
\end{equation*}
$$

Let $G_{n}=\left(\varrho_{n}^{\gamma}-\varrho^{\gamma}\right)\left(\varrho_{n}-\varrho\right)$. One has $G_{n} \in L^{1}(\Omega)$ and $G_{n} \geq 0$ a.e. in $\Omega$. Futhermore:

$$
\int_{\Omega} G_{n} \mathrm{~d} \boldsymbol{x}=\int_{\Omega} p_{n} \varrho_{n} \mathrm{~d} \boldsymbol{x}-\int_{\Omega} p_{n} \varrho \mathrm{~d} \boldsymbol{x}-\int_{\Omega} \varrho^{\gamma} \varrho_{n} \mathrm{~d} \boldsymbol{x}+\int_{\Omega} \varrho^{\gamma} \varrho \mathrm{d} \boldsymbol{x}
$$

Using the weak convergence in $L^{2}(\Omega)$ of $p_{n}$ and $\varrho_{n}$, and (7.18), we obtain:

$$
\limsup _{n \rightarrow+\infty} \int_{\Omega} G_{n} \mathrm{~d} \boldsymbol{x} \leq 0
$$

Then (up to a subsequence), $G_{n} \rightarrow 0$ a.e. and then $\varrho_{n} \rightarrow \varrho$ a.e. (since $y \mapsto y^{\gamma}$ is an increasing function on $\left.\mathbb{R}_{+}\right)$. Finally, $\varrho_{n} \rightarrow \varrho$ in $L^{q}(\Omega)$ for all $1 \leq q<2 \gamma, p_{n}=\varrho_{n}^{\gamma} \rightarrow \varrho^{\gamma}$ in $L^{q}(\Omega)$ for all $1 \leq$ $q<2$, and $p=\varrho^{\gamma}$. We have thus proved the convergence of the approximate pressure and density, which, together with Proposition 2, concludes the proof of Theorem 4.

## 8. Conclusion

In this paper, we considered the MAC scheme for the stationary barotropic compressible NavierStokes equations and proved its convergence in the case $\gamma>3$. This latter restriction on $\gamma$ is used when writing the nonlinear convection term as in (2.15) in order to prove its convergence in the continuous case, in a manner that adapts to the discrete case, which is the case here with the convergence of $Q_{n}$ in (7.13). So far, it is an open question to find a technique of convergence of the nonlinear convection term that would adapt to the discrete case without requiring this condition.

## Appendix A. Existence of a discrete solution

This section is devoted to the proof of Theorem 5 . We now state the abstract theorem which will be used hereafter.

Theorem 6. Let $N$ and $M$ be two positive integers and $V$ be defined as follows:

$$
V=\left\{(x, y) \in \mathbb{R}^{N} \times \mathbb{R}^{M}, y>0\right\}
$$

where, for any real number $c$, the notation $y>c$ is meant componentwise. Let $F$ be a continuous function from $V \times[0,1]$ to $\mathbb{R}^{N} \times \mathbb{R}^{M}$ satisfying:
(1) $\forall \zeta \in[0,1]$, if $v \in V$ is such that $F(v, \zeta)=0$ then $v \in W$ where $W=\left\{(x, y) \in \mathbb{R}^{N} \times\right.$ $\mathbb{R}^{M},\|x\|<C_{1}$, and $\left.\varepsilon<y<C_{2}\right\}$, with $C_{1}, C_{2}$, and $\varepsilon>0$ and $\|\cdot\|$ a norm defined over $\mathbb{R}^{N} ;$
(2) the topological degree of $F(\cdot, 0)$ with respect to 0 and $W$ is equal to $d_{0} \neq 0$.

Then the topological degree of $F(\cdot, 1)$ with respect to 0 and $W$ is also equal to $d_{0} \neq 0$; consequently, there exists at least a solution $v \in W$ such that $F(v, 1)=0$.

Let us now prove the existence of a solution to (3.3). Let us define

$$
V=\left\{(\boldsymbol{u}, \varrho) \in \mathbf{H}_{\mathcal{E}, 0} \times L_{\mathcal{M}}, \varrho_{K}>0 \forall K \in \mathcal{M}\right\}
$$

and consider the continuous mapping

$$
\begin{aligned}
F: & \mathbf{H}_{\mathcal{E}, 0} \times L_{\mathcal{M}} \times[0,1] \longrightarrow \mathbf{H}_{\mathcal{E}, 0} \times L_{\mathcal{M}} \\
& (\boldsymbol{u}, \varrho, \zeta) \mapsto F(\boldsymbol{u}, \varrho, \zeta)=(\hat{\boldsymbol{u}}, \varrho)
\end{aligned}
$$

where $(\hat{\boldsymbol{u}}, \hat{\varrho})$ is the unique element of $\mathbf{H}_{\mathcal{E}, 0} \times L_{\mathcal{M}}$ such that

$$
\begin{align*}
& \int_{\Omega} \hat{\boldsymbol{u}} \cdot \boldsymbol{v} \mathrm{d} \boldsymbol{x}=\mu[\boldsymbol{u}, \boldsymbol{v}]_{1, \mathcal{E}, 0}+(\mu+\lambda) \int_{\Omega} \operatorname{div}_{\mathcal{M}} \boldsymbol{u} \operatorname{div}_{\mathcal{M}} \boldsymbol{v} \mathrm{d} \boldsymbol{x} \\
& +\zeta \int_{\Omega} \operatorname{div}_{\widetilde{\mathcal{E}}}(\varrho \boldsymbol{u} \otimes \boldsymbol{u}) \cdot \boldsymbol{v} \mathrm{d} \boldsymbol{x}-\zeta \int_{\Omega} \varrho^{\gamma} \operatorname{div}_{\mathcal{M}} \boldsymbol{v}-\int_{\Omega} \mathcal{P}_{\mathcal{E}} \boldsymbol{f} \cdot \boldsymbol{v} \mathrm{d} \boldsymbol{x}, \forall \boldsymbol{v} \in \mathbf{H}_{\mathcal{E}, 0}  \tag{A.1}\\
& \int_{\Omega} \hat{\varrho} q \mathrm{~d} \boldsymbol{x}=\zeta \int_{\Omega} \operatorname{div}_{\mathcal{M}}^{\mathrm{up}}(\varrho \boldsymbol{u}) q \mathrm{~d} \boldsymbol{x}+\int_{\Omega} C_{s} h_{\mathcal{M}}^{\alpha}\left(\varrho-\varrho^{\star}\right) q \mathrm{~d} \boldsymbol{x}, \forall q \in L_{\mathcal{M}} . \tag{A.2}
\end{align*}
$$

Note that the values of $\hat{u}_{i}, i=1, \cdots, d$, and $\hat{\varrho}$ are readily obtained by setting in this system $v_{i}=1_{D_{\sigma}}, v_{j}=0, j \neq i$ in (A.1) and $q=1_{K}$ in (A.2).
Any solution of $F(\boldsymbol{u}, \varrho, 1)=0$ is a solution of Problem 3.3 where $p=\varrho^{\gamma}$.
The mapping $F$ is continuous.
Let $(\boldsymbol{u}, \varrho) \in \mathbf{H}_{\mathcal{E}, 0} \times L_{\mathcal{M}}$ and $\zeta \in[0,1]$ such that $F(\boldsymbol{u}, \varrho, \zeta)=(0,0)$ (in particular $\varrho>0$ ). Then for any $(\boldsymbol{v}, q) \in \mathbf{H}_{\mathcal{E}, 0} \times L_{\mathcal{M}}$,

$$
\begin{align*}
& \zeta \int_{\Omega} \operatorname{div}_{\tilde{\mathcal{E}}}(\varrho \boldsymbol{u} \otimes \boldsymbol{u}) \mathrm{d} \boldsymbol{x}+\mu[\boldsymbol{u}, \boldsymbol{v}]_{1, \mathcal{E}, 0}+(\mu+\lambda) \int_{\Omega} \operatorname{div}_{\mathcal{M}} \boldsymbol{u} \operatorname{div}_{\mathcal{M}} \boldsymbol{v} \mathrm{d} \boldsymbol{x} \\
& \quad \zeta \int_{\Omega} \varrho^{\gamma} \operatorname{div}_{\mathcal{M}} \boldsymbol{v} \mathrm{d} \boldsymbol{x}=\int_{\Omega} \mathcal{P}_{\mathcal{E}} \boldsymbol{f} \cdot \boldsymbol{v} \mathrm{d} \boldsymbol{x}  \tag{A.3a}\\
& \zeta \int_{\Omega} \operatorname{div}_{\mathcal{M}}^{\operatorname{up}}(\varrho \boldsymbol{u}) q \mathrm{~d} \boldsymbol{x}+\int_{\Omega} C_{s} h_{\mathcal{M}}^{\alpha}\left(\varrho-\varrho^{\star}\right) q \mathrm{~d} \boldsymbol{x}=0 \tag{A.3b}
\end{align*}
$$

Taking $q=1$ as a test function in $(A .3 b)$, and using the conservativity of the fluxes we obtain

$$
\begin{equation*}
\int_{\Omega} \varrho \mathrm{d} \boldsymbol{x}=\|\varrho\|_{L^{1}(\Omega)}=M>0 \tag{A.4}
\end{equation*}
$$

This relation provides a bound for $\varrho$ in the $L^{1}$ norm, and therefore in all norms since the problem is of finite dimension. Taking $\boldsymbol{u}$ as a test function in $(A .3 a)$ and following Step 1 of the proof of Proposition 1 gives

$$
\begin{equation*}
\|\boldsymbol{u}\|_{1, \mathcal{E}, 0}<C_{1} \tag{A.5}
\end{equation*}
$$

where the constant $C_{1}$ depends only on the data of the problem and not on $\zeta$. Now a straightforward computation gives

$$
\varrho_{K} \geq \frac{C_{s} \min _{L \in \mathcal{M}}|L| h_{\mathcal{M}}^{\alpha} \varrho^{\star}}{C_{s} h_{\mathcal{M}}^{\alpha}|\Omega|+\sum_{\sigma \in \mathcal{E}_{\mathrm{int}}, \sigma=K \mid L}|\sigma|\left|u_{K, \sigma}\right|}
$$

Consequently by virtue of (A.5) there exists $\varepsilon>0$ such that

$$
\begin{equation*}
\varrho_{K}>\varepsilon, \forall K \in \mathcal{M} \tag{A.6}
\end{equation*}
$$

where the constant $\varepsilon$ depends only on the data of the problem. Clearly, from (A.4), one has also

$$
\begin{equation*}
\varrho_{K} \leq \frac{M}{\min _{K \in \mathcal{M}}|K|}=C_{2}-1, \forall K \in \mathcal{M} \tag{A.7}
\end{equation*}
$$

Moreover the system $F(\boldsymbol{u}, \varrho, 0)=0$ reads:

$$
\begin{align*}
& \mu[\boldsymbol{u}, \boldsymbol{v}]_{1, \mathcal{E}, 0}+(\mu+\lambda) \int_{\Omega} \operatorname{div}_{\mathcal{M}} \boldsymbol{u} \operatorname{div}_{\mathcal{M}} \boldsymbol{v} \mathrm{d} \boldsymbol{x}=\int_{\Omega} \mathcal{P}_{\mathcal{E}} \boldsymbol{f} \cdot \boldsymbol{v} \mathrm{d} \boldsymbol{x}, \forall \boldsymbol{v} \in \mathbf{H}_{\mathcal{E}, 0}  \tag{A.8a}\\
& \varrho_{K}=\varrho^{\star}, \forall K \in \mathcal{M} \tag{A.8b}
\end{align*}
$$

which has clearly one and only one solution. Let W defined by

$$
W=\left\{(\boldsymbol{u}, \varrho) \in \mathbf{H}_{\mathcal{E}, 0} \times L_{\mathcal{M}} \text { such that }\|\boldsymbol{u}\|<C_{1}, \varepsilon<\varrho_{K}<C_{2}\right\}
$$

Since $F(\boldsymbol{u}, \varrho, 0)=0$ is a linear system which has one and only one solution belonging to $W$, the topological degree $d_{0}$ of $F(\cdot, \cdot, 0)$ with respect to 0 and $W$ is not zero. Then, using the inequalities (A.5), (A.6), (A.7), Theorem 6 applies, which concludes the proof.
