# Wave equation with cone-bounded control laws

Christophe Prieur, Sophie Tarbouriech, João M. Gomes da Silva Jr

**Abstract**—This paper deals with a wave equation with a one-dimensional space variable, which describes the dynamics of string deflection. Two kinds of control are considered: a distributed action and a boundary control. It is supposed that the control signal is subject to a cone-bounded nonlinearity. This kind of feedback laws includes (but is not restricted to) saturating inputs. By closing the loop with such a nonlinear control, it is thus obtained a nonlinear partial differential equation, which is the generalization of the classical 1D wave equation. The well-posedness is proven by using nonlinear semigroups techniques. Considering a sector condition to tackle the control nonlinearity and assuming that a tuning parameter has a suitable sign, the asymptotic stability of the closed-loop system is proven by Lyapunov techniques. Some numerical simulations illustrate the asymptotic stability of the closed-loop nonlinear partial differential equations.

## I. INTRODUCTION

The general problem in this paper is the study of the wave in a one-dimensional media, as considered e.g. when modeling the dynamics of an elastic slope vibrating around its rest position. To be more specific, it is considered the wave equation describing the dynamics of the deformation denoted by  $z(x, t)$ . The control is either defined by an external force  $f(x, t)$ , or by a boundary action  $g(t)$ , where the force and the deformation may depend on the space and the time variables. A scheme of the considered problem is depicted in Figure 1.

Depending on the control action, two classes of partial differential equations (PDEs) are obtained. In the presence of an external distributed force  $f$  when the slope is attached at both extremities, the dynamic of the vibration is described by the following (see e.g. [14, Chap. 5.3]) for all  $t \geq 0$ ,  $x \in (0, 1)$ ,

$$z_{tt}(x, t) = z_{xx}(x, t) + f(x, t) \quad (1)$$

Fig. 1. Vibrating slope subject to a external distributed action  $f(x, t)$  and to a boundary action  $g(t)$ .

where  $z$  stands for the state (the length of the string and other physical parameters are normalized), and  $f(x, t) \in \mathbb{R}$  is the control. The control  $f$  is distributed (in contrast to boundary control), and is given by a bounded control operator. Let us equip this system with the following boundary conditions, for all  $t \geq 0$ ,

$$z(0, t) = 0, \quad (2a)$$

$$z(1, t) = 0, \quad (2b)$$

and with the following initial condition, for all  $x$  in  $(0, 1)$ ,

$$\begin{aligned} z(x, 0) &= z^0(x), \\ z_t(x, 0) &= z^1(x), \end{aligned} \quad (3)$$

where  $z^0$  and  $z^1$  stand respectively for the initial deflection of the slope and the initial deflection speed.

When the control action is only at the boundary, it is necessary to consider the following string equation, for all  $t \geq 0$ ,  $x \in (0, 1)$ ,

$$z_{tt}(x, t) = z_{xx}(x, t) \quad (4)$$

with the boundary conditions, for all  $t \geq 0$ ,

$$z(0, t) = 0 \quad (5a)$$

$$z_x(1, t) = g(t) \quad (5b)$$

where  $g(t)$  is the boundary action at time  $t$ .

When closing the loop with a linear state feedback law, the control problem of such a 1D wave equation is considered in many works, see e.g. [8] where, in particular, stabilizing linear controllers and optimal linear feedback laws are computed respectively by an application of linear semigroup theory and LQR techniques. The aim of this paper is to investigate the well-posedness and the asymptotic stability of these classes of PDEs by means of nonlinear control laws, and more precisely of cone-bounded nonlinear control laws.

Neglecting the presence of nonlinearity in the input can be source of undesirable and even catastrophic behaviors for the closed-loop system. See e.g., [3], where it is shown that in presence of magnitude actuator limitation, even for finite-dimensional systems, the fact of disregarding the nonlinearity in the control loop may yield an unstable system. For an introduction of such nonlinear finite-dimensional systems and techniques on how to estimate the basin of attraction for locally asymptotically stable equilibrium, see [25], [28] among other references. Similarly, in the context of systems with cone-bounded nonlinearities, a quite natural approach to tackle the stability problem consists in combining Lyapunov theory with cone-bounded sector conditions (see e.g., [13], [4]). This allows to provide an estimate of the basin of attraction of the nonlinear systems in appropriate Sobolev spaces. This estimate can be either a neighborhood of the equilibrium in the local case or the whole space in the global case.

To our best knowledge, the well-posedness and the asymptotic stability of PDE by means of a cone-bounded input signal is less investigated than for corresponding finite-dimensional systems. This class of feedback laws includes classical saturation and deadzone nonlinearities as well as more general nonlinear maps. The aim of this work is to study the wave equation in presence of such nonlinear control laws. To prove first the existence and uniqueness of solutions to the PDE (1) (respectively (4)) with the boundary conditions (2) (resp. (5)) and initial conditions (3), when the loop is closed with an odd, Lipschitz and cone-bounded control law (see Theorems 1 and 2 below for precise statements), the nonlinear semigroup theory in appropriate Sobolev spaces is rigorously applied. The second contribution is to prove the global (resp. local) asymptotic stability of the corresponding closed-loop system by exploiting a cone-boundedness assumption on the control as introduced in [13], [25] for finite-dimensional systems, see Theorem 1 (resp. Theorem 2) below for a precise statement. In other words, this paper combines techniques that are usual for finite dimensional systems in closed loop with cone-bounded nonlinear control laws (see e.g. [12], [26]) with Lyapunov theory for PDEs (see e.g. [10], [5], [21]).

It is worth noticing that for both PDEs (1)-(2) and (4)-(5), Lyapunov techniques are applied, but the stability proofs are quite different. To be more specific, the proof of the stability of the PDE (1) with the boundary conditions (2) when closing the loop with a nonlinear feedback law is done by using the LaSalle invariance principle, which needs to state a precompactness property of the solutions. On the other hand, since a strict decreasing Lyapunov function is computed, we do not need to use the LaSalle invariance principle for the PDE (4) with a nonlinear boundary control.

To our best knowledge, the first work considering infinite dimensional systems with bounded control is [24, Thm 5.1] where only compact and bounded control operators with an a priori constraint are considered. In [23] only the case of a distributed saturating control has been considered. On the other hand, the paper [17] suggests to use an observability assumption for the study of PDE in closed loop with saturating controllers. In particular the contraction semigroup obtained from the saturating closed-loop system is compared to the corresponding semigroup without saturation. In the present paper, more general cone-bounded input nonlinearities are considered and different techniques are used, in particular the LaSalle invariance principle. Then, the paper can be considered as complementary to [17] by extending not only the class of nonlinear control laws but also the nature of the used tools. Note finally that both papers [24], [17] do not consider the case of saturation of the *value* of the solution, but rather saturation of the *norm* of the solution (compare [24, Eq. (2.8)] and [17, Eq. (1.6)] with the definition of nonlinear controller (8) below). Dealing with saturation of the value of the solution is more complex and is more relevant for applications, since it yields to a locally defined PDE. However it needs further developments (in particular more regularity is required to ensure that the nonlinear map is well-defined).

The rest of the paper is organized as follows. In Section II, the nonlinear PDE (1) is introduced, and the first main result is stated, namely the well-posedness of the Cauchy problem, along with the global asymptotic stability, when closing the loop with a nonlinear distributed control law. In Section III, the main result is stated for the PDE (4), where a nonlinear boundary action is considered. The proof of the two main results are given respectively in Sections IV and V. Section VI presents numerical simulations to illustrate both main results. Some concluding remarks and possible further research lines are presented in Section VII.

**Notation:**  $z_t$  (resp.  $z_x$ ) stands for the partial derivative of the function  $z$  with respect to  $t$  (resp.  $x$ ) (this is a shortcut for  $\frac{\partial z}{\partial t}$ , resp.  $\frac{\partial z}{\partial x}$ ). When there is only one independent variable,  $\dot{z}$  and  $z'$  stand respectively for the time and the space derivative. For a matrix  $A$ ,  $A^\top$  denotes the transpose, and for a partitioned symmetric matrix, the symbol  $\star$  stands for symmetric blocks.  $\Re(s)$  and  $\Im(s)$  stand respectively for the real and imaginary part of a complex value  $s$  in  $\mathbb{C}$ ,  $\bar{s}$  is the conjugate of  $s$ , and  $|s|$  its modulus.  $\|\cdot\|_{L^2}$  denotes the norm in  $L^2(0,1)$  space, defined by  $\|u\|_{L^2(0,1)}^2 = \int_0^1 |u|^2 dx$  for all functions  $u \in L^2(0,1)$ . Similarly,  $H^2(0,1)$  is the set of all functions  $u \in H^2(0,1)$  such that  $\int_0^1 (|u|^2 + |u_x|^2 + |u_{xx}|^2) dx$  is finite. Finally  $H_0^1(0,1)$  is the closure in  $L^2(0,1)$  of the set of smooth functions

that are vanishing at  $x = 0$  and at  $x = 1$ . It is equipped with the norm  $\|u\|_{H_0^1(0,1)}^2 = \int_0^1 |u_x|^2 dx$ . The associate inner products are denoted  $\langle \cdot, \cdot \rangle_{L^2(0,1)}$  and  $\langle \cdot, \cdot \rangle_{H_0^1(0,1)}$ .

## II. WAVE EQUATION WITH A NONLINEAR DISTRIBUTED CONTROL

Consider the PDE (1), with the boundary conditions (2) and the initial condition (3).

Letting for the control, for all  $t \geq 0$  and all  $x \in (0, 1)$ ,

$$f(x, t) = -az_t(x, t), \quad (6)$$

where  $a$  is a constant value, and exploiting properties of the following energy function:

$$V_1 = \frac{1}{2} \int (z_x^2 + z_t^2) dx, \quad (7)$$

for any solution  $z$  to (1) and (2), when closing the loop with the linear controller (6), allow to show that the closed-loop system is (globally) exponentially stable in  $H_0^1(0, 1) \times L^2(0, 1)$ .

This can be formally shown by considering the time derivative of  $V$  along the solutions to (1)-(2), which yields

$$\begin{aligned} \dot{V}_1 &= \int_0^1 (z_x z_{xt} - az_t^2 + z_t z_{xx}) dx \\ &= - \int_0^1 az_t^2 dx + [z_t z_x]_{x=0}^{x=1} \\ &= - \int_0^1 az_t^2 dx \end{aligned}$$

where an integration by parts is performed to get the second line from the first one, and the boundary conditions (2) are applied for the last line. Therefore, for any positive value  $a$ , it is formally obtained that the energy is decreasing as long as  $z_t$  is non vanishing in  $[0, 1]$ . In other words,  $V_1$  is a (non strict) Lyapunov function.

Due to actuator limitations or imperfections, the actual control law applied to the system, instead of (6), can be modeled as follows

$$f(x, t) = -\sigma_1(az_t(x, t)) \quad (8)$$

with  $\sigma_1 : \mathbb{R} \rightarrow \mathbb{R}$  being a bounded and continuous nonlinear function satisfying, for a constant value  $L > 0$  and for all  $(s, \tilde{s}) \in \mathbb{R}^2$ ,

$$(\sigma_1(s) - \sigma_1(\tilde{s}))(s - \tilde{s}) \geq 0, \quad (9a)$$

$$|\sigma_1(s)| \leq L|s|. \quad (9b)$$

Note that (9a) generalizes the odd property. Examples of such functions  $\sigma_1$  include the saturation maps, and are considered in Section VI-A below.

Equation (1) in closed loop with the control (8) becomes

$$z_{tt} = z_{xx} - \sigma_1(az_t). \quad (10)$$

A formal computation gives, along the solutions to (10) and (2),

$$\dot{V}_1 = - \int_0^1 z_t \sigma_1(az_t) dx \quad (11)$$

which asks to handle the nonlinearity  $z_t \sigma_1(az_t)$ . A convergence result is stated below, where the well-posedness is separate from the asymptotic stability property.

**Theorem 1.** *For all positive values  $a$ , and for all bounded and continuous functions  $\sigma_1$  satisfying (9), the model (10) with the boundary conditions (2) is globally asymptotically stable. More precisely the following properties hold:*

- [Well-posedness] *For all  $(z^0, z^1)$  in  $(H^2(0, 1) \cap H_0^1(0, 1)) \times H_0^1(0, 1)$ , there exists a unique solution  $z : [0, \infty) \rightarrow H^2(0, 1) \cap H_0^1(0, 1)$  to (10), with the boundary conditions (2) and the initial condition (3), that is differentiable from  $[0, \infty)$  on  $H_0^1(0, 1)$ .*

- [Global asymptotic stability] *Moreover, for all initial conditions  $(z^0, z^1)$  in  $(H^2(0, 1) \cap H_0^1(0, 1)) \times H_0^1(0, 1)$ , the solution to (10), with the boundary conditions (2) and the initial condition (3), satisfies the following stability property*

$$\begin{aligned} \|z(\cdot, t)\|_{H_0^1(0,1)} + \|z_t(\cdot, t)\|_{L^2(0,1)} \\ \leq \|z^0\|_{H_0^1(0,1)} + \|z^1\|_{L^2(0,1)}, \quad \forall t \geq 0, \end{aligned} \quad (12)$$

together with the attractivity property

$$\|z(\cdot, t)\|_{H_0^1(0,1)} + \|z_t(\cdot, t)\|_{L^2(0,1)} \rightarrow_{t \rightarrow \infty} 0. \quad (13)$$

The proof of Theorem 1 is provided in Section IV.

## III. WAVE EQUATION WITH A NONLINEAR BOUNDARY ACTION

Consider the PDE (4), with the boundary conditions (5) and the initial condition (3).

Letting for the control

$$g(t) = -bz_t(1, t), \quad (14)$$

where  $b$  is a positive tuning parameter, inspired by [16], the following Lyapunov function candidate:

$$\begin{aligned} V_2 = \frac{1}{2} \left( \int_0^1 e^{\mu x} (z_t + z_x)^2 dx \right. \\ \left. + \int_0^1 e^{-\mu x} (z_t - z_x)^2 dx \right), \end{aligned} \quad (15)$$

where  $\mu > 0$  will be prescribed below, is considered. It may be proven that we have asymptotic stability of (4) and (5). With this aim, let us formally compute the time-derivative of  $V_2$  along the solutions of (4) and (5)

as follows

$$\begin{aligned}
\dot{V}_2 &= \int_0^1 e^{\mu x} (z_t + z_x)(z_{tt} + z_{xt}) dx \\
&\quad + \int_0^1 e^{-\mu x} (z_t - z_x)(z_{tt} - z_{xt}) dx \\
&= \int_0^1 e^{\mu x} (z_t + z_x)(z_{xx} + z_{xt}) dx \\
&\quad - \int_0^1 e^{-\mu x} (z_t - z_x)(z_{xt} - z_{xx}) dx \\
&= -\frac{\mu}{2} \int_0^1 e^{\mu x} (z_t + z_x)^2 dx + \frac{1}{2} [e^{\mu x} (z_t + z_x)^2]_{x=0}^{x=1} \\
&\quad - \frac{\mu}{2} \int_0^1 e^{-\mu x} (z_t - z_x)^2 dx - \frac{1}{2} [e^{-\mu x} (z_t - z_x)^2]_{x=0}^{x=1}
\end{aligned}$$

where the partial differential equation (4) has been used in the first equality and two integrations by parts have been performed in the second equality.

Now, note that the boundary condition (5a) implies that  $z_t(0, t) = 0$  and thus, for all  $t \geq 0$ ,

$$\begin{aligned}
[e^{\mu x} (z_t + z_x)^2](0, t) - [e^{-\mu x} (z_t - z_x)^2](0, t) \\
= z_x^2(0, t) - z_x^2(0, t) = 0
\end{aligned}$$

Therefore, with (5b), it is deduced

$$\begin{aligned}
\dot{V}_2 &= -\mu V_2 + \frac{e^\mu}{2} (z_t(1, t) + z_x(1, t))^2 \\
&\quad - \frac{e^{-\mu}}{2} (z_t(1, t) - z_x(1, t))^2
\end{aligned} \tag{16}$$

and thus

$$\begin{aligned}
\dot{V}_2 &= -\mu V_2 + \frac{e^\mu}{2} (z_t(1, t) - bz_t(1, t))^2 \\
&\quad - \frac{e^{-\mu}}{2} (z_t(1, t) + bz_t(1, t))^2 \\
&= -\mu V_2 + \frac{1}{2} (e^\mu(1-b)^2 - e^{-\mu}(1+b)^2) z_t^2(1, t)
\end{aligned}$$

For any positive value  $b$ , it holds  $|1-b| < |1+b|$ . Now, pick any  $\mu > 0$  such that

$$e^\mu(1-b)^2 \leq e^{-\mu}(1+b)^2 \tag{17}$$

holds.

With such a value  $b$ , we get  $\dot{V}_2 \leq -\mu V_2$  and thus the partial differential equation (4), with the boundary condition (5), is exponentially stable.

Now instead of the boundary condition (5) in closed loop with the linear controller (14), consider the boundary conditions, for all  $t \geq 0$ ,

$$\begin{aligned}
z(0, t) &= 0 \\
z_x(1, t) &= -\sigma_2(bz_t(1, t))
\end{aligned} \tag{18}$$

resulting from the boundary condition (5) in closed loop with a bounded and continuous map  $\sigma_2 : \mathbb{R} \rightarrow \mathbb{R}$  satisfying, for all  $(s, \tilde{s}) \in \mathbb{R}$ ,

$$(\sigma_2(s) - \sigma_2(\tilde{s}))(s - \tilde{s}) \geq 0, \tag{19a}$$

$$|\sigma_2(s)| \leq u_2, \tag{19b}$$

with  $u_2 > 0$ . Assume moreover that, for all  $c$  in  $\mathbb{R}$ , and for all  $s$  in  $\mathbb{R}$ , such that  $|(b-c)s| \leq u_2$ , it holds

$$\varphi_2(bs)(\varphi_2(bs) + cs) \leq 0, \tag{19c}$$

where  $\varphi_2(s) = \sigma_2(s) - s$ . Such a function  $\sigma_2$  includes the nonlinear functions satisfying some sector bounded condition, as the saturation maps of level  $u_2$  (see [25, Chap. 1] or [13, Chap. 7]). Since  $\sigma_2$  is a function of  $z_t(1, t)$ , it is needed in the next result a stronger regularity on the initial condition than the one imposed in e.g. [17], so that (18) makes sense.

The stability analysis of the corresponding nonlinear partial differential equation (4) and (18) asks for special care. It is done in our second main result, given below, where, following the notation in [5, Sec. 2.4], it is denoted  $H_{(0)}^1(0, 1) = \{u \in H^1(0, 1), u(0) = 0\}$ , and

$$\|u\|_{H_{(0)}^1(0, 1)} = \sqrt{\int_0^1 |u'|^2(x) dx}, \text{ for all } u \in H_{(0)}^1.$$

**Theorem 2.** *For all positive values  $b$ , and for all continuous functions  $\sigma_2$  satisfying (19), the model (4) with the boundary conditions (18) is globally asymptotically stable. More precisely the following properties hold:*

- [Well-posedness] *For all  $(z^0, z^1)$  in  $\{(u, v), (u, v) \in H^2(0, 1) \times H_{(0)}^1(0, 1), u'(1) + bv(1) = 0, u(0) = 0\}$ , there exists a unique continuous solution  $z : [0, \infty) \rightarrow H^2(0, 1) \cap H_{(0)}^1(0, 1)$  to (4), with the boundary conditions (18) and the initial condition (3), that is differentiable from  $[0, \infty)$  to  $H_{(0)}^1(0, 1)$ .*

- [Global asymptotic stability] *For all initial conditions  $(z^0, z^1)$  in  $\{(u, v), (u, v) \in H^2(0, 1) \times H_{(0)}^1(0, 1), u'(1) + bv(1) = 0, u(0) = 0\}$ , the solution to (4), with the boundary conditions (18) and the initial condition (3), satisfies the following global stability property*

$$\begin{aligned}
\|z(\cdot, t)\|_{H_{(0)}^1(0, 1)} + \|z_t(\cdot, t)\|_{L^2(0, 1)} \\
\leq \|z^0\|_{H_{(0)}^1(0, 1)} + \|z^1\|_{L^2(0, 1)}, \quad \forall t \geq 0,
\end{aligned} \tag{20}$$

together with the attractivity property,

$$\|z(\cdot, t)\|_{H_{(0)}^1(0, 1)} + \|z_t(\cdot, t)\|_{L^2(0, 1)} \rightarrow_{t \rightarrow \infty} 0, \tag{21}$$

holds.

**Remark 1.** *As for many nonlinear control systems, in particular the finite-dimensional ones subject to input saturation (see e.g., [25]), only the local exponential stability can sometimes be obtained, requiring to prove the exponential stability of the system only for a set of admissible initial conditions. Regarding a similar case for an infinite dimensional system, Theorem 2 does not state the global exponential stability, however we are able to prove the global asymptotic stability.*

The proof of Theorem 2 is provided in Section V. Note that perturbation arguments (as considered in e.g., [20, Chap. 3]) may be used to study (10) in closed loop with a saturating controller instead of the nonlinear function  $\sigma_2$ . It yields a local asymptotic stability property without exhibiting any estimate of the basin of attraction,

in contrast to the results given in Theorem 2 where an explicit estimate of the basin of attraction is provided.

#### IV. PROOF OF THEOREM 1

The proof of Theorem 1 is split into two parts: 1) the Cauchy problem has a unique solution, 2) the system is globally asymptotically stable.

*Part 1: Well-posedness of the Cauchy problem (10), (2), (3).*

Let us first prove the existence and unicity of solution to the nonlinear equation (10) with the boundary conditions (2) and the initial condition (3). To do that, let us introduce the following nonlinear operator

$$A_1 \begin{pmatrix} u \\ v \end{pmatrix} = \begin{pmatrix} v \\ u'' - \sigma_1(av) \end{pmatrix}$$

with the domain  $D(A_1) = (H^2(0,1) \cap H_0^1(0,1)) \times H_0^1(0,1)$ .

To prove the well-posedness of the Cauchy problem, we shall state that  $A_1$  generates a semigroup of contractions, and thus we need to prove that  $A_1$  is closed, dissipative, and satisfies a range condition (see (25) below). Let us prove these properties successively.

Note that, using the terminology of [19, Def. 2.6],  $A_1$  is the sum of a closed operator and of the following continuous operator

$$\begin{pmatrix} u \\ v \end{pmatrix} \mapsto \begin{pmatrix} 0 \\ -\sigma_1(av) \end{pmatrix},$$

and it is closed as proved in the following.

**Claim 1.** *The sum of a closed operator and a continuous operator is closed.*

*Proof of Claim 1:* Inspired from [15, Page 296, Ex. 12], consider  $T_1$  a closed operator from  $D(T_1) \subset X$  to  $Y$ , where  $X$  and  $Y$  are two Banach spaces. Let  $T_2$  be a continuous operator from  $X$  to  $Y$ . Let  $(x_n)_{n \in \mathbb{N}}$  be a sequence in  $X$  and  $(x, y)$  in  $X \times Y$  such that  $x_n \rightarrow x$  and  $(T_1 + T_2)x_n \rightarrow y$  as  $n \rightarrow \infty$ . We have to prove that  $(T_1 + T_2)x = y$ . To do this, note first that  $T_2x_n \rightarrow T_2x$  (since  $T_2$  is continuous). Moreover  $\|T_1x_n + T_2x - y\| \leq \|T_1x_n + T_2x_n - y\| + \|T_2x_n - T_2x\| \rightarrow 0$  as  $n \rightarrow \infty$ . Thus  $T_1x_n \rightarrow y - T_2x$  as  $n \rightarrow \infty$ , and (by using the closedness of  $T_1$ )  $T_1x = y - T_2x$ . Therefore  $y = T_1x + T_2x$ .  $\square$

Moreover, following the terminology of [19, Def. 2.4], and using the nonnegativity of  $a$ , we may prove the following lemma.

**Lemma 1.**  *$A_1$  is a dissipative operator.*

*Proof of Lemma 1:* Let us first denote by  $H_1$  the space  $H_0^1(0,1) \times L^2(0,1)$ . It is a Hilbert space equipped with

the inner product

$$\left\langle \begin{pmatrix} u \\ v \end{pmatrix}, \begin{pmatrix} \tilde{u} \\ \tilde{v} \end{pmatrix} \right\rangle = \int_0^1 u'(x) \overline{\tilde{u}'(x)} dx + \int_0^1 v(x) \overline{\tilde{v}(x)} dx, \quad (22)$$

and the norm

$$\left\| \begin{pmatrix} u \\ v \end{pmatrix} \right\| = \sqrt{\int_0^1 |u'(x)|^2 dx + \int_0^1 |v(x)|^2 dx}.$$

Let us enlarge the domain of definition of the function  $\sigma_1$  to the complex numbers, by letting, for all  $s$  in  $\mathbb{C}$ ,

$$\sigma_{1\mathbb{C}}(s) := \sigma_1(\Re(s)) + i\sigma_1(\Im(s)).$$

To ease the notation, we still use  $\sigma_1$  instead of  $\sigma_{1\mathbb{C}}$ . We define  $\varphi_1$  for complex numbers in a similar way.

To check that  $A_1$  is dissipative, using first the definition of  $A_1$  and then recalling the definition of the inner product (22), let us compute the following, for all  $\begin{pmatrix} u \\ v \end{pmatrix}, \begin{pmatrix} \tilde{u} \\ \tilde{v} \end{pmatrix}$  in  $D(A_1)$ ,

$$\begin{aligned} & \left\langle A_1 \begin{pmatrix} u \\ v \end{pmatrix} - A_1 \begin{pmatrix} \tilde{u} \\ \tilde{v} \end{pmatrix}, \begin{pmatrix} u \\ v \end{pmatrix} - \begin{pmatrix} \tilde{u} \\ \tilde{v} \end{pmatrix} \right\rangle \\ &= \int_0^1 (v - \tilde{v})'(x) \overline{(u - \tilde{u})'(x)} dx \\ &+ \int_0^1 [(u'' - \sigma_1(av)) - (\tilde{u}'' - \sigma_1(a\tilde{v}))](x) \\ &\quad \times \overline{(v - \tilde{v})(x)} dx, \\ &= \int_0^1 (v - \tilde{v})'(x) \overline{(u - \tilde{u})'(x)} dx \\ &+ \int_0^1 (u'' - \tilde{u}'')(x) \overline{(v - \tilde{v})(x)} dx \\ &- \int_0^1 (\sigma_1(av) - \sigma_1(a\tilde{v}))(x) \overline{(v - \tilde{v})(x)} dx. \end{aligned} \quad (23)$$

Consider the second integral in the last equation. Performing an integration by parts and using the definition of  $D(A_1)$ , it gives

$$\begin{aligned} & \int_0^1 (u'' - \tilde{u}'')(x) \overline{(v - \tilde{v})(x)} dx \\ &= - \int_0^1 (u' - \tilde{u}')'(x) \overline{(v - \tilde{v})(x)} dx \\ &+ [(u' - \tilde{u}')'(x) \overline{(v - \tilde{v})(x)}]_{x=0}^{x=1} \\ &= - \int_0^1 (u' - \tilde{u}')'(x) \overline{(v - \tilde{v})(x)} dx \end{aligned}$$

Thus, with (23), it follows

$$\begin{aligned} & \Re \left( \left\langle A_1 \begin{pmatrix} u \\ v \end{pmatrix} - A_1 \begin{pmatrix} \tilde{u} \\ \tilde{v} \end{pmatrix}, \begin{pmatrix} u \\ v \end{pmatrix} - \begin{pmatrix} \tilde{u} \\ \tilde{v} \end{pmatrix} \right\rangle \right) \\ &= \Re \left( \int_0^1 (v - \tilde{v})'(x) \overline{(u - \tilde{u})'(x)} dx \right) \\ &- \Re \left( \int_0^1 (u' - \tilde{u}')'(x) \overline{(v - \tilde{v})(x)} dx \right) \\ &- \Re \left( \int_0^1 (\sigma_1(av) - \sigma_1(a\tilde{v}))(x) \right. \\ &\quad \left. \times \overline{(v - \tilde{v})(x)} dx \right), \\ &= - \Re \left( \int_0^1 (\sigma_1(av) - \sigma_1(a\tilde{v}))(x) \right. \\ &\quad \left. \times \overline{(v - \tilde{v})(x)} dx \right). \end{aligned} \quad (24)$$

Note that, due to (9a), it holds, for all  $(s, \tilde{s}) \in \mathbb{C}$ ,

$$\Re \left( (\sigma_1(s) - \sigma_1(\tilde{s})) \overline{(s - \tilde{s})} \right) \geq 0 .$$

Therefore it follows, from (24) and the nonnegativity of  $a$ ,

$$\Re \left( \langle A_1 \begin{pmatrix} u \\ v \end{pmatrix} - A_1 \begin{pmatrix} \tilde{u} \\ \tilde{v} \end{pmatrix}, \begin{pmatrix} u \\ v \end{pmatrix} - \begin{pmatrix} \tilde{u} \\ \tilde{v} \end{pmatrix} \rangle \right) \leq 0 ,$$

and thus  $A_1$  is dissipative.  $\square$

Let us now show that the operator  $A_1$  generates a semigroup of contractions. To do that, we apply [2, Thm 1.3, Page 104] (or [19, Thm 4.2, Page 77]) and we need to prove that

$$D(A_1) \subset \text{Ran}(I - \lambda A_1) \quad (25)$$

for all  $\lambda > 0$  sufficiently small, where  $\text{Ran}(I - \lambda A_1)$  is the range of the operator  $I - \lambda A_1$ . To prove (25), let us pick  $\begin{pmatrix} u \\ v \end{pmatrix}$  in  $D(A_1)$  and let us prove that there exists  $\begin{pmatrix} \tilde{u} \\ \tilde{v} \end{pmatrix}$  in  $D(A_1)$  such that  $(I - \lambda A_1) \begin{pmatrix} \tilde{u} \\ \tilde{v} \end{pmatrix} = \begin{pmatrix} u \\ v \end{pmatrix}$ . Let us first note that this latter equation is equivalent to

$$\begin{cases} \tilde{u} - \lambda \tilde{v} = u , \\ \tilde{v} - \lambda(\tilde{u}'' - \sigma_1(a \tilde{v})) = v , \end{cases}$$

which may be rewritten as

$$\begin{cases} \tilde{v} = \frac{1}{\lambda}(\tilde{u} - u) \\ \tilde{u}'' - \frac{1}{\lambda^2} \tilde{u} - \sigma_1 \left( \frac{a}{\lambda} (\tilde{u} - u) \right) = -\frac{1}{\lambda} v - \frac{1}{\lambda^2} u \end{cases} \quad (26)$$

To check that there exists  $\tilde{u} \in H^2(0, 1) \cap H_0^1(0, 1)$  such that the second line of (26) holds, let us first note that this is a nonhomogeneous nonlinear differential equation in the  $\tilde{u}$ -variable with two boundary conditions (at  $x = 0$  and at  $x = 1$ ), as considered in the following:

**Lemma 2.** *If  $a$  is nonnegative and  $\lambda$  is positive, then there exists  $\tilde{u} \in H^2(0, 1) \cap H_0^1(0, 1)$  solution to*

$$\begin{cases} \tilde{u}'' - \frac{1}{\lambda^2} \tilde{u} - \sigma_1 \left( \frac{a}{\lambda} (\tilde{u} - u) \right) = -\frac{1}{\lambda} v - \frac{1}{\lambda^2} u \\ \tilde{u}(0) = \tilde{u}(1) = 0 \end{cases} \quad (27)$$

*Proof of Lemma 2:* The proof of this lemma follows from classical techniques (see e.g., [19, Page 113], or [5, Page 179]) and uses the Schauder fixed-point theorem (see e.g., [5, Thm B.19]).

To prove this lemma, let us introduce the following map

$$\begin{aligned} \mathcal{T}_1 : L^2(0, 1) &\rightarrow L^2(0, 1) , \\ y &\mapsto z = \mathcal{T}_1(y) , \end{aligned}$$

where  $z = \mathcal{T}_1(y)$  is the unique solution to

$$\begin{cases} z'' - \frac{1}{\lambda^2} z = -\frac{1}{\lambda} v - \frac{1}{\lambda^2} u + \sigma_1 \left( \frac{a}{\lambda} (y - u) \right) , \\ z(0) = z(1) = 0 . \end{cases} \quad (28)$$

This map  $\mathcal{T}_1$  is well-defined as soon as  $-\frac{1}{\lambda^2} \leq 0$ , i.e. as soon as  $\lambda > 0$ . The well-posedness of  $\mathcal{T}_1$  can be seen

as the well-posedness of the associate Sturm Liouville problem<sup>1</sup>.

Let us prove the following intermediate result.

**Claim 2.** *There exists  $M > 0$  such that  $\mathcal{T}_1(L^2(0, 1)) \subset K$ , where  $K$  is the set of functions  $w$  that are continuously differentiable on  $[0, 1]$  and such that  $\|w\|_{C^0([0, 1])} \leq M$  and  $\|w'\|_{C^0([0, 1])} \leq M$ .*

*Proof of Claim 2:* To prove this claim, let us first note that each solution to (28) is a solution to

$$\begin{cases} z'' - \frac{1}{\lambda^2} z = -\frac{1}{\lambda} v - \frac{1}{\lambda^2} u + \sigma_1 \left( \frac{a}{\lambda} (y - u) \right) , \\ z(0) = 0, \quad z'(0) = C_1 . \end{cases} \quad (29)$$

for a suitable  $C_1 \in \mathbb{R}$ . To be more specific, the solution to (29) is given by

$$\begin{aligned} z(x) &= (1 \ 0) e^{\mathcal{A}x} (0 \ C_1)^\top \\ &\quad + \int_0^x e^{\mathcal{A}(x-s)} \left( -\frac{1}{\lambda} v(s) - \frac{1}{\lambda^2} u(s) \right. \\ &\quad \left. + \sigma_1 \left( \frac{a}{\lambda} (y(s) - u(s)) \right) \right) ds \end{aligned}$$

where  $\mathcal{A} = \begin{pmatrix} 0 & 1 \\ \frac{1}{\lambda^2} & 0 \end{pmatrix}$ . It holds  $\mathcal{A}^2 = \frac{1}{\lambda^2} \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$ . Thus, by using a recurrence argument, we may prove that, for all  $x$  in  $[0, 1]$ ,

$$e^{\mathcal{A}x} = \begin{pmatrix} \cosh\left(\frac{\sqrt{x}}{\lambda}\right) & \frac{\lambda \sinh\left(\frac{\sqrt{x}}{\lambda}\right)}{\sqrt{x}} \\ \frac{\sqrt{x} \sinh\left(\frac{\sqrt{x}}{\lambda}\right)}{\lambda} & \cosh\left(\frac{\sqrt{x}}{\lambda}\right) \end{pmatrix} . \quad (30)$$

Recall that  $\sigma_1$  is assumed to be bounded, and consider a bound  $u_1 > 0$  such that, for all  $s \in \mathbb{R}$ ,  $|\sigma_1(s)| \leq u_1$ . By inspecting  $(1 \ 0) e^{\mathcal{A}x} (0 \ C_1)^\top$ , since  $\lambda \sinh\left(\frac{1}{\lambda}\right) \neq 0$  and since, for all  $y \in L^2(0, 1)$ ,  $|\sigma_1\left(\frac{a}{\lambda}(y - u)\right)| \leq u_1$ , we get that the value  $C_1$  lies in a bounded set of  $\mathbb{R}$  (which does not depend on  $y \in L^2(0, 1)$ ) and thus the existence of  $M > 0$  follows, as stated in Claim 2.  $\square$

Moreover  $\mathcal{T}_1$  is a continuous operator. Finally the set  $K$  is convex and compact (by the Ascoli-Arzelà theorem), as a subset of  $L^2(0, 1)$ .

Therefore, by the Schauder fixed-point theorem (see e.g., [5, Thm B.19]), there exists  $\tilde{u} \in K$  such that  $\mathcal{T}_1(\tilde{u}) = \tilde{u}$ . This concludes the proof of Lemma 2.  $\square$

Now from the existence of  $\tilde{u} \in H^2(0, 1) \cap H_0^1(0, 1)$  such that the second line of (26) holds, let us remark that the first line of (26) defines a unique  $\tilde{v}$  in  $H_0^1(0, 1)$ .

Therefore  $(I - \lambda A_1) \begin{pmatrix} \tilde{u} \\ \tilde{v} \end{pmatrix} = \begin{pmatrix} u \\ v \end{pmatrix}$  and (25) hold.

Since  $A_1$  is dissipative (due to Lemma 1), it follows, from [2, Thm 1.3, Page 104] (or [19, Thm 4.2]), that  $A_1$  generates a semigroup of contractions  $T_1(t)$ . Moreover, by [2, Thm 1.2, Page 102] (or [19, Thm 4.5]), for all  $\begin{pmatrix} \tilde{u} \\ \tilde{v} \end{pmatrix}$  in  $D(A_1)$ ,  $T_1(t) \begin{pmatrix} \tilde{u} \\ \tilde{v} \end{pmatrix}$  is differentiable for all

<sup>1</sup>Note that the homogeneous Sturm Liouville problem (i.e. with  $v = u = y$ ) has only the trivial function as the solution, since  $-\frac{1}{\lambda^2} < 0$ . Therefore the Sturm Liouville problem described by  $\mathcal{T}_1$  is well-posed, as proven e.g. in [1, Chap. 14].

$t > 0$  and is a solution to the Cauchy Problem (10), (2) and (3). Moreover due to [19, Thm 4.10], it is the unique solution to this Cauchy problem.

*Part 2: Global asymptotic stability of the nonlinear equation (10) with the boundary conditions (2).*

Let us consider a solution to (10) and (2), for a given initial condition in  $D(A_1)$ . The formal computation yielding (11) makes sense. Therefore with the nonnegativity of  $a$  and with (9a), we get  $\dot{V}_1 \leq 0$ , along the solutions to (10) and (2), for any initial condition in  $D(A_1)$ .

To be able to apply LaSalle's Invariance Principle, we have to check that the trajectories are precompact (see e.g. [9]). This precompactness is a corollary of the following lemma (which is similar to [10, Lem. 2] where different boundary conditions are considered).

**Lemma 3.** *The canonical embedding from  $D(A_1)$ , equipped with the graph norm, into  $H_1$  is compact.*

*Proof of Lemma 3:* Before proving this lemma, recall that its statement is equivalent to prove, for each sequence in  $D(A_1)$ , which is bounded with the graph norm, that it exists a subsequence that (strongly) converges in  $H_1$ .

Recalling the definition of the graph norm, it holds, for all  $\begin{pmatrix} u \\ v \end{pmatrix}$  in  $D(A_1)$ ,

$$\begin{aligned} \|\begin{pmatrix} u \\ v \end{pmatrix}\|_{D(A_1)}^2 &:= \|\begin{pmatrix} u \\ v \end{pmatrix}\|^2 + \|A_1 \begin{pmatrix} u \\ v \end{pmatrix}\|^2 \\ &= \int_0^1 (|u'|^2 + |v|^2 + |v'|^2 \\ &\quad + |u'' - \sigma_1(av)|^2) dx . \end{aligned}$$

Therefore, on the one hand, one gets

$$\|\begin{pmatrix} u \\ v \end{pmatrix}\|_{D(A_1)}^2 \geq \int_0^1 (|v|^2 + |v'|^2) dx, \quad (31)$$

and on the other hand, due to (9b), it holds  $|v| \geq \min(1, \frac{1}{La}) |\sigma_1(av)|$  and  $|u'' - \sigma_1(av)| \geq \min(1, \frac{1}{La}) |u'' - \sigma_1(av)|$ , it holds

$$\begin{aligned} \|\begin{pmatrix} u \\ v \end{pmatrix}\|_{D(A_1)}^2 &\geq \int_0^1 \left( |u'|^2 + \min(1, \frac{1}{L^2 a^2}) |\sigma_1(av)|^2 \right. \\ &\quad \left. + \min(1, \frac{1}{L^2 a^2}) |u'' - \sigma_1(av)|^2 \right) dx . \end{aligned}$$

Since, for all  $(s, \tilde{s}) \in \mathbb{C}^2$ , it holds  $|s + \tilde{s}|^2 \leq 2|s|^2 + 2|\tilde{s}|^2$ , it follows  $2|u'' - \sigma_1(av)|^2 + 2|\sigma_1(av)|^2 \geq |u''|^2$  and thus

$$\begin{aligned} \|\begin{pmatrix} u \\ v \end{pmatrix}\|_{D(A_1)}^2 &\geq \int_0^1 (|u'|^2 + \frac{\min(1, \frac{1}{L^2 a^2})}{2} |u''|^2) dx, \\ &\geq \frac{\min(1, \frac{1}{L^2 a^2})}{2} \int_0^1 (|u'|^2 + |u''|^2) . \end{aligned} \quad (32)$$

Consider now a sequence  $\begin{pmatrix} u_n \\ v_n \end{pmatrix}_{n \in \mathbb{N}}$  in  $D(A_1)$  bounded for the graph norm of  $D(A_1)$ . From (31) and (32), it follows that this sequence is bounded in the product space  $(H^2(0, 1) \cap H_0^1(0, 1)) \times H^1(0, 1)$ . Since the canonical embedding from  $H^2(0, 1)$  to  $H_0^1(0, 1)$  (resp. from  $H^1(0, 1)$  to  $L^2(0, 1)$ ) is compact, there exists a subsequence still denoted  $\begin{pmatrix} u_n \\ v_n \end{pmatrix}_{n \in \mathbb{N}}$  such that

$$u_n \rightarrow u \text{ in } H_0^1(0, 1), \quad v_n \rightarrow v \text{ in } L^2(0, 1)$$

and thus  $\begin{pmatrix} u \\ v \end{pmatrix}$  belongs to  $H_1$ , which proves the lemma.  $\square$

Inspired by [11, Thm 1, (iii)], using the dissipativity (see Lemma 1) it follows that the function

$$t \mapsto \left\| \begin{pmatrix} z(\cdot, t) \\ z_t(\cdot, t) \end{pmatrix} \right\| \quad (33)$$

is a nonincreasing. Moreover, since  $A_1$  is single valued, the canonical restriction of  $A_1$  equals  $A_1$  (see [19, Def. 2.7] for the introduction of this notion), and thus with [19, Cor. 3.7], we get that

$$t \mapsto \left\| A_1 \begin{pmatrix} z(\cdot, t) \\ z_t(\cdot, t) \end{pmatrix} \right\| \quad (34)$$

is also a nonincreasing function. Therefore, with Lemma 3, the trajectory  $\begin{pmatrix} z(\cdot, t) \\ z_t(\cdot, t) \end{pmatrix}$  is precompact in  $H_1$ . Moreover the  $\omega$ -limit set  $\omega \left[ \begin{pmatrix} z(\cdot, 0) \\ z_t(\cdot, 0) \end{pmatrix} \right] \subset D(A_1)$ , is not empty and invariant with respect to the nonlinear semigroup  $T_1(t)$  (see [24, Thm 3.1]).

We now use LaSalle's invariance principle to show that  $\omega \left[ \begin{pmatrix} z(\cdot, 0) \\ z_t(\cdot, 0) \end{pmatrix} \right] = \{0\}$ . To do that, consider a solution such that  $\dot{V}_1(t) = 0$ , for all  $t \geq 0$ . It follows from (11) that  $z_t(x, t) = 0$  for almost all  $x$  in  $(0, 1)$  and for all  $t \geq 0$ . Due to (9b) and the continuity of  $\sigma_1$ , it follows  $\sigma_1(0) = 0$ . Therefore  $z$  is a solution to the linear equation (1) with the boundary conditions (2), such that  $z_{tt}(x, t) = z_{xx}(x, t) = 0$  which implies that  $z = 0$ . Therefore  $\omega \left[ \begin{pmatrix} z(\cdot, 0) \\ z_t(\cdot, 0) \end{pmatrix} \right] = \{0\}$ , and the convergence property (13) holds along the solutions to the nonlinear equation (10) with the boundary conditions (2).

This concludes the proof of Theorem 1.  $\square$

## V. PROOF OF THEOREM 2

*Part 1: Well-posedness of the Cauchy problem (4), (3), (18).*

Let us first prove the existence and unicity of solution to the nonlinear equation (4), with the boundary conditions (18) and the initial condition (3). To do that, let us

introduce the following nonlinear operator

$$A_2 \begin{pmatrix} u \\ v \end{pmatrix} = \begin{pmatrix} v \\ u'' \end{pmatrix}$$

with the domain  $D(A_2) = \{(u, v), (u, v) \in H^2(0, 1) \times H^1(0, 1), u_x(1) + \sigma_2(bv(1)) = 0, u(0) = 0, v(0) = 0\}$ .

To prove the well-posedness of the Cauchy problem, we shall state that  $A_2$  generates a semigroup of contractions by applying [2, Thm 1.3, Page 104], and thus we need to prove that  $A_2$  is closed, dissipative, and satisfies a range condition (see (25) below). Let us prove these properties successively.

The nonlinear operator  $A_2$  is closed, and using the nonnegativity of  $b$ , we may prove the following lemma.

**Lemma 4.**  $A_2$  is a dissipative operator.

*Proof of Lemma 4:* Recall that  $H_{(0)}^1(0, 1)$  is a Hilbert space with the inner product

$$\langle u, \tilde{u} \rangle_{H_{(0)}^1(0, 1)} = \int_0^1 u'(x) \overline{\tilde{u}'(x)} dx.$$

Now denote by  $H_2$  the space  $H_{(0)}^1(0, 1) \times L^2(0, 1)$ . It is a Hilbert space equipped with the same inner product as for  $H_1$ , that is (22).

To check that  $A_2$  is dissipative, using first the definition of  $A_2$  and then recalling the definition of the inner product in  $H_2$ , let us compute the following, for all  $\begin{pmatrix} u \\ v \end{pmatrix}, \begin{pmatrix} \tilde{u} \\ \tilde{v} \end{pmatrix}$  in  $D(A_2)$ ,

$$\begin{aligned} & \langle A_2 \begin{pmatrix} u \\ v \end{pmatrix} - A_2 \begin{pmatrix} \tilde{u} \\ \tilde{v} \end{pmatrix}, \begin{pmatrix} u \\ v \end{pmatrix} - \begin{pmatrix} \tilde{u} \\ \tilde{v} \end{pmatrix} \rangle \\ &= \left\langle \begin{pmatrix} v - \tilde{v} \\ u'' - \tilde{u}'' \end{pmatrix}, \begin{pmatrix} u - \tilde{u} \\ v - \tilde{v} \end{pmatrix} \right\rangle, \\ &= \int_0^1 (v - \tilde{v})'(x) \overline{(u - \tilde{u})'(x)} dx \\ &+ \int_0^1 (u'' - \tilde{u}'')(x) \overline{(v - \tilde{v})(x)} dx. \end{aligned} \quad (35)$$

Consider the second integral in the last equation. Performing an integration by parts and using the definition of  $D(A_2)$ , it gives

$$\begin{aligned} & \int_0^1 (u'' - \tilde{u}'')(x) \overline{(v - \tilde{v})(x)} dx \\ &= - \int_0^1 (u' - \tilde{u}')(x) \overline{(v' - \tilde{v}')(x)} dx \\ &+ [(u' - \tilde{u}')(x) \overline{(v - \tilde{v})(x)}]_{x=0}^{x=1} \\ &= - \int_0^1 (u' - \tilde{u}')(x) \overline{(v' - \tilde{v}')(x)} dx \\ &+ (u'(1) - \tilde{u}'(1)) \overline{(v(1) - \tilde{v}(1))} \\ &= - \int_0^1 (u' - \tilde{u}')(x) \overline{(v' - \tilde{v}')(x)} dx \\ &+ (-\sigma_2(bv(1)) + \sigma_2(b\tilde{v}(1))) \overline{(v(1) - \tilde{v}(1))}. \end{aligned}$$

By combining the previous equation with (35), we conclude the proof of Lemma 4 using (19a) as in the end of Lemma 1.  $\square$

Let us now show that the operator  $A_2$  generates a semigroup of contractions. To do that, we apply [2, Thm 1.3, Page 104] (or [19, Thm 4.2, Page 77]) and we need to prove that

$$D(A_2) \subset \text{Ran}(I - \lambda A_2) \quad (36)$$

for all  $\lambda > 0$  sufficiently small, where  $\text{Ran}(I - \lambda A_2)$  is the range of the operator  $I - \lambda A_2$ . To prove (36), let us pick  $\begin{pmatrix} u \\ v \end{pmatrix}$  in  $D(A_2)$  and let us prove that there exists  $\begin{pmatrix} \tilde{u} \\ \tilde{v} \end{pmatrix}$  in  $D(A_2)$  such that  $(I - \lambda A_2) \begin{pmatrix} \tilde{u} \\ \tilde{v} \end{pmatrix} = \begin{pmatrix} u \\ v \end{pmatrix}$ . Let us first note that this latter equation is equivalent to

$$\begin{cases} \tilde{u} - \lambda \tilde{v} = u, \\ \tilde{v} - \lambda \tilde{u}'' = v, \end{cases}$$

which may be rewritten as

$$\begin{cases} \tilde{v} = \frac{1}{\lambda}(\tilde{u} - u), \\ \tilde{u}'' - \frac{1}{\lambda^2} \tilde{u} = -\frac{1}{\lambda} v - \frac{1}{\lambda^2} u. \end{cases} \quad (37)$$

To check that there exists  $\tilde{u} \in H^2(0, 1)$  such that  $\tilde{u}(0) = 0, \tilde{u}'(1) = -\sigma_2(\frac{b}{\lambda} \tilde{u}(1) - bu(1))$ , and such that the second line of (37) holds, let us first note that this is a nonhomogeneous nonlinear differential equation in the  $\tilde{u}$ -variable with two boundary conditions (at  $x = 0$  and at  $x = 1$ ), as considered below:

**Lemma 5.** If  $\lambda$  is positive, then there exists  $\tilde{u} \in H^2(0, 1)$  solution to

$$\begin{aligned} & \tilde{u}'' - \frac{1}{\lambda^2} \tilde{u} = -\frac{1}{\lambda} v - \frac{1}{\lambda^2} u \\ & \tilde{u}(0) = 0, \tilde{u}'(1) = -\sigma_2(\frac{b}{\lambda} \tilde{u}(1) - bu(1)) \end{aligned} \quad (38)$$

*Proof of Lemma 5:* To prove this lemma, let us introduce the following map

$$\begin{aligned} \mathcal{T}_2 : H^1(0, 1) &\rightarrow L^2(0, 1), \\ y &\mapsto z = \mathcal{T}_2(y), \end{aligned}$$

where  $z = \mathcal{T}_2(y)$  is the unique solution to

$$\begin{aligned} & z'' - \frac{1}{\lambda^2} z = -\frac{1}{\lambda} v - \frac{1}{\lambda^2} u, \\ & z(0) = 0, z'(1) = -\sigma_2(\frac{b}{\lambda} y(1) - bu(1)). \end{aligned} \quad (39)$$

This map  $\mathcal{T}_2$  can be seen as a boundary value problem, and it is well-defined for all  $\lambda > 0$ . In a similar way as in the proof of Claim 2, we have the following claim.

**Claim 3.** There exists  $M > 0$  such that  $\mathcal{T}_2(L^2(0, 1)) \subset K$ , where  $K$  is the set of functions  $w$  that are continuously differentiable on  $[0, 1]$  and such that  $\|w\|_{C^0([0, 1])} \leq M$  and  $\|w'\|_{C^0([0, 1])} \leq M$ .

*Proof of Claim 3:* As for the proof of Claim 2, let us first note that each solution to (39) is such that

$$\begin{aligned} z'(x) &= (0 \ 1) e^{\mathcal{A}x} (0 \ C_2)^\top \\ &+ \int_0^x e^{\mathcal{A}(x-s)} \left(-\frac{1}{\lambda} v - \frac{1}{\lambda^2} u\right) ds \end{aligned}$$

for a suitable value of  $C_2$ , where the matrix  $\mathcal{A}$  is defined in the proof of Claim 2 and  $e^{\mathcal{A}x}$  is given by (30). The

value of  $C_2$  is so that  $z'(1) = -\sigma_2(\frac{b}{\lambda}y(1) - bu(1))$ . Recall (19b). By inspecting  $(0 \ 1)e^A(0 \ C_2)^\top$ , since  $\cosh(\frac{1}{\lambda}) \neq 0$  and since, for all  $y \in L^2(0, 1)$ ,  $|\sigma_2(\frac{b}{\lambda}y(1) - bu(1))| \leq u_2$ , we get that the value  $C_2$  lies in a bounded set of  $\mathbb{R}$  (which does not depend on  $y \in L^2(0, 1)$ ) and thus the existence of  $M > 0$  follows, as stated in Claim 3.  $\square$

Moreover  $\mathcal{T}_2$  is a continuous operator. Finally the set  $K$  is convex and compact (by the Ascoli-Arzelà theorem), as a subset of  $L^2(0, 1)$ .

Therefore, by the Schauder fixed-point theorem (see e.g., [5, Thm B.19]), there exists  $\tilde{u} \in K$  such that  $\mathcal{T}_2(\tilde{u}) = \tilde{u}$ . This concludes the proof of Lemma 5.  $\square$

Now from the existence of  $\tilde{u} \in H^2(0, 1) \cap H_{(0)}^1(0, 1)$  such that the second line of (37) holds, let us remark that the first line of (37) defines a unique  $\tilde{v}$  in  $H^1(0, 1)$ .

Therefore  $(I - \lambda A_2) \begin{pmatrix} \tilde{u} \\ \tilde{v} \end{pmatrix} = \begin{pmatrix} u \\ v \end{pmatrix}$  and (36) hold.

Since  $A_2$  is dissipative (due to Lemma 4), it follows, from [2, Thm 1.3, Page 104] (or [19, Thm 4.2]), that  $A_2$  generates a semigroup of contractions  $T_2(t)$ . Moreover, by [2, Thm 1.2, Page 102] (or [19, Thm 4.5]), for all  $\begin{pmatrix} \tilde{u} \\ \tilde{v} \end{pmatrix}$  in  $D(A_2)$ ,  $T_2(t) \begin{pmatrix} \tilde{u} \\ \tilde{v} \end{pmatrix}$  is strongly differentiable for all  $t > 0$  and is a solution to the Cauchy problem (4), (18), and (3). Moreover due to [19, Thm 4.10], it is the unique solution to this Cauchy problem.

*Part 2: Global asymptotic stability of the nonlinear equation (4) with the boundary conditions (18).*

Let us consider a solution to (4) and (18) for a given initial condition in  $D(A_2)$ . Now, as in the proof of Theorem 1, using the dissipativity (see Lemma 4) and [19, Cor. 3.7], we get

$$t \mapsto \left\| \begin{pmatrix} z(\cdot, t) \\ z_t(\cdot, t) \end{pmatrix} \right\|, \quad t \mapsto \left\| A_2 \begin{pmatrix} z(\cdot, t) \\ z_t(\cdot, t) \end{pmatrix} \right\|,$$

are two non-increasing functions. The decreasing property of the first function yields the global stability property as written in Theorem 2. Now, by focusing on the second function, it holds, for all  $t \geq 0$ ,

$$\|z_t(\cdot, t)\|_{H_{(0)}^1(0, 1)} \leq \left\| A_2 \begin{pmatrix} z(\cdot, 0) \\ z_t(\cdot, 0) \end{pmatrix} \right\|.$$

Moreover, on the one hand, by definition of  $A_2$  and of  $H_2$ , it holds

$$\left\| A_2 \begin{pmatrix} z^0 \\ z^1 \end{pmatrix} \right\|^2 = \|z^{0''}\|_{L^2(0, 1)}^2 + \|z^1\|_{H_{(0)}^1(0, 1)}^2. \quad (40)$$

On the other hand, since  $z_t(0, t) = 0$ , it holds  $|z_t(1, t)|^2 = |\int_0^1 z_{xt}(\cdot, t) dx|^2 \leq \int_0^1 |z_{xt}(\cdot, t)|^2 dx = \|z_t(\cdot, t)\|_{H_{(0)}^1(0, 1)}^2$ . Thus, with (40), for all  $t \geq 0$ ,

$$|z_t(1, t)| \leq \left\| A_2 \begin{pmatrix} z(\cdot, 0) \\ z_t(\cdot, 0) \end{pmatrix} \right\|. \quad (41)$$

Let us now prove the following

**Lemma 6.** *For each  $b > 0$  and for all  $\epsilon > 0$ , there exist  $\lambda > 0$ ,  $\mu > 0$  and  $c$  in  $\mathbb{R}$  such that*

$$\mathcal{M} = \begin{pmatrix} (1-b)^2 e^\mu - (1+b)^2 e^{-\mu} & * \\ (b-1)e^\mu - (1+b)e^{-\mu} - \lambda c & e^\mu - e^{-\mu} - 2\lambda \end{pmatrix} \leq 0 \quad (42)$$

and  $|b - c| \leq \epsilon$  hold.

*Proof of Lemma 6:* Let  $b > 0$  and  $\epsilon > 0$ . First consider the following matrix

$$\tilde{\mathcal{M}} = \begin{pmatrix} -4b & * \\ -2 - \lambda c & -2\lambda \end{pmatrix}$$

Since the trace of  $\tilde{\mathcal{M}}$  is  $-4b - 2\lambda$ , the sum of the eigenvalues is negative as soon as  $\lambda > 0$  and  $b > 0$ . The determinant is the product of the eigenvalues:  $P = 8b\lambda - (2 + \lambda c)^2$ . Let us denote  $\tilde{\epsilon} = b - c$ , and make a Taylor expansion of  $P$  with respect to  $\tilde{\epsilon}$  at  $\tilde{\epsilon} = 0$ . It holds  $P = 8b\lambda - 4 - 4\lambda b + 4\lambda\tilde{\epsilon} - \lambda^2 b^2 + 2\lambda^2 b\tilde{\epsilon} + o(\tilde{\epsilon}) = -(\lambda b - 2)^2 + 2\tilde{\epsilon}\lambda(2 + \lambda b) + o(\tilde{\epsilon})$ . Therefore letting  $\lambda = 2/b$ , it holds  $P = 16\tilde{\epsilon}/b + o(\tilde{\epsilon})$  which is positive as soon as  $\tilde{\epsilon}$  is sufficiently small and positive. This implies that both eigenvalues of  $\tilde{\mathcal{M}}$  are negative and we conclude that  $\tilde{\mathcal{M}} \leq 0$ . Note now that for  $\mu \rightarrow 0$  we get that matrix  $\tilde{\mathcal{M}}$  approaches  $\mathcal{M}$ . Hence, by the continuity of the eigenvalues of matrix  $\mathcal{M}$  with respect to parameters, we get the existence of  $\lambda > 0$ ,  $c$  in  $\mathbb{R}$  (close to  $b$ ) and  $\mu > 0$  (close to 0) such that (42) and  $|b - c| \leq \epsilon$  hold. This concludes the proof of Lemma 6.  $\square$

Pick  $r > 0$  and an initial condition satisfying  $\|z^{0''}\|_{L^2(0, 1)}^2 + \|z^1\|_{H_{(0)}^1(0, 1)}^2 \leq r^2$ . Apply Lemma 6 with  $b > 0$  and  $\epsilon = u_2/r$ . We obtain that the initial condition satisfies  $|b - c|^2 (\|z^{0''}\|_{L^2(0, 1)}^2 + \|z^1\|_{H_{(0)}^1(0, 1)}^2) \leq u_2^2$ . With (40) and (41), we obtain, along the solutions of (4) and (18) starting from such an initial condition,

$$|(b - c)z_t(1, t)| \leq u_2.$$

Using (19c) with  $s = z_t(1, t)$ , it follows, along the solutions to (4) and (18) starting from such an initial condition,

$$\varphi_2(bz_t(1, t))(\varphi_2(bz_t(1, t)) + cz_t(1, t)) \leq 0. \quad (43)$$

The formal computation (16) of the Lyapunov function candidate  $V_2$  along the solutions to (4) and (18) makes sense and it holds, along the solutions to (4) and (18),

$$\begin{aligned} \dot{V}_2 + \mu V_2 &= e^\mu (z_t(1, t) + z_x(1, t))^2 \\ &\quad - e^{-\mu} (z_t(1, t) - z_x(1, t))^2 \\ &= e^\mu (z_t(1, t) - \sigma_2(bz_t(1, t)))^2 \\ &\quad - e^{-\mu} (z_t(1, t) + \sigma_2(bz_t(1, t)))^2 \\ &= e^\mu (z_t(1, t) - \varphi_2(bz_t(1, t)) - bz_t(1, t))^2 \\ &\quad - e^{-\mu} (z_t(1, t) + \varphi_2(bz_t(1, t)) + bz_t(1, t))^2. \end{aligned}$$

Let us denote  $\varphi_2$  instead of  $\varphi_2(bz_t(1,t))$ . For  $\lambda > 0$  given by Lemma 6, and using (43), it follows

$$\begin{aligned} \dot{V}_2 &\leq -\mu V_2 + e^\mu (z_t(1,t) - \varphi_2 - bz_t(1,t))^2 \\ &\quad - e^{-\mu} (z_t(1,t) + \varphi_2 + bz_t(1,t))^2 \\ &\quad - 2\lambda \varphi_2 (\varphi_2 + cz_t(1,t)) \\ &\leq -\mu V_2 + \begin{pmatrix} z_t(1,t) \\ \varphi_2 \end{pmatrix}^\top \mathcal{M} \begin{pmatrix} z_t(1,t) \\ \varphi_2 \end{pmatrix} \end{aligned}$$

where  $\mathcal{M}$  is defined in (42). With (42), we get  $\dot{V}_2 \leq -\mu V_2$ , along the solutions to (4), (18) and (3) starting from an initial condition satisfying

$$\|z^{0''}\|_{L^2(0,1)}^2 + \|z^1\|_{H_{(0)}^1(0,1)}^2 \leq r^2. \quad (44)$$

As a conclusion, for all  $b > 0$ , and for all  $r > 0$ , for all initial conditions in  $\{(u,v), (u,v) \in H^2(0,1) \times H_{(0)}^1(0,1), u'(1) + bv(1) = 0, u(0) = 0\}$  satisfying (44), there exists  $\mu > 0$  such that  $\dot{V}_2(t) \leq -\mu V_2(t)$ , and thus with the expression of  $V_2$  in (15), it implies (21). This implies the global attractivity as stated in Theorem 2.  $\square$

## VI. NUMERICAL SIMULATIONS

### A. Illustrating Theorem 1

Let us illustrate Theorem 1 by discretizing the PDE (10) with the boundary conditions (2) and the initial condition (3) by means of finite difference method. To do that we compute the values of  $z$  at the next time step by using the values known at the previous two time steps (see e.g. [18] for an introduction on the numerical implementation). It is chosen the time and the space steps so that the stability condition of the numerical scheme is satisfied. Due to the presence of the nonlinear map, an implicit equation has to be solved when discretizing the dynamics.<sup>2</sup>

Consider  $a = 1$ , and the following nonlinear function  $\sigma_1(s) = \text{sat}_1(\sin(s) + s)$ , for  $s \in \mathbb{R}$ , where  $\text{sat}_1$  is the saturation map of level  $u_1 = 1.5$ . This function satisfies (9).

Let us consider the initial condition (3) with  $z^0(x) = \sin(\pi x)$  and  $z^1(x) = 0$ , for  $x \in [0, 1]$ . The time evolution of the numerically computed  $z$ -component of the solution is given in Figure 2 where it is checked that it converges to the equilibrium. Moreover on Figure 3 it can be observed that the control law saturates for small positive time.

<sup>2</sup>The simulation code for both examples can be downloaded from <http://www.gipsa-lab.fr/~christophe.prieur/Codes/code-tacl6.zip>

Fig. 2. Time evolution of the  $z$ -component of the solution to (10), (2) and (3) with  $\sigma_1$ .

Fig. 3. Time evolution of the nonlinear control law with  $\sigma_1$ .

### B. Illustrating Theorem 2

Let us illustrate now Theorem 2 by discretizing the PDE (4) with the boundary conditions (18) and the initial condition (3).

Consider  $b = 1$ , and the following nonlinear function  $\sigma_2(s) = \text{sat}_2(s)$ , for  $s \in \mathbb{R}$ , where  $\text{sat}_2$  is the saturation map of level  $u_2 = 0.05$ . This function satisfies (19).

Let us consider the same initial condition as in the previous subsection.

The time evolution of the numerically computed  $z$ -component of the solution is given in Figure 4 where it is observed that it converges to the equilibrium  $z = 0$ . In Figure 5 it is observed that the control law saturates around 30 times within 20s. Therefore, in spite of the saturation, note that the convergent behavior can be observed as predicted by Theorem 2.

Fig. 4. Time evolution of the  $z$ -component of the solution to (4), (18) and (3) with  $\sigma_2$ .

Fig. 5. Time evolution of the nonlinear control law with  $\sigma_2$ .

#### ACKNOWLEDGEMENT

The authors thank M. Krstic for pointing out Reference [16], useful in particular for the introduction of Lyapunov function  $V_2$ , and the anonymous reviewers for their detailed comments.

#### VII. CONCLUSION

The well-posedness and the asymptotic stability of a class of 1D wave equations have been studied. The PDE under consideration resulted from the feedback connection of a classical wave equation and a cone bounded nonlinear control law. The controller is either applied in the space domain (distributed input) or at one boundary (boundary action). The well-posedness issue has been tackled by using nonlinear semigroup techniques and the

stability has been proven by Lyapunov theory for infinite dimensional systems.

This work lets some questions open. In particular, it could be interesting to use other classes of Lyapunov functions, as those considered in [27] and to compare the obtained domain of attraction with the one estimated in Theorem 2. It would also be interesting to study other PDEs appearing in vibration control theory, such as the beam equation (as considered in [7]). Other hyperbolic systems as the one considered in this paper may also be considered as the conservation laws that are useful for the flow control (see [6], [22]). For such a class of PDEs, Lyapunov theory is an useful tool when designing stabilizing linear controllers, and may be also the key when computing saturating stabilizing feedback laws. Generalization to the design of output feedback laws, instead of state feedback controls as considered in particular in Theorem 1, is also a natural research line.

**Christophe Prieur** was born in Esseyles-Nancy, France, in 1974. He graduated in Mathematics from the Ecole Normale Supérieure de Cachan, France in 2000. He received the Ph.D degree in 2001 in Applied Mathematics from the Université Paris-Sud, France, and the "Habilitation à Diriger des Recherches" (HDR degree) in 2009. From 2002 he was an associate researcher CNRS at the laboratory SATIE, Cachan, France, and at the LAAS, Toulouse, France (2004-2010). In

2010 he joined the Gipsa-lab, Grenoble, France where he is currently a senior researcher of the CNRS (since 2011). His current research interests include nonlinear control theory, hybrid systems, and control of partial differential equations. He was the Program Chair of the 9th IFAC Symposium on Nonlinear Control Systems (NOLCOS 2013) and of the 14th European Control Conference (ECC 2015). He has been a member of the IEEE-CSS Conference Editorial Board and an associate editor for IMA J. Mathematical Control and Information. He is currently a member of the EUCA-CEB and an associate editor for the IEEE Trans. on Automatic Control, European J. of Control, and IEEE Trans. on Control Systems Technology.

**Sophie Tarbouriech** received the PhD degree in Control Theory in 1991 and the HDR degree (Habilitation Diriger des Recherches) in 1998 from University Paul Sabatier, Toulouse, France. Currently, she is full-time researcher (Directeur de Recherche) in LAAS-CNRS, Toulouse. Her main research interests include analysis and control of linear and nonlinear systems with constraints (limited information), hybrid dynamical systems. She is currently Associate Editor for IEEE

Transactions on Automatic Control, IEEE Transactions on Control Systems Technology, Automatica and European Journal of Control. She is also in the Editorial Board of International Journal of Robust and Nonlinear Control. She is also co-Editor-in-Chief of the French journal JESA (Journal Européen des Systèmes Automatisés). Since 1999, she is Associate Editor at the Conference Editorial Board of the IEEE Control Systems Society. She is also a member of the IFAC technical committees on Robust Control and Nonlinear Systems.

**João M. Gomes da Silva Jr** received the Dipl. Eng. in Electrical Engineering from the Universidade Federal do Rio Grande do Sul (UFRGS), Porto Alegre, Brazil in 1992, the M.Sc. degree in Electrical Engineering from the Universidade Federal de Santa Catarina (UFSC), Florianópolis, Brazil in 1994 and the Ph.D. ("Doctorat en Automatique") degree from the Université Paul Sabatier, Toulouse, France in 1997. In 1997 he joined the UFRGS, where he is currently Full Professor and Head of the Department of Automation and Energy. In 2011,

he was Honorary Visiting Fellow in the University of Leicester, UK. Since 2000, he is a researcher of the CNPq/Brazil (National Council for Scientific and Technological Development). From 2013 to 2014 he was General Coordinator of the Program Science without Borders at the CNPq. He is member of the Conference Editorial Board of IEEE Control Systems Society, and member of the IFAC Technical Committee on Linear Control Systems (TC2.2). He was member of the Executive Board of the Brazilian Automation Society (SBA) from 2008 to 2010 and is currently member of its Council. His research topics include: constrained control, time-delay systems, networked control systems, robust control and non-linear systems.
