**HAL** is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

# SATOSHI RISK TABLES

CYRIL GRUNSPAN AND RICARDO PÉREZ-MARCO

**ABSTRACT.** We present Bitcoin Security Tables computing the probability of success  $p(z, q, t)$  of a double spend attack by an attacker controlling a share  $q$  of the hashrate after  $z$  confirmations in time  $t$ .

## 1. INTRODUCTION.

The main breakthrough in [2] is the solution to the *double spend problem* of an electronic currency unit without a central authority. Bitcoin is the first form of *peer-to-peer* (P2P) electronic currency.

A double spend attack can only be attempted with a substantial fraction of the hashrate used in the *Proof-of-Work* of the Bitcoin network. The attackers will start a *double spend race* against the rest of the network to replace the last blocks of the blockchain. The last section of [2] computes the probability that the attackers catch up. Following Nakamoto, by “success of the attackers” we mean catching up the  $z$  blocks, although to replace the blocks the attackers need to validate  $z + 1$ . In [1] we correct Nakamoto’s analysis based on an abusive approximation and give a closed-form formula for the exact probability.

**Theorem 1.** (C. Grunspan, R. Pérez-Marco, [1])

*Let  $0 < q < 1/2$ , resp.  $p = 1 - q$ , the relative hash power of the group of the attackers, resp. of honest miners. After  $z$  blocks have been validated by the honest miners, the probability of success of the attackers is*

$$P(z) = I_{4pq}(z, 1/2) ,$$

*where  $I_x(a, b)$  is the Regularized Incomplete Beta Function*

$$I_x(a, b) = \frac{\Gamma(a + b)}{\Gamma(a)\Gamma(b)} \int_0^x t^{a-1} (1-t)^{b-1} dt .$$

---

2010 *Mathematics Subject Classification.* 68M01, 60G40, 91A60, 33B20.

*Key words and phrases.* Bitcoin, blockchain, double spend, mining, proof-of-work, Regularized Incomplete Beta Function.

We carry out a more accurate risk analysis by considering not only the number of confirmations  $z$  but also the time  $t$  it took for the last  $z$  validated blocks, which is an information that is clearly available.

In practice, in order to avoid a double spend attack, the recipient of the bitcoin transaction waits for  $z \geq 1$  confirmations. He also has the information on the time  $t$  it took to confirm the transaction  $z$  times. Obviously the probability of success of the attackers increases with  $t$  since he has more time to secretly mine his alternative blockchain. In [1] we carry out a more precise risk analysis considering this available data. The relevant dimensionless parameter introduced is the relative deviation from the expected time

$$\kappa = \frac{t}{zt_0} = \frac{pt}{z\tau_0} = \frac{1-q}{z} \frac{t}{\tau_0},$$

where  $\tau_0$  is the expected validation time of a new block ( $\tau_0 = 10$  min for the Bitcoin network). In [1] we give a closed-form formula for the probability  $P(z, q, \kappa)$  that the attackers catch up with the current chain.

**Theorem 2.** (C. Grunspan, R. Pérez-Marco, [1])

We have

$$P(z, q, \kappa) = 1 - Q(z, \kappa z q / p) + \left(\frac{q}{p}\right)^z e^{\kappa z \frac{p-q}{p}} Q(z, \kappa z).$$

After a validation  $z$  has been observed in the network and the time  $t$  being measured, and  $r = \frac{t}{zt_0}$ , one can compute the probabilities

$$\tilde{P}(z, q, r) = P(z, q, (1-q)r),$$

that give the probability of the attackers to catch up the current blockchain. We tabulate these probabilities for  $z = 1, 2, \dots, 10$ .

## 2. USE OF THE TABLES.

The tables are useful to determine the number of confirmations needed for a given transaction. In practice, someone receiving a bitcoin transaction will check after  $z$  confirmations the corresponding table. With the measured time  $t$ , he will compute  $r = \frac{t}{zt_0}$ , and check the value of  $\tilde{P}(z, q, r)$  and then asses the level of risk assumed accepting the payment.

## 3. SATOSHI RISK TABLES.

Below we give the tables for  $z = 1, 2, \dots, 9$  of  $\tilde{P}(z, q, r)$  for different values of  $q$  and  $r$  in % with 2 decimal places. These are what is needed for practical applications.
