HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

SPACE AND TIME INVERSIONS OF STOCHASTIC PROCESSES AND KELVIN TRANSFORM

L. ALILI, L. CHAUMONT, P. GRACZYK, AND T. ŻAK

ABSTRACT. Let X be a standard Markov process. We prove that a space inversion property of X implies the existence of a Kelvin transform of X -harmonic, excessive and operator-harmonic functions and that the inversion property is inherited by Doob h -transforms. We determine new classes of processes having space inversion properties amongst transient processes satisfying the time inversion property. For these processes, some explicit inversions, which are often not the spherical ones, and excessive functions are given explicitly. We treat in details the examples of free scaled power Bessel processes, non-colliding Bessel particles, Wishart processes, Gaussian Ensemble and Dyson Brownian Motion.

1. INTRODUCTION

The following space inversion property of a Brownian Motion $(B_t, t \geq 0)$ in \mathbb{R}^n is well known ([29], [33]). Let I_{sph} be the spherical inversion $I_{sph}(x) = x/\|x\|^2$ on $\mathbb{R}^n \setminus \{0\}$ and $h(x) = \|x\|^{2-n}$, $n \geq 1$. Then

$$(I_{sph}(B_{\gamma_t}), t \geq 0) \stackrel{(d)}{=} (B_t^h, t \geq 0),$$

where $\stackrel{(d)}{=}$ stands for equality in distribution, B^h is the Doob h -transform of B with the function h and the time change γ_t is the inverse of the additive functional $A(t) = \int_0^t \|X_s\|^{-4} ds$. In case $n = 1$, B is a reducible process. Thus, the state space can be reduced to either the positive or negative real line and B killed when it hits zero, usually denoted by B^0 , is used instead of B .

In [9], such an inversion property was shown for isotropic (also called "rotationally invariant" or "symmetric") α -stable processes on \mathbb{R}^n , $0 < \alpha \leq 2$, also with $I_{sph}(x)$ and with the excessive function $h(x) = \|x\|^{\alpha-n}$. The time change γ_t is then the inverse function of $A(t) = \int_0^t \|X_s\|^{-2\alpha} ds$. In the pointwise recurrent case $\alpha > n = 1$ one must consider the process X_t^0 killed at 0. In the recent papers [2, 3, 24], inversions involving dual processes were studied for diffusions on \mathbb{R} and for self-similar Markov processes on \mathbb{R}^n , $n \geq 1$.

The main motivation and objective of this paper was to find new classes of Markov processes having space inversion properties. Moreover, we show that the inversion property of a process X implies the existence of a Kelvin transform of X -harmonic

Key words and phrases. Kelvin transform, self-similar Markov processes, diffusion, time change, inversion, Doob h -transform.

functions.

In this work, $((X_t, t \geq 0); (\mathbb{P}_x)_{x \in E})$ is a standard Markov process with a state space E , where E is the one point Alexandroff compactification of an unbounded locally compact subset of \mathbb{R}^n . Let $I : E \rightarrow E$ be a smooth involution and let f be X -harmonic. One cannot expect that the function $f \circ I$ is again X -harmonic. However, in the case of the Brownian Motion, it is well known, see for instance [4], that if f is a twice differentiable function on $\mathbb{R}^n \setminus \{0\}$ and $\Delta f = 0$ then $\Delta(\|x\|^{2-n} f(I_{sph}(x))) = 0$. The map

$$f \mapsto Kf(x) = \|x\|^{2-n} f(I_{sph}(x))$$

is the classical Kelvin transformation of a harmonic function f on $\mathbb{R}^n \setminus \{0\}$; this was obtained by W. Thomson (Lord Kelvin) in [32].

In the isotropic stable case, Riesz noticed ([30]) that if $K_\alpha f(x) = \|x\|^{\alpha-n} f(I_{sph}(x))$, and $U_\alpha(\mu)$ is the Riesz potential of a measure μ then $K_\alpha(U_\alpha(\mu))$ is α -harmonic. This observation was extended in [7, 8, 9] by proving that K_α transforms α -harmonic functions into α -harmonic functions. Analogous results were proven for Dunkl processes in [20], see Section 2.5 for more details in the stable and Dunkl cases.

In harmonic analysis, the interest in Kelvin transform comes from the fact that it reduces potential-theoretic problems relating to the point at infinity for unbounded domains to those relating to the point 0 for bounded domains, see for instance the examples in [4] where this is applied to solving the Dirichlet problem for the exterior of the unit ball and to obtain a reflection principle for harmonic functions.

Thus, a natural question is whether for other processes X , involutions I and X -harmonic functions f one may "improve" the function $f \circ I$ by multiplying it by an X -harmonic function k (the same for all functions f), such that the product

$$\mathcal{K}f(x) := k(x) f(I(x))$$

is X -harmonic. The transform $\mathcal{K}f$ will be then called Kelvin transform of X -harmonic functions.

An important result of our paper states that a Kelvin transform of X -harmonic functions exists for any process satisfying a space inversion property. Thus a Kelvin transform of X -harmonic functions exists for much larger classes of processes than isotropic α -stable processes, $\alpha \in (0, 2]$ and Dunkl processes. Moreover, we prove that the Kelvin transform also preserves excessiveness.

Throughout this paper X -harmonic functions are considered, except for Section 2.9, where Kelvin transform's existence is proven for operator-harmonic functions, that is for functions harmonic with respect to the Dynkin operator of X and, in the case of diffusions, functions harmonic with respect to the differential generator of X .

Many other important facts for processes with inversion property are proved, for instance, that the inversion property is preserved by the Doob transform and by bijections. In particular, if a process X has the inversion property, then so have the processes X^h and $I(X)$.

Another goal of this paper is to determine new classes of processes having space inversion properties. We show that this is true for transient processes with absolutely continuous semigroups that can be inverted in time. Recall that a homogeneous Markov

process $((X_t, t \geq 0), (\mathbb{P}_x)_{x \in E})$ is said to have the time inversion property (t.i.p. for short) of degree $\alpha > 0$, if the process $((t^\alpha X_{1/t}, t \geq 0), (\mathbb{P}_x)_{x \in E})$ is homogeneous Markov. The processes with t.i.p. were intensely studied by Gallardo and Yor [21] and Lawi [25]. For transient processes with t.i.p. we construct appropriate space inversions and Kelvin transforms. A remarkable feature of this study is that it gives as a by-product the construction of new excessive functions for processes with t.i.p.

Note that we do not restrict our considerations to self-similar processes, see Section 2.10. In Section 4.6, inversion properties for the Hyperbolic Bessel process and the Hyperbolic Brownian Motion (see e.g. [11], [28], [34], and the references therein) are discussed.

2. INVERSION PROPERTY AND KELVIN TRANSFORM OF X -HARMONIC FUNCTIONS

2.1. State space for a process with inversion property. M. Yor considered in [33] the Brownian motion on $\mathbb{R}^n \cup \{\infty\}$ where ∞ is a point at infinity and $n \geq 3$. He was motivated by the work of L. Schwartz [31] who showed that the n -dimensional Brownian motion $(B_t, t \geq 0)$ on $\mathbb{R}^n \cup \{\infty\}$ is a semimartingale until time $t = +\infty$. Furthermore, the Brownian motion indexed by $[0, \infty]$ looks like a bridge between the initial state B_0 and the ∞ state. Observe now that we can write $\mathbb{R}^n \cup \{\infty\} = \{\mathbb{R}^n \setminus \{0\}\} \cup \{0, \infty\}$. Then $S = \{\mathbb{R}^n \setminus \{0\}\} \cup \{0\}$ is a locally compact space, where 0 is an isolated cemetery point. This makes sense from the point of view of involutions because we can extend the spherical inversion on $\mathbb{R}^n \setminus \{0\}$, by setting $I_{sph}(0) = \infty$ and $I_{sph}(\infty) = 0$, to define an involution of $\mathbb{R}^n \cup \{\infty\}$.

Following this basic case, we are now ready to fix the mathematical setting of this paper. Let E be the Alexandroff one point compactification of an unbounded locally compact space $S \subset \mathbb{R}^n$. Without loss of generality, we assume that $0 \in S$. E is endowed with its topological Borel σ -field.

We assume that $((X_t, t \geq 0); (\mathbb{P}_x)_{x \in E})$ is a standard process, we refer to Section I.9 and Chapter V of [6] for an account on such processes. That is X is a strong Markov process with state space E . The process X is defined on some complete filtered probability space $(\Omega, \mathcal{F}, (\mathcal{F}_t)_{t \geq 0}, (\mathbb{P}_x)_{x \in E})$, where $\mathbb{P}_x(X_0 = x) = 1$, for all $x \in E$. The paths of X are assumed to be right continuous on $[0, \infty)$, with left limits, and are quasi-left continuous on $[0, \zeta)$, where $\zeta = \inf\{s > 0 : X_s \notin \mathring{S} \setminus \{0\}\}$ is the lifetime of X , \mathring{S} being the interior of S . Thus X is absorbed at $\partial S \cup \{0, \infty\}$ and it is sent to 0 whenever X leaves $\mathring{S} \setminus \{0\}$ through $\partial S \cup \{0\}$, and to ∞ otherwise. We furthermore assume that X is irreducible, on E , in the sense that starting from anywhere in $\mathring{S} \setminus \{0\}$ we can reach with positive probability any nonempty open subset of E . This is a multidimensional generalization of the situation considered in [2], where we constructed the dual of a one dimensional regular diffusion living on a compact interval $[l, r]$ and killed upon exiting the interval.

2.2. Excessive and invariant functions and Doob h -transform. In this paper, an important role is played by Doob h -transform, which is defined for an excessive function h . Recall that a Borel function h on E is called *excessive* if $\mathbb{E}_x h(X_t) \leq h(x)$ for all x and t and $\lim_{t \rightarrow 0+} \mathbb{E}_x h(X_t) = h(x)$ for all x . An excessive function is said to be *invariant* if $\mathbb{E}_x h(X_t) = h(x)$ for all x and t . Let $D \subset E$ be an open set. A Borel

function h on E is called *excessive (invariant) on D* if it is excessive(invariant) for the process X killed when it exits D .

Let h be an excessive function and set $E_h = \{x : 0 < h(x) < \infty\}$. Following [14], we can define the Doob h -transform (X_t^h) of (X_t) as the Markov or sub-Markovian process with transition semigroup prescribed by

$$P_t^h(x, dy) = \begin{cases} \frac{h(y)}{h(x)} Q_t^h(x, dy) & \text{if } x \in E_h; \\ 0 & \text{if } x \in E \setminus E_h, \end{cases}$$

where $Q_t^h(x, dy)$ is the semigroup of X killed upon exiting E_h . Observe that if h does not vanish or take the value $+\infty$ inside E then this killed process is X itself.

2.3. Definition of Inversion Property(IP). In this section, we let $\{(X_t)_{t \geq 0}, \mathbb{P}_x\}$, X for short, be a standard Markov process with values in a state space E defined as in Section 2.1. We settle the following definition of the inversion property.

Definition 1. *We say that X has the Inversion Property, for short IP, if there exists an involution $I \neq \text{Id}$ of E and a nonnegative X -excessive function h on E , with $0 < h < +\infty$ in the interior of E , such that the processes $I(X)$ and X^h have the same law, up to a change of time γ_t , i.e.*

$$(2.1) \quad (I(X_{\gamma_t}), t \geq 0) \stackrel{(d)}{=} (X_t^h, t \geq 0),$$

where γ_t is the inverse of the additive functional $A_t = \int_0^t v^{-1}(X_s) ds$ with v being a positive continuous function and X^h is the Doob h -transform of X (killed when it exits the interior of E). We call (I, h, v) the characteristics of the IP.

We propose the terminology "Inversion Property" to stress the fact that the involuted ("inversed") process $I(X)$ is expressed by X itself, up to conditioning (Doob h -transform) and a time change. Another important point is that the IP implies that the dual process X^h is obtained by a path *inversion* transformation $I(X)$ of X , up to a time change.

Inversion properties of stochastic processes were studied in many papers. The IP was studied for Brownian motions in dimension $n \geq 3$ and for the spherical inversion in [33]. The IP with the spherical inversion for isotropic stable processes in \mathbb{R}^n was proved in [9]. The continuous case in dimension 1 was studied in [2]. The spherical inversions of self-similar Markov processes under a reversibility condition have been studied in [3], and, in the particular case of 1-dimensional stable processes in [24].

As pointed out above, the involution involved in all known multidimensional inversion properties (or its variants with a dual process, see [3]), is spherical. On the other hand, in the continuous one-dimensional case, see [2], non-spherical involutions systematically appear. In Sections 3 and 4 of this paper we show that many important multidimensional processes satisfy an IP with a non-spherical involution.

2.4. Harmonic and superharmonic functions and their relation with excessiveness. We first recall the definitions of X -harmonic, regular X -harmonic and X -superharmonic functions on an open set $D \subset E$. For short, we will say "(super)harmonic on D " instead of " X -(super)harmonic on D ", and "(super)harmonic"

instead of " X -(super)harmonic on E ".

A function f is *harmonic on D* if for any open bounded set $B \subset \bar{B} \subset D$, we have

$$\mathbb{E}_x(f(X_{\tau_B}), \tau_B < \infty) = f(x),$$

and is *superharmonic on D* if

$$\mathbb{E}_x(f(X_{\tau_B}), \tau_B < \infty) \leq f(x),$$

for all $x \in B$, where τ_B is the first exit time from B , i.e., $\tau_B = \inf\{s > 0; X_s \notin B\}$. A function f is *regular harmonic on D* if $\mathbb{E}_x(f(X_{\tau_D}), \tau_D < \infty) = f(x)$. By the strong Markov property, regular harmonicity on D implies harmonicity on D .

Let us point out the following relations between superharmonic and excessive functions for a standard Markov process.

Proposition 1. *Suppose that X_t is a standard Markov process with state space E and let $f : E \rightarrow [0, \infty]$ be a non-negative function. Let $D \subset E$ be an open set.*

- (i) *If f is excessive on D then f is superharmonic on D .*
- (ii) *If f is superharmonic on D and $\liminf_{t \rightarrow 0+} \mathbb{E}_x f(X_t) \geq f(x)$, for all $x \in D$, then f is excessive on D .*
- (iii) *Suppose that X is a stochastically continuous process or a Feller process and f is a continuous function on E . Then f is superharmonic on D if and only if f is excessive on D .*

Proof. Without loss of generality we suppose $D = \mathring{E}$, otherwise we consider the process X_t killed when exiting D .

Part (i) is from Proposition [6, II(2.8)] of the book by Blumenthal and Gettoor. Part (ii) is from Corollary [6, II(5.3)], see also Dynkin's book [16, Theorem 12.4].

In order to prove Part (iii), suppose that f is superharmonic, fix $x \in E$ and take a continuous compactly supported function l , $0 \leq l \leq 1$, such that $l(x) = 1$. Since the function f is continuous, the function $k = lf \in \mathcal{C}_0$. Moreover $f \geq k$, so $\mathbb{E}_x(f(X_t)) \geq \mathbb{E}_x k(X_t)$. We get, using the fact that $\mathbb{E}_x k(X_t)$ converges to $\mathbb{E}_x k(X_0)$ when $t \rightarrow 0+$,

$$\liminf_{t \rightarrow 0+} \mathbb{E}_x f(X_t) \geq \lim_{t \rightarrow 0+} \mathbb{E}_x k(X_t) = \mathbb{E}_x k(X_0) = k(x) = f(x),$$

thus the condition from (ii) is fulfilled and f is excessive. □

2.5. Kelvin transform: definition and dual Kelvin transform. We shall define the Kelvin transform for X -harmonic and X -superharmonic functions. In the Kelvin transform, only functions on open subsets $D \subset E$ are considered. For convenience, we suppose them to be equal to 0 on ∂E (otherwise all the integrals in this section should be written on \mathring{E} , cf. [9].)

Definition 2. *Let $I : E \rightarrow E$ be an involution. We say that there exists a Kelvin transform \mathcal{K} on the space of X -harmonic functions if there exists a Borel function $k \geq 0$, on E , with $k|_{\partial E} = 0$, such that the function $x \mapsto \mathcal{K}f(x) = k(x) f(I(x))$ is X -harmonic on $I(D)$, whenever f is X -harmonic on an open set $D \subset E$.*

A useful tool in the study of the Kelvin transform is provided by the dual Kelvin transform \mathcal{K}^* acting on positive measures μ on E and defined formally by

$$(2.2) \quad \int f d(\mathcal{K}^*\mu) = \int \mathcal{K}f d\mu$$

for all positive Borel functions f on E , with $f|_{\partial E} = 0$ and $\mathcal{K}f := k f \circ I$, cf. [30, 9].

Looking at the right-hand side of (2.2) we see that it is equal to $\int f(I(y)) k(y) d\mu(y)$.

Consequently, $\mathcal{K}^*\mu = (k\mu) \circ I^{-1} = (k\mu) \circ I$, i.e. $\mathcal{K}^*\mu$ is simply the image (transport) of the measure $k d\mu$ by the involution I . This shows that $\mathcal{K}^*\mu$ exists and is a positive measure on $I(F)$ for any positive measure μ supported on $F \subset E$.

Former results on Kelvin transform only concern the Brownian Motion (see e.g. [4]), the isotropic α -stable processes and the Dunkl Laplacian and they always refer to the spherical involution $I_{sph}(x) = x/\|x\|^2$.

In the isotropic stable case, let $K_\alpha(f)(x) = \|x\|^{\alpha-n} f(I_{sph}(x))$. Riesz noticed in 1938 (see [30, Section 14, p.13]) the following transformation formula for the Riesz potential $U_\alpha(\mu)$ of a measure μ , in the case $\alpha < n$:

$$K_\alpha(U_\alpha(\mu)) = U_\alpha(K_\alpha^*\mu),$$

see also [9, formula (80), p.115]. It follows that the function $K_\alpha(U_\alpha(\mu))$ is α -harmonic. The α -harmonicity of the Kelvin transform $K_\alpha(f)$ for all α -harmonic functions was proven in [7, 8]. In [9] it was strengthened to regular α -harmonic functions.

In the Dunkl process case, let Δ_k be the Dunkl Laplacian on \mathbb{R}^n (see e.g. [3, Section 4C]). Let $Ku = hu \circ I_{sph}$, where $h(x) = \|x\|^{2-n-2\gamma}$ is the Dunkl-excessive function from [3, Cor.4.7]. In [20, Th.3.1] it was proved that if $\Delta_k u = 0$ then $\Delta_k(Ku) = 0$. In [13] the equivalence between operator-harmonicity $\Delta_k u = 0$ and X -harmonicity of u is announced.

2.6. Kelvin transform for processes with IP. Now we relate the Kelvin transform to the inversion property. In the following result we will prove that a Kelvin transform exists for processes satisfying the IP of Definition 1. The proof is based on the ideas of the proof of [9, Lemma 7] in the isotropic α -stable case.

Theorem 1. *Let X be a standard Markov process. Suppose that X has the inversion property (2.1) with characteristics (I, h, v) . Let $D \subset E_h$ be an open set. Then the Kelvin transformation $\mathcal{K}f(x) = h(x)f(I(x))$ has the following properties:*

- (i) *If f is regular harmonic on $D \subset E_h$ and $f = 0$ on D^c then $\mathcal{K}f$ is regular harmonic on $I(D)$.*
- (ii) *If f is superharmonic on $D \subset E_h$ then $\mathcal{K}f$ is superharmonic on $I(D)$.*

Proof. Recall that $E_h = \{x \in E : 0 < h(x) < \infty\}$ and consider an open set $D \subset E_h$, and $x \in D$. Let ω_D^x be the harmonic measure for the process X departing from x and leaving D , i.e. the probability law of $X_{\tau_D^x}^x$. In the first step of the proof, we show that the Inversion Property of the process \tilde{X} implies the following formula for the dual

Kelvin transform of the harmonic measure (cf. [9, (67)])

$$(2.3) \quad \mathcal{K}^* \omega_D^x = h(x) \omega_{I(D)}^{I(x)}, \quad D \subset E_h, \quad x \in D.$$

In order to show (2.3), we first notice that if $Y_t = I(X_{\gamma_t})$ then

$$\tau_D^Y = \inf\{t \geq 0 : Y_t \notin D\} = \inf\{t \geq 0 : X_{\gamma_t} \notin I(D)\} = A(\tau_{I(D)}^X),$$

so that, for $B \subset E_h$ and $x \in D$, we get

$$\mathbb{P}_x(Y_{\tau_D^Y} \in B, \tau_D^Y < \infty) = \mathbb{P}_{I(x)}(X_{\gamma(A(\tau_{I(D)}^X))} \in I(B), \tau_{I(D)}^X < \infty) = \omega_{I(D)}^{I(x)}(I(B)).$$

By the Inversion Property satisfied by X , the last probability equals

$$\begin{aligned} \mathbb{P}_x(Y_{\tau_D^Y} \in B, \tau_D^Y < \infty) &= \mathbb{P}_x((X^h)_{\tau_D^{X^h}} \in B, \tau_D^{X^h} < \infty) \\ &= \frac{1}{h(x)} \mathbb{E}_x h(X_{\tau_D^X} \mathbf{1}_B(X_{\tau_D^X}), \tau_D^X < \infty) \\ &= \frac{1}{h(x)} \int h(y) \mathbf{1}_B(y) \omega_D^x(dy). \end{aligned}$$

We conclude that

$$\begin{aligned} h(x) \omega_{I(D)}^{I(x)}(I(B)) &= \int h(y) \mathbf{1}_{I(B)}(I(y)) \omega_D^x(dy) \\ &= \int \mathcal{K} \mathbf{1}_{I(B)}(y) \omega_D^x(dy) \\ &= \int \mathbf{1}_{I(B)}(y) (\mathcal{K}^* \omega_D^x)(dy) \end{aligned}$$

and (2.3) follows. Now let $f \geq 0$ be a Borel function and $x \in I(D)$. We have, by definition of \mathcal{K}^* and by (2.3),

$$\begin{aligned} \mathbb{E}_x \mathcal{K} f(X_{\tau_{I(D)}^X}) &= \int \mathcal{K} f d\omega_{I(D)}^x = \int f d(\mathcal{K}^* \omega_{I(D)}^x) \\ &= h(x) \int f d\omega_D^{I(x)} = h(x) \mathbb{E}_{I(x)} f(X_{\tau_D^X}). \end{aligned}$$

Hence, if f is any Borel function such that $\mathbb{E}_z |f(X_{\tau_D^X})| < \infty$ for all $z \in D$, then

$$(2.4) \quad \mathbb{E}_x \mathcal{K} f(X_{\tau_{I(D)}^X}) = h(x) \mathbb{E}_{I(x)} f(X_{\tau_D^X}), \quad x \in I(D).$$

Formula (2.4) implies easily the statements (i) and (ii) of the Theorem. For example, in order to prove (ii), we consider f superharmonic on D . For any open bounded set $B \subset \bar{B} \subset D$ and $x \in I(B)$, we have $\mathbb{E}_{I(x)} f(X_{\tau_B^X}) \leq f(I(x))$. Then (2.4) implies that

$$\mathbb{E}_x \mathcal{K} f(X_{\tau_{I(B)}^X}) \leq h(x) f(I(x)) = \mathcal{K} f(x),$$

so $\mathcal{K} f$ is superharmonic on D . □

Now we show that the Kelvin transform also preserves excessiveness of non-negative functions.

Theorem 2. *Let X be a standard Markov process. Suppose that X has the inversion property (2.1) with characteristics (I, h, v) . Let $D \subset E_h$ be an open set. If $H \geq 0$ is an excessive function on D then the function $\mathcal{K}H$ is excessive on the set $I(D)$.*

Proof. Without loss of generality we suppose $D = \mathring{E}$, otherwise we consider the process X killed when exiting D and replace ζ by the first exit time from D of X .

Let H be excessive for X . We can write

$$\begin{aligned} \varphi(\lambda) &:= \int_0^\infty e^{-\lambda t} \mathbb{E}_x \left[\frac{h(X_t)}{h(x)} \frac{H \circ I(X_t)}{H \circ I(x)}, t < \zeta \right] dt \\ &= \int_0^\infty e^{-\lambda t} \mathbb{E}_x \left[\frac{H \circ I(X_t^h)}{H \circ I(x)}, t < \zeta^h \right] dt, \end{aligned}$$

where ζ and ζ^h are the life times of processes X and X^h respectively. Using (2.1) and making the change of variables $\gamma_t = r$, we get

$$\begin{aligned} \varphi(\lambda) &= \int_0^\infty e^{-\lambda t} \mathbb{E}_{I(x)} \left[\frac{H(X_{\gamma_t})}{H \circ I(x)}, t < A_\zeta \right] dt \\ &= \mathbb{E}_{I(x)} \left[\int_0^\zeta e^{-\lambda A_r} \frac{H(X_r)}{H \circ I(x)} dA_r \right] \\ &= \mathbb{E}_{I(x)} \left[\int_0^{\zeta^H} e^{-\lambda A_r^H} dA_r^H \right] \\ &= \int_0^\infty e^{-\lambda t} \mathbb{E}_{I(x)} [t < A_{\zeta^H}^H] dt. \end{aligned}$$

Using Fubini theorem, we get

$$\lambda \varphi(\lambda) = 1 - \mathbb{E}_x e^{-\lambda A_{\zeta^H}^H} \rightarrow 1 \text{ as } \lambda \rightarrow \infty,$$

because $\mathbb{P}_x(A_{\zeta^H}^H = 0) = \mathbb{P}_x(\zeta^H = 0) = \mathbb{P}_x(\zeta = 0) = 0$. By the injectivity of Laplace transform, we conclude that

$$\mathbb{E}_x \left[\frac{h(X_t)}{h(x)} \frac{H \circ I(X_t)}{H \circ I(x)}, t < \zeta \right] = \mathbb{E}_x [t < A_{\zeta^H}^H] \leq 1 \text{ for a.e. } t \geq 0.$$

Thus, we have the supermartingale property of $h(X)H \circ I(X)$. We also get that $\lim_{\lambda \rightarrow \infty} \lambda \varphi(\lambda) = 1$. By the Tauberian theorem, we get that

$$\lim_{t \rightarrow 0^+} \mathbb{E}_x \left[\frac{h(X_t)}{h(x)} \frac{H \circ I(X_t)}{H \circ I(x)}, t < \zeta \right] = 1.$$

We have proven that $h H \circ I$ is excessive. □

Remark 1. *Suppose that the process X is stochastically continuous or a Feller process. Then by Proposition 1(iii) we see that Theorem 1(ii) and Theorem 2 coincide for continuous functions f and H . Without additional conditions on X , f and H , Theorem 1(ii) and Theorem 2 require independent proofs.*

Corollary 1. *Suppose that X has the inversion property (2.1) with characteristics (I, h, v) . Then there exists $c > 0$ such that the function $h h \circ I = c$ is constant on E .*

By considering, from now on, the dilated function h/\sqrt{c} in place of h , we have

$$(2.5) \quad h \circ I = 1/h \quad \text{and} \quad v \circ I = 1/v.$$

Proof. Assume that X satisfies (2.1). Then, for any Borel measurable function F and $x \in E$, we can write

$$\begin{aligned} \psi(\lambda) &:= \int_0^\infty e^{-\lambda t} \mathbb{E}_x \left[\frac{h(X_t)}{h(x)} \frac{h \circ I(X_t)}{h \circ I(x)} F(X_t), t < \zeta \right] dt \\ &= \int_0^\infty e^{-\lambda t} \mathbb{E}_x \left[\frac{h \circ I(X_t^h)}{h \circ I(x)} F(X_t^h), t < \zeta^h \right] dt. \end{aligned}$$

By using (2.1) and making the change of variables $\gamma_t = r$, we obtain

$$\begin{aligned} \psi(\lambda) &= \int_0^\infty e^{-\lambda t} \mathbb{E}_{I(x)} \left[\frac{h(X_{\gamma_t})}{h \circ I(x)} F(I(X_{\gamma_t})), t < A_\zeta \right] dt \\ &= \mathbb{E}_{I(x)} \left[\int_0^\zeta e^{-\lambda A_r} \frac{h(X_r)}{h \circ I(x)} F(I(X_r)) dA_r \right] \\ &= \mathbb{E}_{I(x)} \left[\int_0^{\zeta^H} e^{-\lambda A_r^h} F(I(X_r^h)) dA_r^h \right]. \end{aligned}$$

Let $M_r = \int_0^r (v \circ I(X_{\gamma_s}))^{-1} ds$ and let m_r be the inverse of M_r . Using again (2.1) and substituting $M_r = v$, we get

$$\begin{aligned} \psi(\lambda) &= \mathbb{E}_x \left[\int_0^{A_\zeta} e^{-\lambda M_r} F(X_{\gamma_r}) dM_r \right] \\ &= \mathbb{E}_x \left[\int_0^\zeta e^{-\lambda v} F(X_{\gamma_{m_v}}) dv \right] \end{aligned}$$

By the injectivity of Laplace transform, we obtain

$$\mathbb{E}_x \left[\frac{h(X_t)}{h(x)} \frac{h \circ I(X_t)}{h \circ I(x)} F(X_t), t < \zeta \right] = \mathbb{E}_x [F(X_{\gamma_{m_t}}); t < \zeta]$$

for almost every $t > 0$.

By Theorem 2, the function $h \circ I$ is excessive. The last equality implies that X has the same distribution as the Doob transform $X^{h \circ I}$ time changed. This is possible only if $h \circ I$ is constant and $\gamma_{m_t} = t$, for $t > 0$. We easily check that the inverse of γ_{m_t} is $M_{A_t} = \int_0^t (v \circ I(X_s))^{-1} ds$. So $M_{A_t} = t$, $t \geq 0$, holds if and only if $v \circ I = 1/v$. Hence, equations (2.5) are proved. \square

We point out now the following bijective property of the Kelvin transform.

Proposition 2. *Suppose that X has the inversion property (2.1) with characteristics (I, h, v) . Let \mathcal{K} be the Kelvin transform. Then*

- (i) \mathcal{K} is an involution operator on the space of X -harmonic (X -superharmonic) functions i.e. $\mathcal{K} \circ \mathcal{K} = \text{Id}$.
- (ii) Let $D \subset E$ be an open set. \mathcal{K} is a one-to-one correspondence between the set of X -harmonic functions on D and the set of X -harmonic functions on $I(D)$.

Proof. The first formula of (2.5) implies by a direct computation that $\mathcal{K}(\mathcal{K}f) = f$. Then (ii) is obvious. \square

2.7. Invariance of IP by a bijection and by a Doob transform. We shall now give some general properties of spatial inversions. We start with the following proposition which is useful when proving that a process has IP. Its proof is simple and hence is omitted.

Proposition 3. *Suppose that X has the inversion property (2.1) with characteristics (I, h, v) . Assume that $\Phi : E \mapsto F$ is a bijection. Then the mapping $J = \Phi \circ I \circ \Phi^{-1}$ is an involution on F . Furthermore, the process $Y = \Phi(X)$ has IP with characteristics $(J, h \circ \Phi^{-1}, v \circ \Phi^{-1})$.*

In the following result we prove that we can extend the inversion property of a process on a state space E to an inversion property for the processes conditioned not to exit a subset F of E .

Proposition 4. *Suppose that X has the inversion property (2.1) with characteristics (I, h, v) .*

Let $F \subseteq E$ be such that $I(F) = F$ and suppose that there exists an excessive function $H : F \rightarrow \mathbb{R}_+$ for X killed when it exits F . Consider $Y = X^H$, the Doob H -transform of X . Then the process Y has the IP with characteristics (I, \tilde{h}, v) , with $\tilde{h} = \mathcal{K}H/H$, where $\mathcal{K}H = hH \circ I$ is the Kelvin transform of H .

Proof. To simplify notation, set $Z = X^h$ and denote by γ_t^H the inverse of the additive functional $A_t^H(t) = \int_0^t \frac{ds}{v(X_s^H)}$. Below, using the properties of a time-changed Doob transform in the first equality and the IP for X in the second equality, we can write for all test functions g

$$\begin{aligned} \mathbb{E}_x[g(I(X_{\gamma_t^H}^H)), t < A_\infty^H] &= \mathbb{E}_x[g(I(X_{\gamma_t}) \frac{H \circ I(I(X_{\gamma_t}))}{H \circ I(I(x))}), t < A_\infty] \\ &= \mathbb{E}_{I(x)}[g(Z_t) \frac{H \circ I(Z_t)}{H \circ I(I(x))}, t < A_\infty] \\ &= \mathbb{E}_{I(x)}[g(X_t) \frac{H \circ I(X_t)h(X_t)}{H \circ I(I(x))h(I(x))}, t < A_\infty] \\ &= \mathbb{E}_{I(x)}[g(X_t) \frac{\mathcal{K}H(X_t)}{\mathcal{K}H(I(x))}, t < A_\infty]. \end{aligned}$$

By Theorem 2, the function $\mathcal{K}H$ is X -excessive, so the Doob transform $X^{\mathcal{K}H}$ is well defined. Thus the processes $(I(X_{\gamma_t^H}^H))$ and $(X_t^{\mathcal{K}H})$ are equal in law. We have $X = Y^{1/H}$, so $X_t^{\mathcal{K}H} = Y_t^{\mathcal{K}H/H}$, and the IP for the process Y follows. \square

The aim of the following result is to show that processes X^h and $I(X)$ inherit IP from the process X and to determine the characteristics of the corresponding inversions.

Proposition 5. *Suppose that X has the inversion property (2.1) with characteristics (I, h, v) . Then the following inversion properties hold:*

- (i) *The process X^h has IP with characteristics (I, h^{-1}, v) .*

(ii) *The process $I(X)$ has IP with characteristics (I, h^{-1}, v^{-1}) .*

Proof. (i) Proposition 1 implies that $\mathcal{K}h/h = 1/h$. The assertion follows from an application of Proposition 4.

(ii) Proposition 3 implies that $I(X)$ has IP with characteristics $(I, h \circ I, v \circ I)$. We conclude using formulas (2.5). \square

2.8. Dual inversion property and Kelvin transform. There are other types of inversions which involve weak duality (see the books [6] or [14] for a survey on duality). Two E -valued Markov processes $\{(X_t)_{t \geq 0}, \mathbb{P}_x\}$ and $\{(\hat{X}_t)_{t \geq 0}, \hat{\mathbb{P}}_x\}$, with semigroups $(P_t)_{t \geq 0}$ and $(\hat{P}_t)_{t \geq 0}$ respectively, are in weak duality with respect to some σ -finite measure $m(dx)$ if for all positive measurable functions f and g , we have

$$(2.6) \quad \int_E g(x) P_t f(x) m(dx) = \int_E f(x) \hat{P}_t g(x) m(dx).$$

The following definition is analogous to Definition 1, but in place of X on the right-hand side we put a dual process \hat{X} .

Definition 3. *Let $\{(X_t)_{t \geq 0}, \mathbb{P}_x\}$ be a standard Markov process on E . We say that X has the Dual Inversion Property, for short DIP, if there exists an involution $I \neq \text{Id}$ of E and a nonnegative \hat{X} -harmonic function \hat{h} on E , with $0 < \hat{h} < +\infty$ in the interior of E , such that the processes $I(X)$ and $\hat{X}^{\hat{h}}$ have the same law, up to a change of time γ_t , i.e.*

$$(2.7) \quad (I(X_{\gamma_t}), t \geq 0) \stackrel{(d)}{=} (\hat{X}_t^{\hat{h}}, t \geq 0),$$

where γ_t is the inverse of the additive functional $A_t = \int_0^t v^{-1}(X_s) ds$ with v being a positive continuous function, \hat{X} is in weak duality with X with respect to the measure $m(dx)$, where $m(dx)$ is a reference measure on E , and $\hat{X}^{\hat{h}}$ is the Doob \hat{h} -transform of \hat{X} (killed when it exits E). We call (I, \hat{h}, v, m) the characteristics of the DIP.

Remark 2. *We notice that if X is self-dual then IP and DIP are equivalent.*

Remark 3. *Self-similar Markov processes having the DIP with spherical inversions were studied in [3]. Non-symmetric 1-dimensional stable processes were also investigated in [24] and they provide examples of processes that have the DIP, while no IP is known for them.*

Theorem 3. *Let X have DIP property (2.7). There exists the following Kelvin transform:*

Let f be a regular harmonic (resp. superharmonic, excessive) function for the process X . Then $\hat{\mathcal{K}}f(x) := \hat{h}(x)f(I(x))$ is regular harmonic (resp. superharmonic, excessive) for the process \hat{X} .

Proof. The proof is similar to the proofs of Theorem 1 and of Theorem 2. \square

Example 1. Let X be a stable process with $\alpha \geq 1$ which is not spectrally one-sided. Let $\rho^- = P(X_1 < 0)$, $\rho^+ = P(X_1 > 0)$. Let $x_+ = \max(0, x)$. The function $H(x) = x_+^{\alpha\rho^-}$ is X -invariant (see [12]), so also superharmonic on $(0, \infty)$. Moreover $H(0) = 0$. Theorem 1 applied to Corollary 2 of [3] implies the existence of the Kelvin transform for regular α -harmonic functions on \mathbb{R}^+ , vanishing at 0. Thus

$$\hat{K}H(x) = \pi(-1)|x|^{\alpha\rho^+-1}\mathbf{1}_{\mathbb{R}^-}(x)$$

is regular α -harmonic on \mathbb{R}^- . We conclude, by considering $-X$ in place of X , that the function $G(x) = x_+^{\alpha\rho^- - 1}$ is superharmonic on \mathbb{R}^+ . It is known (see [12]) that $G(x)$ is excessive on $(0, \infty)$. It is interesting to see that the functions H and G are related by the Kelvin transform.

2.9. IP for X and Kelvin transform for operator-harmonic functions. In analytical potential theory, the term "harmonic function" usually means $Lf = 0$, for some second order differential operator L . Note that for a Feller process X with generator L_X and state space E , if E is unbounded then there are no non-zero L_X -harmonic functions which are in the domain $D(L_X)$ of L_X , i.e. if $f \in D(L_X) \subset \mathcal{C}_0$ and $L_X f = 0$ then $f=0$. However, this is no longer true if, for a standard Markov process X , instead of its generator, we consider its Dynkin characteristic operator A_X

$$(2.8) \quad A_X f(x) = \lim_{U \searrow \{x\}} \frac{\mathbb{E}_x f(X_{\tau_U}) - f(x)}{\mathbb{E}_x \tau_U},$$

with U any sequence of decreasing bounded open sets such that $\cap U = \{x\}$ (see [16], where A_X is denoted by \mathcal{U} .) We stress that the Dynkin characteristic operator exists and characterizes all standard Markov processes. For diffusions, we may consider the differential generator L of X , defined (see [16], 5.19), as the restriction of A_X to \mathcal{C}_2 . L is the second order elliptic differential operator coinciding with the generator L_X of X on its domain $D(L_X) \subset \mathcal{C}_0 \cap \mathcal{C}_2$.

Definition 4. Define the following:

- (a) For any standard Markov process X , a function f on $D \subset E$ is called **Dynkin-harmonic** on D if $A_X f = 0$ on D .
- (b) For a diffusion X on \mathbb{R}^n , a function f on $D \subset E$ is called **differential generator harmonic** on D if $Lf = 0$ on D .

In both cases (a) and (b), harmonicity is defined by means of operators which is the reason why such functions are called *operator-harmonic functions*. The main aim of this section is to prove that the Kelvin transform preserves, under some natural conditions, the operator-harmonic property. We will need the following proposition. We provide a proof because we have not found a reference where both assertions (i) and (ii) are proved.

Proposition 6. Let X be a standard Markov process with $X_0 = x$.

- (i) If φ is a homeomorphism from E onto E then the Dynkin operator of the process $\varphi(X)$ is expressed in terms of the Dynkin operator of the process X in the following way

$$A_{\varphi(X)} f(x) = A_X(f \circ \varphi)(\varphi^{-1}(x)).$$

for functions from the domain of A_X and $A_{\varphi(X)}$.

- (ii) Let $h \geq 0$ be P_t^X -excessive. The Dynkin operator A^h of the Doob h -transform X^h of X is given by the formula:

$$A^h(f) = h^{-1}A_X(hf)$$

Proof. (i) This assertion is straightforward by making use of the definition of Dynkin's operator.

- (ii) Let $\lambda > 0$. The λ -potential of the h -process X^h equals

$$U_\lambda^h(x, dy) = \frac{h(y)}{h(x)}U_\lambda^X(x, dy)$$

where U_λ^X is the λ -potential of X .

Let B be the Dynkin operator of the process X^h . Define

$$K_\lambda f = h^{-1}A_X(hf) - \lambda f$$

To prove (ii) it is enough to show that $B - \lambda Id = K_\lambda$. This in turn will be proved if we show that

$$K_\lambda U_\lambda^h = -Id$$

(since $(B - \lambda Id)U_\lambda^h = -Id$, the λ -potential operator U_λ^h is a bijection from \mathcal{C}_0 into the domain of B and $B - \lambda Id$ is the unique inverse operator). We compute, for a test function f ,

$$\begin{aligned} K_\lambda U_\lambda^h f &= \frac{1}{h(x)}A_X\left[h(x) \int \frac{h(y)}{h(x)}U_\lambda^X(x, y)f(y)dy\right] - \lambda \int \frac{h(y)}{h(x)}U_\lambda^X(x, y)f(y)dy \\ &= \frac{1}{h(x)}(A_X - \lambda Id)U_\lambda^X(hf) \\ &= \frac{1}{h(x)}(-h(x)f(x)) = -f(x), \end{aligned}$$

hence $K_\lambda U_\lambda^h = -Id$. □

Theorem 4. *Suppose that the process X satisfies IP for an involution I and a positive excessive function h . Then the Kelvin transform preserves A_X -harmonicity, i.e., for any open set $D \subset E$, if H is an A_X -harmonic function on D then the function $x \mapsto \mathcal{K}H(x) = h(x)H(I(x))$ is A_X -harmonic on $I(D)$.*

Proof. Let H be A_X -harmonic. Denote $\tilde{H} = H \circ I$. Let A^I denote the Dynkin operator of the process $I(X)$. By Proposition 6(i) we have

$$A^I(\tilde{H}) = A_X(\tilde{H} \circ I) \circ I^{-1} = (A_X H) \circ I = 0.$$

Thus \tilde{H} is A^I -harmonic on $I(D)$. By IP, this is equivalent to be A^h -harmonic (the Dynkin operators of $I(X)$ and X^h differ by a positive factor corresponding to the time change, see [16], Th. 10.12). Consequently $A^h(\tilde{H}) = 0$. We now use Proposition 6(ii) in order to conclude that $A_X(h\tilde{H}) = 0$. Thus $h\tilde{H} = hH \circ I$ is A_X -harmonic on $I(D)$ whenever H is A_X -harmonic on D . □

Corollary 2. *Let X be a diffusion on \mathbb{R}^n having IP with characteristics (I, h, v) where I and h are continuous. If f is twice continuously differentiable on D and $Lf = 0$ then $L(\mathcal{K}f) = 0$.*

Proof. By Theorem 4, we have $A_X(\mathcal{K}f) = 0$. By the continuity of f, I and h , the function $\mathcal{K}f$ is continuous. Theorem 5.9 of [16] then implies that $\mathcal{K}f$ is twice continuously differentiable and that $L(\mathcal{K}f) = 0$. \square

We end this section by pointing out relations between X -harmonic functions on a subset D of E and Dynkin A_X -harmonic functions on D .

Proposition 7. *Let X be a standard Markov process, $D \subset E$ and $f : D \rightarrow \mathbb{R}$. The following assertions hold true.*

- (i) *If f is X -harmonic then $A_X f = 0$, on D .*
- (ii) *If X is a diffusion and f is continuous then f is X -harmonic if and only if it is A_X -harmonic, on D . Moreover, this happens if and only if f is L -harmonic on D .*

Proof. Part (i) is evident by definition (2.8) of A_X . It gives the "only if" part of the first part of (ii). If f is continuous and A_X -harmonic on D then, by Theorem 5.9 of [16], f is twice continuously differentiable and $Lf = 0$ on D . A strengthened version of Dynkin's formula [16, (13.95)] implies that if $Lf = 0$ on D then f is X -harmonic on D . This completes the proof of (ii). \square

Remark 4. *Theorem 6 and Proposition 7(ii) give another "operator-like" proof of Theorem 1 when X is a one dimensional diffusion and for continuous X -harmonic functions, see Remark 7 in [2].*

2.10. Inversion property and self-similarity. We end this Section by a discussion on the relations between the IP and self-similarity. In [2] the IP of non necessarily self-similar one-dimensional diffusions is proven and corresponding non-spherical involutions are given. There are h -transforms of Brownian motion on intervals which are not self-similar Markov processes. On the other hand IP is preserved by conditioning, see Proposition 4, but self-similarity is not.

This shows that self-similar Feller processes are not the only ones having the inversion property with the spherical inversion and a harmonic function being a power of the modulus.

3. INVERSION OF PROCESSES HAVING THE TIME INVERSION PROPERTY

3.1. Characterization and regularity of processes with t.i.p. Now let us introduce a class of processes that can be inverted in time. Let S be a non trivial cone of \mathbb{R}^n , for some $n \geq 1$, i.e. $S \neq \emptyset$, $S \neq \{0\}$ and $x \in S$ implies $\lambda x \in S$ for all $\lambda \geq 0$. We take E to be the Alexandroff one point compactification $S \cup \{\infty\}$ of S . Let $((X_t, t \geq 0); (\mathbb{P}_x)_{x \in E})$ be a homogeneous Markov process on E absorbed at $\partial S \cup \{\infty\}$. X is said to have the *time inversion property* (t.i.p. for short) of degree $\alpha > 0$, if the process $((t^\alpha X_{1/t}, t \geq 0), (\mathbb{P}_x)_{x \in E})$ is a homogeneous Markov process. Assume that the

semigroup of X is absolutely continuous with respect to the Lebesgue measure, and write

$$(3.9) \quad p_t(x, dy) = p_t(x, y)dy, \quad x, y \in \mathring{S}.$$

The process $(t^\alpha X_{\frac{1}{t}}, t > 0)$ is usually an inhomogenous Markov process with transition probability densities $q_{s,t}^{(x)}(z, y)$, for $s < t$ and $x, y \in S$, satisfying

$$\mathbb{E}_x[f(t^\alpha X_{\frac{1}{t}}) | s^\alpha X_{\frac{1}{s}} = z] = \int f(y)q_{s,t}^x(z, y) dy$$

where

$$(3.10) \quad q_{s,t}^{(x)}(a, b) = t^{-n\alpha} \frac{p_{\frac{1}{t}}(x, \frac{b}{t^\alpha})p_{\frac{1}{s}-\frac{1}{t}}(\frac{b}{t^\alpha}, \frac{a}{s^\alpha})}{p_{\frac{1}{s}}(x, \frac{a}{s^\alpha})}.$$

We shall now extend the setting and conditions considered by Gallardo and Yor in [21]. Suppose that

$$(3.11) \quad p_t(x, y) = t^{-n\alpha/2} \phi\left(\frac{x}{t^{\alpha/2}}, \frac{y}{t^{\alpha/2}}\right) \theta\left(\frac{y}{t^{\alpha/2}}\right) \exp\left\{-\frac{\rho(x) + \rho(y)}{2t}\right\},$$

where the functions $\phi : \mathring{S} \times \mathring{S} \rightarrow \mathbb{R}_+$ and $\theta, \rho : \mathring{S} \rightarrow \mathbb{R}_+$ satisfy the following properties: for $\lambda > 0$ and $x, y \in \mathring{S}$

$$(3.12) \quad \begin{cases} \phi(\lambda x, y) = \phi(x, \lambda y), \\ \rho(\lambda x) = \lambda^{2/\alpha} \rho(x), \\ \theta(\lambda x) = \lambda^\beta \theta(x). \end{cases}$$

Under conditions (3.11) and (3.12), using (3.10) we immediately conclude that X has the time inversion property. We need also the following technical condition

$$(3.13) \quad (\rho^{1/2}(X_t), t \geq 0) \quad \text{is a Bessel process of dimension } (\beta + n)\alpha$$

or is a Doob transform of it, up to time scaling $t \rightarrow ct, c > 0$.

To simplify notations let us settle the following definition of a regular process with t.i.p.

Definition 5. *A regular process with t.i.p. is a Markov process on $S \cup \{\infty\}$ where S is a cone in \mathbb{R}^n for some $n \geq 1$, with an absolutely continuous semigroup with densities satisfying conditions (3.11)–(3.13) and $\rho(x) = 0$ if and only if $x = 0$.*

The requirement of *regularity* for a process with t.i.p. is not very restrictive; all the known examples of processes with t.i.p. satisfy it. In case when $S = \mathbb{R}^n$, the authors of [21] and [25] showed that if the above densities are twice differentiable in the space and time then X has time inversion property if and only if it has a semigroup with densities of the form (3.11), or if X is a Doob h -transform of a process with a semigroup with densities of the form (3.11). It is proved in [1] that when $\mathring{S} = \mathbb{R}$ or $(-\infty, 0)$ or $(0, +\infty)$ and the semigroup is conservative, i.e. $\int p_t(x, dy) = 1$, and absolutely continuous with densities which are twice differentiable in time and space, then (3.13) is necessary for the t.i.p. to hold. A similar statement is proved in [5] in higher dimensions under the additional condition that ρ is continuous on $S = \mathbb{R}^n$ and $\rho(x) = 0$ if and only if $x = 0$.

Remark 5. *Under the conservativeness condition, it is an interesting problem to find a way to read the dimension of the Bessel process $\rho^{1/2}(X)$, in (3.13), from (3.11). If we could do that then we would be able to replace condition (3.13) with the weaker condition that $\rho(X)$ is a strong Markov process. Indeed, it was proved in [1] that the only processes having the t.i.p. living on $(0, +\infty)$ are α powers of Bessel processes and their h -transforms. $\rho(X)$ has the time inversion property and so, if it is Markov then it is the power of a Bessel process or a process in h -transform with it.*

3.2. A natural involution and IP for processes with t.i.p.

Proposition 8. *The map I defined for $x \in S \setminus \{0\}$ by $I(x) = x\rho^{-\alpha}(x)$, and by $I(0) = \infty$, is an involution of E . Moreover, the function $x \rightarrow x\rho^{-\nu}(x)$ is an involution on $S \setminus \{0\}$ if and only if $\nu = \alpha$.*

Proof. It is readily checked that $I \circ I = I$ by using the homogeneity property of ρ from (3.12). \square

We know by [21, 25] that a regular process with t.i.p. X is a self-similar Markov process, thus so is $I(X)$. That's why $I(x) = x\rho^{-\alpha}(x)$ is a natural involution for such an X .

We now compute the potential of the involuted process $I(X)$.

Proposition 9. *Assuming that X is transient for compact sets, the potential of $I(X)$ is given by*

$$(3.14) \quad U^{I(X)}(x, dy) = V(y) \frac{h(y)}{h(x)} U^X(x, dy),$$

where $h(x) = \rho(x)^{1-(\beta+n)\alpha/2}$, $V(y) = \text{Jac}(I)(y)\rho(y)^{n\alpha-2}$ and $\text{Jac}(I)$ is the modulus of the Jacobi determinant of I .

Proof. Recall that X is transient for compact sets if and only if its potential $U^X(x, y)$ is finite. The potential kernel of $I(X)$ is given by

$$U^I(x, y) = \int_0^\infty p_t(I(x), I(y)) \text{Jac}(I(y)) dt.$$

First we compute $p_t^{I(X)}(x, y) = p_t(I(x), I(y)) \text{Jac}(I(y))$. According to formula (3.11) we find

$$p_t^{I(X)}(x, y) = t^{-(n+\beta)\alpha/2} \phi(x, \frac{y}{(t\rho(x)\rho(y))^\alpha}) \rho^{-\alpha\beta}(y) \theta(y) \exp[-\frac{\rho(x) + \rho(y)}{t\rho(x)\rho(y)}] \text{Jac}(I(y)).$$

Making the substitution $t\rho(x)\rho(y) = s$ we obtain easily formula (3.14). \square

We are now ready to prove the main result of this section.

Theorem 5. *Suppose that X is a transient regular process with t.i.p. Then X has the IP with characteristics (I, h, ν) with $I(x) = x\rho^{-\alpha}(x)$, $h(x) = \rho(x)^{1-(\beta+n)\alpha/2}$ and $\nu(x) = (\text{Jac}(I)(x))^{-1}\rho(x)^{2-n\alpha}$ where $\text{Jac}(I)$ is the modulus of the Jacobi determinant of I .*

Moreover, if X is the Doob h -transform of a regular process Z having IP with characteristics (I, h, v) , then X has the IP with characteristics I and v , and excessive function $\mathcal{K}_Z(H)/H$.

Proof. First suppose that the process X is regular, so its semigroup has the form (3.11). We use the fact that if two transient Markov processes have equal potentials $U^X = U^Y < \infty$ then the processes X and Y have the same law (compare with [19], page 356 or [27], Theorem T8, page 205).

Remind that the function $h(x) = x^{2-\delta}$ is BES(δ)-excessive, see e.g. [3, Cor.4.4]. This can also be explained by the fact that if $(R_t, t \geq 0)$ is a Bessel process of dimension δ then $(R_t^{2-\delta}, t \geq 0)$ is a local martingale (it is a strict local martingale when $\delta > 2$), cf. [18].

Using condition (3.13), we see that the function $h(x) = \rho(x)^{1-(\beta+n)\alpha/2}$ appearing in (3.14) is X -excessive. Thus the process $I(X)$ is a Doob h -transform of the process X when time-changed appropriately.

In the case when $X = Z^H$ is a Doob H -transform of Z whose semigroup has the form (3.11), we use Proposition 4. \square

Remark 6. A remarkable consequence of Theorem 5 is that it gives as a by-product the construction of new excessive functions which are functions of $\rho(X)$ and not of $\theta(X)$. For example, for Wishart processes, the known harmonic functions are in terms of $\det(X)$ and not of $\text{Tr}(X)$, see [15] and Subsection 4.3 below.

In view of applications of Theorem 5, the aim of the next result is to give a sufficient condition for X to be transient for compact sets.

Proposition 10. Assume that ϕ satisfies

- (a) $\phi(x, y/t) \approx c_1(x, y)t^{\gamma_1(x, y)}e^{-\frac{c_2(x, y)}{t}}$ as $t \rightarrow 0$;
- (b) $\phi(x, y/t) \approx c_3(x, y)t^{\gamma_2(x, y)}$ as $t \rightarrow \infty$;

where c_1, c_2, c_3 and γ_1, γ_2 are functions of x and y . If

- (1) $\rho \geq 0$;
- (2) $\rho(x) + \rho(y) - 2c_2(x, y) > 0$ for all $x, y \in E$;
- (3) $\gamma_1(x, y) > -1 + \frac{(n+\beta)\alpha}{2} > \gamma_2(x, y)$;

then X is transient for compact sets.

Proof. We easily check that the integral for $U^X(x, y)$ converges if the hypotheses of the proposition are satisfied. \square

3.3. Self-duality for processes with t.i.p.

Proposition 11. Suppose that $\phi(x, y) = \phi(y, x)$ for $x, y \in E$. Then the process X is self-dual with respect to the measure

$$m(dx) = \theta(x)dx.$$

Proof. Formula (3.11) implies that the kernel

$$\tilde{p}_t(x, y) := p_t(x, y)\theta(x)$$

is symmetric, i.e. $\tilde{p}_t(x, y) = \tilde{p}_t(y, x)$. It follows that for all $t \geq 0$ and bounded measurable functions $f, g : E \rightarrow \mathbb{R}^+$, we have

$$\int f(x) \mathbb{E}_x(g(X_t)) m(dx) = \int \mathbb{E}_x(f(X_t)) g(x) m(dx).$$

□

By Proposition 11, all classical processes with t.i.p. considered in [21] and [25] are self-dual: Bessel processes and their powers, Dunkl processes, Wishart processes, non-colliding particle systems (Dyson Brownian motion, non-colliding BESQ particles).

Remark 7. Let $n \geq 2$ and let X be a transient regular process with t.i.p., with non-symmetric function ϕ . By Theorem 5, X has an IP, whereas a DIP for X is unknown. This observation, together with Remark 3 shows that in the theory of space inversions of stochastic processes, both IP and DIP must be considered.

4. APPLICATIONS

4.1. Free scaled power Bessel processes. Let $R^{(\nu)}$ be a Bessel process with index $\nu > -1$ and dimension $\delta = 2(\nu + 1)$. A time scaled power Bessel process is realized as $((R_{\sigma^2 t}^{(\nu)})^\alpha, t \geq 0)$, where $\sigma > 0$ and $\alpha \neq 0$ are real numbers. Let $\underline{\nu}$ and $\underline{\sigma}$ be vectors of real numbers such that $\sigma_i > 0$ and $\nu_i > -1$ for all $i = 1, 2, \dots, n$, and let $R^{(\nu_1)}, R^{(\nu_2)}, \dots, R^{(\nu_n)}$ be independent Bessel processes of index $\nu_1, \nu_2, \dots, \nu_n$, respectively. We call the process X defined, for a fixed $t \geq 0$, by

$$X_t := \left((R_{\sigma_1^2 t}^{(\nu_1)})^\alpha, (R_{\sigma_2^2 t}^{(\nu_2)})^\alpha, \dots, (R_{\sigma_n^2 t}^{(\nu_n)})^\alpha \right)$$

a free scaled power Bessel process with indexes $\underline{\nu}$, scaling parameters $\underline{\sigma}$ and power α , for short FSPBES($\underline{\nu}, \underline{\sigma}, \alpha$). If we denote by $q_t^\nu(x, y)$ the density of the semi-group of a BES(ν) with respect to the Lebesgue measure, found in [29], then the densities of a FSPBES($\underline{\nu}, \underline{\sigma}, \alpha$) are given by

$$\begin{aligned} (4.15) \quad p_t(x, y) &= \prod_{i=1}^n (1/\alpha) y_i^{\frac{1}{\alpha}-1} q_{\sigma_i^2 t}^{\nu_i}(x_i^{1/\alpha}, y_i^{1/\alpha}) \\ &= \prod_{i=1}^n (1/\alpha) y_i^{\frac{1}{\alpha}-1} \frac{x_i^{1/\alpha}}{\sigma_i^2 t} \left(\frac{y_i}{x_i} \right)^{(\nu_i+1)/\alpha} I_{\nu_i} \left(\frac{(x_i y_i)^{1/\alpha}}{\sigma_i^2 t} \right) e^{-\frac{x_i^{2/\alpha} + y_i^{2/\alpha}}{2\sigma_i^2 t}}. \end{aligned}$$

From (4.15) we read that $p_t(x, y)$ takes the form (3.11) with

$$(4.16) \quad \begin{cases} \phi(x, y) = \prod_{i=1}^n \frac{I_{\nu_i} \left(\frac{(x_i y_i)^{1/\alpha}}{\sigma_i^2} \right)}{\left((x_i y_i)^{1/\alpha} / \sigma_i^2 \right)^{\nu_i}}, \\ \rho(x) = \sum_{i=1}^n x_i^{2/\alpha} / \sigma_i^2, \\ \theta(y) = \frac{1}{\alpha^n (\prod_{i=1}^n \sigma_i)^\alpha} \prod_{i=1}^n \left(\frac{y_i}{|\sigma_i|^\alpha} \right)^{2(1+\nu_i)/\alpha-1}. \end{cases}$$

It follows that the degree of homogeneity of θ is $\beta = 2(n + \sum_{i=1}^n \nu_i) / \alpha - n$. If X is a FSPBES($\underline{\nu}, \underline{\sigma}, \alpha$) then clearly $\rho^{1/2}(X)$ is a Bessel process of dimension $n\bar{\delta} = 2n(\bar{\nu} + 1)$, where $\bar{\delta} = (\sum_1^n \delta_i) / n$ and $\bar{\nu} = (\sum_1^n \nu_i) / n$. Note that with this notation $\bar{\nu} = \frac{\alpha}{2n}(\beta + n) - 1$

and $\bar{\delta} = \frac{\alpha}{n}(\beta+n)$. We deduce that $\rho(X)$ is point-recurrent if and only if $0 < 2n(\bar{\nu}+1) < 2$, i.e., $0 < n\bar{\delta} < 2$.

Interestingly, the distribution of X_t , for a fixed $t > 0$, depends on the vector $\underline{\nu}$ only through the mean $\bar{\nu}$. Furthermore, we can recover the case $\sigma_1 \neq 1$ from the case $\sigma_1 = 1$ by using the scaling property of Bessel processes. In other words, for a fixed time $t > 0$, the class of all free power scaled Bessel processes yields an $n + 1$ -parameter family of distributions.

Corollary 3. *Let X be a FSPBES($\underline{\nu}, \underline{\sigma}, \alpha$). If $n\bar{\delta} = 2n(\bar{\nu} + 1) > 2$ then X is transient and has the Inversion Property with characteristics*

$$I(x) = \frac{x}{\rho^\alpha(x)}, \quad h(x) = \rho^{1-\frac{n\bar{\delta}}{2}}(x), \quad v(x) = \rho(x)^2,$$

where $\rho(x)$ is given by (4.16).

Proof. We quote from ([26], p.136) that the modified Bessel function of the first kind I_ν has the asymptotics for $\nu \geq 0$

$$I_\nu(x) \sim \frac{x^\nu}{2^\nu \Gamma(1 + \nu)}, \quad \text{as } x \rightarrow 0$$

and

$$I_\nu(x) \sim \frac{e^x}{\sqrt{2\pi x}}, \quad \text{as } x \rightarrow \infty.$$

From the above and (4.15) it follows that

$$p_t(x, y) \sim \frac{c(x, y)}{t^{n(1+\bar{\nu})}}, \quad \text{as } t \rightarrow \infty$$

and

$$p_t(x, y) \sim \frac{c(x, y)e^{-\frac{\rho(x)+\rho(y)}{2t}}}{t^{n/2}}, \quad \text{as } t \rightarrow 0,$$

hence if $n\bar{\delta} = 2n(\bar{\nu} + 1) > 2$, then $\int_0^\infty p_t(x, y) dt < \infty$ and the process is transient. The process $\rho^{1/2}(X)$ is a Bessel process of dimension $2n(\bar{\nu} + 1) = (\beta + n)\alpha$, so the condition (3.13) is satisfied and we can apply Theorem 5.

We compute the Jacobian $Jac(I)(x) = -\rho(x)^{-n\alpha}$ similarly as the Jacobian of the spherical inversion $x \mapsto x/\|x\|^2$ and we get $v(x) = |(Jac(I)(x))^{-1}|\rho(x)^{2-n\alpha} = \rho(x)^2$. \square

4.2. Gaussian Ensembles. Stochastic Gaussian Orthogonal Ensemble GOE(m) is an important class of processes with values in the space of real symmetric matrices $Sym(m, \mathbb{R})$ which have t.i.p. and IP. Recall that

$$Y_t = \frac{N_t + N_t^T}{2}$$

where N_t is a Brownian $m \times m$ matrix. Thus the upper triangular processes $(Y_{ij}(t))_{1 \leq i \leq j \leq m}$ of Y are independent, Y_{ii} are Brownian motions and Y_{ij} , $i < j$, are Brownian motions dilated by $\frac{1}{\sqrt{2}}$.

Let $M \in Sym(m, \mathbb{R})$. We denote by $\mathbf{x} \in \mathbb{R}^m$ the diagonal elements of M and by $\mathbf{y} \in \mathbb{R}^{m(m-1)/2}$ the terms $(M_{ij})_{1 \leq i < j \leq m}$ above the diagonal of M . We denote by $M(\mathbf{x}, \mathbf{y})$ such a matrix M .

We have $(\mathbf{x}, \mathbf{y}) \in \mathbb{R}^{m(m+1)/2}$ and the map $(\mathbf{x}, \mathbf{y}) \mapsto M(\mathbf{x}, \mathbf{y})$ is an isomorphism between $\mathbb{R}^{m(m+1)/2}$ and $Sym(m, \mathbb{R})$.

Let $\Phi(\mathbf{x}, \mathbf{y}) = (\mathbf{x}, \mathbf{y}/\sqrt{2})$. The map Φ is a bijection of $\mathbb{R}^{m(m+1)/2}$ and $Sym(m, \mathbb{R})$, such that the image of the Brownian Motion B_t on $\mathbb{R}^{m(m+1)/2}$ is equal to Y_t . Proposition 3 implies the Inversion Property of the process Y . More precisely, we obtain the following

Corollary 4. *The Stochastic Gaussian Orthogonal Ensemble $GOE(m)$ has IP with characteristics:*

$$I(M) = \frac{M}{\|M\|^2}, \quad h(M) = \|M\|^{2-n}, \quad v(M) = \|M\|^4,$$

where $\|M\| = \sqrt{\sum_{1 \leq i, j \leq m} M_{ij}^2}$ is the trace norm of M .

On the other hand, the time inversion property of Y follows from the expression of the transition semigroup of Y which is straightforward. Theorem 5 provides another proof of Corollary 4.

Analogously, IP and t.i.p. hold true for Unitary and Symplectic Gaussian Ensembles.

4.3. Wishart Processes. Now we look at matrix squared Bessel processes which are also known as Wishart processes. Let S_m^+ be the set of $m \times m$ real non-negative definite matrices. X is said to be a Wishart process with shape parameter δ , if it satisfies the stochastic differential equation

$$dX_t = \sqrt{X_t} dB_t + dB_t^* \sqrt{X_t} + \delta I_m dt, \quad X_0 = x, \quad \delta \in \{1, 2, \dots, m-2\} \cup [m-1, \infty),$$

where B is an $m \times m$ Brownian matrix whose entries are independent linear Brownian motions, and I_m is the $m \times m$ identity matrix. Notice that when δ is a positive integer, the Wishart process is the process N^*N where N is a $\delta \times m$ Brownian matrix process and N^* is the transpose of N . We refer to [15] for Wishart processes.

In [21] and [25] it was shown that these processes have the t.i.p. The semi-group of X is absolutely continuous with respect to the Lebesgue measure, i.e. $dy = \prod_{i \leq j} dy_{ij}$, with transition probability densities

$$q_\delta(t, x, y) = \frac{1}{(2t)^{\delta m/2}} \frac{1}{\Gamma_m(\delta/2)} e^{-\frac{1}{2t} \text{Tr}(x+y)} (\det(y))^{(\delta-m-1)/2} {}_0F_1\left(\frac{\delta}{2}, \frac{xy}{4t^2}\right),$$

for $x, y \in S_m^+$, where Γ_m is the multivariate gamma function and ${}_0F_1(\cdot, \cdot)$ is the matrix hypergeometric function. In particular, we have $\rho(x) = \text{Tr}(x)$, $\alpha = 2$ (X is self-similar with index 1) and $\beta = \frac{1}{2}m(\delta - m - 1)$. Observe that, by Proposition 11, the Wishart process is self-dual with respect to the measure

$$\theta(y) dy = (\det(y))^{(\delta-m-1)/2} dy, \quad y \in S_m^+,$$

known as a Riesz measure, generating the Wishart family of laws of X_t as a natural exponential family. Next, X is transient for $m \geq 3$ and for $m = 2$ and $\delta \geq 2$. For a proof of this fact, we use the s.d.e. of the trace of X given by

$$d(\text{Tr}(X_t)) = 2\sqrt{\text{Tr}(X_t)} dW_t + m\delta dt.$$

Thus, $\text{Tr}(X)$ is a 1-dimensional squared Bessel process of dimension $m\delta$. Since $\delta \in \{1, \dots, m-2\} \cup [m-1, \infty)$, we have $\delta \geq 1$, so $m\delta \geq 3$ unless, possibly the case $m=2$ and $\delta=1$. Thus, for $m \geq 3$ and for $m=2$ and $\delta \geq 2$, we have $\|X_t\|_1 = \sum_{i,j} |(X_t)_{ij}| \geq \text{Tr}(X_t) \rightarrow \infty$ as $t \rightarrow \infty$ and the process X is transient.

Corollary 5. *Let X be a Wishart process on S_m^+ , with shape parameter δ . The process X has the IP property with characteristics*

$$I(x) = \frac{x}{(\text{Tr}(x))^2}, \quad h(x) = (\text{Tr}(x))^{1-\frac{\delta m}{2}}, \quad v(x) = \frac{1}{m-1}(\text{Tr}(x))^2.$$

The function $h(x) = (\text{Tr}(x))^{1-\frac{\delta m}{2}}$ is X -excessive.

Proof. In the transient case we apply Theorem 5. Condition (3.13) is fulfilled as $\rho(X) = \text{Tr}(X)$ is a 1-dimensional squared Bessel process of dimension $m\delta = (n + \beta)\alpha$, where $n = m(m+1)/2$. For the time change function, the computation of the Jacobian of $I(X)$ is crucial. It is equal to $(m-1)(\text{Tr}(X))^{-m(m+1)}$.

In the case $m=2$ and $\delta=1$ it is easy to see that the process X is not transient, e.g. by checking that the integral $\int_0^\infty q(t, 0, y) dt = \infty$. Nevertheless, the IP holds with the same characteristics as above. In order to prove this we can use the following description of the generator of X found in [10]. If f and F are C^2 functions on, respectively, \mathcal{S}_2^+ and on $\mathcal{M}(1, 2)$, the space of 1×2 real matrices, such that for all $y \in \mathcal{M}(1, 2)$ we have $F(y) = f(y^*y)$, then $Lf = \frac{1}{2}\Delta f$. Thus, the proof of the IP works like the one for the 2-dimensional Brownian motion, see [33]. \square

4.4. Dyson Brownian Motion. Let $X_1 \leq X_2 < \dots \leq X_n$ be the ordered sequence of the eigenvalues of a Hermitian Brownian motion. Dyson showed in [17] that the process (X_1, \dots, X_n) has the same distribution as n independent real-valued Brownian motions conditioned never to collide. Hence its semigroup densities $p_t(x, y)$ can be described as follows. Let q_t be the probability transition function of a real-valued Brownian motion. We have

$$(4.17) \quad p_t(x, y) = \frac{H(y)}{H(x)} \det[q_t(x_i, y_j)], \quad x, y \in \mathbb{R}_<^n,$$

where

$$H(x) = \prod_{i < j}^n (x_j - x_i) \quad \text{and} \quad \mathbb{R}_<^n = \{x \in \mathbb{R}^n; x_1 < x_2 < \dots < x_n\}.$$

Following Lawi [25], X has the time inversion property. This follows from the fact that (4.17) can be written in the form (3.11) with

$$\theta = (2\pi)^{n/2} H(y)^2, \quad \rho(x) = \|x\|^2, \quad \phi(x, y) = \frac{\det[e^{x_i y_j}]_{i,j=1}^n}{H(x)H(y)}.$$

Corollary 6. *The n -dimensional Dyson Brownian Motion has IP with characteristics: I is the spherical inversion on $\mathbb{R}_<^n$, $h(x) = \|x\|^{2-n^2}$ and $v(x) = \|x\|^4$.*

Proof. We compute $(n + \beta)\alpha = n^2$. Applying Theorem 5 to the Dyson Brownian Motion will be justified if we prove that $\|X\|^2$ is BESQ(n^2). This can be shown by writing the SDE for $\|X\|^2$, using the SDEs for X_i 's and the Itô formula.

Another proof consists in observing that H is harmonic for the n -dimensional Brownian Motion B_t killed when exiting the set $\mathbb{R}_<^n$ and is used in conditioning of B_t to get the Dyson Brownian Motion. An application of Proposition 4 yields the Corollary. \square

4.5. Non-colliding Squared Bessel Particles. Let $X_1 \leq X_2 < \dots \leq X_n$ be the ordered sequence of the eigenvalues of a complex Wishart process, called a Laguerre process. König and O'Connell showed in [23] that the process (X_1, \dots, X_n) has the same distribution as n independent BESQ(δ) processes on \mathbb{R}^+ conditioned never to collide, $\delta > 0$. Hence its semigroup densities $p_t(x, y)$ can be described as follows. Let q_t be the probability transition function of a BESQ(δ) process. We have

$$(4.18) \quad p_t(x, y) = \frac{H(y)}{H(x)} \det[q_t(x_i, y_j)], \quad x, y \in \mathbb{R}_<^n$$

where H is, as above, the Vandermonde function and $E = \mathbb{R}_<^n = \{x \in \mathbb{R}^n : x_1 < x_2 < \dots < x_n\}$. Lawi [25] observed that X has the time inversion property.

The same two reasonings presented for the Dyson Brownian Motion can be applied, in order to prove that X has IP. However, the first reasoning, using Theorem 5 and formula (4.18), applies only in the transient case $\delta > 2$.

Let us present the second reasoning where we use the results of the Section 2.7. First, we prove the following corollary.

Corollary 7. *The n -dimensional free Squared Bessel process $Y = (Y^{(1)}, \dots, Y^{(n)})$ where the processes $Y^{(i)}$ are independent Squared Bessel processes of dimension δ , has IP with characteristics $I(x) = x/(x_1 + \dots + x_n)^2$, $h(x) = (\sum_{i=1}^n x_i)^{1-n\delta/2}$ and $v(x) = (\sum_{i=1}^n x_i)^2$.*

Proof. It is an application of (IP) for free Bessel processes, proved in [3, Corollary 4] and the Proposition 3. We use the bijection $\Phi(x_1, \dots, x_d) = (x_1^2, \dots, x_d^2)$. \square

Next, we apply Proposition 4, with H as above, in order to get the following result.

Corollary 8. *Let (X_1, \dots, X_n) be n independent BESQ(δ) processes on \mathbb{R}^+ conditioned never to collide, $\delta > 0$. The process $X_1 \leq X_2 < \dots \leq X_n$ has IP with characteristics:*

$$I(x) = x/(x_1 + \dots + x_n)^2, \quad \tilde{h}(x) = \left(\sum_{i=1}^n x_i\right)^{1-n\delta/2-n(n-1)}, \quad v(x) = \left(\sum_{i=1}^n x_i\right)^2.$$

4.6. Hyperbolic Brownian Motion. Let us recall some basic information about the ball realization of real hyperbolic spaces (cf. [22, Ch.I.4A p.152], [28]). Let \mathbb{D}^n be the n -dimensional hyperbolic ball, i.e. $\mathbb{D}^n = \{x \in \mathbb{R}^n : \|x\| < 1\}$ and \mathbb{D}^n is equipped with the metrics $ds^2 = 4\|dx\|^2/(1 - \|x\|^2)^2$. \mathbb{D}^n is a Riemannian manifold. This is the ball model of the real hyperbolic space of dimension n . The spherical coordinates on \mathbb{D}^n are defined by $x = \sigma \tanh \frac{r}{2}$ where $r > 0$ and $\sigma \in S^{n-1} \subset \mathbb{R}^n$ are unique. Then the Laplace-Beltrami operator on \mathbb{D}^n is given by

$$Lf(x) = \frac{\partial^2 f}{\partial r^2}(x) + (n-1) \coth r \frac{\partial f}{\partial r}(x) + \frac{1}{\sinh^2 r} \Delta_{S^{n-1}} f(x),$$

where $\Delta_{S^{n-1}}$ is the spherical Laplacian on the sphere $S^{n-1} \subset \mathbb{R}^n$.

Let X be the n -dimensional Hyperbolic Brownian Motion on \mathbb{D}^n , defined as a diffusion

generated by $\frac{1}{2}L$ (cf. [28] and the references therein). Define a new process Y by setting $Y_t := \delta(X_t)$, $t \geq 0$, where $\delta(x)$ is the hyperbolic distance between $x \in \mathbb{D}^n$ and the ball center $\mathbf{0}$. The process Y is the n -dimensional Hyperbolic Bessel process on $(0, \infty)$. According to [2], the process Y has the Inversion Property, with characteristics (I_0, h_0, v_0) that can be determined by [2, Theorem 1]. It is natural to conjecture that the Hyperbolic Brownian Motion X has IP with characteristics (I, h, v_0) , where

$$I(x) = \sigma \tanh \frac{I_0(r)}{2} \quad \text{and} \quad h(x) = h_0(r).$$

When $n = 3$, by [2, Section 5.2], we have $I_0(r) = \frac{1}{2} \ln \coth r$, $h_0(t) = \coth r - 1$ and $v_0(r) = 2 \cosh r \sinh r$. If the Hyperbolic Brownian Motion X_t had IP with the involution I and the excessive function h , then, by Theorem 1 and Proposition 7, if $Lf = 0$ then $L(hf \circ I) = 0$. By a direct but tedious calculation of $L(hf \circ I)$ in spherical coordinates, we see that there exist continuous functions f such that $Lf = 0$ but $L(hf \circ I) \neq 0$, so X does not have IP with characteristics I and h .

To our knowledge, no inversion property is known for the Hyperbolic Brownian Motion. We believe that this question was first raised by T. Byczkowski about ten years ago, while he was working on potential theory of the Hyperbolic Brownian Motion ([11]).
