HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L’archive ouverte pluridisciplinaire HAL, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d’enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.
ABSTRACT
Real-time 3D interaction with augmented reality (AR) environments is one of the main features of any AR system. However, selecting and manipulating distant 3D virtual objects in AR still suffer from lack of accuracy and precision. In this paper, we propose an alternate 3D interaction technique called “Zoom-in” for selection and manipulation distant objects in immersive video see-through augmented reality. Zoom-in interaction technique is based on the idea of zooming the captured images. This allows bringing closer both of real and virtual distant objects, while keeping the spatial registration between the virtual and the real scenes thanks to a robust real-time computer vision algorithm for pose estimation. An evaluation and comparison with other well-known technique are given at the end of this paper, in order to validate our proposed approach.

CCS Concepts
• Computing methodologies → Mixed / augmented reality • Human-centered computing → HCI design and evaluation methods • Computing methodologies → Object recognition.

Keywords
Augmented reality; 3D interaction; Computer vision.

1. INTRODUCTION
The increasing performance of computational and graphics hardware on both headsets and mobile devices makes the AR omnipresent. Thus, the interaction with the virtual objects became required. Several 3D interaction techniques in augmented reality environments have been proposed. One of the main issues is how to provide selection and manipulation of distant 3D virtual objects with precision. On the other hand, how to ensure the spatio-temporal registration between the virtual and the real worlds during the interaction task. However, most of those techniques still have limitations in providing intuitive and precise interaction in mobile AR.

In this work, we introduce a novel 3D interaction technique, called Zoom-In, whereby users can select and manipulate distant virtual object in precision. This paper is organized as follows: Section 2 presents a brief related work of selection/manipulation techniques. Section 3 describes the proposed Zoom-in interaction technique. Section 4 presents results and evaluates the proposed technique. Finally, Section 5 concludes and summarizes this paper.

2. RELATED WORK
Various interaction techniques are proposed for selection and manipulation of distant 3D object in augmented reality. However, most of these techniques are inspired by those proposed for virtual reality. Some of these techniques include Ray Casting, Go-Go, WIM, Image Plan, Voodoo Dolls and HOMER.

The Voodoo Dolls technique [1] allows users to scale the virtual objects by selecting a voodoo doll that has a size relative to the desired environment size. In addition, this technique allows the user to interact with distant objects by essentially bringing a representation of them closer to the user. The World in Miniature (WIM) technique [2] displays a miniature copy of the virtual world close to the user. Through direct manipulation, the user is able to interact with the miniature versions of the objects, which causes the full-sized versions of the objects to move in the same manner. However, in augmented reality, those two techniques do not ensure spatial registration of the virtual objects with the real word. Because they separate the two worlds from each other. With Image Plan techniques [3], the user interacts with the 2D projections that 3D objects in the scene make on his image plane. This allows the interaction with distant objects. Nevertheless, the interaction is limited in 2D.

The ray casting technique [4] extends a ray from the user’s hand out into the desired virtual object and allows distant objects to be selected. However, it does not provide manipulations along the Z-axis, and does not allow occluded objects selection. Many techniques have been developed to improve this issue. Olwal and Feiner [5] proposed a flexible pointer that addresses the occlusion problem. This technique makes it easier to point to obscured objects. The GARDEN technique [6], which based on ray-casting metaphor, allows pointing and selection virtual object in augmented reality. Yet, it does provide manipulation of distant objects. Go-Go technique [7] provides a non-linear scaling of the user’s arm, which allows an interaction with distant objects. However, the non-linear amplification results an imprecise manipulation of the selected objects.

The HOMER technique [8] uses ray casting to select an object, once object selected, virtual hand occurs and extends to the object. The user can directly interact with this object. This provides true 6DOF manipulation of distant objects. However, HOMER cannot ensure precise interaction with small and occluded virtual objects. Ha et al. [9] proposed a robust interactive augmented reality system for grabbing and manipulating 3D object. This system addresses the occlusion problem. However, it has limitations in distant object selection and manipulation.

In order to address such drawbacks, we propose in this paper, an alternate 3D interaction technique. This technique brings both of virtual and real objects closer to provide a precise selection and manipulation of virtual objects. While keeping the spatial registration between the two worlds.
3. PROPOSED APPROACH

Zoom-In is a hybrid interaction technique that combines the camera zoom for object selection, and the virtual hand metaphor for object manipulation. Thus, this technique aims to facilitate the selection and manipulation of virtual objects, in particular distant objects, while remaining linked to the real world in augmented immersive reality.

Therefore, our technique relies on the idea that the zoom of the captured images makes it possible to bring the two distant, real and virtual objects, closer together. While maintaining the spatial registration between the virtual objects and the real scene thanks to a real-time computer vision algorithm for 3D pose estimation.

3.1 Setup Design

We built a prototype, which is composed of a “Leap Motion” controller mounted on a “Vizux 1200AR” video-see-through headset. The HMD is equipped with an RGB camera. In order to avoid the occultation of the user’s hand by the virtual objects, we rotated the Leap Motion by 45° downwards relative to the RGB camera (see Figure 1.a). Then, we aligned the virtual controller of the Leap Motion with the virtual camera. So that the user can see his virtualized hands (textured 3D hands models) on the headset display (see Figure 1.b).

![Figure 1. Zoom-In technique prototype setup. a) Leap Motion is rotated by 45° downwards relative to the RGB camera. b) 3D virtual hands are displayed on the HMD.](image)

Therefore, in order to select and manipulate a distant 3D object using our proposed technique. This can be performed in three steps (see Figure 2):

1. First, the user points to the desired object.
2. Then, a camera zoom is activated until the desired virtual object is close enough to be within the user’s reach.
3. Thereafter, the user can use the standard Virtual Hand metaphor to grab and manipulate the object.

![Figure 2. Zoom-In technique steps: a) Pointing to the desired object. b) Captured image zooming. c) Grabbing and manipulating the object](image)

In order to get the distant object at user’s hand reach, the system has to calculate first the distance between the virtual object and the virtual hand of the user. Then it estimates the zoom factor $F$ to be applied to the captured image and the part of the image that must be zoomed. We can formulate this problem as follow.

3.2 Problem Formulation

Let $T_{oc}$ be the transformation matrix of an object $O$ with respect to the camera $C$. This matrix is obtained by the product of the two matrices $T_{oc}$ and $T_{om}$ which are the transformation matrices Objet-Map and Camera-Map respectively. Let $Z_{oc}$ be the translation of the object on the Z-axis obtained from the matrix $T_{oc}$. (See Figure 3).

$T_{hc}$ is the transformation matrix of the virtual hand with respect to the camera, and $Z_{hc}$ its translation on the Z-axis extracted from the matrix $T_{hc}$.

![Figure 3. Zoom-In technique functioning principle.](image)

Let $I(H, W)$ be the image captured by the camera with dimensions $W$ (width) and $H$ (height). $I'(H', W')$ is a part of the image $I$ such that $H' / W' = H / W$ that represents the part of the image where the selected virtual object is projected (See Figure 3).

We aim to make the selected object within the user’s hand reach. This means to reduce its distance from $Z_{oc}$ to $Z_{hc}$, which results by zooming the image $I'$ with the factor $F = \frac{Z_{oc}}{Z_{hc}}$.

Once the zoom factor $F$ is calculated, we can calculate the dimensions $H'$ and $W'$ respectively by (Equation 1 and 2):

$$H' = \frac{H}{F} \quad (1)$$

$$W' = \frac{W}{F} \quad (2)$$

On the other hand, in order to determine the part of the image to be zoomed (Figure 4), we project the 3D position $O(x, y, z)^r$ of the selected virtual object on the image plane $I$. Then we calculate its 2D position $(u, v, 1)^r$ with the respect to the captured image $I$. This results by the following equation (equation 3), which is the equation of the camera pinhole model [10].

$$s \begin{bmatrix} u \\ v \\ 1 \end{bmatrix} = A T_{oc} O \begin{bmatrix} X \\ Y \\ Z \end{bmatrix} \quad (3)$$

With $s$ scale factor and $A$ the matrix of the intrinsic parameters of the camera.
Once we have the 2D position \((u, v)\) of the object on the image I, we can extract the image \(I'\) from the image I as follows (equations 4 and 5).

\[
\begin{align*}
px & = u - \frac{w'}{2} \\
py & = v - \frac{h'}{2}
\end{align*}
\]

The extracted image \(I'\), can be then scaled by the zoom factor \(F\) calculated above.

### 3.3 Virtual Object Registration

In order to ensure a stable registration of virtual objects throughout the entire augmentation process, we are based on a natural feature tracking approach. This latter uses MOBIL technique [11][12] for keypoints detection and description, and CoPlanar POSIT [13] for the pose estimation.

Therefore, during the interaction process. We consider the captured image I as a reference image, i.e. we change the virtual object reference from the old map \(T_{oa}\) to the new image reference that we call \(T_{oi}\). Then, for each scaled image \(I'\), we applied the natural feature tracking technique to match this image with the reference image I. The result of matching is then multiplied by \(T_{oi}\) in order to obtain the final virtual object 3D pose. In this posture, the user can see the virtual object closer within his hand reach. Thus, he can use the Virtual Hand metaphor to grab and manipulate that object.

In addition, the proposed interaction technique allows the user to grab and manipulate neighboring virtual objects without having to repeat the entire zoom process. Furthermore, this makes it possible to select and manipulate the occluded virtual objects, which cannot be reached by other interaction technique, like Ray-casting or HOMER.

Once all the manipulations are finished, the user can terminate the interaction process by making a specific gesture by his hand (in this case, we chose the Open Palm gesture), then, a zoom-out animation is activated to restore the actual size of the captured image.

### 4. TEST AND EVALUATION

We implemented our proposed technique under Unity3D version 5.3 and Visual Studio C# 2013. We used OpenCV 2.1 and Leapmotion SDK 2.0. Running on PC with i3 3.20GHz Intel® Core™ and 6Go of RAM.

Thus, in order to test and evaluate the Zoom-In technique, we have developed a puzzle game application whose objective is to put virtual geometric shapes in their proper locations in a real box as quickly and as accurately as possible. (See Figure 5.a). We have four virtual objects with different geometric shapes: Cube, Prism, Parallelogram and Sphere. The dimensions of the objects vary between 3 and 8 cm. The real box size is 20x20x10 cm. With four holes of different shapes on the top, which correspond to the virtual objects forms.

The main purpose of this evaluation is to compare the accuracy and the time to accomplish a task with a similar selection-manipulation technique, namely the HOMER technique that we have implemented under Unity3D with the same conditions as those of the Zoom-In.

For this purpose, we have defined the following two hypotheses:

- **H0**: The task completion time of the Zoom-In technique, is less than or equal to that of the HOMER technique.
- **H1**: The precision of the Zoom-In technique when performing a given task is better than that of the HOMER technique.

We took a group of 12 participants of different ages (26-38), different gender (4 women, 8 men) and different years of experience in the field of AR, interaction 3D and video games. All of these participants were right-handed and none of them had an identified eye problem. After explaining the principle of the game, as well as the operation of the two Zoom-In and HOMER interaction techniques, the 12 participants made familiarization tests of 5 minutes with each technique using the developed game.

Thereafter, the participants began their evaluation experiments in turns, using the developed puzzle game separately (Figure 5.b). Each participant put on the HMD (equipped by the Leapmotion) and seated at a distance of 2m from the puzzle game (the real box with the four virtual forms). Each one must repeat the experiment twice, with each interaction technique. In order to avoid a transfer of knowledge, the participants did not carry out the experiments using the two techniques in the same order.

In each experiment, we calculated the task completion time (selection time + manipulation time) for each single object. As well as the accuracy (the error in millimeters when putting the geometric shape in its location).

### 4.1 Objective Evaluation

We performed an ANOVA on the collected data to study the effect of the used interaction technique on time and accuracy. The results obtained were \(F = 5.321, p <0.013\) for task completion time and \(f = 4.83, p <0.021\) for accuracy. This reveals a significant effect of the interaction technique on these two indicators (time and precision). Overall, most of participant carried out the tasks faster and more precisely with the Zoom-In technique than with the HOMER technique (Figure 6).
to select and manipulate distant virtual objects, while maintaining the spatial registration between the virtual and the real scenes, thanks to a proposed real-time pose estimation approach.

The evaluation experiments carried out on this technique have led to satisfactory and competitive results compared to HOMER technique in both precision and completion time.
