HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

Robust Adaptive Sampling for Monte-Carlo-based rendering

Anthony Pajot, Loïc Barthe, Mathias Paulin

Monte-Carlo rendering

- Value of each pixel defined as the expected value of a random variable X

$$I = E[X]$$

- estimated using samples of X

$$\langle I \rangle = \frac{1}{N} \sum_{i=1}^N x_i$$

Our goals

- **Focus** processing power where convergence is harder to reach during Monte-Carlo based rendering

- Make the error over the pixels **uniform** at any moment for progressive or time-constrained rendering

Previous work and their limitations

- Adaptive sampling based on the statistical nature of the estimation [Purgathofer 1987]

Not a relative error: does not take into account dynamic reduction during tonemapping

- Adaptive sampling based on information-theoretic approaches and entropy measures [Xu et al 2007]

Does not make the error uniform during rendering, thus less adapted for progressive or time-constrained rendering

Both approaches can lead to poor sampling due to low-samples error estimations which underestimate the actual error

Our approach

- Use a **relative error** to avoid focusing all processing power on areas receiving more energy. These zones are not necessarily the most noticeable after tonemapping, e.g. undersampling in shadows leads to highly visible noise

- **Alternate** between uniform and adaptive sampling, to ensure that error estimations of all pixels improve during rendering

Relative error and robustness to outliers

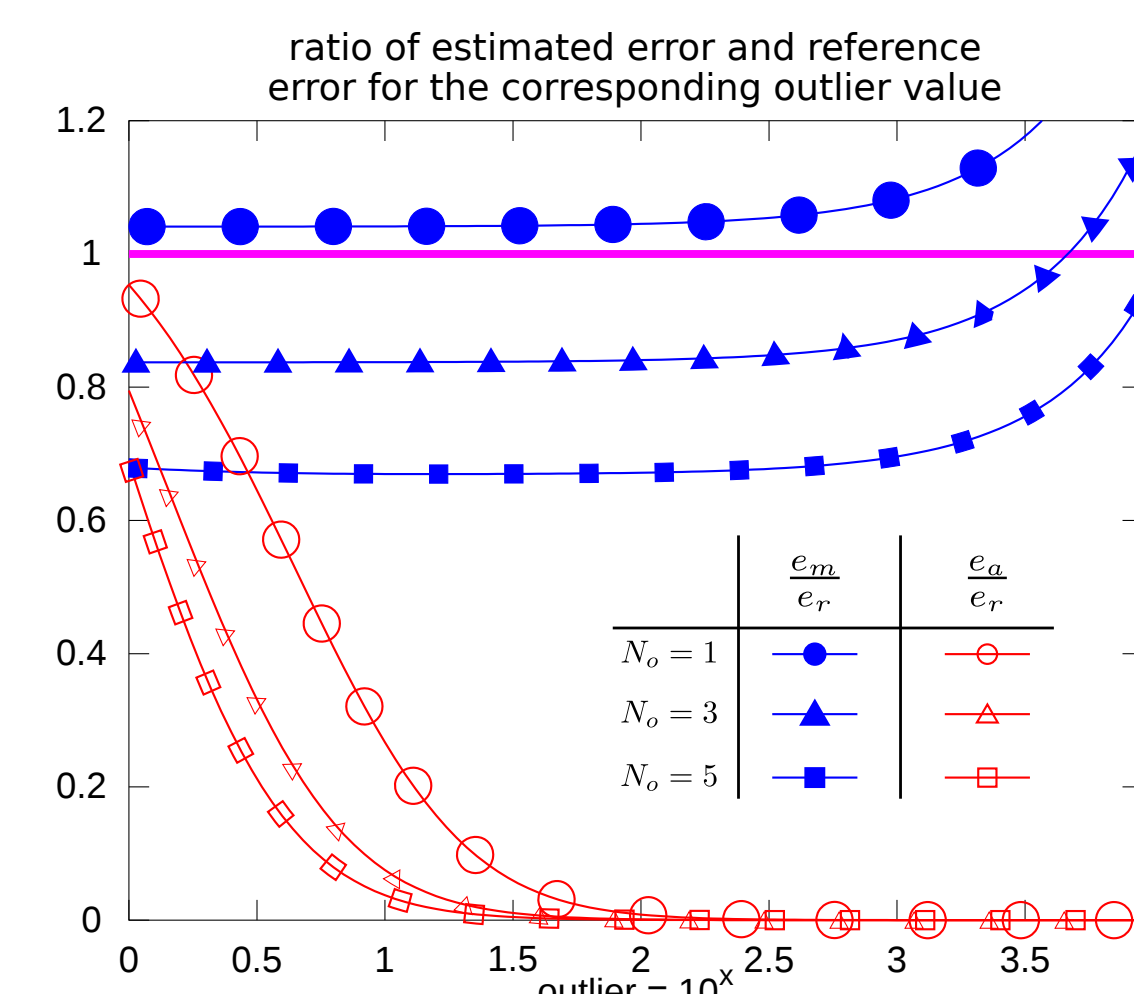

For each pixel, relative error:

$$e_r(I) = \frac{V(x_1, \dots, x_n)}{E[X]}$$

Standard estimation:

$$e_a(I) = \frac{V(x_1, \dots, x_n)}{\langle I \rangle}$$

Not robust to outliers
→ **underestimation**

Our proposal:
approximate median

$$e_m(I) = \frac{V(x_1, \dots, x_n)}{M_x}$$

M_x = average of median of chunks of samples

Goal: focus on bright spots

Scene prone to bright spots

using e_a : too uniform

using e_m : focused on bright spots

Alternation: avoid poor low-samples error estimation

Adaptive sampling based on error measure.

poor error estimate
→ **poor sampling**

Our proposal:
alternate adaptive and uniform sampling

Complete scene.
Penumbra prone to poor sampling

Uniform sampling

Adaptive sampling, no alternation.
Patterns in the penumbra

Adaptive sampling, alternation.
No patterns in the penumbra

Complete adaptive sampling algorithm

Comparison with Tsallis entropy [Xu, Sbert, Xinh and Zhan 2007]
