**HAL** is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

# Asymmetric Awareness and Heterogeneous Agents

Antoine Dubus\*

May 11, 2017

## Abstract

I consider the principal-agent model with asymmetric awareness and introduce heterogeneity of the agents on their aversion to effort. I discuss the optimal contract and market structure in a market with an aware principal and unaware agents. When the principal faces two types of agents, one being more effort-averse than the other, the contract he proposes either pools them, separates them, or excludes the more effort-averse agents of the market depending on their proportion. In a first-best world, all the agents remain unaware. In a second-best one, the principal increases the awareness of the agents, to a level which depends on the nature of the contract.

**Keywords:** Economics of Contract: Theory; Unawareness; Asymmetric and Private Information; Insurance

**JEL Classification:** D82; D83; D86; G22.

# 1 Introduction

The traditional agency problem with hidden efforts and moral hazard assumes that the principal and the agent have the same knowledge over the contingencies affected by the agent's efforts. However, as Auster (2013) shows, asymmetric awareness can be used by one of the contracting party to design the contract. Until now, models including awareness asymmetry have not introduced market refinements such as heterogeneity over the cost to effort of the agents. In this paper I introduce this heterogeneity into a model of contract with unawareness. Namely, the agents can be of two types, one being more effort-averse than the other. The main question of our paper is to know how this heterogeneity affects the design of the contract, especially in terms of level of awareness revealed to the agents. In an extension, I also study the equilibrium resulting from competition, and the associated level of awareness disclosed by the principal.

Consider contracting in the health-insurance market. The current contracts stipulate a compensation based on an outcome that is the health of the agent. The insurance company that proposes the contract is probably more aware of what behavior affects the health of its clients than they do themselves. It will design the contract using this higher awareness as a way to maximize its profits. Assume that exerting a lifestyle effort increases the chances of the clients not to have a disease, for instance walking a certain distance each day reduces the chances of having a heart attack. Assume also that the clients are of two types, one very averse to effort and the other less. The question I answer is whether the insurance company will reveal to every agents that they should walk a certain distance every day, and if it will contract with both types of agent. Indeed, the trade-off emphasized by Auster (2013) is that revealing this contingency increases the agent's incentive to adopt a healthier behavior, but it also tightens the participation constraint.

Allowing for heterogeneous agents has strong implications for market equilibrium compared to the initial model. Namely, I allow for partially covered markets, thus, questions of market structure arise. Will the principal deal with one type of agents only,

with both of them identically or with each of them differently? It is shown that it is not always optimal for the principal to offer a unique contract, but that depending on the proportions of high and low-type agents, he will either propose a contract fitting with the more effort-averse agent, or one offering two separate contracts for the two agents, or even one fitting with the less effort-averse agent, and implicitly excluding the other type from the market. In the second case, the more effort-averse agent will be motivated to exert a low-level effort while the other type will be encouraged to exert a high effort. The degree to which the awareness of the agents is enlarged depends on the type of contract chosen.

I use the model of agency with unawareness developed initially by Auster (2013) and extend it to the case of agents with heterogeneous effort-costs. A risk-neutral principal proposes a contract to a risk-averse agent over the uncertain outcomes of some task. More precisely, the outcome is a function of the stochastic realization of binary contingencies. Awareness-asymmetry arises over the knowledge of the contingencies, since the principal knows the whole set and the agent only part of it. The agent exerts a hidden effort that affects the realization of the contingency. The effort can be of two types, high or low, and the different effort-aversions of the agents come from a higher effort-cost for the low-type agent than for the high-type one.

The consequence of the asymmetric awareness is that the agents will maximize their utilities using the probabilities of occurrence of each outcome as they perceive it. Auster (2013) shows first that the agents' unawareness implies that they won't contract on some outcomes and won't get a retribution for it. She also shows that, in the second-best contract, the principal reveals some contingencies to the agents in order to increase their motivation to exert an effort, meaning that more awareness relaxes the IC constraint; but it also results in tightening the participation constraint of the agents. They will ask for more retribution since they know more precisely the impacts of their effort.

In this set-up, I show that in first-best contracts, awareness will always be minimal whatever the regime chosen by the principal. In second-best contracts however, the

agents' awareness will be increased (but not always complete). Awareness will be the highest in separating contracts, and the lowest in excluding contracts; pooling contracts will present in-between levels of awareness. I also show that the principal's strategy changes between the first and second-best contracts for identical rates of high effort-cost agents in the population. For some agent-types proportions that in the first-best world imply a separating contract, skipping to the second-best implies that the contract will become either pooling or separating (depending on the proportion).

I provide a brief review of the literature in section 2. Section 3 is devoted to the description of the model of contract with unawareness. In section 4 the solution of the first-best world is outlined, while section 5 gives the results for the second-best world. Section 6 is devoted to an extension to a market in duopoly, and section 7 proposes a discussion over the market structures in equilibrium.

## 2 A review of the literature

The classical economic theory assumes that the economic agents have the same awareness on the factors affecting an outcome (see Holmstrom (1979) and Grossman and Hart (1983)). Maskin and Tirole (1999) put this symmetric-awareness assumption into question by explaining that "contractual incompleteness" occurs, and affects the structures of markets and even political systems. The aim of their paper is to show the irrelevance of transaction costs as a way to model why agents cannot apprehend contingencies ex ante. In particular, they emphasize the lack of a theory that allows for bounded rationality in the agency problem.

The literature on awareness aims at filling this gap. Starting with the seminal works by Modica and Rustichini (1994) and Dekel and al. (1998) papers like Heifetz et al. (2006) or Galanis (2011) propose models that allow for unawareness in non-standard state-space model, and thus construct environments that allow for bounded rationality. One of the ideas behind trying to allow for unawareness in state-space model is to be able to transpose this notion to contract-models.

Different approaches coexist based on their works. For instance, while most models allow for unawareness in terms of knowledge and ignorance, Heifetz et al. (2013) allow for different probabilistic beliefs over the realization of outcomes depending on the awareness of the agents; Meier and Schipper (2012a), for their part, develop Bayesian games with unawareness, with the introduction of a Nash equilibrium with unawareness, and define some equilibrium refinements.

Modeling the impact of asymmetric awareness on probabilistic beliefs several agents are aware of allows in particular to design models with moral-hazard under unawareness.

In this line, Zhao (2008) considers a contract with moral-hazard and unawareness where both the principal and the agent can be unaware, while Von Thadden and Zhao (2014) propose a model with a fully aware principal and an unaware agent.

In a more recent paper, Li et al. (2016) study an applied situation involving unawareness, and study when it is interesting for a company to increase the awareness degree of the agents. I refer to Schipper (2014) for a detailed survey of the literature.

The model used adopts the generalized state space model introduced by Heifetz et al. (2006) and Auster (2013), and extends it with a heterogeneous population of agents. As in Auster (2013), under the assumption of independence of the contingencies, the model respects the justifiability condition required by Filiz-Ozbay (2012), that is, on the agents' point of view, the principal must behave rationally, even if the agents are only partially aware. Our model is in line with the evolutions that happened to the research on unawareness, translating from the theoretical structure of unawareness in the agent's expected utility to more applied considerations such as what is the optimal awareness revelation in a contract with asymmetric awareness, with implications for industrial organization.

### 3 The Model

The model is adapted from Auster (2013), including heterogeneity in the consumer's effort cost. The problem is an agency contract, with a profit-maximizing principal neutral to risk, contracting with utility-maximizing agents averse to risk. The agents can be of two

types. Agents of type  $\theta_H$  have a low cost to effort  $\mathcal{C}(e)$ , while agents of type  $\theta_L$ : have a high cost to effort  $e$ .

**Assumption 1:**  $e_L > \mathcal{C}(e_L)$ ,  $\Delta e = e_H - e_L > \Delta \mathcal{C}(e) = \mathcal{C}(e_H) - \mathcal{C}(e_L)$ .

This assumption states that for the effort-averse agent, exerting a low effort will be more costly than the same effort for the other type of agents; also, the difference between a high effort and a low effort is bigger for the effort-averse agent. It is coherent with the notion of effort-aversion and allows for more mathematical tractability. Also, let us note  $P(\theta = \theta_H) = \alpha$  the proportion of  $\theta_H$  in the population.

Besides this heterogeneity, the model is strictly identical to Auster (2013); I describe it below.

The agents engage in a task for an effort  $e$ , and with an outcome  $y \in \mathcal{Y} = \{y_1, \dots, y_k\}$ ,  $y_i \in \mathbb{R}$ . Both the profit of the principal and the utilities of the agents are derived from the outcome.

The principal derives a profit from the outcome  $y$ , and loses profit on the money transfer  $C$  to the agents. The agents get a positive utility from monetary transfers  $C$  and a negative utility from exerting an effort  $e$ . The outcome is observable and verifiable. While the outcome are fixed,  $C(y)$  is a variable that the principal can use in order to design the contract.

- **Principal:**  $U_P(y) = y - C(y)$  where  $C : \mathbb{R} \rightarrow \mathbb{R}^+$  is a compensation function.
- **Agents:**  $U_A^H(y, e) = V(C(y)) - \mathcal{C}(e)$  for the high-type and  $U_A^L(y, e) = V(C(y)) - e$  for the low-type, where  $V : \mathbb{R} \rightarrow \mathbb{R}$  verifies the Inada conditions;<sup>1</sup>  $e \in \{e_H, e_L\}$ ;  $e_H > e_L$  is a costly effort that the agents exert and that affects the probability of occurrence of  $y$ .

Let us denote by  $\Upsilon = \{v_1, v_2, \dots, v_n\}$ , with  $v_i = 0$  or 1 a set of contingencies affecting the outcome. Out of this set is derived the set of states of the world  $S = \{s_1, \dots, s_{2^{|\Upsilon|}}\}$

---

<sup>1</sup>For  $x \in [0, +\infty[$ ,  $V$  is continuously differentiable;  $V(0)=0$ ;  $V'(x)>0$ ;  $V''(x)<0$ ;  $\lim_{x \rightarrow +\infty} V'(x) = 0$ ;  $\lim_{x \rightarrow 0} V'(x) = +\infty$ .

composed by the combinations of the contingencies. The agents perceive  $\Upsilon_A \subseteq \Upsilon$  and  $S_A \subseteq S$  because of their unawareness. As an illustration, I take Auster's example on the state of the world structure: for  $\Upsilon = \{v_1, v_2\}$  and  $\Upsilon_A = \{v_1\}$ , the resulting sets are:  $S = \{(0, 0), (1, 1), (1, 0), (0, 1)\}$  and the one perceived by the agent is  $S_A = \{(0), (1)\}$ .

**Assumption 2:** The random variables  $v$  and  $v'$  are conditionally independent given  $e$  for any  $v, v' \in \Upsilon$ .

This assumption is crucial in Auster's set-up, not for the trade-off result between incentive and participation constraint, but for it allows the contract to respect the justifiability constraint. Thanks to it, from the agent's point of view, the principal is always perceived as rational. This is not always the case if contingencies are not independent. This assumption does not always reflect reality.

Uncertainty occurs by the way of a mapping  $M : S \rightarrow \mathcal{Y}$  that defines for each  $s$  a lottery over the set  $\mathcal{Y}$ ;  $y = f(s)$ , with  $f$  a density function. Introducing probabilities illustrates the fact that for a given state of the world, outcomes are stochastic. The mapping perceived by the agent is defined in the following way:  $y = \hat{f}(s) = f(s, 0, \dots, 0)$  for  $s \in \hat{S}$ .

Stochasticity is also introduced at the contingency level. The agents' effort impacts the values of the contingencies ( $P(v_i = 1|e_H)$  is not always equal to  $P(v_i = 1|e_L)$  for  $v_i \in \Upsilon$ ). To sum-up, the probability of occurrence of an outcome  $y$ ,  $P(y|e_H)$  is in general different from  $P(y|e_L)$ . The agents exert an effort that increases the chances of some contingency to take a certain value, and a distribution of probability of occurrence over the set of outcome is inferred from the resulting state of the world.

The notion of effort here is associated with costly actions for the agents that increase the probabilities of occurrence of outcomes profitable for the principal. For some outcomes  $Y$ , we have  $P(Y|e_H) > P(Y|e_L)$  and overall  $E[Y|e_H] > E[Y|e_L]$ .

In this setting, following Auster (2013), considering our objective function it is assumed that it is always preferable to implement a high effort. However, implementation of a low effort by one type of the agents may occur, in order for the principal to distinguish the

types of the agents.

The principal computes expected utilities using the whole set  $\Upsilon$  and thus the full sets  $S$  and  $\mathcal{Y}$ . The notion of awareness is introduced here in the way the agents compute their expected utilities. Indeed, they only use part of the sets to infer the probabilities. More precisely, they compute it over the set  $\Upsilon_A \subseteq \Upsilon$ , with  $v_i = 0$  if  $v_i \in \Upsilon \setminus \Upsilon_A$ . Note that I assume that both agents always have the same degree of awareness. The principal can't offer contracts with different degrees to the agents. I make this assumption that fits with a screening behavior of the agents when screening is costless.

Following Filiz-Ozbay (2012) and Auster (2013), I define a contract in our set-up.

**Definition 1:** A contract is a triplet  $(\hat{\Upsilon}, C, e)$ , with  $\Upsilon_A \subseteq \hat{\Upsilon} \subseteq \Upsilon$ ,  $C : \mathcal{Y} \rightarrow \mathbb{R}^+$  and  $e \in \{e_L, e_H\}$ .

The notion of incomplete contract given by Filiz-Ozbay (2012) and Auster (2013) is also introduced.

**Definition 2:** A contract  $(\hat{\Upsilon}, C, e)$  is incomplete if  $\hat{\Upsilon} \neq \Upsilon$ , otherwise it is complete.

The principal and the agents play the following game:

1. The principal proposes a contract over the outcome  $y$ , with two parameters  $(\hat{\Upsilon}, C(y))$  where  $\Upsilon_A \subseteq \hat{\Upsilon} \subseteq \Upsilon$
2. The agents learn their types and choose a level of effort  $e \in \{e_H, e_L\}$ .
3. A stochastic outcome  $y$  occurs depending on the states of the world.
4. The principal pays  $C(y)$ , depending on the  $y$  that occurred.

The principal designs the contract following his expected profit,

$$E[U_P(y, e, C(\cdot))] = \sum_{y \in \mathcal{Y}} P(y|e)[y - C(y)]$$

Similarly, the agents decide to accept or reject it considering their expected utilities,

$$E_{\hat{\Upsilon}}[U_A^L(y, e, C(\cdot))] = \sum_{y \in \hat{\Upsilon}} \hat{P}(y|e)V(C(y)) - e$$

$$E_{\hat{\Upsilon}}[U_A^H(y, e, C(\cdot))] = \sum_{y \in \hat{\Upsilon}} \hat{P}(y|e)V(C(y)) - C(e)$$

They compute it depending on their degree of awareness. We normalize reservation profit and utility to zero, below which the principal or the agents don't accept the contract.

$\hat{P}(y|e_H)$  is the perceived probability of occurrence of outcome  $y$  for a reduced contingency-set size  $\hat{Y}$  (associated with reduced sets  $\hat{S}$  and  $\hat{Y}$ ) that the agent is made aware of by the principal as part of the contract.

The perceived-probability associated with incomplete awareness is computed thanks to Bayes formula:  $\hat{P}(y|e) := \frac{P(y|e)}{P(\hat{v}|e)}$  for  $y \in \hat{Y}$  where  $P(\hat{v}|e) = \prod_{v \notin \hat{v}} P[v = 0|e]$ .

We now solve the agency problem in the first-best contract, and find the optimal strategy for the principal, and the resulting level of awareness.

## 4 Equilibrium contract: first-best

We first solve the problem with observable efforts as a benchmark, which also gives us insights on the impact of monitoring technologies such as IoT in markets with unawareness. We treat the case with hidden types, since observable types allow the principal to perfectly discriminate between the agents, and thus gives the exact same results as in Auster (2013) for the first-best contract.

Note that the results still verify the justifiability constraint, by the same arguments as Auster relying on the assumption of independence of the contingencies.

The principal wants to maximize his utility under constraints that differ depending on the strategy that he chooses. Namely, the problem is to choose the one that gives him the higher profit among the three following ones:

1. Pooling equilibrium, with identical compensation for both types.
2. Excluding equilibrium where only the  $\theta_H$  agent is served.
3. Separating equilibrium based on different implementations of efforts depending on the type:  $\theta_L$  implements  $e_L$ ,  $\theta_H$  implements high effort at cost  $\mathcal{C}(e_H)$ . (the opposite would necessarily be suboptimal, since the effort-cost gap is bigger for  $\theta_L$ )

**Pooling equilibrium problem:**

$$\begin{aligned} & \max_{\hat{v}, C(\cdot)} \{E[U_P(y, e_H, C(\cdot))]\} \\ & \text{s.t. : } PC_L : E_{\hat{Y}}[U_A^L(y, e_H, C(\cdot))] \geq 0 \end{aligned}$$

The principal proposes one contract that respects the participation constraints of both agents' types.  $PC_L$  implies that  $\theta_H$  agents will participate.

**Excluding equilibrium problem:**

$$\begin{aligned} & \max_{\hat{v}, C_{HS}(\cdot)} \{\alpha E[U_P(y, e_H), C_{HS}(\cdot)]\} \\ & \text{s.t. : } PC_H : E_{\hat{Y}}[U_A^H(y, e_H, C_{HS}(\cdot))] \geq 0 \end{aligned}$$

The principal proposes one contract that adapts to the constraints of  $\theta_H$  only.  $\theta_L$  don't participate and only a proportion  $\alpha$  of the population is served.

**Separating equilibrium problem:**

$$\begin{aligned} & \max_{\hat{v}, C_H(\cdot), C_L(\cdot)} \{\alpha E[U_P(y, e_H), C_H(\cdot)] + (1 - \alpha)E[U_P(y, e_L), C_L(\cdot)]\} \\ & \text{s.t. : } PC_\theta : E_{\hat{Y}}[U_A^\theta(y, e_\theta, C_\theta(\cdot))] \geq 0 \\ & IC_\theta : E_{\hat{Y}}[U_A^\theta(y, e_\theta, C_\theta(\cdot))] \geq E_{\hat{Y}}[U_A^\theta(y, e_i, C_i(\cdot))] \end{aligned}$$

Where  $\theta = H$  or  $L$  and  $i = L$  if  $\theta = H$  and inversely.

Besides ensuring the participation of both agent's types, the principal has to motivate the agents to exert different effort levels that will allow him to distinguish them. Intuitively, he will have  $\theta_L$  exert a low effort, and inversely for  $\theta_H$ . Two other constraints add to the initial ones that concern the effort level.

Non-negative compensation is required in each problem.

**Proposition 1.a:** A first-best contract with hidden types is always incomplete with minimum awareness disclosure by the principal:  $\hat{\Upsilon}^O = \Upsilon_A$ . This holds whatever the strategy adopted by the principal.

This result is in line with the first-best ones of Auster (2013) where the same effect of tightening of the participation constraint happens when contingencies are disclosed.

**Proposition 1.b:** For some  $\alpha_{p-s}^O, \alpha_{s-e}^O \in [0, 1]$ ,  $\alpha_{p-s}^O < \alpha_{s-e}^O$  the principal chooses the following strategies:

- One unique contract pooling the agents for  $\alpha \in [0, \alpha_{p-s}^O]$
- Two separated contracts for  $\alpha \in [\alpha_{p-s}^O, \alpha_{s-e}^O]$
- One excluding contract for  $\alpha \in [\alpha_{s-e}^O, 1]$

Pooling implies that the principal loses revenue from  $\theta_H$ , whose utility won't be fully extracted. But since the principal doesn't identify the type of the agent, he won't lose revenue on the identification. The lower the  $\alpha$ , the less he loses on  $\theta_H$ , since they are less represented. On the opposite, for a high proportion of  $\theta_H$ , it is less profitable for the principal to separate the agents, for it is costly, while serving only  $\theta_H$  and excluding  $\theta_L$  allows for full extraction of  $\theta_H$ , and no separation cost. Excluding can thus be more profitable than separating, despite the fact that profits are made over a proportion  $\alpha$  of the population only.

See the Annex for the proofs.

## 5 Equilibrium contract: second-best

We now look at the problem with hidden efforts, where the types are still hidden. In this second-best problem, the principal still wants to maximize his utility choosing between pooling, excluding and separating the agents.

The problems are the following:

**Pooling-equilibrium problem:**

$$\begin{aligned} & \max_{\hat{v}, C(\cdot)} \{E[U_P(y, e_H), C(\cdot)]\} \\ \text{s.t. : } & PC_L : E_{\hat{Y}}[U_A^L(y, e_H, C(\cdot))] \geq 0 \\ & IC_L : E_{\hat{Y}}[U_A^L(y, e_H, C(\cdot))] \geq E_{\hat{Y}}[U_A^L(y, e_L, C(\cdot))] \end{aligned}$$

To the initial pooling contract adds the need for the principal to motivate a high effort. Again, motivating it for  $\theta_L$  intuitively implies it for  $\theta_H$ .

**Excluding-equilibrium problem:**

$$\begin{aligned} & \max_{\hat{v}, C_{ExcH}(\cdot)} \{E[U_P(y, e_H), C_{ExcH}(\cdot)]\} \\ \text{s.t. : } & PC_H : E_{\hat{Y}}[U_A^L(y, e_H, C_{ExcH}(\cdot))] \geq 0 \\ & IC_H : E_{\hat{Y}}[U_A^L(y, e_H, C_{ExcH}(\cdot))] \geq E_{\hat{Y}}[U_A^L(y, e_L, C_{ExcH}(\cdot))] \end{aligned}$$

The principal faces the same problem of agent-participation and motivation as above, but only cares about having  $\theta_H$  respecting it. As in the first-best contract, excluding  $\theta_L$  implies that he only makes profits over  $\alpha$  of the population.

**Separating-equilibrium problem:**

$$\begin{aligned} & \max_{\hat{v}, C_H(\cdot), C_L(\cdot)} \{\alpha E[U_P(y, e_H), C_H(\cdot)] + (1 - \alpha)E[U_P(y, e_L), C_L(\cdot)]\} \\ \text{s.t. : } & PC_\theta : E_{\hat{Y}}[U_A^\theta(y, e_\theta, C_\theta(\cdot))] \geq 0 \\ & IC_\theta^e : E_{\hat{Y}}[U_A^\theta(y, e_\theta, C_\theta(\cdot))] \geq E_{\hat{Y}}[U_A^\theta(y, e_i, C_\theta(\cdot))] \\ & IC_\theta^{\text{type}} : E_{\hat{Y}}[U_A^\theta(y, e_\theta, C_\theta(\cdot))] \geq E_{\hat{Y}}[U_A^\theta(y, e_i, C_i(\cdot))] \end{aligned}$$

Where  $\theta = H$  or  $L$  and  $i = L$  if  $\theta = H$  and inversely.

Again the principal has to ensure the participation of both types of agents. He also has to ensure that the agents choose the right contract ( $IC_\theta^{\text{type}}$ ), and that once this contract is chosen they exert the effort contracted on ( $IC_\theta^e$ ).

Solving for these problems gives us the following propositions.

**Proposition 2** : In the second-best contract with hidden types, for some  $\alpha_{p-s}^H, \alpha_{s-e}^H \in [0, 1]$ ,  $\alpha_{p-s}^H < \alpha_{s-e}^H$  the principal chooses the following strategies and awareness level:

- One unique contract pooling the agents for  $\alpha \in [0, \alpha_{p-s}^H]$  with awareness  $\hat{\Upsilon}_p^H$ .
- Two separated contracts for  $\alpha \in [\alpha_{p-s}^H, \alpha_{s-e}^H]$ , with  $\hat{\Upsilon}_s^H$ .
- One excluding contract for  $\alpha \in [\alpha_{s-e}^H, 1]$ ,  $\hat{\Upsilon}_e^H$ .

Also, we have  $\Upsilon_A \subseteq \hat{\Upsilon}_e^H \subseteq \hat{\Upsilon}_p^H \subseteq \hat{\Upsilon}_s^H$

**Assumption 3** : We assume that the awareness structure and optimal compensation scheme follow the rule in Annex.

**Proposition 3** : Under Assumption 3, the different  $\alpha$  at the frontier between two strategies in equilibrium change between the first and the second-best, and follow the ranking below:

$$0 \leq \alpha_{p-s}^O \leq \alpha_{p-s}^H \leq \alpha_{s-e}^H \leq \alpha_{s-e}^O \leq 1$$

See the Annex for the proofs.

## 6 Extension: duopoly market

I now study the impacts of competition on the market structures and equilibrium. It is assumed that both firms know the same set of contingencies, and several cases of competition are considered: a duopoly with both firms in a second-best world; a duopoly where one of the firms has a technology allowing to observe the effort while the other doesn't; and a duopoly where both firms can monitor, and are thus in a first-best world. I look for symmetric Nash equilibrium. The degree of awareness-disclosure is identical in both contracts proposed by the firms. I don't add this constraint in order to have more insights on the problem, but because it results from the rational screening behavior of an economic agent facing two different contracts, and is then more realistic. From now on, let us note Firm A the type of firms that observe the efforts of the agents, and firm B the ones that don't.

### 6.1 Case 1 and 2: symmetric competition

Both situations of symmetric competition are studied here: with and without the monitoring technology. Naturally, symmetric competition leads to zero profits for both firms, following a Bertrand mechanism. This zero-profit result is analyzed by Auster (2013). The questions that remain concern what type of contract will be proposed to the agents, and what awareness disclosure results from it.

**Proposition 4.a:** If firms contract with observable efforts, awareness is necessarily maximal, and profits are entirely redistributed. The contract offered is pooling.

Indeed, Bertrand competition is equivalent for the firms to maximize the agents' utilities under limited-liability constraint. This problem has full redistribution of the profits and full awareness for solution, in a first-best world. Consider an equilibrium where the firms offer partial awareness-disclosure to the agents, then, a firm that deviates to full awareness and almost-full redistribution necessarily increases the utility of the agents, and gets the whole demand. Thus, the only Nash equilibrium offers full awareness and full profits redistribution.

Suppose that the contract is excluding. Then, a symmetric equilibrium implies that both firms make zero profits over the part of the population that is served, and don't serve the other part. It is thus optimal for the firms to deviate from the equilibrium and serve the excluded part of the population. Since it is assumed that exerting a high effort is in general more profitable for the firm and for the agents, both firms will offer a contract that will eventually corresponds to the high-type-agent contract. Thus, every agent will have the same contract that will be pooling.

Assume now that the contract is separating, both firms will again make zero profits on both parts of the population. It is then optimal for them to deviate to a pooling contract where they lower their constraint compared to both initial contracts. Pooling the contracts is again the equilibrium solution.

**Proposition 4.b:** If firms contract with hidden efforts, there exist a partial awareness degree below which no contract is a Nash equilibrium, and above which to every degree of awareness, full awareness included, corresponds a compensation scheme that makes the contract a Nash equilibrium.

Again, this result comes from computing the contract that maximizes the agents' utilities under limited-liability constraint of the company and incentive-compatibility constraint. In monopoly, this problem leads to partial awareness in a second-best world, with an optimal degree of awareness corresponding to the threshold one mentioned above.

Consider an equilibrium where both firms propose a degree of awareness below the

optimal one. They both make zero profits. The firms will then deviate to the optimal degree of awareness that maximizes the agents' utilities for complete redistribution. Both firms will deviate, since if one of the firms remains with the initial contract the other one can lower the retribution and still capture the whole demand. Any contract with an awareness disclosure below the optimal one will not be an equilibrium.

Consider now an equilibrium where both firms have the same awareness disclosure, above the optimal one. A firm that deviates to a lower awareness contract will decrease the agents' utilities, since he will now compute it with his extended awareness level. On the other hand, deviating to a higher level of awareness is not necessarily optimal for the firms, as stated in Auster (2013). We can note that full awareness is also an equilibrium, from the arguments developed above.

By the same mechanism as in the first-best world, the equilibrium contract will be pooling.

## 6.2 Case 3: asymmetric competition

I look at the awareness-symmetric equilibrium in a competition asymmetric over the technology. I start by tackling the question of the nature of the contract, then I focus on the awareness disclosure.

**Proposition 5.a:** Firm B will make zero profits, Firm A will make profits identical to a monopolist constrained on awareness and profits.

As in the technology-symmetric competition, assume that the firms are in an excluding equilibrium. Then the problem that they face, in order to maximize the agents' utilities and get the whole demand is for Firm A:

$$\begin{aligned} & \max_{\hat{v}, C(\cdot)} \{E[U_P(y, e_H), C(\cdot)]\} \\ & \text{s.t. : } PC : E_{\hat{Y}}[U_A^L(y, e_H, C(\cdot))] = 0 \end{aligned}$$

While Firm B wants to solve the same with hidden efforts:

$$\begin{aligned}
& \max_{\hat{v}, C(\cdot)} \{E[U_P(y, e_H), C(\cdot)]\} \\
& s.t. : PC : E_{\hat{Y}}[U_A^L(y, e_H, C(\cdot))] = 0 \\
& IC : E_{\hat{Y}}[U_A^L(y, e_L, C(\cdot))] = 0
\end{aligned}$$

A Bertrand competition with asymmetric information on efforts drives the profits down until Firm B cannot increase the agents' utilities without violating the IC constraint. This maximal awareness corresponds to the threshold awareness in the symmetric duopoly. At this stage, Firm A can get the whole demand by increasing the compensation by  $\epsilon$ . Note that again, a higher level of awareness corresponds to a Nash equilibrium, with zero profits for Firm B.

Eventually, Firm A will face the problem of maximizing its profits, under a reservation utility for the agents corresponding to the utility they get by turning to Firm B, tightening the PC constraint.

**Proposition 5.b:** The contracts proposed by the firms will necessary be pooling.

Assume that both firms exclude the low-type agent. Firm B by making zero profits in the equilibrium as described above, will turn to the low-type agent. Again, following our assumption that the high effort is optimal for the principal and the agents, Firm B will propose a high effort contract, that will be a better alternative for the high-type agent than the one they are offered by Firm A (it is immediate to show by rewriting the optimization problems).

Again, if both firms propose separating contracts, Firm B will make zero profits, and thus will have interest to deviate to pooling contracts, for it will lower the constraints compared to the initial contracts. It will intensify the competitive pressure on Firm A that will have to propose also a pooling contract.

Eventually, one contract will be offered to the agents that will be pooling.

It has been shown that competing implies no profits for the firms, however, situations occur where the firms can anticipate this zero-profit result, and cover the market in such

way that they make positive profits. I study such a situation in the section below.

### **6.3 Case 4: Optimal market structure with a historical actor and a new entrant.**

In this sub-section, a two-stage game where one of the firms is in monopoly in the first step, and the other arrives at the second step is considered.

I want to show that this sequential structure allows the firms to make positive profits. I solve this game in this regard. As shown above it is not profitable for the new entrant to start a frontal competition with the historical player. Specifically, if firms are technology-symmetric, direct competition will lead both of them to zero profits. It is thus optimal for the historical player (present in stage 1) to leave some room to the new entrant.

By backward induction, the traditional player will design its contracts anticipating that a new entrant arrives at stage 2.

Let us see what strategy is optimal in stage 2:

- If the contract offered in stage 1 is pooling, separating, or excluding under the constraints I used until now, frontal competition will occur, leading to zero profits.
- If the contract offered in stage 1 is excluding, with the additional separating constraint that the high-type agents don't skip to a hypothetical second contract for the low-type, taking the form of a separating contract, it is optimal for the second player to propose a low-type agents low-effort contract, which will result in a separation of the market in the same way as in the previous separating contracts, each firm dealing with one type of agents.
- If the contract offered in stage one is pooling, with exertion of a low effort, in the same fashion as in the previous separating contracts, the second agent can offer a high-effort contract with the constraint that only high type agents accept it, and the market will have the same separating structure as above, but with the second player dealing with the high type agents.

The historical player will choose either strategy to maximize his profits in the first stage, and to make zero profits in the second, or to lower its profits in the first stage and make positive ones in the second, depending on its discount factor. Also, the firm will either propose an excluding contract, or a low-effort pooling one depending on the proportion of the agents. If there is room in the market, the new entrant will avoid frontal competition *whatever the proportion of the agents*, and will make positive profits. It implies that constraints appear for both firms, that correspond to the ones in separating contracts.

If the traditional player has the technology, he might accept frontal competition, to the extent that the competitive pressure is low enough. Similarly, if the new entrant is the one with the technology, he might start frontal competition also, under conditions of the same nature.

## 7 Discussion

Allowing for awareness asymmetry in moral-hazard models with heterogeneous agents allows for a better understanding of market structures and a better evaluation of the consumer's utilities and the firm profits. The two factors of high interest in our set-up, that are the strategy of the firms and the degree of awareness given in the contracts, are altered compared to the traditional model.

Comparing our set-up with the traditional one without unawareness shows several consequences. I begin with noticing that the contracts without unawareness are included in our set-up and corresponds to the case where  $\Upsilon = \Upsilon_A$ .

A first effect that's quite immediate to observe is that, since disclosing awareness is a non-financial lever for the firm to increase its profits, the utilities of the agents in contracts with unawareness are always below the utilities with symmetric awareness. I can thus start by noting that the agent's utilities decrease compared to the traditional set-up.

A second effect concerns the nature of the contract chosen by the company. Indeed,

I have shown that awareness disclosure is the highest for separating contracts in second-best world, then for the pooling one, and finally for the excluding one. A consequence of these different degrees of awareness is that, since excluding and pooling contracts use the higher awareness more than the separating one in order to maximize the principal's profits, skipping to symmetric awareness implies that, for proportions that would initially be offered a pooling or an excluding contract, they will be offered a separating one in symmetric awareness.

Taking into account unawareness changes the market structures for some proportions of low types in the population, and shows that actually, pooling and excluding equilibrium occur in more situations than the symmetric awareness set-ups were proving. Again this result is crucial for regulators, especially in markets such as the health-insurance market.

Turning to the comparison between first and second-best world in contract with unawareness, I have shown that introducing a monitoring technology strongly affects the degree of awareness disclosure, the awareness being automatically driven down to its minimum possible. In the second-best world, this awareness takes different values that are always above the minimum. To that extent the introduction of the technology is a major drawback for the consumers. Note that including awareness as a lever for the principal to design the contract naturally decreases the agents' utilities.

Considering now the market structure, the technology widens the case where separating contracts are chosen by the principal. This occurs in two ways, by proposing pooling contracts in less cases, and similarly for excluding contracts.

The interpretation of these results clearly depends on the nature of the market studied, the implications of more separating contracts being incomparable between the loan market and the market for health-insurance for instance. In the health-insurance market, the dominant paradigm is risk-pooling at the society level. Offering contracts that allow to discriminate between two types of agents violates this paradigm, to a further extent if one of the agents is encouraged to exert a low effort in order to maximize the firm's profits. This question is central since, with the introduction of the IoT in health insur-

ance market, and the use of data to design specific contracts in the US, more separating contracts are expected.

## 8 Conclusion

By introducing unawareness in contract-models with heterogeneous agents, I derive some strong implications on economic agents' utilities and market mechanisms, with a significant social impact. Namely, I show that, compared to the symmetric awareness set-ups, the principal's profits are higher and the agent's utility is lower. Also, while in these set-up, for some agent's-type proportions, the contract are pooling or excluding, they turn to be separating when unawareness is introduced.

Comparing our results with the one of contract-model with unawareness and homogeneous agents allows us to capture the implications of unawareness on the structures of the market. In particular, while with homogeneous agents the market was always covered, I show here that several cases may occur, where the degree of awareness disclosure is used by the principal to maximize its profits.

Eventually, I clarify the equilibrium in competition for several configurations of the use of a monitoring technology. Also, I show that, in sequential games, some collusion can occur, leading to a higher extraction of the agents' surplus.

This paper is in line with the trend of the literature, that looks for more applicability of the results of the theory of unawareness and incomplete contracts to industrial organization. More specifically, I believe that considering markets such as health-insurance with the scope of awareness-asymmetric contracts offers a more precise understanding of the process of contract-design. Comparing the market equilibrium in the first and the second-best world helps to understand the changes that will occur with the introduction of monitoring technologies.

## Annex

Proof 1.a:

Pooling equilibrium:

The proof is the same as in Auster (2013). The profit is

$$\Pi(\hat{v}, C_p^O(\cdot)) = \sum_{y \in Y} P(y|e_H)y - \sum_{y \in \hat{Y}} P(y|e_H)C_p^O$$

Excluding equilibrium:

The proof is again similar, and the profit is:

$$\Pi(\hat{v}, C_e^O(\cdot)) = \alpha[\sum_{y \in Y} P(y|e_H)y - \sum_{y \in \hat{Y}} P(y|e_H)C_e^O]$$

Separating equilibrium:

We see immediately that  $PC_H$  is not binding.

$$\begin{aligned} \sum_{y \in \hat{Y}} \hat{P}(y|e_H)V(C_H(y)) - \mathcal{C}(e_H) &\geq \sum_{y \in \hat{Y}} \hat{P}(y|e_L)V(C_L(y)) - \mathcal{C}(e_L) \geq \sum_{y \in \hat{Y}} \hat{P}(y|e_L)V(C_L(y)) - e_L \geq 0 \\ \implies \sum_{y \in \hat{Y}} \hat{P}(y|e_H)V(C_H(y)) - \mathcal{C}(e_H) &\geq 0 \end{aligned}$$

Thus  $PC_L + IC_H \implies PC_H$ .

$$\max_{\hat{v}, C_H(\cdot), C_L(\cdot)} \left\{ \alpha \sum_{y \in Y} P(y|e_H)[y - C_H(y)] + (1 - \alpha) \sum_{y \in Y} P(y|e_L)[y - C_L(y)] \right\}$$

$$s.t. : PC_L : \sum_{y \in \hat{Y}} \hat{P}(y|e_L)V(C_L(y)) - e_L \geq 0$$

$$IC_H : \sum_{y \in \hat{Y}} \hat{P}(y|e_H)V(C_H(y)) - \mathcal{C}(e_H) \geq \sum_{y \in \hat{Y}} \hat{P}(y|e_L)V(C_L(y)) - \mathcal{C}(e_L)$$

$$IC_L : \sum_{y \in \hat{Y}} \hat{P}(y|e_L)V(C_L(y)) - e_L \geq \sum_{y \in \hat{Y}} \hat{P}(y|e_H)V(C_H(y)) - e_H$$

With respectively  $\lambda, \mu, \gamma$  the Lagrange coefficients for  $PC_L, IC_H$  and  $IC_L$ .

We have:  $\lambda > 0, \mu > 0, \gamma = 0$

By contradiction: assume  $\lambda = 0$ , then we must have (to respect the Inada condition over  $V$ ) simultaneously the strict positivity of  $\mu - \gamma$  and  $\gamma - \mu$ , impossible. Thus,  $\lambda > 0$ .

Then, assume  $\mu = 0$ , then the positivity of the right hand term of the first equation is not respected anymore. Thus,  $\mu > 0$ .

$$\text{We thus have: } \sum_{y \in \hat{Y}} \hat{P}(y|e_L)V(C_L(y)) = e_L$$

$$\sum_{y \in \hat{Y}} \hat{P}(y|e_H)V(C_H(y)) = \Delta\mathcal{C}(e) + e_L$$

Replacing the constant compensations into the binding constraints gives us

$$C_{SB}^H = V^{-1}(e_L + \Delta\mathcal{C}(e)) \text{ and } C_{SB}^L = V^{-1}(e_L).$$

This optimal allocation is the same with  $IC_L$  or not, thus  $\gamma = 0$

Optimal awareness size:

$$V'(C_H(y)) = \frac{\alpha}{\mu - \gamma} \Pi(\Upsilon = 0|e_H) \text{ and}$$

$$V'(C_L(y)) = \frac{(1-\alpha)}{\lambda - \mu + \gamma} \Pi(\Upsilon = 0|e_L)$$

require both to have a minimum awareness size so that  $C_H$  and  $C_L$  are the lower possible ( $\iff V'(C_H)$  and  $V'(C_L)$  are the bigger possible).

The profit is:

$$\Pi(\hat{v}, C_{H,s}^O(\cdot), C_{L,s}^O(\cdot)) = \alpha \sum_{y \in Y} P(y|e_H)y + (1-\alpha) \sum_{y \in Y} P(y|e_L)y - \{\alpha \sum_{y \in \hat{Y}} P(y|e_H)C_{H,s}^O + (1-\alpha) \sum_{y \in \hat{Y}} P(y|e_L)C_{L,s}^O\}$$

□

Proof 1.b:

Which strategy is preferable between separating and pooling?

$$\begin{aligned} \Pi(\hat{v}, C_H(\cdot)) - \Pi(\hat{v}, C_{H,s}^O(\cdot), C_{L,s}^O(\cdot)) &= (1-\alpha) \sum_{y \in Y} y(P(y|e_H) - P(y|e_L)) \\ &\quad + \alpha \sum_{y \in \hat{Y}} (P(y|e_H)(C_{H,s}^O - C_p^O)) \\ &\quad + (1-\alpha) \left( \sum_{y \in \hat{Y}} (P(y|e_L)C_{L,s}^O) - \sum_{y \in \hat{Y}} (P(y|e_H)C_p^O) \right) \end{aligned}$$

For  $\alpha \geq \alpha_{p-s}^O$  separating is preferable, with

$$\alpha_{p-s}^O = \frac{\sum_{y \in Y} y(P(y|e_H) - P(y|e_L)) + (\sum_{y \in \hat{Y}} (P(y|e_L)C_{L,s}^O) - \sum_{y \in \hat{Y}} P(y|e_H)C_p^O)}{\sum_{y \in Y} y(P(y|e_H) - P(y|e_L)) + \sum_{y \in \hat{Y}} P(y|e_L)C_{L,s}^O - \sum_{y \in \hat{Y}} P(y|e_H)C_{H,s}^O}$$

Which strategy is preferable between excluding and separating?

$$\begin{aligned} \Pi(\hat{v}, C_e^O(\cdot)) - \Pi(\hat{v}, C_{H,s}^O(\cdot), C_{L,s}^O(\cdot)) &= (1 - \alpha) \left[ \sum_{y \in \hat{Y}} P(y|e_L) C_{L,s}^O - \sum_{y \in Y} P(y|e_L) y \right] \\ &+ \alpha \left[ \sum_{y \in \hat{Y}} P(y|e_H) C_{H,s}^O - \sum_{y \in \hat{Y}} P(y|e_H) C_e^O \right] \end{aligned}$$

For  $\alpha \geq \alpha_{s-e}^O$  excluding is preferable, with

$$\forall \alpha \geq \alpha_{s-e}^O = \frac{\sum_{y \in Y} P(y|e_L) y - \sum_{y \in \hat{Y}} P(y|e_L) C_{L,s}^O}{\sum_{y \in Y} P(y|e_L) y - \sum_{y \in \hat{Y}} P(y|e_L) C_{L,s}^O + \sum_{y \in \hat{Y}} P(y|e_H) C_{H,s}^O - \sum_{y \in \hat{Y}} P(y|e_H) C_e^O}$$

Finally:  $0 \leq \alpha_{p-s}^O \leq \alpha_{s-e}^O \leq 1 \square$

Proof 2:

I start by considering the separating equilibrium problem. I then compare the constraints to the ones of the other two configuration, and infer the different levels of awareness disclosure from the constraints.

Separating equilibrium:

It's again immediate to show that  $PC_H$  is not binding.

FOCs on  $C_H$  and  $C_L$  give us, with  $\lambda, \mu, \gamma, \theta$  and  $\delta$  respectively the Lagrange coefficients of  $PC_L, IC_H^e, IC_L^e, IC_H^\theta$  and  $IC_L^\theta$ .

$$\begin{aligned} C_{H,s}^H: \frac{\alpha}{V_H'} &= \frac{1}{P(v=0|e_H)} [(\mu + \theta - \delta) - \mu \frac{P(v|e_L)}{P(v|e_H)}] \\ C_{L,s}^H: \frac{1-\alpha}{V_L'} &= \frac{1}{P(v=0|e_L)} [(\lambda + \delta - \theta + \gamma) - \gamma \frac{P(v|e_H)}{P(v|e_L)}] \end{aligned}$$

We always have  $\lambda > 0$

Indeed, FOC on  $C_{H,s}^H$  implies that  $\theta - \delta > 0$ , but then, we necessarily have  $\lambda > 0$  in the second FOC. Thus,  $PC_L$  is always binding, and  $\sum_{y \in \hat{Y}} \hat{P}(y|e_L) V(C_{L,s}^H(y)) = e_L$

Note that an immediate condition for this problem to have a solution is to have  $e_H \geq \Delta C(e) + e_L$

We always have  $\theta > 0$ , or else, on FOC on  $C_{H,s}^H$ , the positivity of the left hand side is not guaranteed.

Thus,  $IC_H^\theta$  is binding, and  $\sum_{y \in \hat{Y}} \hat{P}(y|e_H) V(C_{H,s}^H(y)) = \Delta C(e) + e_L$ . It implies immediately that  $IC_L^\theta$  is slack, and we can remove it from the list of the constraints.

We always have  $\mu > 0$ : assume it is not the case.

$$\text{Then: FOC on } C_{H,s}^H: \frac{\alpha}{V_H'} = \frac{1}{P(v=0|e_H)} (\theta - \delta)$$

this is a constant over  $y$ , thus  $C_{H,s}^H(\cdot)$  does not depend on  $y$ .

But then,  $V(C_{H,s}^H) = \Delta C(e) + e_L > e_L$ , and  $IC_H^e$  is violated.

Thus  $IC_H^e$  is binding and  $\mu > 0$ .

I show now that  $IC_L^e$  is slack.

Solving the problem

$$\max_{\hat{v}, C_{H,s}^H(\cdot), C_{L,s}^H(\cdot)} \left\{ \alpha \sum_{y \in Y} P(y|e_H)[y - C_{H,s}^H(y)] + (1 - \alpha) \sum_{y \in Y} P(y|e_L)[y - C_{L,s}^H(y)] \right\}$$

$$PC_L : \sum_{y \in \hat{Y}} \hat{P}(y|e_L)V(C_{L,s}^H(y)) = e_L$$

$$IC_H^e : \sum_{y \in \hat{Y}} \hat{P}(y|e_L)V(C_{H,s}^H(y)) = e_L$$

$$IC_H^\theta : \sum_{y \in \hat{Y}} \hat{P}(y|e_H)V(C_{H,s}^H(y)) = \Delta C(e) + e_L$$

Gives us  $C_{L,s}^H(y) = cst$

Adding  $IC_L^e : e_H \geq \sum_{y \in \hat{Y}} \hat{P}(y|e_H)V(C_{L,s}^H(y))$ , the same constant compensation still satisfies the constraints.

thus this constraint is slack and we are back to problems for which Auster's result apply.

Let us compare the three problems.

Pooling

$$\max_{\hat{v}, C_p^H(\cdot)} \left\{ \sum_{y \in Y} P(y|e_H)[y - C_p^H(y)] \right\}$$

$$s.t. : PC : \sum_{y \in \hat{Y}} \hat{P}(y|e_H)V(C_p^H(y)) = e_H$$

$$IC : \sum_{y \in \hat{Y}} \hat{P}(y|e_L)V(C_p^H(y)) = e_L$$

Separating

$$\max_{\hat{v}, C_{H,s}^H(\cdot), C_{L,s}^H(\cdot)} \left\{ \alpha \sum_{y \in Y} P(y|e_H)[y - C_{H,s}^H(y)] + (1 - \alpha) \sum_{y \in Y} P(y|e_L)[y - C_{L,s}^H(y)] \right\}$$

$$PC_L : \sum_{y \in \hat{Y}} \hat{P}(y|e_L)V(C_{L,s}^H(y)) = e_L$$

$$IC_H^e : \sum_{y \in \hat{Y}} \hat{P}(y|e_L)V(C_{H,s}^H(y)) = e_L$$

$$IC_H^\theta : \sum_{y \in \hat{Y}} \hat{P}(y|e_H)V(C_{H,s}^H(y)) = \Delta C(e) + e_L$$

Excluding

$$\max_{\hat{v}, C_e^H(\cdot)} \left\{ \alpha \sum_{y \in Y} P(y|e_H)[y - C_e^H(y)] \right\}$$

$$s.t. : PC : \sum_{y \in \hat{Y}} \hat{P}(y|e_H)V(C_e^H(y)) = C_H$$

$$IC : \sum_{y \in \hat{Y}} \hat{P}(y|e_L)V(C_e^H(y)) = C_L$$

It is again immediate to prove that the compensation over the contingencies that the agents are not aware of are  $C = 0$  whatever the type of the agents.

Let us compare the difference in profits for the pooling and separating equilibrium strategy:

Pooling profits:

$$\Pi_P(\hat{v}_P, C_p^H(\cdot)) = \sum_{y \in Y} P(y|e_H)y - \sum_{y \in \hat{Y}_P} P(y|e_H)C_p^H(y)$$

Separating profits:

$$\begin{aligned} \Pi_S(\hat{v}_S, C_{H,s}^H(\cdot), C_{L,s}^H(\cdot)) = & \alpha \left\{ \sum_{y \in Y} P(y|e_H)y - \sum_{y \in \hat{Y}_S} P(y|e_H)C_{H,s}^H(y) \right\} \\ & + (1 - \alpha) \left\{ \sum_{y \in Y} P(y|e_L)y - \sum_{y \in \hat{Y}_S} P(y|e_L)C_{L,s}^H(y) \right\} \end{aligned}$$

Difference in profits pooling-separating:

$$\begin{aligned}
\Pi_P(\hat{v}_P, C_p^H(\cdot)) - \Pi_S(\hat{v}_S, C_{H,s}^H(\cdot), C_{L,s}^H(\cdot)) = \\
(1 - \alpha) \left\{ \sum_{y \in Y} P(y|e_H)y - \sum_{y \in Y} P(y|e_L)y \right\} \\
+ \alpha \left\{ \sum_{y \in \hat{Y}_S} P(y|e_H)C_{H,s}^H(y) - \sum_{y \in \hat{Y}_P} P(y|e_H)C_p^H(y) \right\} \\
+ (1 - \alpha) \left\{ \sum_{y \in \hat{Y}_S} P(y|e_L)C_{L,s}^H(y) - \sum_{y \in \hat{Y}_P} P(y|e_H)C_p^H(y) \right\}
\end{aligned}$$

We can again define a threshold  $\alpha_{p-s}^H$  such that  $\forall \alpha > \alpha_{p-s}^H$  separating is more profitable for the principal:

$$\alpha_{p-s}^H = \frac{\sum_{y \in Y} P(y|e_H)y - \sum_{y \in Y} P(y|e_L)y + \sum_{y \in \hat{Y}_S} P(y|e_L)C_{L,s}^H(y) - \sum_{y \in \hat{Y}_P} P(y|e_H)C_p^H(y)}{\sum_{y \in Y} P(y|e_H)y - \sum_{y \in Y} P(y|e_L)y + \sum_{y \in \hat{Y}_S} P(y|e_L)C_{L,s}^H(y) - \sum_{y \in \hat{Y}_S} P(y|e_H)C_{H,s}^H(y)}$$

Difference in profits excluding-separating:

$$\Pi_P(\hat{v}_P, C_e^H(\cdot)) = \alpha \sum_{y \in Y} P(y|e_H)y - \alpha \sum_{y \in \hat{Y}_e^H} P(y|e_H)C_e^H(y)$$

The difference is then:

$$\begin{aligned}
\Pi_P(\hat{v}_P, C_e^H(\cdot)) - \Pi_S(\hat{v}_S, C_{H,s}^H(\cdot), C_{L,s}^H(\cdot)) = \\
(1 - \alpha) \left[ \sum_{y \in \hat{Y}_S} P(y|e_L)C_{L,s}^H(y) - \sum_{y \in Y} P(y|e_L)y \right] \\
+ \alpha \left\{ \sum_{y \in \hat{Y}_S} P(y|e_H)C_{H,s}^H(y) - \sum_{y \in \hat{Y}_e^H} P(y|e_H)C_e^H(y) \right\}
\end{aligned}$$

$$\alpha \geq \alpha_{s-e}^H$$

$$\alpha_{s-e}^H = \frac{\sum_{y \in Y} P(y|e_L)y - \sum_{y \in \hat{Y}_S} P(y|e_L)C_{L,s}^H(y)}{\sum_{y \in Y} P(y|e_L)y - \sum_{y \in \hat{Y}_S} P(y|e_L)C_{L,s}^H(y) + \sum_{y \in \hat{Y}_S} P(y|e_H)C_{H,s}^H(y) - \sum_{y \in \hat{Y}_e^H} P(y|e_H)C_e^H(y)}$$

$$\Upsilon_s^H \geq \Upsilon_p^H \geq \Upsilon_e^H$$

Different degrees of awareness are chosen by the principal depending on the regime:

PC constraint is tighter for both sub-problems of the separating case, while IC constraint remain identical, thus, awareness is higher in separating than in pooling.

Both PC and IC constraint have more slack on the excluding equilibrium. Consider both problems without IC constraints. the optimal compensation schemes are in both case constant retribution without awareness. Adding the constraint is what will impose awareness increasing. Since the IC constraint is tighter in pooling than in separating, awareness will be higher in pooling.

Note: when separating equilibrium,  $\theta_L$  can be satisfied without any awareness, while  $\theta_H$  require an awareness extension. Since all constraints have to be satisfied, and since I assume awareness homogeneous among the agents, separating implies an increase of awareness on the agents' side.  $\square$

**Proof 3:**  $0 \leq \alpha_{p-s}^O \leq \alpha_{p-s}^H \leq \alpha_{s-e}^H \leq \alpha_{s-e}^O \leq 1$

under the rule below which are sufficient condition:

1.  $\sum_{y \in Y} P(y|e_H)y - \sum_{y \in \hat{Y}} \hat{P}(y|e_H)C_p^{obs}(y) \geq \sum_{y \in Y} P(y|e_L)y - \sum_{y \in \hat{Y}} \hat{P}(y|e_L)C_{L,s}^{obs}(y)$
2.  $\sum_{y \in \hat{Y}} \hat{P}(y|e_L)C_{L,s}^{hid}(y) - \sum_{y \in \hat{Y}} \hat{P}(y|e_H)C_{H,p}^{hid}(y) - \sum_{y \in \hat{Y}} \hat{P}(y|e_L)C_{L,s}^{obs}(y) + \sum_{y \in \hat{Y}} \hat{P}(y|e_H)C_{H,p}^{obs}(y)$   
 $\geq \sum_{y \in \hat{Y}} \hat{P}(y|e_L)C_{L,s}^{hid}(y) - \sum_{y \in \hat{Y}} \hat{P}(y|e_H)C_{H,s}^{hid}(y) - \sum_{y \in \hat{Y}} \hat{P}(y|e_L)C_{L,s}^{obs}(y) - \sum_{y \in \hat{Y}} \hat{P}(y|e_H)C_{H,s}^{obs}(y)$
3.  $\sum_{y \in Y} P(y|e_H)y - \sum_{y \in \hat{Y}} \hat{P}(y|e_H)C_{H,s}^{hid}(y)$   
 $\geq \sum_{y \in Y} P(y|e_H)y - \sum_{y \in \hat{Y}} \hat{P}(y|e_H)C_{H,p}^{hid}(y) + \sum_{y \in \hat{Y}} \hat{P}(y|e_H)C_{H,s}^{hid}(y) - \sum_{y \in \hat{Y}} \hat{P}(y|e_H)C_{H,e}^{hid}(y)$
4.  $\sum_{y \in \hat{Y}} \hat{P}(y|e_H)C_{H,s}^{hidden}(y) - \sum_{y \in \hat{Y}} \hat{P}(y|e_H)C_{H,e}^{hidden}(y) \geq \sum_{y \in \hat{Y}} \hat{P}(y|e_H)C_{H,s}^{obs}(y) - \sum_{y \in \hat{Y}} \hat{P}(y|e_H)C_{H,e}^{obs}(y)$
5.  $\sum_{y \in \hat{Y}} \hat{P}(y|e_H)C_{H,s}^{hidden}(y) \geq \sum_{y \in \hat{Y}} \hat{P}(y|e_H)C_{H,e}^{hidden}(y)$

The proof is immediate when we compare the different  $\alpha$ .

$$\alpha_{p-s}^O \geq 0$$

It' is immediate to see that the positivity is guaranteed as long as

$$\sum_{y \in Y} P(y|e_H)y - \sum_{y \in \hat{Y}} \hat{P}(y|e_H)C_p^{obs}(y) \geq \sum_{y \in Y} P(y|e_L)y - \sum_{y \in \hat{Y}} \hat{P}(y|e_L)C_{L,s}^{obs}(y)$$

This condition is in line with the assumption that the implementation of a high effort is always preferred by the principal.

$$\alpha_{p-s}^H \geq \alpha_{p-s}^O$$

Comparing these two values is equivalent to comparing

$$(\sum_{y \in Y} P(y|e_H)y - \sum_{y \in Y} P(y|e_L)y + \sum_{y \in \hat{Y}} \hat{P}(y|e_L)C_{L,s}^{hid}(y) - \sum_{y \in \hat{Y}} \hat{P}(y|e_H)C_p^{hid}(y))$$

$$\times (\sum_{y \in Y} P(y|e_H)y - \sum_{y \in Y} P(y|e_L)y + \sum_{y \in \hat{Y}} \hat{P}(y|e_L)C_{L,s}^{obs}(y) - \sum_{y \in \hat{Y}} \hat{P}(y|e_H)C_{H,p}^{obs}(y))$$

and

$$(\sum_{y \in Y} P(y|e_H)y - \sum_{y \in Y} P(y|e_L)y + \sum_{y \in \hat{Y}} \hat{P}(y|e_L)C_{L,s}^{obs}(y) - \sum_{y \in \hat{Y}} \hat{P}(y|e_H)C_{H,p}^{obs}(y))$$

$$\times (\sum_{y \in Y} P(y|e_H)y - \sum_{y \in Y} P(y|e_L)y + \sum_{y \in \hat{Y}} \hat{P}(y|e_L)C_{L,s}^{hid}(y) - \sum_{y \in \hat{Y}} \hat{P}(y|e_H)C_{H,s}^{hid}(y))$$

$\iff$

A sufficient condition for the first term to be greater than the second is to assume

$$\begin{aligned} & \sum_{y \in \hat{Y}} \hat{P}(y|e_L) C_{L,s}^{hid}(y) - \sum_{y \in \hat{Y}} \hat{P}(y|e_H) C_{H,p}^{hid}(y) + \sum_{y \in \hat{Y}} \hat{P}(y|e_L) C_{L,s}^{obs}(y) - \sum_{y \in \hat{Y}} \hat{P}(y|e_H) C_{H,s}^{obs}(y) \\ & \geq \sum_{y \in \hat{Y}} \hat{P}(y|e_L) C_{L,s}^{obs}(y) - \sum_{y \in \hat{Y}} \hat{P}(y|e_H) C_{H,p}^{obs}(y) + \sum_{y \in \hat{Y}} \hat{P}(y|e_L) C_{L,s}^{hid}(y) - \sum_{y \in \hat{Y}} \hat{P}(y|e_H) C_{H,s}^{hid}(y) \end{aligned}$$

or equivalently

$$\begin{aligned} & \sum_{y \in \hat{Y}} \hat{P}(y|e_L) C_{L,s}^{hid}(y) - \sum_{y \in \hat{Y}} \hat{P}(y|e_H) C_{H,p}^{hid}(y) - \sum_{y \in \hat{Y}} \hat{P}(y|e_L) C_{L,s}^{obs}(y) + \sum_{y \in \hat{Y}} \hat{P}(y|e_H) C_{H,p}^{obs}(y) \\ & \geq \sum_{y \in \hat{Y}} \hat{P}(y|e_L) C_{L,s}^{hid}(y) - \sum_{y \in \hat{Y}} \hat{P}(y|e_H) C_{H,s}^{hid}(y) - \sum_{y \in \hat{Y}} \hat{P}(y|e_L) C_{L,s}^{obs}(y) - \sum_{y \in \hat{Y}} \hat{P}(y|e_H) C_{H,s}^{obs}(y) \end{aligned}$$

The interpretation of this assumption is that the difference of compensation between observable and hidden efforts is greater between the low compensation of the separating contract and the pooling compensation than between the low and the high compensations of the separating contract.

$$\alpha_{s-e}^H \geq \alpha_{p-s}^H$$

Comparing these two values is equivalent to comparing

$$\begin{aligned} & (\sum_{y \in \hat{Y}} \hat{P}(y|e_L) y - \sum_{y \in \hat{Y}} \hat{P}(y|e_L) C_{L,s}^{hid}(y)) \\ & \times (\sum_{y \in Y} P(y|e_H) y - \sum_{y \in Y} P(y|e_L) y + \sum_{y \in \hat{Y}} \hat{P}(y|e_L) C_{L,s}^{hid}(y) - \sum_{y \in \hat{Y}} \hat{P}(y|e_H) C_{H,s}^{hid}(y)) \end{aligned}$$

and

$$\begin{aligned} & (\sum_{y \in Y} P(y|e_H) y - \sum_{y \in Y} P(y|e_L) y + \sum_{y \in \hat{Y}} \hat{P}(y|e_L) C_{L,s}^{hid}(y) - \sum_{y \in \hat{Y}} \hat{P}(y|e_H) C_{H,p}^{hid}(y)) \\ & \times (\sum_{y \in Y} P(y|e_L) y - \sum_{y \in \hat{Y}} \hat{P}(y|e_L) C_{L,s}^{hid}(y) + \sum_{y \in \hat{Y}} \hat{P}(y|e_H) C_{H,s}^{hid}(y) - \sum_{y \in \hat{Y}} \hat{P}(y|e_H) C_{H,e}^{hid}(y)) \end{aligned}$$

As before, assuming

$$\begin{aligned} & \sum_{y \in Y} P(y|e_H) y - \sum_{y \in \hat{Y}} \hat{P}(y|e_H) C_{H,s}^{hid}(y) \\ & \geq \sum_{y \in Y} P(y|e_H) y - \sum_{y \in \hat{Y}} \hat{P}(y|e_H) C_{H,p}^{hid}(y) + \sum_{y \in \hat{Y}} \hat{P}(y|e_H) C_{H,s}^{hid}(y) - \sum_{y \in \hat{Y}} \hat{P}(y|e_H) C_{H,e}^{hid}(y) \end{aligned}$$

is a sufficient condition to have the inequality.

This assumption can be understood as requiring that the partial profits of the principal on the high-type agents for the separating contract in the hidden effort case is greater than his profits on the pooling contracts with hidden efforts plus the difference of cost between the low type in separating contract and the excludng contract in the case with hidden efforts.

$$\alpha_{s-e}^O \geq \alpha_{s-e}^H$$

Comparing the  $\alpha$  is equivalent to comparing

$$(\sum_{y \in Y} P(y|e_L)y - \sum_{y \in \hat{Y}} \hat{P}(y|e_L)C_{L,s}^{obs}(y))$$

$$x(\sum_{y \in Y} P(y|e_L)y - \sum_{y \in \hat{Y}} \hat{P}(y|e_L)C_{L,s}^{hidden}(y) + \sum_{y \in \hat{Y}} \hat{P}(y|e_H)C_{H,s}^{hidden}(y) - \sum_{y \in \hat{Y}} \hat{P}(y|e_H)C_{H,e}^{hidden}(y))$$

and

$$\sum_{y \in Y} P(y|e_L)y - \sum_{y \in \hat{Y}} \hat{P}(y|e_L)C_{L,s}^{hidden}(y)$$

$$x(\sum_{y \in Y} P(y|e_L)y - \sum_{y \in \hat{Y}} \hat{P}(y|e_L)C_{L,s}^{obs}(y) + \sum_{y \in \hat{Y}} \hat{P}(y|e_H)C_{H,s}^{obs}(y) - \sum_{y \in \hat{Y}} \hat{P}(y|e_H)C_{H,e}^{obs}(y)).$$

We see first that since the constraints on the low-type separating contract are higher in the observable than in the hidden case:

$$\sum_{y \in \hat{Y}} \hat{P}(y|e_L)C_{L,s}^{hidden}(y) \geq \sum_{y \in \hat{Y}} \hat{P}(y|e_L)C_{L,s}^{obs}(y)$$

and

$$\sum_{y \in Y} P(y|e_L)y - \sum_{y \in \hat{Y}} \hat{P}(y|e_L)C_{L,s}^{obs}(y) \geq \sum_{y \in Y} P(y|e_L)y - \sum_{y \in \hat{Y}} \hat{P}(y|e_L)C_{L,s}^{hidden}(y)$$

We see then that assuming that

$$\sum_{y \in \hat{Y}} \hat{P}(y|e_H)C_{H,s}^{hidden}(y) - \sum_{y \in \hat{Y}} \hat{P}(y|e_H)C_{H,e}^{hidden}(y) \geq \sum_{y \in \hat{Y}} \hat{P}(y|e_H)C_{H,s}^{obs}(y) - \sum_{y \in \hat{Y}} \hat{P}(y|e_H)C_{H,e}^{obs}(y)$$

is a sufficient condition to have  $\alpha_{s-e}^O \geq \alpha_{s-e}^H$

It can be seen as having the difference in cost for the high type between separating and excluding contracts greater in the hidden effort case than in the observable effort case.

$$1 \geq \alpha_{s-e}^O$$

We see here that this inequality is guaranteed as long as

$$\sum_{y \in \hat{Y}} \hat{P}(y|e_H)C_{H,s}^{hidden}(y) \geq \sum_{y \in \hat{Y}} \hat{P}(y|e_H)C_{H,e}^{hidden}(y)$$

This is always verified since the constraints are lower in the excluding equilibrium problem than in the separating one for the high type.

□

Proof 4.a: If firms contract with observable efforts, awareness is necessarily maximal, and profits are entirely redistributed. The contract offered is pooling.

First-best:

Bertrand competition is equivalent for the firms to maximize the agents' utilities under limited-liability constraint. This problem can be written (in a simplified way) as:

$$\begin{aligned} & \max_{\hat{v}, C(\cdot)} \left\{ \sum_{y \in \hat{Y}} P(y|e_H) V(C(y)) - e_H \right\} \\ & \text{s.t. : } LL : \sum_{y \in Y} P(y|e_H) [y - C(y)] \geq 0 \end{aligned}$$

Note that maximizing one agent's utility implies the maximization of the other, since the effort-cost is linear.

The utility-maximizing compensation respects the following condition:

$$\frac{\partial L}{\partial C(y)} = 0 \iff V'(C(y)) = \lambda \text{ for } y \in \hat{Y}$$

It has a corner solution for  $y \in Y \setminus \hat{Y}$  that gives  $C(y) = 0$

$\lambda$  being a constant, and  $V(\cdot)$  being strictly concave, since this equation is true for any  $y$ , we can conclude that  $C(\cdot)$  is constant whatever  $y \in \hat{Y}$ .

The SC constraint is binding it can be written:

$$\sum_{y \in Y} P(y|e_H) y = \sum_{y \in \hat{Y}} P(y|e_H) C(y)$$

Since  $C(\cdot)$  is a constant we obtain:

$$\frac{\sum_{y \in Y} P(y|e_H) y}{\sum_{y \in \hat{Y}} P(y|e_H)} = C_{FB}$$

Considering now the optimal level of awareness, we see that it impacts both the value of  $C_{FB}$  and the size of the sum in the agent's utility. The problem can be written:

$$\max_{\hat{v}} \left\{ V \left( \frac{\sum_{y \in Y} P(y|e_H) y}{\sum_{y \in \hat{Y}} P(y|e_H)} \right) \sum_{y \in \hat{Y}} P(y|e_H) \right\}$$

The assumption

$\left[ xV\left(\frac{\beta}{x}\right) \right]' \geq 0$  for any  $x \in [0, 1]$  and  $\beta \geq 0$ , which is verified by classical utility functions, like  $V(x) = \frac{x^{1-\rho}}{1-\rho}$  for  $x \in [0, +\infty]$  and  $\rho \in ]0, 1[$

guarantees that the above function increases with the size of  $\hat{v}$ .  $\square$

Proof 4.b: Again, this result comes from computing the contract that maximizes the agents' utilities under limited-liability constraint of the company and incentive-compatibility constraint.

Second-best: The problem becomes the following one:

$$\begin{aligned}
& \max_{\hat{v}, C(\cdot)} \left\{ \sum_{y \in \hat{Y}} P(y|e_H) V(C(y)) - e_H \right\} \\
& \text{s.t. : } LL : \sum_{y \in Y} P(y|e_H) [y - C(y)] \geq 0 \\
& \text{and : } IC : \sum_{y \in \hat{Y}} \hat{P}(y|e_H) V(C(y)) - e_H \geq \sum_{y \in \hat{Y}} \hat{P}(y|e_L) V(C(y)) - e_L
\end{aligned}$$

The constrained optimization problem respects the following condition:

$$\frac{\lambda}{V'(C(y))} = 1 + \frac{\gamma}{P(\hat{v}|e_H)} \left[ 1 - \frac{\hat{P}(y|e_L)}{\hat{P}(y|e_H)} \right]$$

In particular we have immediately  $C(y) = 0, \forall y \in \mathcal{Y} \setminus \hat{\mathcal{Y}}$ .

Let us prove that  $\lambda > 0$  and  $\gamma > 0$ :

Suppose  $\lambda = 0$ . Then  $\sum_{y \in \hat{\mathcal{Y}}} \hat{P}(y|e_H) = \sum_{y \in \hat{\mathcal{Y}}} \hat{P}(y|e_L) = 1$ , and  $\hat{P}(\cdot|e_H) \neq \hat{P}(\cdot|e_L)$ , there must exist some  $y \in \hat{\mathcal{Y}}$  such that  $\hat{P}(\cdot|e_L) - \hat{P}(\cdot|e_H) < 0$ .

Since  $\gamma \geq 0, \lambda = 0 \implies \gamma < 0$ , impossible. Thus,  $\lambda > 0$ .

Suppose now  $\gamma = 0$ . Then,  $\frac{\lambda}{V'(C(y))} = 1$ , which implies  $C(y) = V'^{-1}(\lambda)$ , which does not depend on  $y$ . Thus,  $C(\cdot)$  is constant over the set of awareness of the agents, implying that she receives the same compensation for different outcome.

Under this hypothesis, the IC constraint cannot hold.

Thus,  $\gamma > 0$ .

Both constraints are binding. The problem can be written as below:

$$\begin{aligned}
& \sum_{y \in Y} P(y|e_H) [y - C(y)] = 0 \\
& \sum_{y \in \hat{Y}} \hat{P}(y|e_H) V(C(y)) - e_H = \sum_{y \in \hat{Y}} \hat{P}(y|e_L) V(C(y)) - e_L
\end{aligned}$$

I answer now the second question:

Are the agents made fully aware?

Following the notations of Auster (2013) I denote  $E_{\Upsilon_A U v}$  and  $C_{\Upsilon_A U v}$  respectively the expectation operator and the optimal compensation under awareness  $\Upsilon_A U v$ .

Consider the binding IC constraint under the agents' initial level of awareness:

$$E_{\Upsilon_A}(V(C_{\Upsilon_A}(y))|e_H) - e_H = E_{\Upsilon_A}(V(C_{\Upsilon_A}(y))|e_L) - e_L$$

In a generic way we have

$$P(v = 0|e_H) = 1 - \epsilon, P(v = 1|e_H) = \epsilon, P(v = 0|e_L) = 1 - \epsilon', P(v = 1|e_L) = \epsilon' \text{ with } \epsilon, \epsilon' \in [0, 1]$$

Increasing awareness by one contingency, but keeping the same compensation scheme in a first step gives us the following relation:

$$E_{\Upsilon_A U v}(V(C_{\Upsilon_A}(y))|e_H, v = 0) - \epsilon \{E_{\Upsilon_A U v}(V(C_{\Upsilon_A}(y))|e_H, v = 0) - E_{\Upsilon_A U v}(V(C_{\Upsilon_A}(y))|e_H, v = 1)\} - e_H$$

$$\ddagger E_{\Upsilon_A U v}(V(C_{\Upsilon_A}(y))|e_L, v = 0) - \epsilon' \{E_{\Upsilon_A U v}(V(C_{\Upsilon_A}(y))|e_L, v = 0) - E_{\Upsilon_A U v}(V(C_{\Upsilon_A}(y))|e_L, v = 1)\} - e_L$$

Adding this contingency allows for more slack iff

$$\epsilon \{E_{\Upsilon_A U v}(V(C_{\Upsilon_A}(y))|e_H, v = 0) - E_{\Upsilon_A U v}(V(C_{\Upsilon_A}(y))|e_H, v = 1)\}$$

$$> \epsilon' \{E_{\Upsilon_A U v}(V(C_{\Upsilon_A}(y))|e_L, v = 1) - E_{\Upsilon_A U v}(V(C_{\Upsilon_A}(y))|e_L, v = 0)\}$$

- For fixed differences on both sides of the inequality, the SP has more interest to add the contingency for a bigger relative impact of exerting a high effort.
- For a fixed difference in probabilities conditionally on the effort, the slack results from the relatively lower difference of what a  $v = 1$  adds compared to a 0 one, conditionally on the effort.

This problem leads to partial awareness in a second-best world.  $\square$
