Abstract

The method presented below focuses on the numerical approximation of the Euler compressible system. It pursues a two-fold objective: being able to accurately follow slow material waves as well as strong shock waves in the context of low Mach number flows. The resulting implicit-explicit fractional step approach leans on a dynamic splitting designed to react to the time fluctuations of the maximal flow Mach number. When the latter rises suddenly, the IMEX scheme, so far driven by a material-wave Courant number, turn into a time-explicit approximate Riemann solver constrained by an acoustic-wave Courant number. It is also possible to enrich the dynamic splitting in order to capture high pressure jumps even when the flow Mach number is low. One-dimensional low Mach number test cases involving single or multiple waves confirm that the present approach is as accurate and efficient as an IMEX Lagrange-Projection method. Besides, numerical results suggest that the stability of the present method holds for *any Mach number* if the Courant number related to the *convective* subsystem arising from the splitting is of order unity.

Keywords: Fractional Step, Implicit-Explicit Schemes, Multi-scale Flows, Low Mach Number, Relaxation Schemes, Hyperbolic Equations

1. Introduction

The present work deals with the construction of a time implicit-explicit scheme providing a sketch of answer to cope with multi-scale wave scenarios and more specifically with what is called a *condensation induced water hammer* (CIWH).

Indeed, in the very first instants of this phenomenon, one is interested in following a slow interface between hot vapor and cooler liquid water. Since the speed of such a material wave is of the order of 1 m.s^{-1} , which is considerably smaller than the acoustic wave speeds in both phases, the interface dynamics is typical of low Mach number flows. Nonetheless, as time goes on, shear instabilities and steep temperature gradients entail the trapping and then the sudden condensation of vapor pockets. This leads finally to the production of strong shock waves in the liquid phase. The objective is thus to design a numerical scheme accurate for material waves in a low Mach number flow while being able to capture high pressure gradients.

On one hand, fulfilling both aims might seem contradictory if one considers the Euler or Navier-Stokes incompressible systems since their divergence-free constraint prohibits any compressible effects and hence the occurrence of compressive shock waves. On the other hand, the pioneering works of Joukowski [1] and Allievi [2] state that, at constant temperature, pressure jumps in a low Mach number compressible flow are given by: $\Delta p = \rho^0 c^0 \Delta u$; with ρ^0 (respectively c^0) the constant density (respectively the constant speed of sound) of the fluid. See also [3] for a review of the water hammer theory. Thus, in the case of liquid water, at 295 K , $\rho^0 \approx 10^3 \text{ kg.m}^{-3}$, $c^0 \approx 1.5 \times 10^3 \text{ m.s}^{-1}$. If one assumes

*Corresponding author: david.iampietro@edf.fr

18 that $\Delta u \approx 1 \text{ m.s}^{-1}$, pressure jumps amplitude is of 15 bar which is the order of magnitude observed experimentally in
19 [4].

20 From a numerical point of view, different strategies have been adopted in order to be accurate on slow material
21 waves in the case of low Mach number flows. Preconditioning methods stemming from [5] and improved in [6, 7, 8]
22 aim at modifying the Jacobian eigenvalues of hyperbolic systems in order to get rid of their constraining acoustic
23 part. Asymptotic preserving schemes (AP schemes), introduced by Jin in [9], are based on the identification of a
24 non-stiff and a stiff part of hyperbolic systems. The latter is then discretized using a time-implicit method which
25 allows the scheme to be consistent, for fixed time and space-steps, with a targeted asymptotic discrete solver as a
26 scale parameter tends towards zero. Recently in [10, 11, 12, 13], different kinds of AP schemes have been derived
27 to seize the incompressible limit of the Euler or the Navier-Stokes system as the flow Mach number tends towards
28 zero. It results in an implicit-explicit (IMEX) algorithm providing a time-implicit discretization for the hydrodynamic
29 pressure gradient, and a time-explicit discretization for the convective terms. Besides, if one considers the Courant
30 number \mathcal{C} based on the slowest material waves of the flow, a key property for the above AP schemes is also to remain
31 stable for $\mathcal{C} \approx 1$ at any Mach number. This typical issue has been explored using the “modified equation” tools as well
32 as the spectral theory by Noelle and his collaborators in [14, 15]. See also [16] in which the AP property as well as the
33 Mach-uniform stability property has been proved for a Lagrange-Projection method described in [17].

34 If the Mach number flow is small, the above strategies produce satisfying results when one seeks to seize the slow
35 material waves dynamics as well as the pressure incompressible profile. However, no satisfying solution has been yet
36 found in order to dynamically capture strong shock waves if they suddenly appear in such a configuration.

37 Continuing ideas suggested in [18, 19, 20], the present work derives an IMEX scheme based on a Mach-sensitive
38 splitting of the Euler system. Such a splitting stems from the pioneering work of Baraille *et al.* [21] extended by
39 Buffard *et al.* [22]. Contrary to [21, 13, 22, 17], the splitting evolves dynamically in time thanks to a parameter
40 measuring *a priori* the instantaneous maximal Mach number of the flow. It results in a dynamically Weighted Fractional
41 Step Approach (WFSA) enabling to cope with a wide panel of situations. Indeed, in the context of a low Mach
42 number flow, starting from a completely decoupled IMEX formulation with $\mathcal{C} \approx 1$, it offers the possibility to retrieve
43 a time-explicit Godunov-like solver for the overall Euler system if a sudden rise of the Mach number is detected. The
44 CFL condition adapts itself and is re-based on the fastest physically relevant wave speed, *i.e.* the acoustic one. Thus, if
45 this rise of the Mach number is associated with the production of shock waves, they will be optimally captured. What
46 is more, the temporal splitting parameter can be enriched by a simple “shock detector” ensuring that a time-explicit
47 solver is recovered when high amplitude shock waves arise *even if* the material velocity is low. Then, strong water
48 hammer pressure jumps occurring in low Mach number flows can also be handled.

49 The second section of this article is a condensed presentation of the Mach-sensitive splitting fully described
50 in [19, 20]. The readers are notably referred to this work for the construction of a time-explicit scheme for both
51 convective and acoustic parts of the Mach-sensitive splitting. Hence, the third and the fourth section of the present
52 manuscript are entirely dedicated to the study and then the derivation of a time-implicit scheme related to the acoustic
53 part of the splitting. It leans on the relaxation schemes theory and particularly on a Suliciu-like relaxation procedure
54 detailed in [23, 24, 18, 25]. The fifth section aggregates four types of one-dimensional numerical results. A first part
55 briefly describes the effect of the Courant number when an IMEX scheme is triggered on isolated shock or contact
56 waves in the context of a low Mach number flow. Secondly, the accuracy and the efficiency of the present approach
57 are compared with the Lagrange-Projection fractional step method described in [17]. This comparative study is based
58 on a low-Mach shock tube test case in which pressure fluctuations remain small. Thirdly a double Riemann problem
59 involving a stiffened gas equation of state is examined. It aims at modeling the occurrence of water hammers in a
60 low-Mach number flow. Finally, in the last part of the numerical results, the ability of the proposed IMEX scheme
61 to deal with very specific low-velocity flow regimes is assessed. It focuses on the capture of constant states initially
62 perturbed by small amplitude acoustic waves as well as the capacity to compute weakly compressible approximate
63 solutions.

65 2. A Mach-Sensitive Fractional Step Approach

The present work focuses on the Euler compressible system. However its extension to the two-phase Homogeneous Equilibrium Model (HEM, [26]) in which both phases have the same velocity \mathbf{u} , pressure p , temperature T and chemical potential is straightforward since it results in the same conservation law structure, namely:

$$\partial_t \rho + \operatorname{div}(\rho \mathbf{u}) = 0, \quad (2.1a)$$

$$\partial_t(\rho \mathbf{u}) + \operatorname{div}(\rho \mathbf{u} \otimes \mathbf{u} + p \mathbf{I}) = \mathbf{0}, \quad (2.1b)$$

$$\partial_t(\rho e) + \operatorname{div}((\rho e + p) \mathbf{u}) = 0, \quad (2.1c)$$

$$e = \frac{|\mathbf{u}|^2}{2} + \varepsilon, \quad \varepsilon = \varepsilon^{EOS}(\rho, p), \quad (2.1d)$$

$$(\rho c)^2 = (\partial_p \varepsilon_\rho)^{-1} (p - \rho^2 \partial_\rho \varepsilon_p), \quad (2.1e)$$

66 with ρ the density of the mixture and ε its specific internal energy. The function $\varepsilon^{EOS}(\cdot, \cdot)$ defines the equation of state
67 between the thermodynamic variables while c is the sound speed involved in the nonlinear wave propagation.

68 As described in [19, 20], it is possible to derive a scheme able to deal with highly compressible flows as well as low
69 Mach number flows by splitting the system (2.1) into a convective (\mathcal{C}) and an acoustic (\mathcal{A}) subsystem:

$$\mathcal{C}: \begin{cases} \partial_t \rho + \operatorname{div}(\rho \mathbf{u}) = 0, \\ \partial_t(\rho \mathbf{u}) + \operatorname{div}(\rho \mathbf{u} \otimes \mathbf{u} + \mathcal{E}_0^2(t) p \mathbf{I}) = \mathbf{0}, \\ \partial_t(\rho e) + \operatorname{div}((\rho e) + \mathcal{E}_0^2(t) p) \mathbf{u}) = 0, \end{cases} \quad (2.2) \quad \mathcal{A}: \begin{cases} \partial_t \rho = 0, \\ \partial_t(\rho \mathbf{u}) + \operatorname{div}((1 - \mathcal{E}_0^2(t)) p \mathbf{I}) = \mathbf{0}, \\ \partial_t(\rho e) + \operatorname{div}((1 - \mathcal{E}_0^2(t)) p \mathbf{u}) = 0. \end{cases} \quad (2.3)$$

Here, $\mathcal{E}_0(t) \in]0, 1]$ is a dynamic splitting parameter designed to be equal to one in the case of sonic or supersonic flows or equal to the maximal flow Mach number in the case of subsonic flows:

$$\begin{aligned} \mathcal{E}_0(t) &= \max(M_{inf}, \min(M_{max}(t), 1)), \\ M_{max}(t) &= \sup_{x \in \Omega} \left(M(x, t) = \frac{|u(x, t)|}{c(x, t)} \right), \end{aligned} \quad (2.4)$$

with M_{inf} a given lower bound preventing $\mathcal{E}_0(t)$ from being exactly equal to zero. As shown in [19, 20], both subsystems are hyperbolic for a stiffened gas EOS provided that the pressure remains positive throughout space and time. In one dimension, their eigenvalues are:

$$\begin{aligned} \lambda_1^{\mathcal{C}} &= u - \mathcal{E}_0 c_{\mathcal{C}} & \leq \lambda_2^{\mathcal{C}} &= u \leq \lambda_3^{\mathcal{C}} = u + \mathcal{E}_0 c_{\mathcal{C}}, \\ \lambda_1^{\mathcal{A}} &= -(1 - \mathcal{E}_0^2) c_{\mathcal{A}} & \leq \lambda_2^{\mathcal{A}} &= 0 \leq \lambda_3^{\mathcal{A}} = (1 - \mathcal{E}_0^2) c_{\mathcal{A}}, \end{aligned} \quad (2.5)$$

with $c_{\mathcal{C}}$ (respectively $c_{\mathcal{A}}$) the convective (respectively the acoustic) celerity defined by:

$$\begin{aligned} (\rho c_{\mathcal{C}}(\rho, p))^2 &= (\partial_p \varepsilon_\rho)^{-1} (\mathcal{E}_0^2 p - \rho^2 \partial_\rho \varepsilon_p), \\ (\rho c_{\mathcal{A}}(\rho, p))^2 &= (\partial_p \varepsilon_\rho)^{-1} p, \end{aligned} \quad (2.6)$$

and:

$$(c_{\mathcal{C}})^2 + (1 - \mathcal{E}_0^2) (c_{\mathcal{A}})^2 = c^2. \quad (2.7)$$

70 What is more, for both subsystems, the 1-wave and 3-wave are associated to genuinely non-linear fields whereas the
71 2-wave field is linearly degenerate.

72 It can be noticed that, when the Mach number is small so that $\mathcal{E}_0(t)$ is close to zero, pressure terms completely
73 disappear from the subsystem \mathcal{C} which only conserves the convective spatial operator $\operatorname{div}(\mathbf{u} \cdot)$. Pressure terms are
74 retrieved in the subsystem \mathcal{A} which turns out to hold most of the acoustic effects. That is why, in the case of low
75 Mach number flows, if the physics of interest is essentially related to material waves propagating at speed $|u| \ll c$, a
76 time-implicit discretization will be provided for subsystem \mathcal{A} while \mathcal{C} will be solved with a time-explicit scheme.

Indeed, define Δx the space-step of the computational domain. If Δt is the time-step guaranteeing the stability of the numerical scheme, one can formally introduce several Courant numbers related to the above wave speeds, namely:

$$\begin{aligned}
\mathcal{C}_E &= \frac{\Delta t}{\Delta x} (|u| + c) && \text{Euler Courant number,} \\
\mathcal{C}_{|u|} &= \frac{\Delta t}{\Delta x} |u| && \text{Convective Courant number,} \\
\mathcal{C}_C &= \frac{\Delta t}{\Delta x} (|u| + \mathcal{E}_0 c_C) && \text{Courant number related to } C, \\
\mathcal{C}_{\mathcal{A}} &= \frac{\Delta t}{\Delta x} ((1 - \mathcal{E}_0^2) c_{\mathcal{A}}) && \text{Courant number related to } \mathcal{A}.
\end{aligned} \tag{2.8}$$

By using a time-implicit scheme for the resolution of the subsystem \mathcal{A} , one seeks to be relieved from most of the time-explicit stability condition: $\mathcal{C}_E < 1$. Particularly, if the scheme allows to fulfill $\mathcal{C}_C \approx 1$ when $\mathcal{E}_0 \ll 1$, one expects a substantial drop of the numerical diffusion holding on the material waves propagating at speed $|u|$. We refer the readers to [19, 20] for the complete study of both continuous subsystems C and \mathcal{A} as well as the derivation of a *full time-explicit* fractional step involving relaxation schemes. A short description of the time-explicit convective flux related to the subsystem C is written in Appendix A.

In the following, the derivation of the \mathcal{A} -time-implicit C -time-explicit fractional step approach is presented. As the C -time-explicit scheme described in [19, 20] is given in Appendix A, focus is only given on the \mathcal{A} -time-implicit integration.

3. A Suliciu-like Relaxation Scheme for the Acoustic Subsystem

Let us introduce a new Suliciu-like *relaxation* subsystem \mathcal{A}^μ as:

$$\mathcal{A}^\mu : \begin{cases} \partial_t \rho = 0, \\ \partial_t (\rho u) + \partial_x ((1 - \mathcal{E}_0^2(t)) \Pi) = 0, \\ \partial_t (\rho \Pi) + \partial_x ((1 - \mathcal{E}_0^2(t)) a_{\mathcal{A}}^2 u) = \frac{\rho(p - \Pi)}{\mu}, \\ \partial_t (\rho e) + \partial_x ((1 - \mathcal{E}_0^2(t)) \Pi u) = 0, \end{cases} \tag{3.9}$$

$$(\mathcal{A}^\mu)^{NC} : \begin{cases} \partial_t \tau = 0, \\ \partial_t u + (1 - \mathcal{E}_0^2(t)) \tau \partial_x \Pi = 0, \\ \partial_t \Pi + (1 - \mathcal{E}_0^2(t)) a_{\mathcal{A}}^2 \tau \partial_x u = \frac{(p - \Pi)}{\mu}, \\ \partial_t e + (1 - \mathcal{E}_0^2(t)) \tau \partial_x (\Pi u) = 0. \end{cases} \tag{3.10}$$

More details on relaxation schemes can be found in [23, 27, 25]. Moreover, the derivation of the above relaxation subsystem can be found in [19, 20]. Recall that Π is the relaxation pressure forced to converge towards the real pressure p thanks to a source term of timescale $\mu \ll 1$. Besides, $a_{\mathcal{A}}$ is a relaxation constant encapsulating the thermodynamic nonlinearity. In order to provide sufficient diffusion to the relaxation subsystem, one can exhibit (see [28, 17, 19, 20]) the following subcharacteristic condition:

$$a_{\mathcal{A}} > \rho c_{\mathcal{A}}. \tag{3.11}$$

Let us define $\tau = 1/\rho$ the specific volume. Using the fact that the density is independent of time, the relaxation subsystem \mathcal{A}^μ is equivalent to its non-conservative version $(\mathcal{A}^\mu)^{NC}$. Then, one can easily prove that the relaxation subsystem is hyperbolic, and that its eigenvalues are:

$$\lambda_1^{\mathcal{A},\mu} = -(1 - \mathcal{E}_0^2) a_{\mathcal{A}} \tau < \lambda_2^{\mathcal{A},\mu} = \lambda_3^{\mathcal{A},\mu} = 0 < \lambda_4^{\mathcal{A},\mu} = (1 - \mathcal{E}_0^2) a_{\mathcal{A}} \tau. \tag{3.12}$$

Besides all its characteristic fields are linearly degenerate. Let us now introduce W and R as:

$$\begin{aligned} W &= u - \Pi/a_{\mathcal{A}}, \\ R &= u + \Pi/a_{\mathcal{A}}. \end{aligned} \quad (3.13)$$

It is worth noticing that the non-conservative subsystem $(\mathcal{A}^\mu)^{NC}$ is equivalent to:

$$\begin{cases} \partial_t \tau = 0, \\ \partial_t W + \lambda_1^{\mathcal{A},\mu} \partial_x W = -\frac{(p-\Pi)}{a_{\mathcal{A}}\mu}, \\ \partial_t R + \lambda_4^{\mathcal{A},\mu} \partial_x R = \frac{(p-\Pi)}{a_{\mathcal{A}}\mu}, \\ \partial_t e + (1 - \mathcal{E}_0^2(t))\tau \partial_x (\Pi u) = 0. \end{cases} \quad (3.14)$$

87 with $u(W, R) = (R + W)/2$ and $\Pi(W, R) = a_{\mathcal{A}}(R - W)/2$. Thus, W (respectively R) is constant along the 1-characteristic
 88 curves (respectively the 4-characteristic curves). What is more, it is a 1-strong Riemann invariant (respectively a 4-
 89 strong Riemann invariant) meaning that it is constant through the 2,3 and 4 waves (respectively the 1 and 2,3 waves).
 90 In Figure 1 the domains of invariance of R and W are drawn.

Figure 1: Strong Riemann Invariants Behaviors

As already noticed in [18, 29], if one formally removes the relaxation terms $\pm(p-\Pi)/(a_{\mathcal{A}}\mu)$ from the PDEs (3.14), the dynamics of W and R become totally uncoupled. Besides the energy flux depends only on these two quantities since according to equation (3.13):

$$\Pi u = \frac{a_{\mathcal{A}}}{4} (R^2 - W^2). \quad (3.15)$$

91 In the next subsection, the time-implicit scheme for the subsystem \mathcal{A} is derived. It is based on the discretization of
 92 the simple transport dynamics of the quantities W and R .

93 4. The Acoustic Time-Implicit Scheme

94 This section focuses on the space and time discretization of the acoustic subsystem \mathcal{A} . It is split in three parts.
 95 Subsections 4.1 and 4.2 provide the way to derive the time-implicit acoustic flux. Subsection 4.3 points out some
 96 properties of the overall IMEX scheme while subsection 4.4 concentrates of the discrete time-step construction.

97 4.1. A One-dimensional Implicit-Solver for the Evolution Step

The numerical resolution of the acoustic relaxation subsystem \mathcal{A}^μ is split into two steps: the first one, sometimes called *the evolution step* corresponds to the resolution of the *homogeneous* subsystem where the term $(p-\Pi)/\mu$ has been removed. It becomes active afterwards in an additional step which consists in solving:

$$\partial_t \Pi = (p-\Pi)/\mu. \quad (4.16)$$

However, in the present approach, the relaxation pressure Π is relaxed instantaneously. Then, $\mu = 0$ and the resolution of Eq (4.16) is replaced by the *projection onto the equilibrium manifold*:

$$\{\mathbf{W} = [\rho, \rho u, \rho \Pi, \rho e]^T, \varepsilon = e - u^2/2, \text{ s.t. } p(\rho, \varepsilon) = \Pi\}. \quad (4.17)$$

98 For the sake of simplicity, this second step is called the *projection step*.

Suppose that the computational domain $\Omega = [0, L]$ is made of N_{cells} cells. Let us define $\Delta x = L/N_{\text{cells}}$ (respectively Δt) the space-step (respectively the time-step) of the scheme. For $i \in [1, \dots, N_{\text{cells}}]$ let us set $x_i = (i - 1/2)\Delta x$, the coordinate of the cell center i and $x_{i+1/2} = x_i + \Delta x/2$, the coordinate of face $i + 1/2$. Finally define $\Omega_i =]x_{i-1/2}, x_{i+1/2}[$. Suppose that at time t^{n+} , the set of states $\mathbf{U}_i^{n+} = [\rho_i^{n+}, (\rho u)_i^{n+}, (\rho e)_i^{n+}]^T$, $i \in [1, \dots, N_{\text{cells}}]$ produced after the resolution of the *convective* subsystem C is provided to \mathcal{A}^μ as an initial piece-wise constant datum on $\sqcup_{i=1}^{N_{\text{cells}}} \Omega_i$. Then, by averaging the W -equation and the R -equation in (3.14) over $\Omega_i \times]t^{n+}, \bar{t}^n > t^{n+}[$ one obtains:

$$\begin{aligned} \frac{W_i^{\bar{n}} - W_i^{n+}}{\Delta t} - \frac{(1 - (\mathcal{E}_0^n)^2)(a_{\mathcal{A}})^{n+} \tau_i^{n+}}{\Delta x} (W_{i+1/2}(t^{n+}, \bar{t}^{\bar{n}}) - W_{i-1/2}(t^{n+}, \bar{t}^{\bar{n}})) &= 0, \\ \frac{R_i^{\bar{n}} - R_i^{n+}}{\Delta t} + \frac{(1 - (\mathcal{E}_0^n)^2)(a_{\mathcal{A}})^{n+} \tau_i^{n+}}{\Delta x} (R_{i+1/2}(t^{n+}, \bar{t}^{\bar{n}}) - R_{i-1/2}(t^{n+}, \bar{t}^{\bar{n}})) &= 0, \end{aligned} \quad (4.18)$$

with W_i^{n+} the spatial average over Ω_i at time t^{n+} , $W_{i+1/2}(t^{n+}, \bar{t}^{\bar{n}}) = (1/(\bar{t}^{\bar{n}} - t^{n+})) \times \int_{t^{n+}}^{\bar{t}^{\bar{n}}} W(x_{i+1/2}/t) dt$, and $(a_{\mathcal{A}})^{n+} = K \max_{i \in [1, N_{\text{cells}}]} (\rho_i^{n+} (c_{\mathcal{A}})_i^{n+})$, $K > 1$, the discrete acoustic relaxation constant fulfilling inequality (3.11) throughout the whole computational domain. Eventually the Mach-sensitive discrete parameter, built using the initial states \mathbf{U}_i^n , $i \in [1, \dots, N_{\text{cells}}]$ before the convective subsystem resolution, is given by:

$$\begin{aligned} \mathcal{E}_0^n &= \max(M_{\text{inf}}, \min(M_{\text{max}}^n, 1)), \\ \text{with: } M_{\text{max}}^n &= \max_{i \in [1, N_{\text{cells}}]} \left(\frac{|u_i^n|}{c_i^n} \right). \end{aligned} \quad (4.19)$$

99 **Remark 4.1.** *Averaging over a non-conservative term:*

100 *One can notice that, even if the R and W PDEs are non-conservative because of the $\tau \partial_x(\cdot)$ operator, the fact*
 101 *that $\partial_t \tau = 0$ in the acoustic subsystem of the current splitting and the piecewise continuous structure of the computed*
 102 *solution at time t^n allow to derive exactly relations (4.18). This, is a key point to make sure that the discrete acoustic*
 103 *relaxation subsystem is conservative which, for the present IMEX scheme, is a necessary condition to ensure that the*
 104 *overall fractional step approach is conservative (see **Proposition 4.2** below). Finally, it has to be mentioned that, up*
 105 *to the Mach-sensitive parameter, similar equations have already been obtained in the framework of the Lagrange-*
 106 *Projection methods where a mass variable m such as $\partial_m = \tau \partial_x$ is at stake. See [18, 17] for more details.*

The end of the scheme derivation follows naturally by remembering that W (respectively R) is constant over the 2,3 and 4-waves (respectively the 1 and 2,3-waves). Indeed, the signs of the different eigenvalues drawn in Figure 1 suggest that $W_{i+1/2}(t^{n+}, \bar{t}^{\bar{n}})$ (respectively $R_{i+1/2}(t^{n+}, \bar{t}^{\bar{n}})$) can be approximated by $W_{i+1}^{\bar{n}}$ (respectively by $R_{i-1}^{\bar{n}}$). Finally the two discrete dynamics write:

$$\begin{aligned} \frac{W_i^{\bar{n}} - W_i^{n+}}{\Delta t} - \frac{(1 - (\mathcal{E}_0^n)^2)(a_{\mathcal{A}})^{n+} \tau_i^{n+}}{\Delta x} (W_{i+1}^{\bar{n}} - W_i^{\bar{n}}) &= 0, \\ \frac{R_i^{\bar{n}} - R_i^{n+}}{\Delta t} + \frac{(1 - (\mathcal{E}_0^n)^2)(a_{\mathcal{A}})^{n+} \tau_i^{n+}}{\Delta x} (R_i^{\bar{n}} - R_{i-1}^{\bar{n}}) &= 0. \end{aligned} \quad (4.20)$$

107 Thus, $(W_i^{\bar{n}})_{i \in [1, N_{\text{cells}}]}$ (respectively $(R_i^{\bar{n}})_{i \in [1, N_{\text{cells}}]}$) is solution of an uncoupled linear system involving an upper-bidiagonal
 108 matrix (respectively a lower-bidiagonal matrix). If transmissive boundary conditions are used by introducing fictitious
 109 states $\underline{W}_0^{\bar{n}} = \underline{W}_1^{\bar{n}}$ and $\underline{R}_{N_{\text{cells}}+1}^{\bar{n}} = \underline{R}_{N_{\text{cells}}}^{\bar{n}}$, then $W_{N_{\text{cells}}+1}^{\bar{n}} = W_{N_{\text{cells}}}^{\bar{n}}$ and $W_0^{\bar{n}} = W_1^{\bar{n}}$. The matrices involved in (4.20) are then non
 110 singular since all their diagonal terms are strictly positive. What is more their bidiagonal structure, inherited from
 111 the transport dynamics of the strong relaxation Riemann invariants W and R , allows to invert them without using any
 112 particular linear solver.

113 *4.2. Projection Step and Time-Implicit Acoustic Flux*

114 Once the two uncoupled linear systems (4.20) have been solved, the time-implicit acoustic flux related to the
115 subsystem \mathcal{A}^μ can be deduced immediately. It reads:

$$\begin{aligned} \mathbf{H}_{\mathcal{A}i+1/2}^{\mu \bar{n}} &= (1 - (\mathcal{E}_0^n)^2) \begin{bmatrix} 0 \\ (\Pi_{\mathcal{A}}^*)_{i+1/2}^{\bar{n}} \\ (a_{\mathcal{A}}^{n+})^2 (u_{\mathcal{A}}^*)_{i+1/2}^{\bar{n}} \\ (\Pi_{\mathcal{A}}^*)_{i+1/2}^{\bar{n}} (u_{\mathcal{A}}^*)_{i+1/2}^{\bar{n}} \end{bmatrix}, \\ (u_{\mathcal{A}}^*)_{i+1/2}^{\bar{n}} &= \frac{R_i^{\bar{n}} + W_{i+1}^{\bar{n}}}{2}, \\ (\Pi_{\mathcal{A}}^*)_{i+1/2}^{\bar{n}} &= \frac{(a_{\mathcal{A}}^{n+}) (R_i^{\bar{n}} - W_{i+1}^{\bar{n}})}{2}. \end{aligned} \quad (4.21)$$

In the present work, the projection step is performed instantaneously. Indeed, μ is forced to tend fictively towards zero such that $p = \Pi$. Particularly, the time-implicit acoustic pressure at face $i + 1/2$ can be defined as: $(p_{\mathcal{A}}^*)_{i+1/2}^{n+1} = (\Pi_{\mathcal{A}}^*)_{i+1/2}^{\bar{n}}$. The other flux quantities remain invariant through the projection step and one can rewrite $(u_{\mathcal{A}}^*)_{i+1/2}^{\bar{n}}$ as $(u_{\mathcal{A}}^*)_{i+1/2}^{n+1}$. Finally the time-implicit scheme for the acoustic subsystem \mathcal{A} writes:

$$\begin{aligned} \mathbf{U}_i^{n+1} &= \mathbf{U}_i^{n+} - \frac{\Delta t}{\Delta x} (\mathbf{H}_{\mathcal{A}i+1/2}^{n+1} - \mathbf{H}_{\mathcal{A}i-1/2}^{n+1}), \\ \text{with } \mathbf{H}_{\mathcal{A}i+1/2}^{n+1} &= (1 - (\mathcal{E}_0^n)^2) \begin{bmatrix} 0 \\ (p_{\mathcal{A}}^*)_{i+1/2}^{n+1} \\ (p_{\mathcal{A}}^*)_{i+1/2}^{n+1} (u_{\mathcal{A}}^*)_{i+1/2}^{n+1} \end{bmatrix}. \end{aligned} \quad (4.22)$$

One can notice that, up to the factor $(1 - (\mathcal{E}_0^n)^2)$, the obtained time-implicit acoustic flux is identical to the one derived in [17, 29]. Furthermore, the relaxation constant $a_{\mathcal{A}}$ makes it independent of the fluid EOS. As already stated, it requires no particular linear solver since the two uncoupled systems (4.20) can be inverted by hand. Besides, as proved in Appendix A, solving the discrete momentum equation of (4.22) is equivalent to setting:

$$u_i^{n+1} = \frac{R_i^{n+1} + W_i^{n+1}}{2}, \quad (4.23)$$

116 provided that $u_i^{n+} = \frac{R_i^{n+} + W_i^{n+}}{2}$.

117 In the sequel, some additional properties of the overall IMEX fractional step are presented.

118 *4.3. The IMEX Scheme Properties*

119 Three properties are underlined below. The two first deal with the conservativity and the maximum principle
120 whereas the last one concerns the discrete preservation of the Riemann Invariants of single contact discontinuities.

121 **Proposition 4.2.** *Conservativity and maximum principle of the overall IMEX scheme:*

- 122 • *Conservativity:*

123 Let us formally introduce $\mathbf{H}_{C i+1/2}^n(\mathbf{U}_i^n, \mathbf{U}_{i+1}^n)$ the time-explicit numerical flux associated to the subsystem C (see
124 [19, 20] or (A.7) in Appendix A for a definition). Then, the overall IMEX scheme is conservative and writes:

$$\mathbf{U}_i^{n+1} = \mathbf{U}_i^n - \frac{\Delta t}{\Delta x} (\mathbf{H}_{C i+1/2}^n(\mathbf{U}_i^n, \mathbf{U}_{i+1}^n) + \mathbf{H}_{\mathcal{A} i+1/2}^{n+1} - \mathbf{H}_{C i-1/2}^n(\mathbf{U}_{i-1}^n, \mathbf{U}_i^n) - \mathbf{H}_{\mathcal{A} i-1/2}^{n+1}). \quad (4.24)$$

- 125 • *Maximum principle:*

126 Consider $\rho \phi$ a given conservative variable such as $\forall (x, t): \partial_t(\rho \phi) + \partial_x(\rho \phi u) = 0$. Assume that $(\rho \phi)_i^n \in$
127 $[(\rho \phi)_{Min}, (\rho \phi)_{Max}]$. Then, the maximum principle preservation $(\rho \phi)_i^{n+1} \in [(\rho \phi)_{Min}, (\rho \phi)_{Max}]$ depends only on the con-
128 vective sub-step discretization. It naturally holds under a non-restrictive sufficient condition written in [19]: p.17,

129 **Lemma 1 (Positivity of intermediate density).**

130 It is well known that the above global conservativity result, which in this case is directly obtained because the acoustic
 131 sub-step discretization is conservative by construction, is a necessary step in order to capture the Euler physical shock
 132 fronts (see [30]). As for the maximum principle preservation for purely convected quantities, it can be considered as
 133 a first step towards the L^∞ stability of the overall scheme.

134 **Proposition 4.3.** *Discrete preservation of the contact discontinuity Riemann invariants:*

135 *Assume that the equation of state is such that $(\rho\varepsilon)^{EOS}(\rho, p) = C(p)\rho + B(p)$, with $p \rightarrow C(p)$ and $p \rightarrow B(p)$ smooth
 136 functions such as $(\rho\varepsilon)_p^{EOS} : p \rightarrow C(p)\rho + B(p)$ is injective on the domain of definition of p (see [31] or Appendix A for
 137 an explanation of such hypothesis); then, the overall IMEX scheme exactly preserves the constant velocity and the
 138 constant pressure of an isolated contact discontinuity from one time-step to another.*

139 According to [31], the above general expression of $(\rho\varepsilon)^{EOS}(\rho, p)$ belongs to the category of the ‘‘T1’’ equation of
 140 state. One can notably notice that the stiffened gas EOS: $\rho\varepsilon = p + \gamma\Pi$, is included in it. However the Van der Waals
 141 EOS: $\rho\varepsilon = \frac{(p+a\rho^2)(1-b\rho)}{\gamma-1} - a\rho^2$ is out of it. The above proposition will be useful in the sequel to detect the appearance of
 142 instabilities related to high convective Courant number $\mathcal{C}_{|u|}$. Proofs, including a brief description of the time-explicit
 143 convective flux related to subsystem C , can be found in Appendix A. The next subsection is devoted to the discrete
 144 time-step specification.

145 4.4. Construction of the numerical time-step

146 The time-step of the IMEX scheme is built using the convective eigenvalues λ_1^C and λ_3^C written in equation (2.5).
 147 As described in [19, 20], the convective subsystem C is discretized using the same relaxation techniques as the one
 148 described in Section 3. The eigenvalues of the resulting relaxation system C^μ then write: $\lambda_1^{C,\mu} = u - \mathcal{E}_0 a_C \tau$, $\lambda_{2,3}^{C,\mu} = u$
 149 and $\lambda_4^{C,\mu} = u + \mathcal{E}_0 a_C \tau$. They are related to the subcharacteristic condition $a_C > \rho c_C$.

For a given convective Courant number \mathcal{C}_C , the time-step at the n -th iteration of the numerical scheme is:

$$\Delta t_C^n = \mathcal{C}_C \frac{\Delta x}{\max_{i+1/2} \left(\max \left(\left| u_i^n - \mathcal{E}_0^n (a_C)_{i+1/2}^n \tau_i^n \right|, \left| u_{i+1}^n + \mathcal{E}_0^n (a_C)_{i+1/2}^n \tau_{i+1}^n \right| \right) \right)}, \quad (4.25)$$

$$(a_C^n)_{i+1/2} = K \max(\rho_i^n (c_C)_i^n, \rho_{i+1}^n (c_C)_{i+1}^n), \quad K > 1.$$

150 Let us assume that the stiffness of the discrete pressure gradient in the acoustic subsystem \mathcal{A} has been completely
 151 removed thanks to the time-implicit integration. In that case one should expect that the present IMEX scheme is
 152 stable under the convective CFL condition: $\mathcal{C}_C \approx 1$.

From a numerical stability point of view, the time-step definition (4.25) is thus the only admissible one regarding the
 waves produced by the convective subsystem. However, these waves never exist in the overall Euler system. For low
 Mach number flows under convective time-scales, the acoustic waves have vanished and the leading phenomenon is
 driven by the material velocity u . For that reason, one can introduce another time-step as:

$$\Delta t^n = \mathcal{C}_{|u|} \frac{\Delta x}{\max_i (|u_i^n|)}. \quad (4.26)$$

153 Once again, let us stress that the time-step definition (4.26) is essentially motivated by physical considerations. In
 154 the context of IMEX schemes based on convective-acoustic splittings, its formulation has also the advantage of being
 155 completely independent of the way to split as well as the way to discretize the associated subsystems. That is why, in
 156 the following numerical results section, the cases appealing to a fine accuracy or stability comparison between IMEX
 157 schemes are performed using the physical and universal time-step formula (4.26). On the contrary, more complicated
 158 configurations requiring the proposed approach to be stable in order to capture some specific asymptotic regimes at
 159 low Mach number are tested with the convective-like time-step (4.25).

160 5. Numerical Results

161 The following section is devoted to one-dimensional numerical results produced by the present IMEX approach.
 162 Subsection 5.1 focuses on the sensitivity w.r.t $\mathcal{C}_{|u|}$ of the acoustic and material waves propagation. Subsection 5.2
 163 mainly concentrates on grid-convergence studies completed by efficiency comparisons between time-explicit and
 164 time-implicit solvers. For the reasons given in the above paragraph, IMEX schemes involved in subsection 5.1 and
 165 5.2 use the discrete time-step (4.26). Nevertheless for each value of $\mathcal{C}_{|u|}$ an estimation of \mathcal{C}_C is systematically provided.
 166 Subsection 5.3 deals with the appearance, in a fluid endowed with a stiff equation of state, of strong pressure jumps
 167 in an uniformly low-Mach number flow. Finally, subsection 5.4 aims at testing the ability of the present approach to
 168 treat a larger application spectrum like weakly compressible flows. In the last two subsections, the proposed method
 169 is systematically combined with the convective-like time-step (4.25).

170 5.1. Low Mach Isolated Waves

171 The first part of the numerical results is dedicated to the influence of the Courant number on quantities varying
 172 through the acoustic or material waves. Indeed, it is well known (see [32, 33, 34, 35, 36, 37]) that full time-implicit
 173 schemes, even with the use of high-order accurate discretizations in space, are only accurate on σ -like waves when the
 174 time-steps Δt are such that $\mathcal{C}_\sigma = (|\sigma| \Delta t) / \Delta x \approx 1$. In the following, one seeks to investigate the accuracy of the above
 175 IMEX fractional step with respect to $\mathcal{C}_{|u|}$ and compare it with an other IMEX Lagrange-Projection (LP) fractional step
 176 described in [17, 38] in the context of low Mach number flows. Two low Mach number cases are thus evaluated. The
 177 first one details the propagation of a single 3-shock wave while the second one corresponds to the evolution of a single
 178 contact wave. In both cases, a particular attention will be paid to the diffusive or stiffening effects associated with the
 179 increase of $\mathcal{C}_{|u|}$. Transmissive conditions are used at the inlet and the outlet of the computational domain.

180 5.1.1. Isolated Shock Wave

For this test case, the fluid is endowed with an ideal gas EOS:

$$\varepsilon = \frac{p}{(\gamma - 1)\rho}, \text{ and } c = \sqrt{\frac{\gamma p}{\rho}}, \quad (5.27)$$

with $\gamma = 7/5$, the heat capacity ratio. The left state of the considered 3-isolated shock wave is completely defined by:

$$\rho_L^0 = 1 \text{ (kg.m}^{-3}\text{)}, p_L^0 = 10^4 \text{ (Pa)}, \text{ and } u_L^0 = M_0 \times c_L^0, \quad (5.28)$$

181 with $M_0 = 10^{-2}$ the maximal Mach number of the flow. What is more, the shock wave speed σ is fixed equal to
 182 $c_L^0 \approx 118.32 \text{ (m.s}^{-1}\text{)}$. The three remaining unknowns ρ_R^0 , u_R^0 and p_R^0 are the solutions of the corresponding Rankine-
 183 Hugoniot problem and can then be found analytically. Besides, the resulting right state abides by the Lax entropy
 184 criterion: $u_R^0 + c_R^0 < \sigma < u_L^0 + c_L^0$. The analytical solution is then composed of a single 3-shock wave.

185 In Figure 2, the isolated 3-shock wave pressure profile is shown. The physical time of the simulation is such that the
 186 initial discontinuity located at $x_0 = 0.5 \text{ m}$ stops at $x = 0.75 \text{ m}$. The mesh is made of 10^3 cells.

187 Different curves are plotted; Sp-(M) stands for the current splitting presented in Eqs (2.2) and (2.3) whereas Sp-LP
 188 refers to a Lagrange-Projection splitting method fully described in [17] and taken as a benchmark in this work. Besides
 189 the abbreviation ‘‘Exp’’ indicates that the acoustic part of the Sp-(M) splitting (respectively the Sp-LP splitting) has
 190 been discretized using a time-explicit scheme detailed in [19, 20] (respectively [17]). In this case, the CFL condition
 191 is such that $\mathcal{C}_E = 1$. On the contrary ‘‘Imp’’ refers to the above time-implicit approach.

192 Two different convective Courant numbers values have been tested in the implicit-explicit approaches: the first one
 193 $\mathcal{C}_{|u|} = 0.01$ ($\mathcal{C}_C \approx 2.37 \times 10^{-2}$) has been deliberately chosen to provide time-steps close to those based on the constraint
 194 $\mathcal{C}_E \approx 1$ since formally $\mathcal{C}_{|u|} = M/(1 + M)\mathcal{C}_E$ and $M = 10^{-2}$. The other value $\mathcal{C}_{|u|} = 0.3$ ($\mathcal{C}_C \approx 7.11 \times 10^{-1}$) corresponds to
 195 $\mathcal{C}_E \approx 30$ and is thus expected to be too high for the IMEX scheme to accurately follow the shock wave front.

196 In this low Mach number case, it turns out that the sharper pressure profiles are those provided by the time-explicit
 197 schemes complying with the constraint: $\mathcal{C}_E \approx 1$. On the contrary the higher is \mathcal{C}_E , the more diffused the shock profile
 198 is. Besides, for a fixed Euler Courant number $\mathcal{C}_E \approx 1$, the averaging effect of the time-implicit schemes relatively
 199 to the time-explicit ones can be observed as the profile of ‘‘Sp-(M)-Imp: $\mathcal{C}_{|u|} = 0.01$ ’’ is largely more diffused than
 200 ‘‘Sp-(M)-Exp: $\mathcal{C}_E = 1$ ’’.

Figure 2: Pressure profile, Ideal Gas, $M = 10^{-2}$, with $N_{cells} = 10^3$

201 Finally, one can notice that, for all the Courant number values involved here, the Sp-(M) splitting is as accurate as the
 202 Sp-LP method. These results, obtained in the context of the Euler system, seem to be close to the predictions given
 203 by the linear stability analysis in [37].

204 The above simple test case, involving a fast acoustic wave related to a genuinely non-linear field, has allowed to test
 205 the robustness with respect to $\mathcal{C}_{|u|}$ of the present approach compared with the LP method. In the sequel the same study
 206 is performed on a slow material wave associated with a linearly degenerate field.

207 5.1.2. Isolated Contact Discontinuity

For the same thermodynamical law, a single contact discontinuity is created by imposing:

$$\begin{aligned}
 \rho_L^0 &= 1 \text{ (kg.m}^{-3}\text{)}, \rho_R^0 = 0.125 \text{ (kg.m}^{-3}\text{)}, \\
 p_L^0 &= p_R^0 = p^0 = 10^4 \text{ (Pa)}, \\
 u_L^0 &= u_R^0 = M_0 \times c_R^0 = u^0,
 \end{aligned}
 \tag{5.29}$$

208 with $M_0 = 10^{-2}$. This wave linked to a linearly degenerate field propagates at speed $u_0 \approx 3.35 \text{ (m.s}^{-1}\text{)}$.

209 In Figure 3, one can observe the density profiles. As it was expected, the isolated contact discontinuity sharpens as the
 210 convective Courant number $\mathcal{C}_{|u|}$ reaches 1. Once again, for the same Courant number, the profiles between the present
 211 IMEX scheme and the IMEX-LP scheme overlap quasi-perfectly.

Figure 3: Density profile, Ideal Gas, $M_{min} = 10^{-2}$, with $N_{cells} = 10^3$

However, one can notice that the ideal target associated to $\mathcal{C}_{|u|} = 0.95 \approx 1$ has only been achieved for the LP method. Indeed, for this test case, the present splitting and the resulting IMEX approach triggers instabilities for $\mathcal{C}_{|u|}$ above 0.44. Trying to connect this threshold with a reconstructed value of the convective Courant number \mathcal{C}_C , one can

define:

$$(\mathcal{C}_C)_{i+1/2}^n = \frac{\max\left(\left|u_i^n - \mathcal{E}_0^n (aC)_{i+1/2}^n \tau_i^n\right|, \left|u_{i+1}^n + \mathcal{E}_0^n (aC)_{i+1/2}^n \tau_{i+1}^n\right|\right) \Delta t^n}{\Delta x}, \quad (5.30)$$

with Δt^n the discrete time-step defined in equation (4.26) and used in this test case. In Figure 4 the value of $(\mathcal{C}_C)_{i+1/2}^n$ is displayed at the final simulation time and overall the computational domain. One can observe that the reconstructed

Figure 4: Reconstructed local convective Courant number

convective Courant number is strictly higher than one in the region where the Mach number is minimal. Let us recall that, as the term \mathcal{E}_0 decreases, the proportion of the pressure gradient that is discretized using a time-implicit integration increases as $(1 - \mathcal{E}_0^2)$ according to the definition of the time-implicit acoustic flux (4.22). Then, when \mathcal{E}_0 is small enough, the amount of numerical diffusion produced by the time-implicit part of the scheme is sufficient to balance the anti-diffusive effect brought by the time-explicit discretization if $\mathcal{C}_C > 1$. Such a phenomenon is analyzed in [14, 15] using the *modified equation* tool.

Conversely, when M_0 is high enough, the splitting parameter \mathcal{E}_0 tends towards one so that the time-implicit numerical diffusion is canceled out. The classical time-explicit CFL condition $\mathcal{C}_C \approx 1$ is then retrieved.

Details dealing with the stability of the proposed IMEX scheme when applied to this test case with varying Mach number M_0 are provided in Appendix B. The residual term $\mathcal{E}_0 c_C$ prevents from reaching the material CFL condition $\mathcal{C}_{|u|} = 1$ proved by Zakerzadeh in [16] for the IMEX LP scheme. This is the price to be paid after having introduced $\mathcal{E}_0^2 p$ into the convective subsystem C . Nevertheless, in this test case, the stability of the proposed IMEX scheme holds under $\mathcal{C}_C \approx 1$ for *any value of the flow Mach number*. These numerical observations support a ‘‘Mach-uniform’’ \mathcal{C}_C -stability property of the present method.

In the sequel, accuracy and efficiency of the above IMEX schemes are compared with their full time-explicit versions in the context of low Mach number flows.

5.2. A Low Mach Sod Shock Tube

By imposing a common Courant number relying on the material velocity u , the above isolated wave test cases have pointed out some stability differences between the proposed IMEX scheme and the LP-IMEX method. In the sequel, one wishes to refine the comparison by adding some grid-convergence and efficiency results obtained from a multiple wave test case.

Herein, a low Mach number shock tube is computed. The fluid is endowed with the same previous ideal gas EOS. The initial conditions are made of a density discontinuity, a constant velocity, and a slightly discontinuous pressure:

$$\begin{aligned} \rho_L^0 &= 1 \text{ kg m}^{-3}, \quad \rho_R^0 = 0.125 \text{ kg m}^{-3} \\ u_L^0 &= u_R^0 = u^0 = 1 \text{ m s}^{-1} \\ p_L^0 &= 10080 \text{ Pa}, \quad p_R^0 = 10000 \text{ Pa}. \end{aligned} \quad (5.31)$$

235 It results in a left-going 1-rarefaction wave, a 2-contact discontinuity propagating to the right and a right-going 3-shock
 236 wave. The maximal Mach number of the flow, reached in the head of the rarefaction wave, is equal to 1.26×10^{-2} .
 237 Various time-explicit schemes have been tested: “no-Sp” corresponds to the case where $\mathcal{E}_0^n = 1$ is imposed along
 238 the simulation. Thus, the splitting is not triggered. “Sp- (\sqrt{M}) ” is the weighted splitting approach with $\mathcal{E}_0^n =$
 239 $\max(\sqrt{M_{inf}}, \min(\sqrt{M_{max}^n}, 1))$ while “Sp- (M) ” involves \mathcal{E}_0^n defined in formula (4.19) which is *a priori* optimal for
 240 a time-explicit scheme, because, as shown in [19, 20], it minimizes the numerical diffusion of the subsystem C
 241 in the low-Mach number case. Lastly, “Sp-LP” is again the Lagrange Projection splitting method, described in [17].
 242 Besides, the mention “-corr” means that a low-Mach correction inspired from [39] and written in [19, 20] is triggered.
 243 As observed in [19, 20, 17, 38], it aims at considerably reducing the numerical diffusion in the case of low Mach
 244 number flows.

Regarding the time-implicit schemes, two values for $\mathcal{C}_{|u|}$ have been tested. As shown in Appendix E, the ratio between
 $\mathcal{C}_{|u|}$ the convective Courant number based on u^0 and $\mathcal{C}_E^{0,*}$ the most constraining Euler Courant number is:

$$\mathcal{C}_{|u|}^0 \approx 1.5 \times 10^{-3} \mathcal{C}_E^{0,*}. \quad (5.32)$$

245 Then, the selected convective Courant numbers are $\mathcal{C}_{|u|} = 1.5 \times 10^{-2}$ ($\mathcal{C}_E^{0,*} \approx 10$, $\mathcal{C}_C \approx 6.34 \times 10^{-2}$) and $\mathcal{C}_{|u|} = 4.5 \times 10^{-2}$
 246 ($\mathcal{C}_E^{0,*} \approx 30$, $\mathcal{C}_C \approx 1.9 \times 10^{-1}$).

Figure 5: Convergence curve (left), Efficiency curve (right) for the pressure variable p : $M = 1.26 \times 10^{-2}$

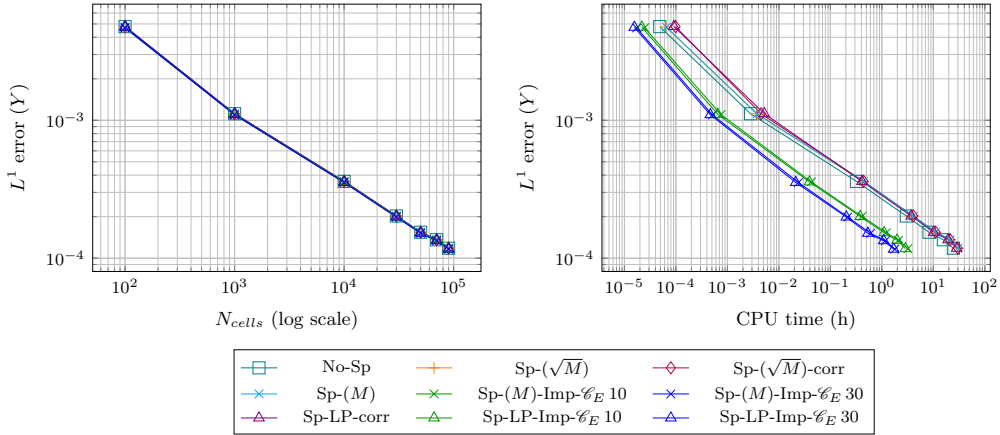

Figure 6: Convergence curve (left), Efficiency curve (right) for the passive tracer variable Y : $M = 1.26 \times 10^{-2}$

In this test case, in order to isolate the effect of the IMEX scheme on the contact discontinuity, a passive tracer Y has been added to the Euler system. Its PDE writes:

$$\partial_t(\rho Y) + \partial_x(\rho Y u) = 0. \quad (5.33)$$

247 Starting from $Y_L^0 = 1$ and $Y_R^0 = 0.5$, the exact solution jumps only through the contact discontinuity.
 248 Figure 5 (respectively Figure 6) presents the convergence curve and the efficiency curve for the pressure (respectively
 249 Y) variable. As already pointed out in [19, 20], for such a low Mach number, and focusing on the pressure (or
 250 any variable jumping through the genuinely non-linear fields), the time-explicit schemes with the low Mach number
 251 correction Sp- (\sqrt{M}) -corr and Sp-LP-corr, are the most accurate as well as the most efficient. As already observed
 252 in the isolated 3-shock wave test case, time-implicit schemes such that $\mathcal{C}_E > 1$ are less accurate than any of the time-
 253 explicit schemes. Besides, according to the pressure efficiency curve, this lack of accuracy is not compensated by
 254 a substantial gain in CPU time. Indeed, for a given pressure L^1 -error level, time-implicit schemes are still more
 255 CPU-consuming than the time-explicit ones.
 256 In the case of the passive tracer Y , no specific difference on the convergence curve can be noticed between the time-
 257 explicit and the time-implicit schemes. Indeed, the convective Courant number $\mathcal{C}_{|u|} \leq 4.5 \times 10^{-2}$ is still very far from
 258 one. Thus for every scheme, numerical diffusion has uniformly smoothed the variables only jumping through the slow
 259 material wave. Nevertheless, as shown in Table 1, time-implicit schemes are clearly more efficient, for the Y variable,
 260 than the time-explicit ones, the latter being 7 (respectively 13) times more CPU-consuming than time-implicit schemes
 261 when setting $\mathcal{C}_E^{0,*} = 10$ (respectively $\mathcal{C}_E^{0,*} = 30$).

N_{cells}	$\mathcal{C}_E = 10$	$\mathcal{C}_E = 30$
10^2	1.97	2.80
10^3	3.75	5.51
10^4	7.52	13.36
3×10^4	7.26	13.71
5×10^4	6.74	13.66
7×10^4	7.39	13.34
9×10^4	7.67	13.78

Table 1: $T_{No-Sp}^{CPU} / T_{Sp-(M)-Imp}^{CPU}$

262 As announced in the introduction, one of the objective of the present approach is to capture high amplitude pressure
 263 jumps in low velocity areas as it is noticed in water-hammer events. This is the purpose of the next numerical example.

264 5.3. A Double Riemann Problem With Stiff Thermodynamics

265 In the following test case, two Riemann problems are triggered at $x_0 = 0.55m$ and $x_1 = 1.23m$ in a domain of length
 266 $L = 2m$. The three initial condition areas are written in Table 2.

	Left state ($x < x_0$)	Middle state ($x_0 < x < x_1$)	Right state ($x_1 < x$)
ρ ($kg.m^{-3}$)	$\rho_L^0 = 10^3$	$\rho_m^0 = 9.98 \times 10^2$	$\rho_R^0 = 9.97 \times 10^2$
u ($m.s^{-1}$)	$u_L^0 = 1$	$u_m^0 = 1$	$u_R^0 = 1$
p (bar)	$p_L^0 = 10^3$	$p_m^0 = 10$	$p_R^0 = 1$
Y	$Y_L^0 = 0.7$	$Y_m^0 = 0.2$	$Y_R^0 = 0.1$

Table 2: Double Riemann Problem: initial conditions

The fluid is endowed with a stiffened gas EOS, *i.e.*:

$$\varepsilon = \frac{p + P_\infty}{(\gamma - 1)\rho}, \text{ and } c = \sqrt{\frac{\gamma(p + P_\infty)}{\rho}}, \quad (5.34)$$

267 with $\gamma = 7.5$ and $P_\infty = 3 \times 10^3$ bar. These constants have been chosen such that, at a given temperature $T = 295$ K, the
 268 value of the speed of sound is approximately $c \approx 1.5 \times 10^3$ m.s⁻¹. It is representative of the liquid water behavior.
 269 The analytical solution of the present test case is composed of two successive shock tubes whose waves are similar
 270 to these presented in subsection 5.2. The maximal Mach number of the Riemann problem initially located at x_0
 271 (respectively x_1) is $M_{max}^{x_0} \approx 2 \times 10^{-2}$ (respectively $M_{max}^{x_1} \approx 8.6 \times 10^{-4}$). Thus, the flow Mach number is uniformly low.
 272 Besides the important variations of the Mach number are associated with strong velocity fluctuations. It passes from
 273 $u \approx 32$ m.s⁻¹ in the contact wave related to the Riemann problem located at x_0 to $u \approx 1.3$ m.s⁻¹ in the contact wave of the
 274 one located at x_1 . That is why in the sequel, the Riemann problem initially located at x_0 is referred as “high-velocity”
 275 shock tube, whereas the one initially located at x_1 is called “low-velocity” shock tube.
 276 In any case, the stiffened gas EOS combined with high initial pressure discontinuities produce strong shock waves
 277 in both Riemann problems. The pressure jump amplitude associated with the high-velocity shock tube (respectively
 278 the low-velocity shock tube) is approximately 480 bar (respectively 4.5 bar). The above test case represents the
 279 sudden occurrence of high amplitude shock waves in a uniformly low Mach number flow as it can be observed in
 280 water-hammer scenarios.

In the sequel, a comparison between the IMEX fractional steps Sp-(M)-Imp and Sp-LP-Imp is done. For each numerical scheme, the time-step is only provided by the waves produced by the convective subsystem: Δt_C^n written in formula (4.25) for the present splitting and

$$\begin{aligned} \Delta t_{LP}^n &= \mathcal{C}_C \frac{\Delta x}{\max_{i+1/2} \left(\left((u_{\mathcal{A}}^*)_{i-1/2}^n \right)^+ - \left((u_{\mathcal{A}}^*)_{i+1/2}^n \right)^- \right)}, \\ (u_{\mathcal{A}}^*)_{i+1/2}^n &= \frac{u_{i+1}^n + u_i^n}{2} - \frac{1}{2a_{i+1/2}^n} (p_{i+1}^n - p_i^n), \\ a_{i+1/2}^n &= K \max(\rho_i^n c_i^n, \rho_{i+1}^n c_{i+1}^n), \quad K > 1, \end{aligned} \quad (5.35)$$

for the Lagrange-Projection splitting (see [17]). For both time-steps, the convective Courant number \mathcal{C}_C is set to 0.9. What is more, the discrete splitting parameter \mathcal{E}_0^n defined in Eqs (4.19) is here enriched for the present test case with a simple hand-made shock detector:

$$\begin{aligned} \mathcal{E}_0^n &= \max(M_{inf}, \min(\max(M_{max}^n, M_{S,max}^n) 1)), \\ \text{with } M_{max}^n &= \max_{i \in [1, N_{cells}]} \left(\frac{|u_i^n|}{c_i^n} \right), \quad M_{S,max}^n = \max_{i \in [1, N_{cells}]} \left(\frac{|(\sigma_S)_{i+1/2}^n|}{\max(c_{i+1}^n, c_i^n)} \right), \end{aligned} \quad (5.36)$$

and

$$(\sigma_S)_{i+1/2}^n = \begin{cases} \frac{(\rho u)_{i+1}^n - (\rho u)_i^n}{\rho_{i+1}^n - \rho_i^n} & \text{if } |\rho_{i+1}^n - \rho_i^n| > \epsilon^{\text{thres}} \max(\rho_{i+1}^n, \rho_i^n) \\ 0 & \text{otherwise,} \end{cases} \quad (5.37)$$

where $\epsilon^{\text{thres}} = 10^{-8}$. One can notice that in Eqs (5.36), $(\sigma_S)_{i+1/2}^n$ corresponds to the exact shock front speed formula in the case of an isolated shock wave separating the states \mathbf{U}_i^n and \mathbf{U}_{i+1}^n . If one considers the waves related to the genuinely non-linear fields, *i.e.* $u \pm c$, the Lax entropy conditions related to admissible shock waves then give:

$$u_i^n \pm c_i^n > (\sigma_S)_{i+1/2}^n > u_{i+1}^n \pm c_{i+1}^n. \quad (5.38)$$

281 Hence, in the case of a low Mach number flow, for which $|u_{i+1}^n|/c_{i+1}^n \ll 1$ and $|u_i^n|/c_i^n \ll 1$, the term $|(\sigma_S)_{i+1/2}^n|$ should
 282 approximately belong to $[\min(c_{i+1}^n, c_i^n), \max(c_{i+1}^n, c_i^n)]$. Besides, the low compressibility of a fluid endowed with the
 283 above stiffened gas EOS involves very small variations of ρ if $p \ll P_\infty$. Then, c should remain constant at least in the
 284 low-velocity shock tube area. Thus, in the case of shock waves, $M_{S,max}^n$ should be of order one and the present IMEX
 285 approach should turn into a fully time-explicit Godunov-like solver.

286 The number of cells is 2×10^3 and the simulation time $T_{\text{end}} = 1.95 \times 10^{-4} \text{ s}$ is set in order to avoid interactions between
 287 the 3-right-going shock wave of the high-velocity shock tube and the 1-left-going rarefaction wave of the low-velocity
 288 shock tube. Transmissive boundary conditions have been used.

289 Figure 7 and Figure 8 show the pressure and the velocity profiles for both successive shock tubes. Figure 9 displays
 290 the passive tracer profile Y which only jumps through the contact waves.

Figure 7: Pressure profile, stiffened gas EOS, $N_{\text{cells}} = 2 \times 10^3$

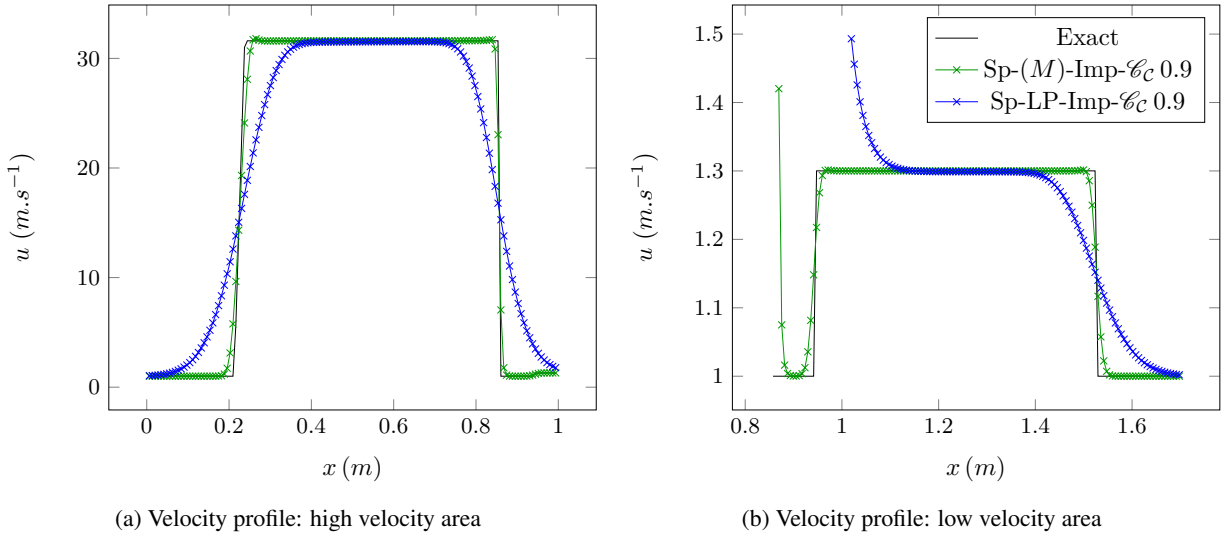

Figure 8: Velocity profile, stiffened gas EOS, $N_{\text{cells}} = 2 \times 10^3$

In the case of Sp-(M)-Imp, once the different waves have appeared, the measured shock detector $M_{S,\text{max}}^n$ is of order one through the rarefaction and the shock waves. Then after several time-steps $\mathcal{E}_0^n = 1$, and a full time-explicit

Riemann solver associated with an Euler-like time-steps,

$$\Delta t_C^n \approx \mathcal{C}_C \frac{\Delta x}{\max_{i+1/2} \left(\max(|u_i^n - c_i^n|, |u_{i+1}^n + c_{i+1}^n|) \right)}, \quad (5.39)$$

$$\mathcal{C}_C = 0.9,$$

is recovered. Thanks to the degree of freedom offered by \mathcal{E}_0^n , the present fractional step is therefore able to select the appropriate time-discretization for the acoustic flux *and in the same time* the right time-step adapted to the physics of interest. On the contrary, the acoustic part of the Lagrange-Projection fractional step is still discretized using a time-implicit scheme linked to a CFL condition based on a very low material velocity such as $u \ll c$. Then, it is far less accurate at capturing stiff rarefaction and shock waves in both “high-” and “low-velocity” shock tubes. One can notably observe in Figure 7b and Figure 8b that, on this mesh, Sp-LP-Imp fails to capture the initial state (u_m^0, p_m^0) between the 1-right-going shock wave of the high-velocity shock tube and the 3-left-going rarefaction wave of the low-velocity one. This is due to an excessive numerical dissipation through the associated waves.

Figure 9: Y profile, stiffened gas EOS, $N_{cells} = 2 \times 10^3$

Eventually, as seen in Figure 9, both IMEX schemes produce similar results regarding the accuracy of the Y profile. It can be explained because the simulation time T_{end} is based on the fast acoustic waves, the exact contact discontinuities only move a few space-steps. One can assume that, on a larger time of simulation, the Sp-LP-Imp should be more accurate on Y than Sp-(M)-Imp. Indeed, the LP time-step is directly based on slow material velocities. Therefore, this test case has shown that the degree of freedom offered by the splitting parameter \mathcal{E}_0^n allows to automatically switch from a scheme designed to follow slow material dynamics to a scheme able to capture fast acoustic waves even when the flow Mach number is low. The next section proposes to widen the application fields of the present IMEX scheme. Indeed, it aims at assessing the scheme ability to seize some simple constant states as well as weakly compressible flows.

5.4. Applications to some other asymptotic regimes

5.4.1. Constant state perturbed by small amplitude acoustic waves^{Remark 3}

The first configuration is a “dimensionalized” version of a Riemann problem taken from [13]. The fluid at stake is endowed with an ideal gas EOS with $\gamma = 1.4$. Its density and pressure are initially constant: $\rho^0 = 1 \text{ kg.m}^{-3}$, $p^0 = 1 \text{ bar}$. Let us also introduce $u^0 = 1 \text{ m.s}^{-1}$ and a reference Mach number $M^0 = u^0/c^0$ with $c^0 \equiv \sqrt{p^0/\rho^0}$. For these values, one obtains $M^0 \approx 3.2 \times 10^{-3}$.

315 As detailed in Table 3, the computational domain of length $L^0 = 1\text{ m}$ is split in three areas in which the constant velocity
 316 u^0 is perturbed by a term scaling as $O(M^0)$. The initial conditions are thus “well-prepared” according to the definition
 written in [39, 8].

	(zone 1): $x < 0.2$ or $x > 0.8$	(zone 2): $x \in [0.2, 0.25]$ or $x \in [0.75, 0.8]$	(zone 3): $x \in [0.25, 0.75]$
ρ (kg.m^{-3})	ρ^0	ρ^0	ρ^0
u (m.s^{-1})	$u_L^0 = u^0 \times (1 - M^0/2)$	$u_R^0 = u^0 \times (1 + M^0/2)$	$u_m^0 = u^0$
p (bar)	p^0	p^0	p^0

Table 3: Dimarco *et al* Riemann Problem: initial conditions

317 As time goes on, the four discontinuities of the initial velocity field will produce interacting non-linear waves of small
 318 amplitude. For long convective time-scales one expects that these waves fade away and leave a constant velocity field.
 319 Here, the ability of the present IMEX approach to seize this almost incompressible state is analyzed.
 320 Once again the proposed IMEX method is compared with the LP-IMEX scheme. The time-steps are given by formulas
 321 (4.25) and (5.35) and the computational domain is made of a 10^3 cells mesh. The physical time of the simulation
 322 is $T_{\text{end}} = 0.05 \times t^0$ with $t^0 = L^0/u^0$ the convective time-scale of reference. Finally periodic boundary conditions are
 323 imposed so that the acoustic waves are constantly re-introduced in the computational domain. Let us end the setting
 324 description by mentioning that the shock detector presented in equations (5.36), (5.37) has been unplugged in this test
 325 case.
 326

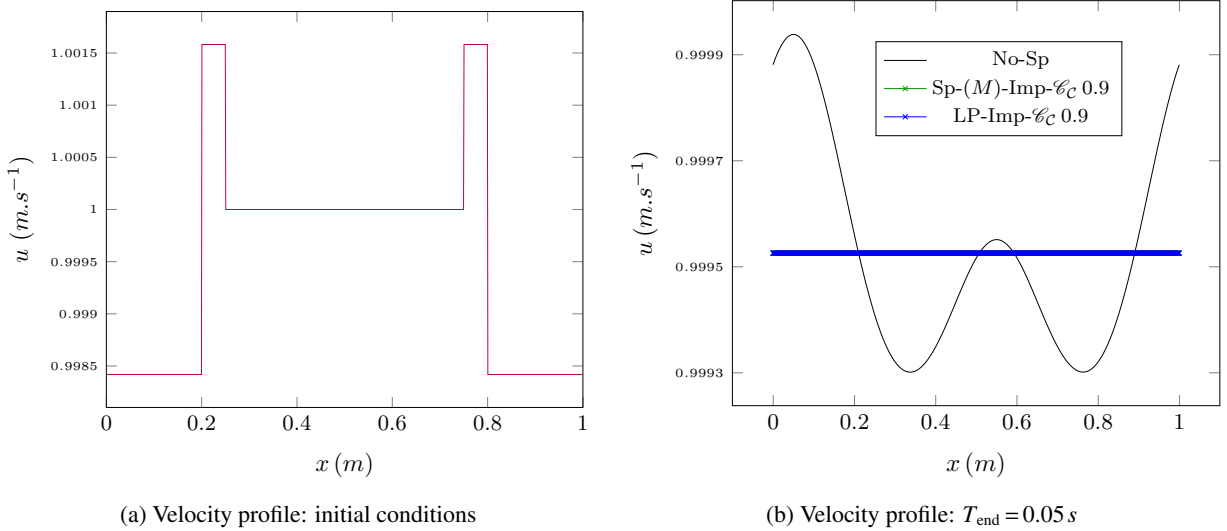

Figure 10: Dimarco’s *et al* Riemann problem: initial conditions and comparison with a full time-explicit scheme

At the final simulation time, Figure 10a shows the velocity initial distribution while Figure 10b displays the profiles, of the present approach, the LP-IMEX method and a full time-explicit Riemann solver No-Sp. The latter has already been used in subsection 5.2 and is obtained by imposing $\mathcal{E}_0^n = 1$ at every time-step during the simulation. One can notice that both IMEX schemes manage to reach a plateau by the end of the simulation. On the contrary, No-Sp continues to solve all the details produced by the acoustic waves interaction. A closer look at Figure 11a reveals that both time-implicit methods reach the constant value $u^* \approx 0.999526\text{ m.s}^{-1}$. Such a velocity is consistent with the total momentum conservation since periodic boundary conditions are at stake:

$$\begin{aligned}
 \int_{\Omega} \rho^0 u^* d\Omega &= \int_{\Omega} \rho^0 u(x, t=0) d\Omega, \\
 \Leftrightarrow \rho^0 u^* &= \rho^0 u^0 [0.4(1 - M^0/2) + 0.5 + 0.1(1 + M^0/2)], \\
 \Leftrightarrow u^* &\approx 0.9995256.
 \end{aligned}
 \tag{5.40}$$

(a) Velocity profile: $T_{\text{end}} = 0.05 \text{ s}$, (zoom)

(b) Pressure profile: $T_{\text{end}} = 0.05 \text{ s}$, (zoom)

Figure 11: Dimarco's *et al* Riemann problem: zoom on the constant incompressible state

327 Finally, a look at Figure 11b confirms that the pressure obtained from the IMEX methods also remains constant at the
 328 end of the simulation.

329 5.5. Weakly Compressible Colliding Pulses

The last test considered has been taken from [40] and is also treated in [12, 13]. It deals with weakly compressible flows whose solutions are made of long wave acoustic pressure and density pulses. Here, the ability of the present IMEX scheme to follow smooth but fast acoustic waves associated with an intermediate value of the Mach number is assessed. The fluid is endowed with an ideal gas EOS with $\gamma = 1.4$. The non-dimensional initial conditions presented in [40] read:

$$\begin{aligned}
 \bar{\rho}(x, 0) &= \bar{\rho}_0 + \left(\frac{M_{\text{ref}}^0}{2}\right) \bar{\rho}_1 \left(1 - \cos\left(\frac{2\pi x}{L}\right)\right), \quad \bar{\rho}_0 = 0.955, \quad \bar{\rho}_1 = 2, \\
 \bar{u}(x, 0) &= -\frac{\bar{u}_0}{2} \text{sign}(x) \left(1 - \cos\left(\frac{2\pi x}{L}\right)\right), \quad \bar{u}_0 = 2\sqrt{\gamma}, \\
 \bar{p}(x, 0) &= \bar{p}_0 + \left(\frac{M_{\text{ref}}^0}{2}\right) \bar{p}_1 \left(1 - \cos\left(\frac{2\pi x}{L}\right)\right), \quad \bar{p}_0 = 1, \quad \bar{p}_1 = 2\gamma.
 \end{aligned} \tag{5.41}$$

The Mach number of reference M_{ref}^0 has been taken equal to $1/11 \approx 9.1 \times 10^{-2}$. The computational domain Ω is $[-L, L]$ with $L = 2/M_{\text{ref}}^0$. Thus, the first-order pulses w.r.t M_{ref}^0 evolve with a large space-scale variable $\xi = M_{\text{ref}}^0 x$. Let us introduce p_{ref}^0 (respectively ρ_{ref}^0 , u_{ref}^0) a reference pressure (respectively a reference density, a reference velocity) such that:

$$\begin{aligned}
 \rho_{\text{ref}}^0 &= 1 \text{ kg.m}^{-3}, \quad u_{\text{ref}}^0 = 1 \text{ m.s}^{-1}, \\
 p_{\text{ref}}^0 &= \frac{\rho_{\text{ref}}^0 \bar{p}_0}{\gamma} \left(\frac{u_{\text{ref}}^0 \bar{u}_0}{M_{\text{ref}}^0}\right)^2.
 \end{aligned} \tag{5.42}$$

330 The reference pressure p_{ref}^0 has been set such that the exact maximal value of the initial Mach number is of the order of
 331 M_{ref}^0 . The dimensional initial conditions then write: $\rho(x, 0) = \rho_{\text{ref}}^0 \bar{\rho}(x, 0)$, $u(x, 0) = u_{\text{ref}}^0 \bar{u}(x, 0)$ and $p(x, 0) = p_{\text{ref}}^0 \bar{p}(x, 0)$.
 332 Figure 12 and Figure 13 display the pressure and velocity profiles at two physical times. The first one captures the
 333 time when the two pulses collide producing an over-pressure peak at the center of the computational domain. The
 334 second one corresponds to the instant where the two pressure pulses have separated again.

(a) Pressure profile: $t = 3.78 \times 10^{-1} s$

(b) Pressure profile: $t = 8.41 \times 10^{-1} s$

Figure 12: Pressure: just after the pulses super-position (a), once the pulses have separated again (b)

335 The present IMEX approach with no shock detector, is compared with the LP-IMEX and No-Sp schemes. The
 336 non-dimensional initial conditions have been added as a dashed line in order to observe the diffusion and dispersion
 337 introduced w.r.t the initial pulses.

338 In Figure 12a, one can notice that both IMEX methods manage to catch the over-pressure peak although they are
 339 slightly more diffusive than the full time-explicit scheme. However, in Figure 12b, the full time-implicit discretization
 340 of the pressure gradient in the LP-Imp approach combined with a CFL condition based on u completely diffuses
 341 the re-appearing pressure pulses. On the contrary, in the case of the present IMEX method, one can notice that \mathcal{E}_0^n
 342 remains of order M_{ref}^0 during most of the simulation. For example, at time $t = 8.41 \times 10^{-1} s$, $M_{\text{max}}^n = 7.4 \times 10^{-2} = \mathcal{E}_0^n$.
 343 The intermediate value of \mathcal{E}_0 is enough to produce considerably lower time-steps which are more appropriate to follow
 344 the long acoustic waves. As a result, even if it is more diffused compared with the full-time explicit scheme, the global
 345 shape of the pressure pulses is retrieved. However, the present approach suffers from the same drawback as the one
 346 noticed in [40]: in the vicinity of the locations $x \approx \pm 18.5 m$, the pressure gradient stiffens such that the long-length scale
 347 acoustic wave hypothesis no longer holds, and the time-implicit discretization of the acoustic subsystem considerably
 348 smears the appearing discontinuities. In any case, a specific additional work should be undertaken if one is interested
 349 in capturing the fast acoustic dynamics related to first-order pressure terms w.r.t M_{ref}^0 .

(a) Velocity profile: $t = 3.78 \times 10^{-1} s$

(b) Velocity profile: $t = 8.41 \times 10^{-1} s$

Figure 13: Velocity: just after the pulses super-position (a), once the pulses have separated again (b)

6. Conclusion

The present work focuses on the derivation of an IMEX version of the Mach-sensitive fractional step introduced in [19, 20]. The time-implicit scheme derived for the acoustic subsystem is based on the non-conservative dynamics of strong Riemann invariants provided by the relaxation schemes framework. Although such a technique stems from the Lagrange-Projection theory [18, 29], it can be extended to the present splitting because of density time invariance in the acoustic sub-step and the piece-wise constant structure of the computed solution. The resulting IMEX scheme is simple, the implicit part being inverted by hand, and conservative by construction. What is more, the maximum principle preservation for purely convected quantities holds under a non-restrictive condition for the time-explicit convective flux.

A low Mach number shock tube involving an ideal gas thermodynamics and small pressure jumps has highlighted a trade-off in the use of IMEX schemes. Indeed, if one is interested by pressure jumps through shock waves, then using an IMEX scheme with $\mathcal{C}_E \gg 1$ might be inappropriate in terms of accuracy. Besides, the gain in CPU time is not sufficient to compensate the implicit diffusion and dispersion errors: for the pressure variable, IMEX schemes are still less efficient than full time-explicit ones. However, any quantities varying only through material waves should be depicted more efficiently and with a sufficient accuracy.

When the thermodynamics becomes stiffer, high amplitude pressure jumps can occur in low-Mach number flows. This is for example the case during water-hammer events. Then, one can complete the splitting parameter \mathcal{C}_0^n with a basic “shock detector” which enforces the initial IMEX scheme associated with a convective-like CFL condition to turn into a fully time-explicit approximate Riemann solver related to an acoustic-like CFL condition. Hence, the splitting parameter allows to select the acoustic-flux time-discretization *and in the same time* the time-step adapted to the physical-scale looked at. The application of such a strategy to a double Riemann problem endowed with a stiffened gas EOS has shown that, contrary to the IMEX version of the Lagrange-Projection fractional step, the present IMEX approach is able to accurately follow stiff rarefaction and shock waves even in low velocity regions.

Besides, when the fluid is at rest, the proposed IMEX scheme is able to filter out small amplitude acoustic waves of no interest in order to retrieve the underlying constant state. The present IMEX approach has also been tried on intermediate configurations in which smooth and large-scale acoustic waves associated with first order terms w.r.t the flow Mach number propagate and need to be followed. The proposed method provides lower time-steps than the one produced by the LP-IMEX scheme. It is thus able to capture the global shape of the pressure colliding or re-appearing pulses but considerably smears the solution in regions where the pressure gradient stiffens.

Finally, the different test cases presented in this study show that the present IMEX scheme is stable, whatever the Mach number, under $\mathcal{C}_C \approx 1$; with \mathcal{C}_C the Courant number based on the eigenvalues of the convective subsystem C .

381 Even if it is not yet rigorously proved, the *Mach-uniform- \mathcal{C}_C* stability property seems to hold.

382 The fact is that, at a given instant, the computational domain can feature subsonic areas as well as sonic or
383 supersonic ones. Thus, the spatial dependence of the splitting parameter could also been examined. Indeed, provided
384 that the consistency of the overall fractional step is not deteriorated, such a spatial dependence would allow to capture
385 local fluctuations of the Mach number, and the present approach to react more finely. In addition, some improvements
386 regarding the construction of the “shock detector” could also be proposed.

387 **Acknowledgements**

388 The first author received a financial support through the EDF-CIFRE contract 0561-2015. Computational facilities
389 were provided by EDF.

390 The authors would also like to thank the reviewers who have spent time reading this paper. Indeed, the remarks and
391 questions they have pointed out have considerably allowed the present work to be improved.

392 **Appendix A. Discrete Preservation of the Contact Discontinuity Riemann Invariants**

393
394 Before focusing on the preservation of the contact discontinuity Riemann invariants property, let us have a look
395 on the discrete momentum equation related to the flux (4.22).

$$\begin{aligned}
& \text{Assume that: } u_i^{n+} = \frac{R_i^{n+} + W_i^{n+}}{2}, \text{ then:} \\
u_i^{n+1} &= \frac{R_i^{n+1} + W_i^{n+1}}{2} \\
\Leftrightarrow \frac{u_i^{n+1} - u_i^{n+}}{\Delta t} &= \frac{1}{2} \left[\frac{R_i^{n+1} - R_i^{n+}}{\Delta t} + \frac{W_i^{n+1} - W_i^{n+}}{\Delta t} \right] \\
\Leftrightarrow \frac{u_i^{n+1} - u_i^{n+}}{\Delta t} &= -\frac{(1 - (\mathcal{E}_0^n)^2)(a_{\mathcal{A}})^{n+} \tau_i^{n+}}{2} \left[\frac{R_i^{n+1} - R_{i-1}^{n+1}}{\Delta x} - \frac{W_{i+1}^{n+1} - W_i^{n+1}}{\Delta x} \right] \\
\overbrace{\Leftrightarrow}^{\rho_i^{n+1} = \rho_i^{n+}} \frac{\rho_i^{n+1} u_i^{n+1} - \rho_i^{n+} u_i^{n+}}{\Delta t} &+ \frac{(1 - (\mathcal{E}_0^n)^2)(a_{\mathcal{A}})^{n+}}{\Delta x} \left[\frac{R_i^{n+1} - W_{i+1}^{n+1}}{2} - \frac{R_{i-1}^{n+1} - W_i^{n+1}}{2} \right] = 0 \\
\Leftrightarrow \frac{\rho_i^{n+1} u_i^{n+1} - \rho_i^{n+} u_i^{n+}}{\Delta t} &+ (1 - (\mathcal{E}_0^n)^2) \frac{(p_{\mathcal{A}}^*)^{n+1/2} - (p_{\mathcal{A}}^*)_{i-1}^{n+1/2}}{\Delta x} = 0, \\
& \text{with: } (p_{\mathcal{A}}^*)_{i+1/2}^{n+1} = (a_{\mathcal{A}})^{n+} \frac{R_i^{n+1} - W_{i+1}^{n+1}}{2}.
\end{aligned} \tag{A.1}$$

396 Thus:

$$\begin{aligned}
u_i^{n+} &= \frac{R_i^{n+} + W_i^{n+}}{2}, \text{ and } u_i^{n+1} = \frac{R_i^{n+1} + W_i^{n+1}}{2} \Leftrightarrow \\
u_i^{n+} &= \frac{R_i^{n+} + W_i^{n+}}{2}, \text{ and } \frac{(\rho u)_i^{n+1} - (\rho u)_i^{n+}}{\Delta t} + (1 - (\mathcal{E}_0^n)^2) \frac{(p_{\mathcal{A}}^*)_{i+1/2}^{n+1} - (p_{\mathcal{A}}^*)_{i-1}^{n+1/2}}{\Delta x} = 0.
\end{aligned} \tag{A.2}$$

397 Then, if $u_i^{n+} = (R_i^{n+} + W_i^{n+})/2$, solving the momentum equation is strictly equivalent to directly setting $u_i^{n+1} =$
398 $(R_i^{n+1} + W_i^{n+1})/2$.

399 *Appendix A.1. Discrete Preservation of the Riemann Invariants of a Contact Discontinuity*

400

Consider an equation of state such that:

$$(\rho \varepsilon)^{\text{EOS}}(\rho, p) = C(p)\rho + B(p), \tag{A.3}$$

401 with $p \rightarrow C(p)$ and $p \rightarrow B(p)$ smooth functions such as $(\rho \varepsilon)_\rho^{\text{EOS}} : p \rightarrow C(p)\rho + B(p)$ is injective on the domain of defini-
402 tion of p . Formula (A.3) belongs to the ‘‘T1-class’’ of EOS introduced in [31]. One can notice that the stiffened gas
403 EOS is included in this category. In the sequel, the exact invariance of velocity and pressure in the case of an isolated
404 contact wave described in subsection 5.1.2 is checked.

405 *Appendix A.1.1. Acoustic Sub-step*

406

Assume that at the end of the convective sub-step, the isolated contact discontinuity has been preserved:

$$\begin{aligned}
& \forall i: u_i^{n+} = u^0, p_i^{n+} = p^0, \\
\Rightarrow \forall i: W_i^{n+} &= u^0 - \frac{p^0}{a_{\mathcal{A}}^{n+}} = W^{0,n+}, R_i^{n+} = u^0 + \frac{p^0}{a_{\mathcal{A}}^{n+}} = R^{0,n+}.
\end{aligned} \tag{A.4}$$

Considering the discrete dynamics of W and R written in (4.20) coupled with the transparent boundary conditions
 $W_{N_{\text{cells}}+1}^{n+} = W_{N_{\text{cells}}}^{n+}$ and $W_0^{n+} = W_1^{n+}$, one can easily see that:

$$\forall i: W_i^{n+1} = W^{0,n+}, R_i^{n+1} = R^{0,n+}. \tag{A.5}$$

Please note that the constant relaxation hypothesis $(a_{\mathcal{A}})^n = K \max_{i \in [1, N_{\text{cells}}]} (\rho_i^n (c_{\mathcal{A}})_i^n)$, $K > 1$, plays an important role here since a local value of $a_{\mathcal{A}}$ would have been sensible to the density discontinuity preventing W and R to remain constant. Thus, property (A.5) cannot be guaranteed in this case. Then, $(p_{\mathcal{A}}^*)_{i+1/2}^{n+1} = (p_{\mathcal{A}}^*)_{i-1/2}^{n+1} = a_{\mathcal{A}}^{n+1} (R^{0,n+} - W^{0,n+})/2$ and $(u_{\mathcal{A}}^*)_{i+1/2}^{n+1} = (u_{\mathcal{A}}^*)_{i-1/2}^{n+1} = (R^{0,n+} + W^{0,n+})/2$ such that the discrete fluctuation of the time-implicit acoustic flux is null. The mass, momentum and the energy equations thus become:

$$\begin{aligned} \frac{\rho_i^{n+1} - \rho_i^{n+}}{\Delta t} &= 0, & \rho_i^{n+1} &= \rho_i^{n+}, \\ \rho_i^{n+} \frac{u_i^{n+1} - u_i^{n+}}{\Delta t} &= 0, & \Rightarrow u_i^{n+1} &= u_i^{n+} = u^0, \\ \frac{\rho_i^{n+} (\varepsilon_i^{n+1} - \varepsilon_i^{n+}) + ((u_i^{n+1})^2/2 - (u_i^{n+})^2/2)}{\Delta t} &= 0, & (\rho \varepsilon)^{\text{EOS}}(\rho_i^{n+}, p_i^{n+1}) &= (\rho \varepsilon)^{\text{EOS}}(\rho_i^{n+}, p_i^{n+}). \end{aligned} \quad (\text{A.6})$$

407 Since $(\rho \varepsilon)_{\rho}^{\text{EOS}} : p \rightarrow C(p)\rho + B(p)$ is injective, $p_i^{n+1} = p_i^{n+} = p^0$ and the acoustic sub-step exactly preserves the velocity
408 and pressure uniform profiles.

409 Appendix A.1.2. Convective Sub-step

410

The convective flux associated to subsystem C is obtained using the same kind of relaxation method. Details are given in [19, 20]. The convective flux formula at face $i + 1/2$ reads:

$$\mathbf{H}_{C_{i+1/2}}^n = \begin{cases} (\mathbf{F}_C)_i^n & \text{if } u_i^n - \mathcal{E}_0^n (a_C^n)_{i+1/2} \tau_i^n > 0 \\ (\mathbf{F}_C)_{i+1/2}^{*,n} & \text{if } u_i^n - \mathcal{E}_0^n (a_C^n)_{i+1/2} \tau_i^n \leq 0 < (u_C^*)_{i+1/2}^n \\ (\mathbf{F}_C)_{i+1/2}^{**,n} & \text{if } (u_C^*)_{i+1/2}^n \leq 0 < u_{i+1}^n + \mathcal{E}_0^n (a_C^n)_{i+1/2} \tau_{i+1}^n \\ (\mathbf{F}_C)_{i+1}^n & \text{if } u_{i+1}^n + \mathcal{E}_0^n (a_C^n)_{i+1/2} \tau_{i+1}^n \leq 0 \\ (a_C^n)_{i+1/2} = & K \max(\rho_i^n (c_C)_i^n, \rho_{i+1}^n (c_C)_{i+1}^n), K > 1 \\ \mathbf{F}_C(\mathbf{U}) = & [\rho u, \rho u^2 + \mathcal{E}_0^2 p, (\rho e + \mathcal{E}_0^2 p)u]^T, \end{cases} \quad (\text{A.7})$$

where $(a_C^n)_{i+1/2} = K \max(\rho_i^n (c_C)_i^n, \rho_{i+1}^n (c_C)_{i+1}^n)$, $K > 1$, the discrete convective relaxation constant fulfilling the convective subcharacteristic condition, *i.e.* $a_C > \rho c_C$, throughout the whole computational domain and with:

$$\begin{aligned} (\mathbf{F}_C)_{i+1/2}^{*,n} &= \begin{bmatrix} (\rho_C^*)_{i+1/2}^n (u_C^*)_{i+1/2}^n \\ (\rho_C^*)_{i+1/2}^n ((u_C^*)_{i+1/2}^n)^2 + (\mathcal{E}_0^n)^2 (\Pi_C^*)_{i+1/2}^n \\ ((\rho_C^* e_C^*)_{i+1/2}^n + (\mathcal{E}_0^n)^2 (\Pi_C^*)_{i+1/2}^n) (u_C^*)_{i+1/2}^n \end{bmatrix}, \\ (\mathbf{F}_C)_{i+1/2}^{**,n} &= \begin{bmatrix} (\rho_C^*)_{i+1}^n (u_C^*)_{i+1/2}^n \\ (\rho_C^*)_{i+1}^n ((u_C^*)_{i+1/2}^n)^2 + (\mathcal{E}_0^n)^2 (\Pi_C^*)_{i+1/2}^n \\ ((\rho_C^* e_C^*)_{i+1}^n + (\mathcal{E}_0^n)^2 (\Pi_C^*)_{i+1/2}^n) (u_C^*)_{i+1/2}^n \end{bmatrix}, \\ (u_C^*)_{i+1/2}^n &= \frac{u_{i+1}^n + u_i^n}{2} - \frac{\mathcal{E}_0^n}{2(a_C^n)_{i+1/2}} (p_{i+1}^n - p_i^n), \\ (\mathcal{E}_0^n)^2 (\Pi_C^*)_{i+1/2}^n &= (\mathcal{E}_0^n)^2 \frac{p_{i+1}^n + p_i^n}{2} - \frac{\mathcal{E}_0^n (a_C^n)_{i+1/2}}{2} (u_{i+1}^n - u_i^n), \\ (\rho_C^*)_k^n &= 1/(\tau_{k,C}^*)^n, (\tau_{k,C}^*)^n = \tau_k^n + \frac{(-1)^{J_k+1}}{\mathcal{E}_0^n (a_C^n)_{i+1/2}} ((u_C^*)_{i+1/2}^n - u_k^n), \\ (e_C^*)_k^n &= e_k^n + \mathcal{E}_0^n \frac{(-1)^{J_k}}{(a_C^n)_{i+1/2}^n} ((\Pi_C^* u_C^*)_{i+1/2}^n - p_k^n u_k^n), \\ k &\in \{i, i+1\}, J_i = 1, J_{i+1} = 2. \end{aligned} \quad (\text{A.8})$$

The time-explicit scheme solving the convective subsystem then reads:

$$\mathbf{U}_i^{n+} = \mathbf{U}_i^n - \frac{\Delta t}{\Delta x} (\mathbf{H}_{C_{i+1/2}}^n - \mathbf{H}_{C_{i-1/2}}^n). \quad (\text{A.9})$$

In the case of an isolated contact discontinuity with $u^0 > 0$, the convective flux writes:

$$\mathbf{H}_{C_{i+1/2}}^{n, \text{Contact}} = \begin{bmatrix} \rho_i^n u^0 \\ \rho_i^n (u^0)^2 + (\mathcal{E}_0^n)^2 p^0 \\ (\rho \varepsilon)^{\text{EOS}}(\rho_i^n, p^0) u^0 + \rho_i^n \frac{(u^0)^3}{2} + (\mathcal{E}_0^n)^2 p^0 u^0 \end{bmatrix}. \quad (\text{A.10})$$

The mass, momentum and energy dynamics then read:

$$\begin{aligned} \frac{\rho_i^{n+} - \rho_i^n}{\Delta t} + u^0 \frac{\rho_i^n - \rho_{i-1}^n}{\Delta x} &= 0, \\ \frac{\rho_i^{n+} u_i^{n+} - \rho_i^n u^0}{\Delta t} + (u^0)^2 \frac{\rho_i^n - \rho_{i-1}^n}{\Delta x} &= 0, \\ \frac{(\rho \varepsilon)^{\text{EOS}}(\rho_i^{n+}, p_i^{n+}) - (\rho \varepsilon)^{\text{EOS}}(\rho_i^n, p^0)}{\Delta t} + \frac{1}{2} \frac{\rho_i^{n+} (u_i^{n+})^2 - \rho_i^n (u^0)^2}{\Delta t} \\ + u^0 \frac{(\rho \varepsilon)^{\text{EOS}}(\rho_i^n, p^0) - (\rho \varepsilon)^{\text{EOS}}(\rho_{i-1}^n, p^0)}{\Delta x} + \frac{(u^0)^3}{2} \frac{\rho_i^n - \rho_{i-1}^n}{\Delta x} &= 0. \end{aligned} \quad (\text{A.11})$$

By rewriting $\rho_i^{n+} u_i^{n+} - \rho_i^n u^0$ as $\rho_i^{n+} (u_i^{n+} - u^0) + (\rho_i^{n+} - \rho_i^n) u^0$ and using the discrete mass equation, the momentum equation can be simplified:

$$\rho_i^{n+} \frac{u_i^{n+} - u^0}{\Delta t} = 0 \Rightarrow u_i^{n+} = u^0. \quad (\text{A.12})$$

The kinetic part in the discrete energy equation then vanishes by factorizing by $(u^0)^2/2$ and using, once again, the discrete mass equation. Injecting formula (A.3), one obtains:

$$\frac{C(p_i^{n+}) \rho_i^{n+} + B(p_i^{n+}) - (C(p^0) \rho_i^n + B(p^0))}{\Delta t} + u^0 \frac{C(p^0) (\rho_i^n - \rho_{i-1}^n)}{\Delta x} = 0. \quad (\text{A.13})$$

The linear behavior of $(\rho \varepsilon)_p^{\text{EOS}} : \rho \rightarrow C(p) \rho + B(p)$ as well as the fact that $C(p) = C(p^0)$ is a constant in this configuration, play an important role. Indeed, it allows to retrieve the discrete mass equation by factorizing by $C(p^0)$. Finally, one obtains:

$$\begin{aligned} \frac{C(p_i^{n+}) \rho_i^{n+} + B(p_i^{n+}) - (C(p^0) \rho_i^{n+} + B(p^0))}{\Delta t} &= 0 \\ \Leftrightarrow \frac{(\rho \varepsilon)^{\text{EOS}}(\rho_i^{n+}, p_i^{n+}) - (\rho \varepsilon)^{\text{EOS}}(\rho_i^{n+}, p^0)}{\Delta t} &= 0. \end{aligned} \quad (\text{A.14})$$

411 Using the fact that $(\rho \varepsilon)_{\rho_i^{n+}}^{\text{EOS}} : p \rightarrow C(p) \rho_i^{n+} + B(p)$ is injective, it results in $p_i^{n+} = p^0$.

412 Appendix B. Stability Analysis

413 This appendix deals with the definition of a stability criterion for the proposed IMEX scheme. It focuses on the
414 isolated contact discontinuity test case discussed in subsection 5.1.2. As shown in Figure D.15 and Figure D.16 in
415 Appendix D, the present splitting seems to suffer from instabilities when the convective Courant number $\mathcal{C}_{|u|}$ goes
416 over a certain threshold. In the following, the dependence to the Mach number M of such a threshold is examined.
417 One can notably wonder whether the time-explicit CFL condition $\mathcal{C}_{|u|} = M/(1+M)\mathcal{C}_E$ is retrieved as M tends toward
418 zero.

419 In the sequel, Appendix B.1 describes a pragmatic way to measure stable Courant numbers while Appendix B.2
420 endeavors to derive a von Neumann stability analysis predicting stable Courant numbers analytically.

421 *Appendix B.1. Empirical Stable Courant Numbers*

422 As stated in **Proposition 4.3** for a sufficiently simple shape of the equation of state, velocity and pressure are
 423 supposed to be left constant by the overall scheme from one time-step to another. Nonetheless, truncation errors
 424 on double-precision floating-point numbers can be amplified by the scheme's instability and lead to the crash of the
 425 simulation. Thus, the selected criterion to detect the instability appearance is: $\max_i (|p_i^n - p^0|) / p^0 > \eta$ with $\eta = 10^{-7}$
 426 which is nearly the single-precision for floating-point numbers. Besides at the beginning of each calculation a ramp
 427 of CFL is enforced so that the targeted Courant number is reached after 200 time-steps, which corresponds to a
 428 propagation of 0.1 m of the exact contact discontinuity. If the calculation ends without triggering the above pressure
 429 stability criterion then the same calculation is launched again on a five times finer mesh of 5×10^3 cells in order to
 430 make sure that the numerical diffusion has not damped the instability appearance.

431 In Figure B.14, the curve labeled Sp-(M) gathers the different points resulting from the above stable convective
 432 Courant number research. Recall that in this test case the velocity is given by $u^0 = M_{min} c_R^0$, with $c^{0,R} = \sqrt{(\gamma p^0) / \rho_R^0}$ the
 433 maximal sound speed and M_{min} the minimal Mach number of the flow used as an input parameter here. Hence the
 434 stable Courant number upper bound is displayed as a function of M_{min} . The latter starts from $M_{min} = 1$, $u^0 = 335(m.s^{-1})$
 435 and decreases until $M_{min} = 10^{-4}$, $u^0 = 0.0335(m.s^{-1})$.

Figure B.14: Evaluation of an upper bound for the stable convective Courant number $\mathcal{C}_{|u|}$ as function of the Mach number M_{min} : global view (a) and zoom in the region $\mathcal{C}_{|u|} \in [0.2, 0.5]$ (b)

One can observe that for $M_{min} \approx 1$, $\mathcal{E}_0^n \approx 1$ so that the full Euler system is brought back into the time-explicit convective subsystem. The latter is thus bound by the classical CFL condition $\mathcal{C}_E \approx 1$. As $\mathcal{C}_{|u|} = M / (1 + M) \mathcal{C}_E$, this leads to $\mathcal{C}_{|u|} \approx 0.5$ for $M_{min} \approx 1$ which is observed here. Then, as the Mach number decreases, the contribution of the time-implicit part of the acoustic subsystem becomes more and more active. It results in a drop of the Euler time-explicit CFL condition until $M_{min} \approx 0.35$ where $\mathcal{C}_{|u|} = 0.26$.

An attempt at explaining this decline is given in the following. First, as it will be shown, this behavior might be related to the gap between the definition of $\mathcal{C}_{|u|}$ and the Courant number involving the largest eigenvalues of the convective subsystem as given in 4.4:

$$\mathcal{C}_C = \frac{\Delta t}{\Delta x} (|u^0| + \mathcal{E}_0^n c_C^{0,R}) \quad (\text{B.1})$$

with: $c_C^{0,R} = c_C(\rho_R^0, p^0)$.

One can notice that:

$$\begin{aligned}\mathcal{C}_{|u|} &= \left(1 + \mathcal{E}_0^n \frac{c_C^{0,R}}{|u^0|}\right)^{-1} & \mathcal{C}_C &= \left(1 + \frac{\mathcal{E}_0^n}{M_{min}} \frac{c_C^{0,R}}{c^{0,R}}\right)^{-1} \mathcal{C}_C, \\ \text{since: } |u^0| &= M_{min} c^{0,R}, \\ \text{and: } \frac{c_C^{0,R}}{c^{0,R}} &= \sqrt{\left(\mathcal{E}_0^n\right)^2 \frac{\gamma-1}{\gamma} + \frac{1}{\gamma}} \in [1/\gamma, 1].\end{aligned}\tag{B.2}$$

Besides, according to formula (4.19):

$$\begin{aligned}\mathcal{E}_0^n &= \min(M_{max}^n, 1) = \min(|u^0|/c^{0,L}, 1) \\ &= \min\left(M_{min} \sqrt{\frac{\rho_L^0}{\rho_R^0}}, 1\right), \\ \text{then for } M_{min} &\geq M_{thres} = \sqrt{\frac{\rho_R^0}{\rho_L^0}}: \mathcal{E}_0^n = 1, \\ \text{and for } M_{min} &< M_{thres} = \sqrt{\frac{\rho_R^0}{\rho_L^0}}: \mathcal{E}_0^n = M_{min}/M_{thres}.\end{aligned}\tag{B.3}$$

It results that:

$$\mathcal{C}_{|u|} = \begin{cases} \left(1 + \frac{1}{M_{min}}\right)^{-1} \mathcal{C}_C, & \text{if } M_{min} \geq M_{thres}, \\ \left(1 + \frac{1}{M_{thres}} \sqrt{\left(\frac{M_{min}}{M_{thres}}\right)^2 \frac{\gamma-1}{\gamma} + \frac{1}{\gamma}}\right)^{-1} \mathcal{C}_C, & \text{otherwise.} \end{cases}\tag{B.4}$$

436 Define $M_{min} \rightarrow \mathcal{C}_{|u|}^{th}(M_{min})$, the continuous function described by formula (B.4). This function has been plotted as a
437 dashed black line in Figure B.14.

438 For every M_{min} between M_{thres} and 1 the comparison between $\mathcal{C}_{|u|}^{th}$ and the measured stable convective Courant
439 number is fair: the cut-off $M_{min} = M_{thres} \approx 0.35$, the $\mathcal{C}_{|u|}^{th}(M_{thres}) \approx 0.26$ value as well as the global shape of $\mathcal{C}_{|u|}^{th}(\cdot)$ are
440 retrieved. Yet, as M_{min} falls below M_{thres} , the measured stable convective Courant number increases to reach the
441 plateau value $\mathcal{C}_{|u|} = 0.43$ which is bigger than the one predicted by the above analysis.

442 In any case, for this specific test case, $\mathcal{C}_{|u|} \approx 0.26$ or equivalently $\mathcal{C}_C \approx 1$ is sufficient to ensure the scheme stability
443 for every Mach number. Thus, the ‘‘Mach-uniform’’ stability property, $\mathcal{C}_{|u|} \approx 1, \forall M_{min}$, obtained by Zakerzadeh in [16]
444 for the IMEX LP scheme and which can be observed in Figure B.14, is not retrieved for the present method. At a
445 given Mach number, the presence of $\pm \mathcal{E}_0 c_C$ in the eigenvalues of the convective subsystem prevents from reaching
446 the stability condition $\mathcal{C}_{|u|} \approx 1$. However, in the above simple test case, the stable convective Courant number \mathcal{C}_C no
447 longer behaves as $O(M_{min})$ as $M_{min} \rightarrow 0$.

448 This latter result is absolutely not guaranteed by the time-implicit integration of the stiff part of the IMEX approach
449 and strongly depends on the splitting at stake. Indeed, in [14, 15] several IMEX fractional steps on Euler-like systems
450 are studied. It turns out that the ‘‘modified’’ equation obtained from the order two Taylor expansion of a smooth
451 solution of an IMEX fractional step approach exhibits a diffusive operator which can be written as $\mathbf{D}_0 \partial_{xx} \mathbf{U}$; with $\mathbf{D}_0 =$
452 $\beta \mathcal{C}_{|u|} \mathbf{I} - (\mathbf{A}_0^C)^2 + (\mathbf{A}_0^A)^2 + [\mathbf{A}_0^C, \mathbf{A}_0^A]$, β being a coefficient related to the scheme numerical diffusion of the convective
453 sub-step, \mathbf{A}_0^C (respectively \mathbf{A}_0^A) the linearized jacobian matrix related to the convective (respectively the acoustic)
454 subsystem, and $[\mathbf{A}_0^C, \mathbf{A}_0^A] = \mathbf{A}_0^C \mathbf{A}_0^A - \mathbf{A}_0^A \mathbf{A}_0^C$ being the commutator linked to the splitting. The latter can be viewed
455 as a mathematical operator which couples the two subsystems of the fractional step approach. Hence, even if it is
456 discretized using a time-implicit scheme, the acoustic subsystem can still have an influence on the overall fractional
457 step stability through the commutator which can impact the diffusion (or the anti-diffusion) effect of the modified
458 equation. In Figure B.14, the orange-triangle line labeled ‘‘Sp-LP’’ represents the stable convective Courant number

459 obtained with the Lagrange-Projection IMEX approach. As already proven in [16], this scheme is Mach-uniformly
 460 stable for $\mathcal{C}_{|u|} = 1$.
 461 The next subsection provides an analytical stability analysis in order to compare with the above measured stable
 462 Courant numbers.

463 Appendix B.2. A Von Neumann Stability Analysis

464 In order to better understand the shape of the stable Courant number, a von Neumann-like stability analysis based
 465 on a linearized version of the IMEX approach has been performed. This strategy is motivated by the fact that, as
 466 shown in Figure D.15 of Appendix D, the instability seems to appear in a region where ρ , u and p are constant. The
 467 linearization required by the von Neumann analysis is thus justified. However, one should keep in mind that such a
 468 method relies on periodic boundary conditions which is not the case here because of the density discontinuity.

Starting at time-step t^n with a perturbed constant flow:

$$\begin{aligned}\rho_i^n &= \rho^0 + \epsilon \rho_i^{1,n}, \quad \rho^0 = \rho_R, \\ u_i^n &= u^0 + \epsilon u_i^{1,n}, \\ p_i^n &= p^0 + \epsilon p_i^{1,n},\end{aligned}\tag{B.5}$$

the discrete dynamics of the perturbation is derived when a Rusanov scheme is used to solve the first convective subsystem (2.2). The numerical flux at face $i + 1/2$ associated to this scheme reads:

$$\begin{aligned}\mathbf{H}_{\text{rus}_{i+1/2}}^n &= \frac{\mathbf{F}^C(\mathbf{U}_{i+1}^n) + \mathbf{F}^C(\mathbf{U}_i^n)}{2} - \frac{|\lambda_{i+1/2}^n|}{2} (\mathbf{U}_{i+1}^n - \mathbf{U}_i^n), \\ \text{with: } \mathbf{F}^C(\mathbf{U}) &= [\rho u, \rho u^2 + \mathcal{E}_0^2 p, (\rho e + \mathcal{E}_0^2 p) u]^T, \\ \text{and: } |\lambda_{i+1/2}^n| &= \max(|u_{i+1}^n| + (\mathcal{E}_0)^n (c_C)_{i+1}^n, |u_i^n| + (\mathcal{E}_0)^n (c_C)_i^n).\end{aligned}\tag{B.6}$$

Let us define $\rho_i^{n+} = \rho_i^{0,n+} + \epsilon \rho_i^{1,n+}$, $u_i^{n+} = u_i^{0,n+} + \epsilon u_i^{1,n+}$, and $p_i^{n+} = p_i^{0,n+} + \epsilon p_i^{1,n+}$ the solution produced by the Rusanov scheme applied to the convective subsystem. Then, zeroth order and first order dynamics can be decoupled and one obtains:

$$\begin{aligned}\rho_i^{0,n+} &= \rho^0, \\ u_i^{0,n+} &= u^0, \\ p_i^{0,n+} &= p^0, \\ \frac{\rho_i^{1,n+} - \rho_i^{1,n}}{\Delta t} + u^0 \frac{\rho_{i+1}^{1,n} - \rho_{i-1}^{1,n}}{2\Delta x} + \rho^0 \frac{u_{i+1}^{1,n} - u_{i-1}^{1,n}}{2\Delta x} - |\lambda^0| \frac{\rho_{i+1}^{1,n} - 2\rho_i^{1,n} + \rho_{i-1}^{1,n}}{2\Delta x} &= 0, \\ \frac{u_i^{1,n+} - u_i^{1,n}}{\Delta t} + u^0 \frac{u_{i+1}^{1,n} - u_{i-1}^{1,n}}{2\Delta x} + ((\mathcal{E}_0^n)^2 / \rho^0) \frac{p_{i+1}^{1,n} - p_{i-1}^{1,n}}{2\Delta x} - |\lambda^0| \frac{u_{i+1}^{1,n} - 2u_i^{1,n} + u_{i-1}^{1,n}}{2\Delta x} &= 0, \\ \frac{p_i^{1,n+} - p_i^{1,n}}{\Delta t} + u^0 \frac{p_{i+1}^{1,n} - p_{i-1}^{1,n}}{2\Delta x} + \rho^0 (c_C^0)^2 \frac{u_{i+1}^{1,n} - u_{i-1}^{1,n}}{2\Delta x} - |\lambda^0| \frac{p_{i+1}^{1,n} - 2p_i^{1,n} + p_{i-1}^{1,n}}{2\Delta x} &= 0, \\ \text{with: } |\lambda^0| &= |u^0| + (\mathcal{E}_0)^n (c_C^0).\end{aligned}\tag{B.7}$$

If $\forall \phi \in \{\rho, u, p\}$ the following sinus spatial pulse is conjectured $\phi_i^t = \hat{\phi}^t e^{jkx_i}$, $t \in \{n, n+\}$; one can derive the von Neumann gain matrix related to the convective subsystem:

$$\begin{aligned}\begin{bmatrix} \hat{\rho}^{n+} \\ \hat{u}^{n+} \\ \hat{p}^{n+} \end{bmatrix} &= \begin{bmatrix} G & -\frac{\rho^0 \mathcal{E}_{|u|}}{|u^0|} j \sin(k\Delta x) & 0 \\ 0 & G & -\frac{(\mathcal{E}_0^n)^2 \mathcal{E}_{|u|}}{\rho^0 |u^0|} j \sin(k\Delta x) \\ 0 & -\frac{\rho^0 (c_C^0)^2 \mathcal{E}_{|u|}}{|u^0|} j \sin(k\Delta x) & G \end{bmatrix} \begin{bmatrix} \hat{\rho}^n \\ \hat{u}^n \\ \hat{p}^n \end{bmatrix}, \\ \text{with: } G &= 1 - 2 \frac{|\lambda^0|}{|u^0|} \mathcal{E}_{|u|} \sin^2(k\Delta x/2) - j \frac{u^0}{|u^0|} \mathcal{E}_{|u|} \sin(k\Delta x).\end{aligned}\tag{B.8}$$

The spectral radius $|G|_C$ related to this gain matrix can be found easily and one can state that (See Appendix C for a proof):

$$\mathcal{C}_{|u|} < \mathcal{C}_{|u|}^{\text{crit}} = |u^0|/|\lambda^0| \Rightarrow |G|_C < 1. \quad (\text{B.9})$$

469 In particular, when M_{\min} tends towards one, $(\mathcal{E}_0)^n$ tends towards one and c_C^0 tends towards c^0 such that $|G|_C < 1 \Leftrightarrow \mathcal{C}_{|u|} <$
470 $M_{\min}/(1 + M_{\min})$. Thus, the classical CFL condition is retrieved.

The same kind of analysis is performed on the acoustic subsystem. However, the time-implicit flux (4.22) raises new issues in the sense that its energy contribution strongly couples zeroth-order and first-order terms: $(P_{\mathcal{A}}^*)^{n+1/2} (u_{\mathcal{A}}^*)^{n+1/2} = (P_{\mathcal{A}}^{0,*})^{n+1/2} (u_{\mathcal{A}}^{0,*})^{n+1/2} + \epsilon \left((P_{\mathcal{A}}^{1,*})^{n+1/2} (u_{\mathcal{A}}^{1,*})^{n+1/2} + (P_{\mathcal{A}}^{1,*})^{n+1/2} (u_{\mathcal{A}}^{0,*})^{n+1/2} \right)$. What is more, this coupling is strongly non-linear and prevents from deriving a simple von Neumann analysis. That is why, it has been additionally assumed that zeroth-order terms including these taken at time t^{n+1} were constant namely:

$$\begin{aligned} \rho_i^{0,n+1} &= \rho^0, \\ u_i^{0,n+1} &= u^0, \\ p_i^{0,n+1} &= p^0; \end{aligned} \quad (\text{B.10})$$

then, as proved in Appendix C the dynamics of the perturbation reads:

$$\begin{aligned} \frac{\rho_i^{1,n+1} - \rho_i^{1,n}}{\Delta t} &= 0, \\ \frac{u_i^{1,n+1} - u_i^{1,n}}{\Delta t} + (1 - (\mathcal{E}_0^n)^2) \left[\frac{1}{\rho^0} \frac{p_{i+1}^{1,n+1} - p_{i-1}^{1,n+1}}{2\Delta x} - \frac{a_{\mathcal{A}}^0}{\rho^0} \frac{u_{i+1}^{1,n+1} - 2u_i^{1,n+1} + u_{i-1}^{1,n+1}}{2\Delta x} \right] &= 0, \\ \frac{p_i^{1,n+1} - p_i^{1,n}}{\Delta t} + (1 - (\mathcal{E}_0^n)^2) \rho^0 (c_{\mathcal{A}}^0)^2 \left[\frac{u_{i+1}^{1,n+1} - u_{i-1}^{1,n+1}}{2\Delta x} - \frac{1}{a_{\mathcal{A}}^0} \frac{p_{i+1}^{1,n+1} - 2p_i^{1,n+1} + p_{i-1}^{1,n+1}}{2\Delta x} \right] &= 0. \end{aligned} \quad (\text{B.11})$$

The von Neumann gain matrix writes:

$$\begin{aligned} \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 + 2\alpha^n \sin^2(k\Delta x/2) & \frac{\alpha^n}{a_{\mathcal{A}}^0} j \sin(k\Delta x) \\ 0 & \alpha^n (\omega_{\mathcal{A}}^0)^2 a_{\mathcal{A}}^0 j \sin(k\Delta x) & 1 + 2\alpha^n (\omega_{\mathcal{A}}^0)^2 \sin^2(k\Delta x/2) \end{bmatrix} \begin{bmatrix} \hat{\rho}^{n+1} \\ \hat{u}^{n+1} \\ \hat{p}^{n+1} \end{bmatrix} &= \begin{bmatrix} \hat{\rho}^{n+} \\ \hat{u}^{n+} \\ \hat{p}^{n+} \end{bmatrix}, \\ \text{with: } \alpha^n &= (1 - (\mathcal{E}_0^n)^2) \frac{a_{\mathcal{A}}^0 \mathcal{C}_{|u|}}{\rho^0 |u^0|}, \\ \text{and: } \omega_{\mathcal{A}}^0 &= \frac{\rho^0 c_{\mathcal{A}}^0}{a_{\mathcal{A}}^0}. \end{aligned} \quad (\text{B.12})$$

Finally the von Neumann gain matrix related to the fractional step approach reads:

$$\begin{aligned} \begin{bmatrix} G & 0 \\ 0 & \mathbf{G}_{\mathcal{A}}^{-1} \mathbf{G}_C \end{bmatrix}, \\ \text{with:} \\ \mathbf{G}_C &= \begin{bmatrix} G & -\frac{(\mathcal{E}_0^n)^2 \mathcal{C}_{|u|}}{\rho^0 |u^0|} j \sin(k\Delta x) \\ -\frac{\rho^0 (c_C^0)^2 \mathcal{C}_{|u|}}{|u^0|} j \sin(k\Delta x) & G \end{bmatrix}, \\ \mathbf{G}_{\mathcal{A}} &= \begin{bmatrix} 1 + 2\alpha^n \sin^2(k\Delta x/2) & \frac{\alpha^n}{a_{\mathcal{A}}^0} j \sin(k\Delta x) \\ \alpha^n (\omega_{\mathcal{A}}^0)^2 a_{\mathcal{A}}^0 j \sin(k\Delta x) & 1 + 2\alpha^n (\omega_{\mathcal{A}}^0)^2 \sin^2(k\Delta x/2) \end{bmatrix}, \\ \mathbf{G}_{\mathcal{A}}^{-1} &= \frac{1}{\Delta} \begin{bmatrix} 1 + 2\alpha^n (\omega_{\mathcal{A}}^0)^2 \sin^2(k\Delta x/2) & -\frac{\alpha^n}{a_{\mathcal{A}}^0} j \sin(k\Delta x) \\ -\alpha^n (\omega_{\mathcal{A}}^0)^2 a_{\mathcal{A}}^0 j \sin(k\Delta x) & 1 + 2\alpha^n \sin^2(k\Delta x/2) \end{bmatrix}, \quad \Delta = \det \mathbf{G}_{\mathcal{A}}. \end{aligned} \quad (\text{B.13})$$

471 G is a first eigenvalue related to the mass equation. As written in Appendix C, $|G| < 1$ if $\mathcal{C}_{|u|} < \mathcal{C}_{|u|}^{\text{crit}}$. The two remaining
472 eigenvalues are linked to the matrix $\mathbf{G}_{\mathcal{A}}^{-1} \mathbf{G}_C$ which couples the momentum and the energy equations and can not be

473 easily found analytically. Starting from $\mathcal{C}_{|u|}^{\text{crit}}$, a loop on all the k modes $\in [0, 4\pi/\Delta x]$ is performed and the spectral
 474 radius $|G|_{\mathcal{AC}}^k$ associated to $(\mathbf{G}_{\mathcal{A}}^{-1} \mathbf{G}_C)(k)$ is calculated. If, during the loop, $|G|_{\mathcal{AC}}^k > 1$, then $\mathcal{C}_{|u|}^{\text{crit}}$ is slightly decreased and
 475 the loop is restarted. Otherwise the current Courant number is stored and considered as the stable Courant number of
 476 the above von Neumann analysis.

477 In Figure B.14, the curve labeled “VN-Sp” (red line) displays the different stable convective Courant numbers
 478 obtained thanks to the above von Neumann method. Recall that the analytical curve $M \rightarrow \mathcal{C}_{|u|}^{\text{th}}(M)$ is equivalent to
 479 $\mathcal{C}_C = 1$ for this test case. For $M_{\min} \in [7.5 \times 10^{-2}, 1]$, “VN-Sp” and $M \rightarrow \mathcal{C}_{|u|}^{\text{th}}(M)$ overlap quasi-perfectly. Unfortunately,
 480 for very low Mach numbers, $\mathcal{C}_{|u|}$ plunges down. For example, it predicts $\mathcal{C}_{|u|} = 10^{-2}$ when $M_{\min} = 10^{-4}$.

This difference could stem from the assumptions made on the time-implicit acoustic scheme in order to linearize
 it. Indeed the zeroth order terms of the updated solution have been assumed to be constant:

$$\begin{aligned} \rho_i^{0,n+1} &= \rho^0, \\ u_i^{0,n+1} &= u^0, \\ p_i^{0,n+1} &= p^0. \end{aligned} \tag{B.14}$$

481 The resulting dynamics then binds only first-order pressure terms with first-order velocity terms. Yet, in that case the
 482 small perturbation parameter ϵ is not related to the flow Mach number. As formally shown in [19, 20] on the continuous
 483 subsystem \mathcal{A} , one could make the discrete acoustic scheme (4.22) non-dimensional and consider a constant base flow
 484 perturbed by modes written in powers of the Mach number. Then, one would observe that the zeroth-order momentum
 485 term is fed by the second-order pressure gradient. Thus, one could assume that if the amplitude of this second-order
 486 pressure gradient explodes because of an instability, the zeroth-order momentum term would rise too. It would result
 487 in an increase of the Mach number associated with a decrease of the discrete numerical time-step built on the zeroth-
 488 order velocity terms. This might damp the instability. In any case, further investigations should be done in order to
 489 better understand this sudden drop.

490 Appendix C. Study of the von Neumann Gain Matrices

491 This appendix is dedicated to the study of the von Neumann gain matrices written in (B.8) and (B.13). The
 492 derivation of the convective gain matrix being relatively straightforward, special attention is paid to the expression of
 493 its eigenvalues as well as a sufficient condition ensuring that their modulus is strictly lower than one. Besides, the
 494 derivation of the acoustic gain matrix is completely done.
 495

496 Appendix C.1. Analysis of the Convective Gain Matrix Eigenvalues

497

Let us consider the von Neumann gain matrix associated with the convective sub-step:

$$\begin{bmatrix} G & -\frac{\rho^0 \mathcal{C}_{|u|}}{|u^0|} j \sin(k \Delta x) & 0 \\ 0 & G & -\frac{(\mathcal{C}_0^n)^2 \mathcal{C}_{|u|}}{\rho^0 |u^0|} j \sin(k \Delta x) \\ 0 & -\frac{\rho^0 (c_C^0)^2 \mathcal{C}_{|u|}}{|u^0|} j \sin(k \Delta x) & G \end{bmatrix}, \tag{C.1}$$

$$\text{and: } G = 1 - 2 \frac{\mathcal{C}_{|u|}}{\mathcal{C}_{|u|}^{\text{crit}}} \sin^2(k \Delta x / 2) - j \frac{u^0}{|u^0|} \mathcal{C}_{|u|} \sin(k \Delta x),$$

$$\text{with: } \mathcal{C}_{|u|}^{\text{crit}} = |u^0| / |\lambda^0| \in]0, 1[.$$

G is the first eigenvalue of this matrix. Define $X = \sin^2(k\Delta x/2) \in [0, 1]$, then $\sin^2(k\Delta x) = 4X(1-X)$. Thus:

$$|G|^2 = \left(1 - 2 \frac{\mathcal{C}_{|u|}}{\mathcal{C}_{|u|}^{\text{crit}}} X\right)^2 + 4 \mathcal{C}_{|u|}^2 X(1-X), \quad (\text{C.2})$$

$$|G|^2 < 1 \Leftrightarrow \mathcal{C}_{|u|} < \frac{\mathcal{C}_{|u|}^{\text{crit}}}{\left((1 - (\mathcal{C}_{|u|}^{\text{crit}})^2)X + (\mathcal{C}_{|u|}^{\text{crit}})^2\right)}.$$

498 Since $X \in [0, 1]$ the most constraining CFL condition is $\mathcal{C}_{|u|} < \mathcal{C}_{|u|}^{\text{crit}}$.

The two other eigenvalues of the above gain matrix are the roots of the characteristic polynomial function:

$$(G - \lambda)^2 + (\mathcal{E}_0^n)^2 (\mathcal{C}_{|u|})^2 \left(\frac{c_C^0}{u^0}\right)^2 \sin^2(k\Delta x). \quad (\text{C.3})$$

They write:

$$\begin{aligned} \lambda^\pm &= G \mp j \mathcal{E}_0^n \mathcal{C}_{|u|} \left| \frac{c_C^0}{u^0} \right| |\sin(k\Delta x)|, \\ |\lambda^\pm|^2 &= \left(1 - 2 \frac{\mathcal{C}_{|u|}}{\mathcal{C}_{|u|}^{\text{crit}}} X\right)^2 + \mathcal{C}_{|u|}^2 \left[1 + (\mathcal{E}_0^n)^2 \left| \frac{c_C^0}{u^0} \right|^2\right] 4X(1-X) \pm 2 \mathcal{E}_0^n \frac{u^0}{|u^0|} \left| \frac{c_C^0}{u^0} \right| |\sin(k\Delta x)| |\sin(k\Delta x)| \\ \Rightarrow |\lambda^\pm|^2 &\leq \left(1 - 2 \frac{\mathcal{C}_{|u|}}{\mathcal{C}_{|u|}^{\text{crit}}} X\right)^2 + 4 \left(1 + \mathcal{E}_0^n \left| \frac{c_C^0}{u^0} \right|\right)^2 \mathcal{C}_{|u|}^2 X(1-X) = \left(1 - 2 \frac{\mathcal{C}_{|u|}}{\mathcal{C}_{|u|}^{\text{crit}}} X\right)^2 + 4 \left(\frac{\mathcal{C}_{|u|}}{\mathcal{C}_{|u|}^{\text{crit}}}\right)^2 X(1-X). \end{aligned} \quad (\text{C.4})$$

499 A sufficient condition ensuring that $|\lambda^\pm| < 1$ is once again $\mathcal{C}_{|u|} < \mathcal{C}_{|u|}^{\text{crit}}$.

500 Appendix C.2. Derivation of the Linearized Acoustic Dynamics

501

The von Neumann analysis has to be made on the relaxation system (3.9). Define at time t^{n+} :

$$\begin{aligned} W_i^{n+} &= u_i^{n+} - \frac{p_i^{n+}}{a_{\mathcal{A}}^{n+}} = u_i^{n+} - \frac{\Pi_i^{n+}}{a_{\mathcal{A}}^{n+}}, \\ R_i^{n+} &= u_i^{n+} + \frac{p_i^{n+}}{a_{\mathcal{A}}^{n+}} = u_i^{n+} + \frac{\Pi_i^{n+}}{a_{\mathcal{A}}^{n+}}. \end{aligned} \quad (\text{C.5})$$

Then,

$$\begin{cases} \frac{\rho_i^{n+1} - \rho_i^{n+}}{\Delta t} = 0, \\ \frac{(\rho u)_i^{n+1} - (\rho u)_i^{n+}}{\Delta t} + \left(1 - (\mathcal{E}_0^n)^2\right) \frac{(\rho_{\mathcal{A}}^*)^{n+1} - (\rho_{\mathcal{A}}^*)^{n+1}}{\Delta x} = 0, \\ \frac{(\rho \Pi)_i^{n+1} - (\rho \Pi)_i^{n+}}{\Delta t} + \left(1 - (\mathcal{E}_0^n)^2\right) \frac{(a_{\mathcal{A}}^{n+})^2 \frac{(u_{\mathcal{A}}^*)^{n+1} - (u_{\mathcal{A}}^*)^{n+1}}{\Delta x}}{\Delta x} = 0, \\ \frac{(\rho e)_i^{n+1} - (\rho e)_i^{n+}}{\Delta t} + \left(1 - (\mathcal{E}_0^n)^2\right) \frac{(p_{\mathcal{A}}^* u_{\mathcal{A}}^*)^{n+1} - (p_{\mathcal{A}}^* u_{\mathcal{A}}^*)^{n+1}}{\Delta x} = 0, \end{cases} \Leftrightarrow \begin{cases} \frac{\rho_i^{n+1} - \rho_i^{n+}}{\Delta t} = 0, \\ \frac{(\rho u)_i^{n+1} - (\rho u)_i^{n+}}{\Delta t} + \left(1 - (\mathcal{E}_0^n)^2\right) \left[\frac{\Pi_{i+1}^{n+1} - \Pi_{i-1}^{n+1}}{2\Delta x} - \frac{a_{\mathcal{A}}^{n+} u_{i+1}^{n+1} - 2u_i^{n+1} + u_{i-1}^{n+1}}{2\Delta x} \right] = 0, \\ \frac{(\rho \Pi)_i^{n+1} - (\rho \Pi)_i^{n+}}{\Delta t} + \left(1 - (\mathcal{E}_0^n)^2\right) \left[\frac{(a_{\mathcal{A}}^{n+})^2 \frac{u_{i+1}^{n+1} - u_{i-1}^{n+1}}{2\Delta x}}{2\Delta x} - \frac{a_{\mathcal{A}}^{n+}}{2} \frac{\Pi_{i+1}^{n+1} - 2\Pi_i^{n+1} + \Pi_{i-1}^{n+1}}{\Delta x} \right] = 0, \\ \frac{(\rho e)_i^{n+1} - (\rho e)_i^{n+}}{\Delta t} + \left(1 - (\mathcal{E}_0^n)^2\right) \left[\frac{(\Pi u)_{i+1}^{n+1} - (\Pi u)_{i-1}^{n+1}}{2\Delta x} - \frac{1}{4a_{\mathcal{A}}^{n+}} \frac{(\Pi^2)_{i+1}^{n+1} - 2(\Pi^2)_i^{n+1} + (\Pi^2)_{i-1}^{n+1}}{\Delta x} \right. \\ \left. - \frac{a_{\mathcal{A}}^{n+}}{4} \frac{(u^2)_{i+1}^{n+1} - 2(u^2)_i^{n+1} + (u^2)_{i-1}^{n+1}}{\Delta x} \right] = 0. \end{cases} \quad (\text{C.6})$$

Supposing that $\forall \phi \in \{\rho, u, \Pi, e\}$, $\phi_i^{0,n+1} = \phi^0$ a constant, one can extract the linearized dynamics related to (C.6):

$$\begin{aligned}
\frac{\rho_i^{1,n+1} - \rho_i^{1,n+}}{\Delta t} &= 0, \\
\rho^0 \frac{u_i^{1,n+1} - u_i^{1,n+}}{\Delta t} + (1 - (\mathcal{E}_0^n)^2) &\left[\frac{\Pi_i^{1,n+1} - \Pi_i^{1,n+}}{2\Delta x} - \frac{a_{\mathcal{A}}^0}{2} \frac{u_{i+1}^{1,n+1} - 2u_i^{1,n+1} + u_{i-1}^{1,n+1}}{\Delta x} \right] = 0, \\
\rho^0 \frac{\Pi_i^{1,n+1} - \Pi_i^{1,n+}}{\Delta t} + (1 - (\mathcal{E}_0^n)^2) &\left[(a_{\mathcal{A}}^0)^2 \frac{u_i^{1,n+1} - u_i^{1,n+}}{2\Delta x} - \frac{a_{\mathcal{A}}^0}{2} \frac{\Pi_{i+1}^{1,n+1} - 2\Pi_i^{1,n+1} + \Pi_{i-1}^{1,n+1}}{\Delta x} \right] = 0, \\
\rho^0 \frac{e_i^{1,n+1} - e_i^{1,n+}}{\Delta t} + (1 - (\mathcal{E}_0^n)^2) &\left[p^0 \frac{u_i^{1,n+1} - u_i^{1,n+}}{2\Delta x} + u^0 \frac{\Pi_i^{1,n+1} - \Pi_i^{1,n+}}{2\Delta x} \right] \\
&- (1 - (\mathcal{E}_0^n)^2) \left[\frac{p^0}{a_{\mathcal{A}}^0} \frac{\Pi_{i+1}^{1,n+1} - 2\Pi_i^{1,n+1} + \Pi_{i-1}^{1,n+1}}{2\Delta x} + u^0 a_{\mathcal{A}}^0 \frac{u_{i+1}^{1,n+1} - 2u_i^{1,n+1} + u_{i-1}^{1,n+1}}{2\Delta x} \right] = 0.
\end{aligned} \tag{C.7}$$

During the projection step, $\Pi_i^{n+1} = p_i^{n+1} = p^{EOS}(\rho_i^{n+1}, \varepsilon_i^{n+1})$ is imposed with $\varepsilon_i^{n+1} = e_i^{n+1} - (u_i^{n+1})^2/2$. If one assumes that this projection holds separately for zeroth order and first order terms then $\forall \# \in \{n+, n+1\}$:

$$\Pi_i^{1,\#} = p_i^{1,\#} = (\partial_\rho p|_\varepsilon)^0 \rho_i^{1,\#} + (\partial_\varepsilon p|_\rho)^0 (e_i^{1,\#} - u_i^{1,\#}). \tag{C.8}$$

Using the momentum equation, the perturbed pressure dynamics is then:

$$\frac{p_i^{1,n+1} - p_i^{1,n+}}{\Delta t} + (1 - (\mathcal{E}_0^n)^2) (\partial_\varepsilon p|_\rho)^0 \frac{p^0}{\rho^0} \left[\frac{u_{i+1}^{1,n+1} - u_{i-1}^{1,n+1}}{2\Delta x} - \frac{1}{a_{\mathcal{A}}^0} \frac{p_{i+1}^{1,n+1} - 2p_i^{1,n+1} + p_{i-1}^{1,n+1}}{2\Delta x} \right] = 0. \tag{C.9}$$

According to definition (2.6), $(\partial_\varepsilon p|_\rho)^0 \frac{p^0}{\rho^0}$ is exactly equal to $\rho^0 (c_{\mathcal{A}}^0)^2$. The linearized dynamics of the non conservative variables related to the acoustic scheme is then:

$$\begin{aligned}
\frac{\rho_i^{1,n+1} - \rho_i^{1,n+}}{\Delta t} &= 0, \\
\frac{u_i^{1,n+1} - u_i^{1,n+}}{\Delta t} + (1 - (\mathcal{E}_0^n)^2) &\left[\frac{1}{\rho^0} \frac{p_{i+1}^{1,n+1} - p_{i-1}^{1,n+1}}{2\Delta x} - \frac{a_{\mathcal{A}}^0}{\rho^0} \frac{u_{i+1}^{1,n+1} - 2u_i^{1,n+1} + u_{i-1}^{1,n+1}}{2\Delta x} \right] = 0, \\
\frac{p_i^{1,n+1} - p_i^{1,n+}}{\Delta t} + (1 - (\mathcal{E}_0^n)^2) \rho^0 (c_{\mathcal{A}}^0)^2 &\left[\frac{u_{i+1}^{1,n+1} - u_{i-1}^{1,n+1}}{2\Delta x} - \frac{1}{a_{\mathcal{A}}^0} \frac{p_{i+1}^{1,n+1} - 2p_i^{1,n+1} + p_{i-1}^{1,n+1}}{2\Delta x} \right] = 0.
\end{aligned} \tag{C.10}$$

502 Appendix D. Location of the IMEX Instability

503
504 Figure D.15 and Figure D.16 show the growth of the numerical instability observed in the case presented in
505 subsection 5.1.2. The picture is taken at time $t = 2.496 \times 10^{-2} s$ but for a mesh of 10^3 cells (Figure D.15) and for a finer
506 one of 5×10^3 cells (Figure D.16).

507 One can observe than the instability originates from the region located after the contact discontinuity front where
508 the Mach number takes its lowest value. As the mesh is refined, the amplitude of the instability surges considerably
509 since the numerical diffusion is largely diminished.

Figure D.15: p , Ideal Gas, $M_{min} = 10^{-2}$, with $N_{cells} = 10^3$, $\mathcal{E}_{|u|} = 0.49$, iteration 270, ($t = 2.496 \times 10^{-2}$ s)

Figure D.16: p , Ideal Gas, $M_{min} = 10^{-2}$, with $N_{cells} = 5 \times 10^3$, $\mathcal{E}_{|u|} = 0.49$, iteration 1399, ($t = 2.497 \times 10^{-2}$ s)

510 **Appendix E. The Most Constraining Euler Courant Number**

511
 512 Let us consider the shock tube test case presented in subsection 5.2. The fastest Euler eigenvalue is $u^* + c_R^{0,*}$
 513 with $c_R^{0,*} = c(\rho_R^*, p^*)$. It corresponds to the characteristic colliding with the 3-shock wave front speed. Here u^* and
 514 p^* are the intermediate velocity and pressure whose values can be approximatively calculated: $u^* \approx 1.49886 \text{ m s}^{-1}$,
 515 $p^* \approx 10020.9 \text{ Pa}$. What is more, the conservation of entropy through the 3-shock brings: $\rho_R^* = \rho_R^0 (p^*/p_R^0)^{1/\gamma}$, and
 516 $c(\rho_R^*, p^*) = c_R^0 (p^*/p_R^0)^{(\gamma-1)/\gamma} \approx 336.36256 \text{ m s}^{-1}$.

The most constraining time-step got from the above wave speed writes:

$$\Delta t_E^{0,*} = \frac{\mathcal{C}_E^{0,*}}{2} \frac{\Delta x}{u^* + c_R^{0,*}}. \quad (\text{E.1})$$

Besides the time-step related to u^0 writes simply $\Delta t_C^{u^0} = \mathcal{C}_{|u|}^{u^0} \Delta x / u^0$. Then:

$$\Delta t_C^{u^0} = \Delta t_E^{0,*} \Leftrightarrow \mathcal{C}_{|u|}^{u^0} = \frac{u^0}{2(u^* + c_R^{0,*})} \mathcal{C}_E^{0,*} \approx 1.48649 \times 10^{-3} \mathcal{C}_E^{0,*}. \quad (\text{E.2})$$
