June 24, 2017

Abstract

We consider an isothermal gas flowing through a straight pipe and study the effects of a two-way electronic valve on the flow. The valve is either open or closed according to the pressure gradient and is assumed to act without any time or reaction delay. We first give a notion of coupling solution for the corresponding Riemann problem; then, we highlight and investigate several important properties for the solver, such as coherence, consistence, continuity on initial data and invariant domains. In particular, the notion of coherence introduced here is new and related to commuting behaviors of valves. We provide explicit conditions on the initial data in order that each of these properties is satisfied. The modeling we propose can be easily extended to a very wide class of valves.

Keywords: systems of conservation laws, gas flow, valve, Riemann problem, coupling conditions.

2010 AMS subject classification: 35L65, 35L67, 76B75.

1 Introduction

In this paper we consider a model of gas flow through a pipe in presence of a pressure-regulator valve. We deal with a plug flow, which means that the velocity of the gas is constant on any cross-section of the pipe; all friction effects along the walls of the pipe are dropped. To model the flow away from the valve, we use the following equations for conservation of mass and momentum, as done for analogous problems in [3, 4, 6, 16]:

\[
\begin{align*}
\rho_t + (\rho v)_x &= 0, \\
(\rho v)_t + (\rho v^2 + p(\rho))_x &= 0.
\end{align*}
\]

(1.1)

Here \( t > 0 \) is the time and \( x \in \mathbb{R} \) is the space position along the pipe. The state variables are \( \rho \), the mass density of the gas and \( v \), the velocity; we denote by \( q = \rho v \) the linear momentum. Since variations of temperature are not significant in most real situations of gas flows in pipes, we focus on the isothermal case

\[
p(\rho) = a^2 \rho,
\]

(1.2)

for a constant \( a > 0 \) that gives the sound speed. We emphasize that the flow can occur in either directions along the pipe; it can be either subsonic or supersonic. Usually, an hydraulic system is completed by compressors [2, 12, 13, 16, 17] and valves [22, 23]. In this paper we focus on the case of a valve.

Indeed, there are several different kinds of valves, but their common feature consists in regulating the flow. Opening and closing can be partial and may depend either on the flow, or on the pressure, or even on a combination of both. Moreover, a valve may let the gas flow in one direction only or in either.

The simplest and most natural problem for system (1.1) in presence of a valve is clearly the Riemann problem, where the valve induces a substantial modification in the solutions with respect to the free-flow case. However, proposing a Riemann solver that includes the mechanical action of a valve is only the first step toward a good description of the flow for positive times: some natural properties, both from the physical and mathematical point of view, have to be investigated. Such properties are coherence, consistence and continuity with respect to the initial data; at the end, if possible, invariant domains should be properly established. This is the main issue of this paper.

In Section 2 we rigorously define the notions mentioned above; they are stated in the case of system (1.1) but can be readily extended to any “nonstandard” coupling Riemann solver. A very short account
on the Lax curves of (1.1) is then given as well as the definition of the standard Riemann solver for this system. This material is very well known [21], but it is so heavily exploited in the following that any comprehension would be hindered without these details.

Section 3 introduces a “Riemann solver” when an interface condition, such as that given by a valve, is present. Some general results are then given and few simple models of valves (see [19, §2], [22, (6)] or [23, § 4.3.2, § 4.3.3, (1)-(4) page 51]) are provided. In this modeling, we do not take into consideration the flow inside the valve but simply its effects. The framework is that of conservation laws with point constraints, which has so far been developed only for vehicular and pedestrian flows, see [9, 24] and the references therein.

Section 4 contains our main results, which are collected in Theorem 4.1. They concern the coherence, consistence, continuity with respect to the initial data and invariant domains in a very special case, namely that of a pressure-relief valve. They can be understood as a first step in the direction of proving a general existence theorem for initial data with bounded variation. Some technical proofs are collected in Section 5. The final Section 6 resumes our conclusions.

### 2 The gas flow through a pipe

In this introductory section we provide some information about system (1.1), in particular as far as the geometry of the Lax curves is concerned.

#### 2.1 The system and basic definitions

Under (1.2), system (1.1) can be written in the conservative $(\rho, q)$-coordinates as

$$
\begin{align*}
\rho_t + q_x &= 0, \\
q_t + \left(\frac{a^2}{\rho} + a^2\rho\right)_x &= 0.
\end{align*}
$$

(2.1)

We usually refer to the expression (2.1) of the equations and denote $u = (\rho, q)$. We assume that the gas fills the whole pipe and then $u$ takes values in $\Omega = \{(\rho, q) \in \mathbb{R}^2 : \rho > 0\}$. A state $(\rho, q)$ is called **subsonic** if $|q/\rho| < a$ and **supersonic** if $|q/\rho| > a$; the half lines $q = \pm a\rho$, $\rho > 0$, are **sonic lines**.

The Riemann problem for (2.1) is the Cauchy problem with initial condition

$$
\begin{align*}
u(0,x) &= \begin{cases} u_\ell & \text{if } x < 0, \\ u_r & \text{if } x > 0, \end{cases}
\end{align*}
$$

(2.2)

$u_\ell, u_r \in \Omega$ being given constants.

**Definition 2.1.** We say that $u \in C^0((0, \infty); L^\infty(\mathbb{R}; \Omega))$ is a weak solution of (2.1), (2.2) in $[0, \infty) \times \mathbb{R}$ if

$$
\begin{align*}
\int_0^\infty \int_\mathbb{R} [\rho \varphi_t + q \varphi_x] dx \, dt + \rho_\ell \int_{-\infty}^{0} \varphi(0, x) \, dx + \rho_r \int_{0}^{\infty} \varphi(0, x) \, dx = 0, \\
\int_0^\infty \int_\mathbb{R} \left[ q \psi_t + \left(\frac{a^2}{\rho} + a^2\rho\right) \rho \psi_x \right] dx \, dt + q_\ell \int_{-\infty}^{0} \psi(0, x) \, dx + q_r \int_{0}^{\infty} \psi(0, x) \, dx = 0,
\end{align*}
$$

for any test function $\varphi, \psi \in C_c^\infty((0, \infty) \times \mathbb{R}; \mathbb{R})$.

We denote by $\text{BV}(\mathbb{R}; \Omega)$ the space of $\Omega$-valued functions with bounded variation. We can assume that any function in $\text{BV}(\mathbb{R}; \Omega)$ is right continuous by possibly changing the values at countably many points.

**Definition 2.2.** Let $D \subseteq \Omega^2$ and a map $\mathcal{RS} : D \rightarrow \text{BV}(\mathbb{R}; \Omega)$.

- We say that $\mathcal{RS}$ is a Riemann solver for (2.1) if for any $(u_\ell, u_r) \in D$ the map $(t,x) \mapsto \mathcal{RS}[u_\ell, u_r](x/t)$ is a weak solution to (2.1), (2.2) in $[0, \infty) \times \mathbb{R}$.
• A Riemann solver RS is coherent at \((u_\ell, u_r) \in D\) if \(u = RS[u_\ell, u_r]\) satisfies for any \(\xi_o \in \mathbb{R}\):
\[
(u(\xi_o^-), u(\xi_o^+)) \in D;
\]
(\text{ch.0})
\[
RS\left[u(\xi_o^-), u(\xi_o^+)\right](\xi) = \begin{cases}
u(\xi) & \text{if } \xi < \xi_o, \\
u(\xi_o^-) & \text{if } \xi \geq \xi_o.
\end{cases}
\]
(\text{ch.1})

The coherence domain \(CH \subseteq D\) of RS is the set of all pairs \((u_\ell, u_r) \in D\) where RS is coherent.

• A Riemann solver RS is consistent at \((u_\ell, u_r) \in D\) if \(u = RS[u_\ell, u_r]\) satisfies for any \(\xi_o \in \mathbb{R}\):
\[
(u_\ell, u(\xi_o)), (u(\xi_o), u_r) \in D;
\]
(cn.0)
\[
RS\left[u_\ell, u(\xi_o)\right](\xi) = \begin{cases}
u(\xi) & \text{if } \xi < \xi_o, \\
u(\xi_o) & \text{if } \xi \geq \xi_o.
\end{cases}
\]
(cn.1)
\[
RS\left[u(\xi_o), u_r\right](\xi) = \begin{cases}
u(\xi) & \text{if } \xi < \xi_o, \\
u(\xi_o^-) & \text{if } \xi \geq \xi_o
\end{cases};
\]
(cn.2)

The consistence domain \(CN \subseteq D\) of RS is the set of all pairs \((u_\ell, u_r) \in D\) where RS is consistent.

• A Riemann solver RS is \(L^1_{\text{loc}}\)-continuous at \((u_\ell, u_r) \in D\) if for any \(\xi_1, \xi_2 \in \mathbb{R}\) we have
\[
\lim_{(u_\ell, u_r) \to (u_\ell^\varepsilon, u_r^\varepsilon)} \int_{\xi_1}^{\xi_2} \left\|RS\left[u_\ell^\varepsilon, u_r^\varepsilon\right](\xi) - RS\left[u_\ell, u_r\right](\xi)\right\|d\xi = 0.
\]

The \(L^1_{\text{loc}}\)-continuity domain \(L \subseteq D\) of RS is the set of all \((u_\ell, u_r) \in D\) where RS is \(L^1_{\text{loc}}\)-continuous.

• A Riemann solver RS admits \(I \subseteq \Omega\) as invariant domain if \(I^2 \subseteq D\) and \(RS[I, I](\mathbb{R}) \subseteq I\).

Some comments on these definitions are in order. Roughly speaking, for any coherent initial datum, the ordered pair of the traces of the solution belongs to \(D\) by (ch.0) and it is a fixed point of RS by (ch.1). The coherence of a Riemann solver RS is a minimal requirement to develop a numerical scheme with a time discretization based on RS; otherwise, it may happen that the numerical solution of a Riemann problem greatly differs from the analytic one. An analogous condition has been introduced in [11] at the junctions of a network. While coherence is easily seen to be satisfied in the case of a Lax Riemann solver, see Proposition 2.5, it plays a fundamental role in presence of a valve, as we comment later on. Coherence is, in a sense, a local condition (w.r.t. \(\xi\)). On the contrary, the consistency of a Riemann solver is rather a global property: “cutting” or “pasting” Riemann solutions (see (cn.1) and (cn.2), respectively), does not change the structure of the partial or total Riemann solutions. We recall that the consistency of a Riemann solver is a necessary condition for the well-posedness in \(L^1\) of the Cauchy problem for (2.1). Differently from the classical theory for invariant domains [18, Corollary 3.7], here an invariant domain does not necessarily have a smooth boundary and may be disconnected or not closed.

**Proposition 2.3.** If a Riemann solver RS is either coherent or consistent at \((u_0, u_0) \in D\), then RS\([u_0, u_0]\) \(\equiv u_0\).

**Proof.** Fix \((u_0, u_0) \in D\) and let \(u = RS[u_0, u_0]\). By the finite speed of propagation, there exists \(\xi_o \in \mathbb{R}\) such that \(u = u_0\) in \((-\infty, \xi_o]\), whence \(u(\xi_o^+) = u_0\). If RS is either coherent or consistent at \((u_0, u_0)\), then we have RS\([u_0, u_0]\) \(\equiv u_0\) by (ch.1) or by the first condition in (cn.1), respectively.

\[\square\]

### 2.2 The Lax curves

The eigenvalues of (2.1) are \(\lambda_1(u) = \frac{q}{\ell} - a\), and \(\lambda_2(u) = \frac{q}{\ell} + a\). System (2.1) is strictly hyperbolic in \(\Omega\) and both characteristic fields are genuinely nonlinear. Hence, weak solutions can contain both rarefaction
and shock waves (called below waves), but not contact discontinuities. Any discontinuity curve \( x = \gamma(t) \) of a weak solution \( u \) of (2.1) satisfies the Rankine-Hugoniot conditions

\[
\begin{align*}
(\rho_+ - \rho_-) \dot{\gamma} &= q_+ - q_-,
(q_+ - q_-) \dot{\gamma} &= \left( \frac{q_+^2}{\rho_+} + a^2 \rho_+ \right) - \left( \frac{q_-^2}{\rho_-} + a^2 \rho_- \right),
\end{align*}
\]

where \( u_\pm(t) = u(t, \gamma(t)\pm) \) are the traces of \( u \), see [5, 8]. Riemann invariants of (2.1) are \( w(u) = \frac{q}{a\rho} + \log(\rho) \) and \( z(u) = \frac{q}{a\rho} - \log(\rho) \). We introduce new coordinates \((\mu, \nu)\) that make simpler the study of the Lax curves:

\[
\begin{align*}
\mu &= \log(\rho),
\nu &= q/(a\rho),
\rho &= \exp(\mu),
q &= a\nu \exp(\mu),
\end{align*}
\]

or

\[
\begin{align*}
\mu &= (w - z)/2,
\nu &= (w + z)/2,
\end{align*}
\]

We prefer the \((\mu, \nu)\)-coordinates with respect to those induced by the Riemann invariants because we often deal with the locus \( q = q_m \), for some \( q_m \in \mathbb{R} \); moreover, comparing densities \((\rho_1 < \rho_2 \iff \mu_1 < \mu_2 \iff w_1 - z_1 < w_2 - z_2)\) is easier. At last, in [1, Section 3], the wave-front tracking algorithm for (2.1) relies on the bound of the total variation of the solutions in the \( \mu \)-coordinate. We point out that in the \((\mu, \nu)\)-coordinates the set \( \Omega \) becomes \( \mathbb{R}^2 \) and the sonic lines are \( \nu = \pm 1 \). In the sequel it is important to compare the flow corresponding to distinct states; we notice that \( q = 0 \) if and only if \( \nu = 0 \) and \( q_1 < q_2 \) if and only if \( \nu_1 \exp(\mu_1) < \nu_2 \exp(\mu_2) \), see Figure 1.

![Figure 1: The curves \( q = q_m \) (dashed lines) for two values of \( q_m \).](image)

We define \( S_i, R_i : (0, \infty) \times \Omega \to \mathbb{R}, \ i \in \{1, 2\} \), by

\[
\begin{align*}
S_1(\rho, u_+) &= \rho \left[ \frac{q_-}{\rho_+} - a \left( \frac{\rho}{\rho_+} - \frac{\rho}{\rho_*} \right) \right],
R_1(\rho, u_+) &= \rho \left[ \frac{q_+}{\rho_*} - a \log \left( \frac{\rho}{\rho_*} \right) \right],
S_2(\rho, u_+) &= \rho \left[ \frac{q_-}{\rho_*} + a \left( \frac{\rho}{\rho_*} - \frac{\rho}{\rho_+} \right) \right],
R_2(\rho, u_+) &= \rho \left[ \frac{q_+}{\rho_+} + a \log \left( \frac{\rho}{\rho_+} \right) \right].
\end{align*}
\]

Then we define \( \mathcal{F}_i, \mathcal{B}_i : (0, \infty) \times \Omega \to \mathbb{R}, \ i \in \{1, 2\} \), by

\[
\begin{align*}
\mathcal{F}_1(\rho, u_+) &= \begin{cases} 
R_1(\rho, u_+) & \text{if } \rho \in (0, \rho_*], \\
S_1(\rho, u_+) & \text{if } \rho \in (\rho_*, \infty),
\end{cases}
\mathcal{F}_2(\rho, u_+) &= \begin{cases} 
S_2(\rho, u_+) & \text{if } \rho \in (0, \rho_*], \\
R_2(\rho, u_+) & \text{if } \rho \in [\rho_*, \infty),
\end{cases}
\mathcal{B}_1(\rho, u_+) &= \begin{cases} 
S_1(\rho, u_+) & \text{if } \rho \in (0, \rho_*), \\
R_1(\rho, u_+) & \text{if } \rho \in [\rho_*, \infty),
\end{cases}
\mathcal{B}_2(\rho, u_+) &= \begin{cases} 
R_2(\rho, u_+) & \text{if } \rho \in (0, \rho_*), \\
S_2(\rho, u_+) & \text{if } \rho \in [\rho_*, \infty).
\end{cases}
\end{align*}
\]

For any fixed \( u_* \in \Omega \), the forward \( \mathcal{F}_i^{u_*} \) and backward \( \mathcal{B}_i^{u_*} \) Lax curves of the \( i \)-th family through \( u_* \) in the \((\rho, q)\)-coordinates are the graphs of the functions \( \mathcal{F}_i(\cdot, u_*) \) and \( \mathcal{B}_i(\cdot, u_*) \), respectively, see Figure 2. Analogously, the shock \( S_i^{u_*} \) and rarefaction \( R_i^{u_*} \) curves through \( u_* \) in the \((\rho, q)\)-coordinates are the graphs of the functions \( S_i(\cdot, u_*) \) and \( R_i(\cdot, u_*) \), see Figure 2. In the \((\mu, \nu)\)-coordinates the curves \( S_i^{u_*} \)
Above we denote see Figure 3. We observe that
\[ S_{R} - R \] and
\[ Ξ \]
Now we collect the basic properties of the sets \( Ξ \), with a slight abuse of notations, the graphs of the functions
\[ S_1(μ, u_s) \equiv ν_s + Ξ(μ - μ_s), \]
\[ S_2(μ, u_s) \equiv ν_s + Ξ(μ_s - μ), \]
while \( FL_{i}^{u_s} \) and \( BL_{i}^{u_s} \) are the graphs of the functions
\[ FL_1(μ, u_s) \equiv \begin{cases} \mathcal{R}_1(μ, u_s) & \text{if } μ ≤ μ_s, \\ \mathcal{S}_1(μ, u_s) & \text{if } μ > μ_s, \end{cases} \]
\[ FL_2(μ, u_s) \equiv \begin{cases} \mathcal{S}_2(μ, u_s) & \text{if } μ < μ_s, \\ \mathcal{R}_2(μ, u_s) & \text{if } μ > μ_s. \end{cases} \]
\[ BL_1(μ, u_s) \equiv \begin{cases} \mathcal{R}_1(μ, u_s) & \text{if } μ ≤ μ_s, \\ \mathcal{S}_1(μ, u_s) & \text{if } μ > μ_s, \end{cases} \]
\[ BL_2(μ, u_s) \equiv \begin{cases} \mathcal{S}_2(μ, u_s) & \text{if } μ ≤ μ_s, \\ \mathcal{R}_2(μ, u_s) & \text{if } μ > μ_s. \end{cases} \]
Above we denoted
\[ Ξ(ξ) \equiv \exp(-ξ/2) - \exp(ξ/2) = -2 \sinh(ξ/2), \]
see Figure 3. We observe that
\[ Ξ^{-1}(ξ) = 2 \ln \left( \frac{2}{\sqrt{ξ^2 + 4 + ξ}} \right). \]
Obviously both Ξ and Ξ^{-1} are odd functions; for any \( ξ ∈ R \setminus \{0\} \) we have \( Ξ'(ξ) < 0, Ξ''(0) = -1, Ξ''(ξ) < 0, Ξ''(0) = 0, Ξ''(ξ) < 0. \)
Now we collect the basic properties of the sets \( S_i^{u_s}, R_i^{u_s} \); the proof is deferred to Subsection 5.1.

**Proposition 2.4.** Let \( u_s, u_{ss} ∈ Ω \) be distinct and \( i ∈ \{1, 2\} \). Then we have:
\[ \mathcal{R}_i^{u_s} \cap \mathcal{R}_i^{u_{ss}} \neq \emptyset \] if and only if \( \mathcal{R}_i^{u_s} = \mathcal{R}_i^{u_{ss}} \);
\[ \mathcal{S}_i^{u_s} \cap \mathcal{S}_i^{u_{ss}} \text{ has at most two elements;} \]
\[ \text{if } u_{ss} ∈ \mathcal{S}_i^{u_s} \setminus \{u_s\}, \text{ then } \mathcal{S}_i^{u_{ss}} \cap \mathcal{S}_i^{u_s} = \{u_{ss}, u_s\}; \]
\[ (S_i)_{ρ}(0^+, u_s) = (-1)^{i+1}∞ \text{ and } (R_i)_{ρ}(0^+, u_s) = (-1)^{i+1}∞; \]
\[ \mathcal{R}_1^{u_s} \text{ and } \mathcal{S}_1^{u_s} \text{ are strictly concave, while } \mathcal{R}_2^{u_s} \text{ and } \mathcal{S}_2^{u_s} \text{ are strictly convex;} \]
\[ (S_i)_{ρ}(ρ_s, u_s) = (R_i)_{ρ}(ρ_s, u_s) = λ_i(u_s) \text{ and } (S_i)_{ρρ}(ρ_s, u_s) = (R_i)_{ρρ}(ρ_s, u_s) = (-1)^i a/ρ_s; \]
We introduce analogously $\tilde{v}$.

In general $\tilde{v}$ is defined because for any $u$.

$ξ$ is the juxtaposition of a wave of the first family $RS$.

2.3 The Riemann solver $RS_p$

We denote by $RS_p : \Omega^2 \to BV(\mathbb{R}; \Omega)$ the Lax Riemann solver [21]. We recall that $ξ \mapsto RS_p[u_\ell, u_r](ξ)$ is the juxtaposition of a wave of the first family $ξ \mapsto RS_p[u_\ell, \tilde{u}(u_\ell, u_r)](ξ)$, taking values in $FL_1^{ur}$, and a wave of the second family $ξ \mapsto RS_p[\tilde{u}(u_\ell, u_r), u_r](ξ)$, taking values in $FL_2^{ur}$. Notice that $RS_p$ is well defined because for any $u_\ell, u_r \in \Omega$ the curves $FL_1^{ur}$ and $BL_2^{ur}$ always meet and precisely at $\tilde{u}(u_\ell, u_r)$. 
The right states \( u \in \Omega \) that can be connected to a left state \( u_\ell \) by a wave of the first (second) family belong to \( \mathcal{F}_1^{ur} \) (resp., \( \mathcal{F}_2^{ur} \)), see Figure 2. More precisely, the states \( u \) that can be connected to \( u_\ell \) by a shock wave of the first, resp. second, family belong to \( \{ u \in S_1^{ur} : \rho > \rho_\ell \} \), resp. \( \{ u \in S_2^{ur} : \rho > \rho_\ell \} \), and the corresponding speeds of propagation are

\[
s_1(\rho, u_\ell) = v_\ell - a \sqrt{\frac{\rho}{\rho_\ell}}, \quad s_2(\rho, u_\ell) = v_\ell + a \sqrt{\frac{\rho}{\rho_\ell}},
\]

while the states \( u \) that can be connected to \( u_\ell \) by a rarefaction wave of the first, resp. second, family belong to \( \{ u \in R_1^{ur} : \rho \leq \rho_\ell \} \), resp. \( \{ u \in R_2^{ur} : \rho \geq \rho_\ell \} \).

The left states \( u \) that can be connected to a right \( u_r \) by a wave of the first (second) family belong to \( \mathcal{B}_1^{ur} \) (resp., \( \mathcal{B}_2^{ur} \)), see Figure 2. The states \( u \) that can be connected to \( u_r \) by a shock wave of the first, resp. second, family belong to \( \{ u \in S_1^{ur} : \rho < \rho_r \} \), resp. \( \{ u \in S_2^{ur} : \rho > \rho_r \} \), and the corresponding speeds of propagation are respectively \( s_1(\rho, u_r) \) and \( s_2(\rho, u_r) \), while the states \( u \) that can be connected to \( u_r \) by a rarefaction wave of the first, resp. second, family belong to \( \{ u \in R_1^{ur} : \rho \geq \rho_r \} \), resp. \( \{ u \in R_2^{ur} : \rho \leq \rho_r \} \).

In the following, we write “i-shock \((u_-, u_+)\)” in place of “shock of the i-th family from \(u_-\) to \(u_+\),” and so on.

By the jump conditions (2.3), (2.4), the speed of propagation of a shock between two distinct states \( u_\ell \) and \( u_{ss} \) is the slope in the \((\rho, q)\)-plane of the line connecting \( u_\ell \) with \( u_{ss} \), namely \( \sigma(u_\ell, u_{ss}) = (q_s - q_) / (\rho_s - \rho_) \); in the \((x, t)\)-plane an i-rarefaction between two distinct states \( u_\ell \) and \( u_{ss} \) is contained in the cone \( \lambda_i(u_{ss}) \leq x/t \leq \lambda_i(u_{ss}) \).

We now collect the main properties of \( R_S \); the proofs are deferred to Subsection 5.1.

**Proposition 2.5.** The Riemann solver \( R_S \) is coherent, consistent and \( L^{1}_{\text{loc}} \)-continuous in \( \Omega^2 \).

It is well known [18] that for any \( u_0 \in \Omega \), both the singleton \( \{ u_0 \} \) and the convex set

\[
\mathcal{I}_{u_0} = \{ u \in \Omega : z(u) \geq z(u_0), \ w(u) \leq w(u_0) \}, \tag{2.7}
\]

see Figure 5, are invariant domains of \( R_S \). We observe that \( \mathcal{I}_{u_0} \) can be written as

\[
\mathcal{I}_{u_0} = \{ u \in \Omega : R_2(\mu, u_0) \leq \mu \leq R_1(\mu, u_0) \} = \{ u \in \Omega : R_2(\rho, u_0) \leq \rho \leq R_1(\rho, u_0) \}.
\]

![Figure 5: The invariant domain \( \mathcal{I}_{u_0} \).](image)

Whenever it is clear from the context, we denote

\[
u_p = R_S[u_\ell, u_r] \quad \text{and} \quad \nu_p^\pm = u_p(0^\pm).
\]

Recall that \((t, x) \mapsto u_p(x/t)\) is indeed an entropy solution to (2.1), (2.2).

## 3 The gas flow through valves

### 3.1 The model and basic definitions

In this section we consider the case of two pipes connected by a valve at \( x = 0 \). System (2.1) models the flow away from the valve, while at \( x = 0 \) we impose conditions depending on the valve and involving
We say that Definition 3.1. We say that $u \in C^0((0,\infty); L^\infty(\mathbb{R}; \Omega))$ is a coupling solution of the Riemann problem (2.1), (2.2) if

(i) the first Rankine-Hugoniot condition (2.3) is satisfied;

(ii) for any $t > 0$, the functions

$$(t,x) \mapsto \begin{cases} u(t,x) & \text{if } x < 0, \\ u(t,0^-) & \text{if } x \geq 0, \end{cases}$$

are respectively weak solutions to the Riemann problems for (2.1) with initial data

$$u(0,x) = \begin{cases} u_\ell & \text{if } x < 0, \\ u(0,-) & \text{if } x \geq 0, \end{cases}$$

are respectively weak solutions to the Riemann problems for (2.1) with initial data

$$(t,x) \mapsto \begin{cases} u(t,0^+) & \text{if } x < 0, \\ u(t,x) & \text{if } x \geq 0, \end{cases}$$

A coupling solution $u$ is a weak solution of (2.1) for $x \neq 0$ and satisfies $q(t,0^-) = q(t,0^+)$ by (i). In particular, the second Rankine-Hugoniot condition (2.4) is never verified if $u$ has an under-compressive discontinuity; in this case $u$ is not a weak solution of (2.1).

We are now ready to extend the definition of Riemann solver to coupling solutions.

Definition 3.2. Let $D \subseteq \Omega^2$ and $RS : D \to BV(\mathbb{R}; \Omega)$. We say that $RS$ is a coupling Riemann solver for (2.1) if for any $(u_\ell, u_r) \in D$ the map $(t,x) \mapsto RS[u_\ell, u_r](x/t)$ is a coupling solution to (2.1), (2.2) in $(0,\infty) \times \mathbb{R}$.

The definitions of consistence, $L^1_{loc}$-continuity and invariant domains given in Definition 2.2 naturally apply to coupling Riemann solvers. On the other hand, the extension of coherence needs some comments. In fact, a coupling Riemann solver $RS$ is applied only at the valve position, i.e. at $\xi = 0$, while in $\xi \neq 0$ one applies $RS_p$. Since $RS_p$ is coherent in $\Omega^2$, see Proposition 2.5, the coherence of $RS$ reduces to require (ch.0),(ch.1) at $\xi_v = 0$. As a consequence, the coherence of $RS$ reduces to the following definition.

Definition 3.3. Let $D \subseteq \Omega^2$. A coupling Riemann solver $RS : D \to BV(\mathbb{R}; \Omega)$ is coherent at $(u_\ell, u_r) \in D$ if $u \equiv RS[u_\ell, u_r]$ satisfies

$$\left( u(0^-), u(0^+) \right) \in D, \quad (ch_v,0)$$

$$RS\left[u(0^-), u(0^+)\right](\xi) = \begin{cases} u(0^-) & \text{if } \xi < 0, \\ u(0^+) & \text{if } \xi \geq 0. \end{cases} \quad (ch_v,1)$$

It is worth to notice that, from the physical point of view, the coherence of a coupling Riemann solver avoids loop behaviors, such as intermittently and rapidly switching on and off (commuting) of the valve. Moreover, Proposition 2.3 does not hold for coupling Riemann solvers: it may happen that a coupling Riemann solver $RS$ is coherent at $(u_0, u_0) \in D$ but $RS[u_0, u_0] \neq u_0$.

A coupling Riemann solver $RS_v : D_v \to BV(\mathbb{R}; \Omega), D_v \subseteq \Omega^2$, can be constructed by exploiting $RS_p$ as follows. We define

$$RS_v[u_\ell, u_r] = RS_p[u_\ell, u_r] \quad \text{if the valve is open},$$

$$RS_v[u_\ell, u_r](\xi) = \begin{cases} RS_p[u_\ell, u_\ell_m](\xi) & \text{if } \xi < 0, \\ RS_p[u_m^+, u_r](\xi) & \text{if } \xi \geq 0, \end{cases} \quad \text{if the valve is active}. \quad (3.1)$$
Above, \( u_m^+ \in \Omega \) satisfy the conditions imposed at \( x = 0 \) by the valve, namely,

\[
\begin{cases}
  u_m^- = u_m^-(u_\ell, u_r) = \hat{u}(q_m, u_r), \\
  u_m^+ = u_m^+(u_\ell, u_r) = \bar{u}(q_m, u_r),
\end{cases}
\]

where

\[
Q_{u_\ell}^- = \begin{cases}
  (-\infty, \bar{q}(u_\ell)) & \text{if } v_\ell \leq a, \\
  (-\infty, q_\ell) & \text{if } v_\ell > a,
\end{cases}
\]

\[
Q_{u_\ell}^+ = \begin{cases}
  \lfloor q(u_\ell), \infty \rfloor & \text{if } v_r \geq -a, \\
  \lfloor q_r, \infty \rfloor & \text{if } v_r < -a.
\end{cases}
\]

By (2.5) we have \( 0 \in Q_{u_\ell}^- \cap Q_{u_\ell}^+ \neq \emptyset \); by (3.3) it follows \( \rho_m^- \geq \hat{\rho}(u_\ell), \rho_m^+ \geq \bar{\rho}(u_r), q_m^- = q_m^+ = q_m \).

The main rationale of condition (3.3) lies in the fact that according to this choice

\[
\xi \mapsto RS_p[u_\ell, u_m](\xi) \in \mathcal{F}\mathcal{L}^u_{1}^{\infty}
\]

are single waves, with negative and positive speed, respectively. As a consequence, \( RS_p[u_\ell, u_r](0^\pm) = u_m^\pm \).

Moreover, if \( RS_p[u_\ell, u_r] \) contains a stationary under-compressive discontinuity at \( x = 0 \), then \( u_m^\pm \) satisfy the first Rankine-Hugoniot condition (2.3).

In conclusion, a valve is characterized by prescribing both when it is either open or active and the choice of the flow \( q_m \) through the valve when it is active. Once we specify these conditions, then the gas flow through the valve can be modeled by \( RS_p \). For notational simplicity, whenever it is clear from the context, we let

\[
u_\ell \doteq RS_v[u_\ell, u_r] \quad \text{and} \quad u_m^\pm \doteq \nu_v(0^\pm).
\]

For a fixed \( RS_v \), we denote by \( O \) and \( A \) the sets of Riemann data such that \( RS_v \) leaves the valve open or active, respectively. The domain of definition \( D_v \doteq O \cup A \) of \( RS_v \) does not necessarily coincide with the whole \( \Omega^2 \); in this case, we understand Riemann data in \( \Omega^2 \setminus D_v \) as not being in the operating range of the valve. Moreover, it may happen that there exists \( (u_\ell, u_r) \in A \) such that \( u_p \equiv u_v \). This happens, for instance, if \( (u_\ell, u_r) \in A \) is such that \( \hat{u}(u_\ell, u_r) = \bar{u}(0, u_r) = \hat{u}(0, u_r) \) and \( q_m = 0 \) in (3.3): the valve is closed but has no influence on the flow through \( x = 0 \). This motivates the introduction of the sets

\[
A_N \doteq \{(u_\ell, u_r) \in A: u_v \equiv u_p\} = \{(u_\ell, u_r) \in A: \hat{u}(q_m, u_r) = \hat{u}(u_\ell, u_r) = \bar{u}(q_m, u_r)\}, \quad A_l = A \setminus A_N,
\]

of Riemann data for which the valve is active and either influences or not the gas flow, respectively. We also introduce

\[
A_l^c \doteq D_v \setminus A_l = O \cup A_N = \{(u_\ell, u_r) \in D_v: u_v \equiv u_p\}.
\]

**Proposition 3.4.** Assume that \( RS_v \) is coherent at \( (u_\ell, u_r) \).

(i) If \( (u_\ell, u_r) \in A_l^c \), then \( (u_v^-, u_v^+) \in A_l^c \).

(ii) If \( (u_\ell, u_r) \in A_l \) and \( \hat{u}(q_m, \hat{u}(q_m, u_r)) = \bar{u}(q_m, u_r) \), then \( (u_v^-, u_v^+) \in A_l \).

**Proof.** (i) Let \( (u_\ell, u_r) \in A_l^c \) and assume \( (u_v^-, u_v^+) \in A_l \) by contradiction. Since \( u_v \equiv u_p \), we have \( u_v^\pm = u_m^\pm \); hence from (3.1) and (3.2),(3.3) it follows

\[
\begin{cases}
  u_v^- \doteq RS_v[u_v^-, u_v^+](\xi) = RS_p[u_p^- \bar{u}(q_m, u_p^-)](\xi) & \text{if } \xi < 0, \\
  u_v^+ \doteq RS_v[u_v^-, u_v^+](\xi) = RS_p[u_p^+ \bar{u}(q_m, u_p^+)](\xi) & \text{if } \xi > 0,
\end{cases}
\]

with \( \bar{u}(q_m, u_p^-) \neq \bar{u}(q_m, u_p^+) \). The above equation implies that \( \hat{u}(q_m, u_p^-) = u_p^- \) and \( \bar{u}(q_m, u_p^+) = u_p^+ \), whence \( u_p^- \neq u_p^+ \). Thus, \( u_p \) has a stationary shock \( (u_p^-, u_p^+) \), which can be either a 1-shock with \( u_p^- = u_\ell \) and \( u_p^+ = \hat{u}(q_m, u_\ell) = \hat{u}(q_m, u_r) \) if \( q_m > 0 \), or a 2-shock with \( u_p^- = u_r \) and \( u_p^+ = \hat{u}(q_m, u_r) \) if \( q_m < 0 \). In the former case we have \( \hat{u}(q_m, u_p^+) = \hat{u}(q_m, \hat{u}(q_m, u_r)) = \hat{u}(q_m, u_r) \) because \( q_m > 0 \), whence \( \hat{u}(q_m, u_p^-) = \hat{u}(q_m, u_r) = \hat{u}(q_m, u_\ell) = \hat{u}(q_m, u_p^+) \), a contradiction. The latter case is dealt analogously.
(ii) Let \((u_\ell, u_r) \in A_1\) be such that \(\hat{u}(q_m, \hat{u}(q_m, u_\ell)) = \hat{u}(q_m, u_\ell)\); assume \((u_r^-, u_r^+) \in A_1^c\) by contradiction. Since \((u_\ell, u_r) \in A_1\), we have \(u_r^- = \hat{u}(q_m, u_r) \not= \hat{u}(q_m, u_\ell) = u_r^+\) and \(q_r^- = q_r^+ = q_m\). By (chv.1) we have

\[
RS_p[u_r^-, u_r^+](\xi) = RS_v[u_r^-, u_r^+](\xi) = \begin{cases} u_r^- & \text{if } \xi < 0, \\ u_r^+ & \text{if } \xi \geq 0. \end{cases}
\]

Hence, either \(RS_p[u_r^-, u_r^+]\) is a stationary 1-shock with \(u_r^+ = \hat{u}(q_m, u_r^-)\) and \(q_m > 0\), or is stationary 2-shock with \(u_r^- = \hat{u}(q_m, u_r^+)\) and \(q_m < 0\). In the former case \(\hat{u}(q_m, u_r) = u_r^+ = \hat{u}(q_m, u_r^-) = \hat{u}(q_m, \hat{u}(q_m, u_\ell)) = \hat{u}(q_m, u_\ell)\), a contradiction. The latter case is dealt analogously.

**Proposition 3.5.** The coupling Riemann solver \(RS_v\) is consistent at \((u_\ell, u_r) \in D_v\) if and only if:

\[
(u_\ell, u_v(\xi_0)), (u_v(\xi_0), u_r) \in D_v \text{ for any } \xi_0 \in \mathbb{R};
\]

\[
\left\{
\begin{aligned}
& (u_\ell, u_v(\xi_0)) \in A_1^c \text{ and } \hat{u}(q_m, u_v(\xi_0)) = \hat{u}(q_m, u_\ell), & \text{for any } \xi_0 < 0, \\
& (u_v(\xi_0), u_r) \in A_1^c \text{ and } \hat{u}(q_m, u_v(\xi_0)) = \hat{u}(q_m, u_r), & \text{for any } \xi_0 \geq 0, & \text{if } (u_\ell, u_r) \in A_1,
\end{aligned}
\right.
\]

\[
\left\{
\begin{aligned}
& (u_\ell, u_v(\xi_0)) \in A_1^c, & \text{for any } \xi_0 \in \mathbb{R}, & \text{if } (u_\ell, u_r) \in A_1^c.
\end{aligned}
\right.
\]

**Proof.** Clearly (cn.0) is equivalent to (cn.0). Assume that \((u_\ell, u_r) \in A_1\). If \(\xi_0 < 0\) (the case \(\xi_0 \geq 0\) is dealt analogously), then \(u_v(\xi_0) = RS_p[u_\ell, u_m^-](\xi_0)\) and by the consistency of \(RS_p\) we have

\[
\left\{
\begin{aligned}
& u_v(\xi) \text{ if } \xi < \xi_0, \\
& u_v(\xi_0) \text{ if } \xi \geq \xi_0,
\end{aligned}
\right.
\]

\[
\left\{
\begin{aligned}
& RS_p[u_\ell, u_m^-](\xi) \text{ if } \xi < \xi_0 = RS_p[u_\ell, u_v(\xi_0)](\xi), \\
& RS_p[u_\ell, u_m^-](\xi_0) \text{ if } \xi \geq \xi_0.
\end{aligned}
\right.
\]

\[
\left\{
\begin{aligned}
& u_v(\xi_0) \text{ if } \xi < \xi_0, \\
& u_v(\xi) \text{ if } \xi \geq \xi_0,
\end{aligned}
\right.
\]

\[
\left\{
\begin{aligned}
& RS_p[u_\ell, u_m^-](\xi_0) \text{ if } \xi < \xi_0 = RS_p[RS_p[u_\ell, u_m^-](\xi_0), u_m^-](\xi) \text{ if } \xi < 0, \\
& RS_p[RS_p[u_\ell, u_m^-](\xi_0), u_m^-](\xi_0) \text{ if } \xi \geq 0.
\end{aligned}
\right.
\]

Therefore (cn.1) reduces to

\[
(u_\ell, u_v(\xi_0)), (u_v(\xi_0), u_r) \in A_1^c, \quad RS_v[u_v(\xi_0), u_r](\xi) = \begin{cases} RS_p[u_v(\xi_0), u_m^-](\xi) & \text{if } \xi < 0, \\
RS_p[u_m^+, u_r](\xi) & \text{if } \xi \geq 0. \end{cases}
\]

(3.4)

We observe that the above condition also implies (cn.2); indeed, by the consistency of \(RS_p\) we have

\[
\left\{
\begin{aligned}
& RS_v[u_\ell, u_v(\xi_0)](\xi) \text{ if } \xi < \xi_0 = RS_p[u_\ell, u_v(\xi_0)](\xi) \text{ if } \xi < \xi_0, \\
& RS_v[u_v(\xi_0), u_r](\xi) \text{ if } \xi \geq \xi_0 = RS_p[u_v(\xi_0), u_m^-](\xi) \text{ if } \xi \in [\xi_0, 0), \\
& RS_p[u_m^+, u_r](\xi) \text{ if } \xi \geq 0.
\end{aligned}
\right.
\]

To prove that (3.4) is in fact equivalent to (cn.1) it is sufficient to observe that it writes

\[
(u_\ell, u_v(\xi_0)) \in A_1^c, \quad \hat{u}(q_m, u_v(\xi_0)) = u_m^- = \hat{u}(q_m, u_\ell), \quad (u_v(\xi_0), u_r) \in A_1,
\]

and that the second condition above implies the last one because by assumption \((u_\ell, u_r) \in A_1\).

Assume now that \((u_\ell, u_r) \in A_1^c\). In this case \(u_v \equiv u_p\) and (cn.1) reduces to require (cn.1) by the consistency of \(RS_p\). At last, (cn.1) also implies (cn.2) by the consistency of \(RS_p\).  

**Corollary 3.6.** If \((u_0, u_0) \in A_1\), then \(RS_v\) is not consistent at any point of \(\{u_0\} \times \Omega \cup (\Omega \times \{u_0\})\).
Proof. Let \((u_0, u_0) \in A_I\) and fix \(u_\ell, u_r \in \Omega\). By the finite speed of propagation of the waves there exists \(\xi_0 > 0\) sufficiently big such that
\[
(u_0, \mathcal{R} \mathcal{S}_v[u_0, u_r](-\xi_0)) = (\mathcal{R} \mathcal{S}_v[u_\ell, u_0](\xi_0), u_0) = (u_0, u_0) \in A_I.
\]
By Proposition 3.5 it is easy then to conclude that \(\mathcal{R} \mathcal{S}_v\) is consistent neither at \((u_0, u_r)\) nor at \((u_\ell, u_0)\).

If two pipes are connected by a one-way valve, the flow at \(x = 0\) occurs in a single direction only, say positive; in this case we consider coupling Riemann solvers of the form (3.2),(3.3) with \(q_m \geq 0\). Such a valve is also called clack valve, non-return valve or check valve.

### 3.2 Examples of valves

We conclude this section by considering some examples of pressure-relief valves.

**Example 3.7.** Consider a two-way electronic valve which is either open or closed, see Figure 6. More precisely, the valve is equipped with a control unit and two sensors, one on each side of the valve seat. Depending on data \((u_\ell, u_r)\) received from the sensors, the control unit closes the valve if the jump of the pressure across \(x = 0\) corresponding to a closed valve, namely \(|\hat{\rho}(0, u_r) - \hat{\rho}(0, u_\ell)|\), is less or equal than a fixed constant \(M > 0\); otherwise, the control unit opens the valve. Such valve is modeled by the coupling Riemann solver \(\mathcal{R} \mathcal{S}_v\) defined for any \((u_\ell, u_r) \in \Omega^2\) as follows:

- if \(|\hat{\rho}(0, u_r) - \hat{\rho}(0, u_\ell)| \leq M\), then the valve is active (closed) and \(\mathcal{R} \mathcal{S}_v[u_\ell, u_r]\) has the form (3.2),(3.3) with \(q_m = 0\);

- if \(|\hat{\rho}(0, u_r) - \hat{\rho}(0, u_\ell)| > M\), then the valve is open.

This valve is studied in details in Section 4.

**Example 3.8.** Consider a two-way spring-loaded valve, which can be either open or closed, see Figure 7, and let \(M > 0\) be the “resistance” of the spring. Then the valve is closed (active) if the jump of the pressure across \(x = 0\), namely \(|p(\rho_r) - p(\rho_\ell)|\), is less or equal than \(M\); otherwise it is open. In this case \(\mathcal{R} \mathcal{S}_v\) is defined for any \((u_\ell, u_r) \in \Omega^2\) as follows:

- if \(|p(\rho_r) - p(\rho_\ell)| \leq M\), then the valve is active (closed) and \(\mathcal{R} \mathcal{S}_v[u_\ell, u_r]\) has the form (3.2),(3.3) with \(q_m = 0\);

- if \(|p(\rho_r) - p(\rho_\ell)| > M\), then the valve is open.

**Example 3.9.** To each valve considered in the previous examples corresponds a one-way valve, see Figure 6 and Figure 7.
We finally observe that \( \hat{u} \) and so on, whenever it is clear from the context that \( \hat{u} \) is a positive constant. The above condition substitutes the second Rankine-Hugoniot condition (2.4) at \( x = 0 \). Then \( RS_v \) has the form given in (3.2),(3.3) with \( u_m^- = \hat{u}(q_m, u_t), u_m^+ = \hat{u}(q_m, u_r) \) and \( q_m \) satisfying

\[
\hat{p}(q_m, u_t) = \hat{p}(q_m, u_t) - a^2 k \frac{q_m^2}{\hat{p}(q_m, u_t)}, \quad q_m \in Q_{u_t}^- \cap Q_{u_r}^+.
\]

**4 A case study: two-way electronic pressure valve**

In this section we apply the theory developed in the previous sections to model the two-way electronic pressure valve, see Example 3.7. Such a valve is either open or closed (active); this corresponds to a Riemann solver \( RS \). Consider a one-way valve such that \( \text{[10, 1-8, Equation 1-6]} \). Theorem 4.1. We have the following results:

1. The coherence domain of \( \mathcal{RS}_v \) is \( CH = A \cup O_O \), where, see Figure 8,

\[
O_O = \{ (u_t, u_r) \in O : (u_p^-, u_p^+) \in O \}.
\]

Figure 8: Schematic representation of the subsets of \( D_v = \Omega^2 \). The shaded area corresponds to \( A_O^3 \).

We collect in the following theorem our main results; we defer the proof to Subsection 5.2.

**Theorem 4.1.** We have the following results:

1. The coherence domain of \( \mathcal{RS}_v \) is \( CH = A \cup O_O \), where, see Figure 8,
(II) The consistence domain of $RS_v$ is $CN = CN_1 \cup CN_2 = CN_O \cup CN_A$, where

$$CN_1 = \left\{(u_\ell, u_r) \in A_1 : (u_\ell, u_v(\xi_-^w)), (u_v(\xi_+^w), u_r) \in A_1^2, \text{ for any } \xi_-^w < 0 \leq \xi_+^w\right\},$$

$$CN_2 = \left\{(u_\ell, u_r) \in A_2^2 : (u_\ell, u_v(\xi_0)), (u_v(\xi_0), u_r) \in A_2^2, \text{ for any } \xi_0 \in \mathbb{R}\right\},$$

$$CN_O = \left\{(u_\ell, u_r) \in O : (u_\ell, u_\ell), (u_\ell, u_r), (u_\ell, u_\ell), (u_r, u_r) \in A_1^2, \text{ and } q_0 \neq 0 \text{ along any rarefaction}\right\},$$

$$CN_A = \left\{(u_\ell, u_r) \in A : q_\ell \geq 0 \geq q_r, (u_\ell, u_\ell) \in A_1^2, (u_r, u_r) \in A_2^2\right\}.$$

(III) The $L^1_{loc}$-continuity domain of $RS_v$ is $L = \{(u_\ell, u_r) \in \Omega^2 : |\bar{p}_\ell - \bar{p}_r| \neq M\}$.

(IV) If $u_0 \in \Omega$ is such that $q_0 = 0$, then $I_{u_0}$ defined by (2.7) is an invariant domain of $RS_v$.

Since the sets $O_O$ and $O_A \equiv O \setminus O_O = \{(u_\ell, u_r) \in O : (u_\ell^-, u_\ell^+) \in A\}$ play an important role in the coherence of $RS_v$, we provide their characterization in the following proposition; we defer the proof to Subsection 5.3. We introduce, see Figure 9,

$$\Phi(\nu) \doteq \alpha^2 e^{\nu} \left[e^{-t(\nu)} - e^{\nu}\right], \quad \nu \in \mathbb{R}.$$

Figure 9: The function $\Phi$. Notice that $\Phi$ is decreasing in $[\nu_c, \infty)$, with $\nu_c < -1$.

**Proposition 4.2.** We have $O_O = \bigcup_{i=1}^2 O_O^i$ and $O_A = \bigcup_{j=1}^2 O_A^j$, where

$$O_O^1 \doteq \left\{(u_\ell, u_r) \in O : \tilde{\nu} > \max\{0, \nu_\ell\}, \ e^{\nu_\ell + \nu_r} \Phi(-\max\{1, \nu_\ell\} \cdot \min\{1, \tilde{\nu}\}) > M\right\},$$

$$O_O^2 \doteq \left\{(u_\ell, u_r) \in O : \tilde{\nu} < \min\{0, \nu_\ell\}, \ e^{\nu_\ell - \nu_r} \Phi(-\min\{-1, \nu_\ell\} \cdot \max\{-1, \tilde{\nu}\}) > M\right\},$$

$$O_O^3 \doteq \left\{(u_\ell, u_r) \in O : 0 < \tilde{\nu} \leq \nu_\ell\right\},$$

$$O_O^4 \doteq \left\{(u_\ell, u_r) \in O : \nu_r \leq \tilde{\nu} < 0\right\},$$

and

$$O_A^1 \doteq \left\{(u_\ell, u_r) \in O : \tilde{\nu} > \max\{0, \nu_\ell\}, \ e^{\nu_\ell + \nu_r} \Phi(-\max\{1, \nu_\ell\} \cdot \min\{1, \tilde{\nu}\}) \leq M\right\},$$

$$O_A^2 \doteq \left\{(u_\ell, u_r) \in O : \tilde{\nu} < \min\{0, \nu_\ell\}, \ e^{\nu_\ell - \nu_r} \Phi(-\min\{-1, \nu_\ell\} \cdot \max\{-1, \tilde{\nu}\}) \leq M\right\}.$$

The subsets $O_O^i$, $i \in \{1, 2, 3, 4\}$, and $O_A^j$, $j \in \{1, 2\}$, are mutually disjoint.

In general it is difficult to characterize $CH$ in a simple way because an explicit expression for $\bar{u}$ is not available. We introduce in the next corollary a subset of $CH$ that partially answers to this issue.

**Corollary 4.3.** We have

$$CH^\prime \doteq \left\{(u_\ell, u_r) \in \Omega^2 : \nu_r < 0 < \nu_\ell, \ \min\left\{e^{\nu_\ell + \nu_r} \Phi(-\nu_\ell), e^{\nu_\ell - \nu_r} \Phi(\nu_r)\right\} > M\right\} \subseteq CH,$$

see Figure 10. As a consequence, $CH^\prime \cap O \subseteq O_O$.  

13
\textit{Proof}. Clearly CH' = CH'_1 \cap CH'_2, where
\begin{align*}
CH'_1 & = \{(u_\ell, u_r) \in \Omega^2 : \nu_\ell > 0, \ e^{\mu_\ell + \mu_\ell} \Phi(-\nu_\ell) > M\}, \\
CH'_2 & = \{(u_\ell, u_r) \in \Omega^2 : \nu_r < 0, \ e^{\mu_r - \nu_r} \Phi(\nu_r) > M\}.
\end{align*}
We claim that CH'_1 \cap O'_A = \emptyset, j \in \{1, 2\}. To prove the case \( j = 1 \) (the other case is analogous), let \((u_\ell, u_r) \in CH'_1 \cap O'_A\); then \( \tilde{\nu} > \nu_\ell = \max\{0, \nu_r\} \) and so
\begin{align*}
e^{-\mu_\ell - \nu_\ell} M & \geq \Phi(-\max\{1, \nu_\ell\} \cdot \min\{1, \tilde{\nu}\}) = \begin{cases} 
\Phi(-\nu_\ell) & \text{if } \tilde{\nu} > \nu_\ell \geq 1 \\
\Phi(1) & \text{if } \nu_\ell \geq 1 > \nu_\ell \\
\Phi(-\tilde{\nu}) & \text{if } 1 > \tilde{\nu} > \nu_\ell
\end{cases} \\
& \geq \Phi(-\nu_\ell) > e^{-\mu_\ell - \nu_\ell} M,
\end{align*}
see Figure 9, a contradiction. As a consequence CH' \cap O_A = \emptyset because O_A = O'_A \cup O''_A by Proposition 4.2, whence CH' \subseteq CH by Theorem 4.1, (I). \hfill \Box

In the following corollary we prove that any consistent point is also coherent.

\textbf{Corollary 4.4.} We have CN \subset CH.

\textit{Proof}. It is sufficient to prove that CN_O \subset O_O because by Theorem 4.1, (I),(II), we have
\begin{align*}
CN \cap A = CN_A \subset CH \cap A = A, \quad CH \cap O = O_O, \quad CN \cap O = CN_O.
\end{align*}
Let \((u_\ell, u_r) \in CN_O\). Clearly \( \nu_r \equiv u_p \) and \( \tilde{q} \neq 0 \). We have to prove that \((u_p^-, u_p^+) \in O\), namely \( |\hat{p}(u_p^-) - \hat{p}(u_p^+)| > M\).

- Assume that \( u_p^\pm = u_\ell \); the case \( u_p^\pm = u_r \) is analogous. It is sufficient to prove that \( q_\ell \neq 0 \) because we know that \((u_\ell, u_\ell) \in A'^\ell = O \cup A_N\). If by contradiction \( q_\ell = 0 \), then \( \tilde{u} = u_\ell \) because \( u_p^\pm = u_\ell \). As a consequence \( \tilde{q} = 0 \), namely \((u_\ell, u_r) \in A_N\), a contradiction.

- Assume that \( u_p^\pm = \tilde{u} \). Consider the case \( \tilde{q} > 0 \); the case \( \tilde{q} < 0 \) is analogous. Since \( q_p \neq 0 \) along any rarefaction, we have \( q_\ell > 0 \).

\begin{itemize}
\item If \( q_\ell \geq \tilde{q} \), then \((u_\ell, \tilde{u}) \in O\) because \( \tilde{q}(u_\ell, \tilde{u}) = \tilde{q} \neq 0 \); hence \( \hat{p}(u_p^-) - \hat{p}(u_p^+) = \hat{p}(\tilde{u}) - \hat{p}(\tilde{u}) > \hat{p}_\ell - \hat{p}(\tilde{u}) > M\).
\item If \( q_\ell < \tilde{q} \), then \((u_\ell, u_\ell) \in O\) because \( q_\ell > 0 \); hence by (4.1),(4.2)
\begin{align*}
\hat{p}(u_p^-) - \hat{p}(u_p^+) = \hat{p}(\tilde{u}) - \hat{p}(\tilde{u}) &= \alpha^2 \left( e^{\hat{p}(\tilde{u})} - e^{\hat{p}(\tilde{u})} \right) \\
&= e^{\mu_\ell + \mu_\ell} \Phi(-\tilde{\nu}) > e^{\mu_\ell + \mu_\ell} \Phi(-\nu_\ell) = \hat{p}_\ell - \hat{p}_\ell > M,
\end{align*}
because \( \nu_\ell < \tilde{\nu} \leq 1 \) and \( \tilde{\mu} + \tilde{\nu} \geq \mu_\ell + \nu_\ell \).
\end{itemize}
Assume that \( u^+ = \bar{u} \); the case \( u^- = \bar{u} \) is analogous. Since \( q_p \neq 0 \) along any rarefaction, we have \( q_{\ell} > 0 \). Therefore \((u_\ell, u_r) \in \mathcal{O}\) and by (4.1), (4.2)

\[
\bar{p}(u^-) - \bar{p}(u^+)_\ell = \bar{p}(u_\ell) - \bar{p}(u_r) = a^2 \left( e^{\hat{\rho}(u_\ell)} - e^{\hat{\rho}(u_r)} \right) = e^{\mu_{\ell}} \nu_{\ell} (1) > e^{\mu_{r}} \nu_{r} (\nu_{\ell} - \nu_{r}) = \hat{p}_{\ell} - \hat{p}_{r} > M,
\]

because \( \nu_{\ell} < \nu_{r} = 1 \) and \( \mu_{\ell} + 1 = \mu_{r} + \nu_{r} \).

Assume that \( u^- = u_\ell \) and \( u^+ = \bar{u} \); the case \( u^- = \bar{u} \) and \( u^+ = u_r \) is analogous. Since \( u_p \) cannot perform a stationary shock between states with zero flow by (2.4), we have that \( q_{\ell} = q_{r} \neq 0 \). Therefore \((u_\ell, u_r) = (u_\ell, \bar{u}) \in \mathcal{O}\) because \( \bar{q}(u_\ell, \bar{u}) = \hat{q} \neq 0 \).

We now deal with invariant domains. We first state a preliminary result.

**Proposition 4.5.** Let \( \Delta \equiv \{(u, u) : u \in \Omega\} \). Then \( \Delta \cap \mathcal{C} = \Delta \) and \( \Delta \cap \mathcal{C} = \Delta \cap \mathcal{A}_\ell^2 \).

**Proof.** By Theorem 4.1, (I),(II), it is sufficient to prove that

\[
\Delta \cap \mathcal{C} = \Delta \cap \mathcal{A}_\ell^2 \quad \text{and} \quad \Delta \cap \mathcal{C} = \Delta \cap \mathcal{A}_\ell^2 \cap \mathcal{C} = \Delta \cap \mathcal{A}_\ell^2 \cap \mathcal{C}.
\]

If \((u, u) \in \mathcal{O} \cap \mathcal{C} \neq \emptyset\), then \( \mathcal{R}\mathcal{S}[(u, u)] \equiv \mathcal{R}\mathcal{S}[(u, u)] \ni (u, u) \) and clearly \((u, u) \in \mathcal{O} \cap \mathcal{C} \neq \emptyset \). By continuity argument there exists a sufficiently small \( \varepsilon \neq 0 \) such that \( \xi_\ell^\varepsilon \in \mathcal{C} = \Delta \cap \mathcal{A}_\ell^2 \cap \mathcal{C} = \Delta \cap \mathcal{A}_\ell^2 \cap \mathcal{C} \).

\( \mathcal{A}_\ell^2 \cap \mathcal{C} \neq \emptyset \) if and only if \((u, \bar{u}) \in \mathcal{A}_\ell^2 \).

**Corollary 4.6.** Let \( \mathcal{I} \) be an invariant domain of \( \mathcal{R}\mathcal{S}_v \). If there exist \( u_\ell, u_r \in \mathcal{I} \) such that \( u_v \) has a rarefaction taking value \( q = 0 \), \( \mathcal{I} \subseteq \mathcal{C} \).

**Proof.** By Proposition 4.5 we have that \( \mathcal{R}\mathcal{S}_v \) is consistent at no \( (u_0, u_0) \in \mathcal{A}_\ell^2 \). Hence, it is sufficient to prove that there exists \( u_\ell \in \mathcal{I} \) such that \((u_\ell, u_0) \in \mathcal{A}_\ell^2 \). By assumption there exist \( \xi_\ell \in \mathcal{C} \). Clearly \((u_\ell, u_0) \in \mathcal{I} \subseteq \mathcal{C} \subseteq \mathcal{A}_\ell^2 \cap \mathcal{C} \).

\( \mathcal{I} \subseteq \mathcal{C} \cap \mathcal{A}_\ell^2 \).

**Corollary 4.7.** Let \( u \in \Omega \). There exists an invariant domain \( \mathcal{I} \) of \( \mathcal{R}\mathcal{S}_v \) such that \( \{(u, u) \in \mathcal{I} \subseteq \mathcal{C} \subset \mathcal{C} \cap \mathcal{A}_\ell^2 \subset \mathcal{C} \cap \mathcal{A}_\ell^2 \subset \mathcal{C} \).

**Proof.** By Proposition 4.5 we have that \( \mathcal{R}\mathcal{S}_v \) is consistent at no \( (u_0, u_0) \in \mathcal{A}_\ell^2 \). Hence, it is sufficient to prove that there exists \( u_\ell = u_\ell \in \mathcal{I} \) such that \((u_\ell, u_0) \in \mathcal{A}_\ell^2 \). By assumption there exist \( \xi_\ell \in \mathcal{C} \).

\( \mathcal{I} \subseteq \mathcal{C} \cap \mathcal{A}_\ell^2 \).

**Corollary 4.8.** Let \( \mathcal{I} \subseteq \mathcal{A}_\ell^2 \) and \( \mathcal{O} \subseteq \mathcal{A}_\ell^2 \cap \mathcal{C} \subset \mathcal{A}_\ell^2 \cap \mathcal{C} \).

**Proof.** By Proposition 4.5 we have that \( \mathcal{R}\mathcal{S}_v \) is consistent at no \( (u_0, u_0) \in \mathcal{A}_\ell^2 \). Hence, it is sufficient to prove that there exists \( u_\ell = u_\ell \in \mathcal{I} \) such that \((u_\ell, u_0) \in \mathcal{A}_\ell^2 \).

\( \mathcal{I} \subseteq \mathcal{C} \cap \mathcal{A}_\ell^2 \).

It remains to prove that \( \mathcal{D} \) is an invariant domain. This follows by observing that \( \mathcal{D}_2 \subset \mathcal{A} \) and that for any \( u_\ell, u_r \in \mathcal{D} \)

\[
u_u(\mathcal{D}) = \begin{cases} (u_\ell, u_r) \cup \mathcal{R}_2((\hat{\rho}(u_r), \rho_r), u) & \text{if } u_\ell, u_r \in \mathcal{R}_2((\hat{\rho}(u_r), \rho_r), u), \\
(u_\ell, u_r) \cup \mathcal{R}_2((\rho_r, \rho_r), u) & \text{if } u_\ell, u_r \in [\rho_r, \rho_r] \times \{0\}, \\
\{u_\ell, u_r, u_r\} & \text{if } \{u_\ell, u_r\} \subset \mathcal{R}_2((\rho_r, \rho_r), u) \times \{0\}, \\
\{u\} \cup \mathcal{R}_2((\rho, \rho), u) & \text{if } \{u\} \subset \mathcal{R}_2((\rho_r, \rho_r), u) \times \{0\} \times \mathcal{R}_2((\rho, \rho), u), \
\end{cases}
\]

whence \( \mathcal{R}\mathcal{S}_v(\mathcal{D}_2) \subset \mathcal{D} \). By Theorem 4.1, (I), we have \( \mathcal{I} \subseteq \mathcal{A} \subset \mathcal{C} \). By Proposition 4.5 we have \((u, u) \in \mathcal{I} \subseteq \mathcal{I} \subseteq \mathcal{I} \subseteq \mathcal{I} \subseteq \mathcal{I} \subseteq \mathcal{I} \subset \mathcal{I} \subseteq \mathcal{I} \subset \mathcal{I} \subseteq \mathcal{I} \subset \mathcal{I} \subseteq \mathcal{I} \subseteq \mathcal{I} \).

\( \square \)
We now extend the previous corollary by constructing the minimal invariant domain containing two elements of Ω in two particular cases.

**Corollary 4.9.** Fix $u_0, u_1 \in \Omega$ and let $u_2 \doteq \hat{u}(u_1)$ and $u_3 \doteq \hat{u}(u_1)$. Assume that

\[ \nu_0 = 0 < \nu_1, \quad \mu_1 + \nu_1 < \mu_0, \quad (u_1, u_1) \in A_I \]

and let $\mathcal{I}$ be the minimal invariant domain containing \{u_0, u_1\}. Then $\mathcal{I}^2 \not\subseteq \mathcal{N}$ and moreover:

- if $p_0 - p_3 \leq M$, then $\mathcal{I} = \{u_0\} \cup \mathcal{R}_2([\rho_3, \rho_1], u_1) \cup ([\rho_3, \rho_2] \times \{0\})$ and $\mathcal{I}^2 \subseteq \mathcal{C}$;
- if $p_2 - p_3 = M = p_0 - p_2$, then $\mathcal{I} = \mathcal{I}_{u_0}$ and $\mathcal{I}^2 \not\subseteq \mathcal{C}$.

**Proof.** We notice that by assumption we have $\mu_2 < \mu_1 + \nu_1 < \mu_0$. By Proposition 4.5 we deduce $(u_1, u_1) \in \mathcal{I}^2 \setminus \mathcal{N}$. Clearly, see Figure 11, $(u_0, u_0), (u_2, u_2), (u_3, u_3) \in A_{\mathcal{N}}, \rho_3 < \rho_1 < \rho_2$; moreover $\rho_0 > \rho_2$ and $0 < p_2 - p_3 \leq M$ in both the considered cases. By proceeding as in the proof of Corollary 4.8 we have

\[ \mathcal{I} \supseteq \mathcal{D} \doteq \mathcal{R}_2([\rho_3, \rho_1], u_1) \cup ([\rho_3, \rho_2] \times \{0\}). \]

- If $\rho_2 < \rho_0$ and $p_0 - p_3 \leq M$, then $\mathcal{I} = \mathcal{D} \cup \{u_0\}$. This follows by observing that $(\mathcal{D} \cup \{u_0\})^2 \subset A$ and that for any $u_d \in \mathcal{D}$

\[ \mathcal{R}_v[u_d, u_0](\mathbb{R}) = \{u_d, \hat{u}_d, u_0\}, \quad \mathcal{R}_v[u_0, u_d](\mathbb{R}) = \begin{cases} \{u_d, u_0\} & \text{if } q_d = 0, \\ \{u_0\} \cup \mathcal{R}_2([\rho_3, \rho_d], u_1) & \text{if } q_d > 0, \end{cases} \]

are subsets of $\mathcal{D} \cup \{u_0\}$. By Theorem 4.1, (I), we have that $\mathcal{I}^2 \subset A \subset \mathcal{C}$.

- Assume $\rho_2 \leq \rho_0$ and $p_2 - p_3 = M = p_0 - p_2$. We claim that

\[ \mathcal{I} = \mathcal{I}_{u_0}, \]

where $\mathcal{I}_{u_0}$ is defined by (2.7). Differently from the previous case, we have $(u_0, u_1), (u_0, u_3), (u_3, u_0) \in \mathcal{O}$; notice that $(u_1, u_0), (u_2, u_0), (u_0, u_2) \in A_I$. As a consequence

\[ \mathcal{R}_v[u_0, u_3](\mathbb{R}) = \mathcal{R}_1([\rho_4, \rho_0], u_0) \cup \{u_3\}, \quad \mathcal{R}_v[u_3, u_0](\mathbb{R}) = \{u_3\} \cup \mathcal{R}_2([\rho_5, \rho_0], u_5), \]

where $u_4 \in \mathcal{F}_{L_1}^{u_0} \cap \mathcal{B}_{L_2}^{u_3}$ and $u_5 \in \mathcal{F}_{L_1}^{u_3} \cap \mathcal{B}_{L_2}^{u_0}$. Observe that $\mu_4 = \mu_5, \nu_4 = -\nu_5 > 0$ and $\hat{u}(u_5) = \hat{u}(u_4) = u_6$. As a consequence $(u_5, u_4) \in \mathcal{A}_{\mathcal{N}}$ and

\[ \mathcal{R}_v[u_5, u_4](\mathbb{R}) = \mathcal{R}_1([\rho_6, \rho_5], u_5) \cup \mathcal{R}_2([\rho_6, \rho_4], u_6). \]

Clearly $(u_0, u_6), (u_6, u_0) \in \mathcal{O}$ and

\[ \mathcal{R}_v[u_0, u_6](\mathbb{R}) = \mathcal{R}_1([\rho_7, \rho_0], u_0) \cup \{u_6\}, \quad \mathcal{R}_v[u_6, u_0](\mathbb{R}) = \{u_6\} \cup \mathcal{R}_2([\rho_8, \rho_0], u_8), \]
where $u_7 \in \mathcal{F}L_1^{u_6} \cap \mathcal{B}L_2^{u_6}$ and $u_8 \in \mathcal{F}L_1^{u_6} \cap \mathcal{B}L_2^{u_6}$. Observe that $\mu_7 = \mu_8$, $\nu_7 = -\nu_8 > 0$ and $\hat{u}(u_8) = \hat{u}(u_7) = u_0$. By iterating this procedure, we obtain that

$$\mathcal{R}_1(0, \rho_0, u_0) \cup \mathcal{R}_2(0, \rho_0, u_0) \subset \mathcal{I}.$$  

Finally, by letting $u_\ell \in \mathcal{R}_2(0, \rho_0, u_0)$ and $u_r \in \mathcal{R}_1(0, \rho_0, u_0)$ be such that $\mu_\ell = \mu_r$ and $\nu_\ell = -\nu_r < 0$, we have that $(u_\ell, u_r) \in \mathcal{A}_N$ because $\hat{u}_\ell = \hat{u}_r$, hence

$$u_\nu(\mathbb{R}) = \mathcal{R}_1([\hat{\rho}_\ell, \rho_\ell], u_\ell) \cup \mathcal{R}_2([\hat{\rho}_r, \rho_r], \hat{\rho}_r).$$

It is therefore clear that $\mathcal{I}_{u_0} \subseteq \mathcal{I}$. By Theorem 4.1, (IV), we have that $\mathcal{I}_{u_0}$ is an invariant domain, hence $\mathcal{I}_{u_0} = \mathcal{I}$.

We claim that $\mathcal{I}_{u_0} \notin \mathcal{CH}$, namely $\mathcal{I}_{u_0} \cap \mathcal{O}_A \neq \emptyset$. Since $\Phi(-1) < a^2$ and by assumption $p_0 > 2M$, there exist $u_\ell, u_r \in \mathcal{I}_{u_0}$ such that $p_\ell - p_r > M$, $\nu_\ell = 0 = \nu_r$ and $M < p_\ell \leq a^2 M / \Phi(-1) < 2M$. Then $(u_\ell, u_r) \in \mathcal{O}_A$ with $\hat{\nu} > 0 = \nu_\ell$ and $(u_\ell, u_r) \in \mathcal{O}_A$ because

$$e^{\mu_\ell + \nu_\ell} \Phi(-\max(1, \nu_\ell) \cdot \min(1, \hat{\nu})) = \rho_\ell \Phi(-\min(1, \hat{\nu})) \leq \rho_\ell \Phi(-1) \leq M. \qed$$

5 Technical proofs

5.1 Properties of $\mathcal{RS}_p$

Proof of Proposition 2.4. We refer to the $(\mu, \nu)$-coordinates. Property (L1) is obvious because $\mathcal{R}_i^{u_\nu}$ and $\mathcal{R}_i^{u_{\nu\nu}}$ are straight lines with the same slope. Property (L2) follows by reducing to a second order equation in $e^u/2$, see Figure 12. To prove (L3), we notice that $S_1^{u_\nu} \cap S_1^{u_{\nu\nu}}$ has at most two elements by (L2);

![Figure 12: $S_1^{u_\nu} \cap S_1^{u_{\nu\nu}}$ consists either of two points, one or none.](image)

moreover

$$u_{\nu\nu} \in S_1^{u_\nu} \Leftrightarrow \nu_{\nu\nu} = \Xi(\mu_{\nu\nu} - \mu_\nu) + \nu_\nu \Leftrightarrow \nu_\nu = \Xi(\mu_\nu - \mu_{\nu\nu}) + \nu_{\nu\nu} \Leftrightarrow u_\nu \in S_1^{u_{\nu\nu}},$$

and then $S_1^{u_\nu} \cap S_1^{u_{\nu\nu}} = \{u_\nu, u_{\nu\nu}\}$. To prove (L4)–(L6) it is sufficient to observe that

$$(S_i)_\rho(\rho, u_\nu) = \frac{q_\rho}{\rho_\nu} + (-1)^i \frac{a}{2} \left(3 \sqrt{\frac{\rho}{\rho_\nu}} - \sqrt{\frac{\rho_\nu}{\rho}}\right), \quad (S_i)_\rho(\rho, u_{\nu\nu}) = (-1)^i \frac{a}{4\rho} \left(3 \sqrt{\frac{\rho}{\rho_\nu}} + \sqrt{\frac{\rho_\nu}{\rho}}\right),$$

$$(\mathcal{R}_i)_\rho(\rho, u_\nu) = \frac{q_\rho}{\rho_\nu} + (-1)^i \frac{a}{4\rho} \left(1 + \ln\left(\frac{\rho}{\rho_\nu}\right)\right), \quad (\mathcal{R}_i)_\rho(\rho, u_{\nu\nu}) = (-1)^i \frac{a}{\rho}.$$  

At last, (L7) is clear in the $(\mu, \nu)$-coordinates, see Figure 13. \qed

Proof of Proposition 2.5. Conditions (ch.0) and (cn.0) are satisfied because $\mathcal{D}_\rho = \Omega^2$.

About coherence, we prove (ch.1). Fix $(u_\ell, u_r) \in \Omega^2$ and $\xi_o \in \mathbb{R}$. If $u_p(\xi_o^-) = u_p(\xi_o^+)$, then $\mathcal{RS}_p[u_p(\xi_o^-), u_p(\xi_o^+)] \equiv u_p(\xi_o^+)$ since $\mathcal{RS}_p[u, u] \equiv u$ for any $u \in \Omega$ and it is easy to conclude. If $u_p(\xi_o^-) \neq u_p(\xi_o^+)$, namely, $u_p$ has a shock at $\xi_o$, then either $u_p(\xi_o^-) = -u_p(\xi_o^+) = \bar{u}$ or $u_p(\xi_o^-) = \bar{u} \neq u_p(\xi_o^+) = u_*$. In the former case $\rho_\ell < \bar{\rho}$, in the latter $\rho_r < \bar{\rho}$. It is then easy to conclude by observing that $\bar{u}(u_\ell, \bar{u}) = \bar{u} = \bar{u}(u_\ell, u_r)$.
It follows that $u$.

Now, if by contradiction (ch $v$

Proof. $u$

The consistence domain of $\text{Proposition 5.2}$. $u$

We split the proof of Theorem 4.1 into the following propositions.

5.2 Proof of Theorem 4.1

Proposition 5.1. The coherence domain of $\text{Proposition 5.2}$. $u$

About consistence, it is sufficient to observe that for any $\xi \in \mathbb{R}$ we have

$$\tilde{u}(u_\ell, u_p(\xi_0)) = \begin{cases} u_p(\xi_0) & \text{if } u_p(\xi_0) \in \mathcal{RS}_p[u_\ell, \tilde{u}](\mathbb{R}), \\ \tilde{u} & \text{if } u_p(\xi_0) \notin \mathcal{RS}_p[\tilde{u}, u_\ell](\mathbb{R}), \end{cases}$$

$$\tilde{v}(u_\ell, u_p(\xi_0), u_r) = \begin{cases} \tilde{u} & \text{if } u_p(\xi_0) \in \mathcal{RS}_p[\tilde{u}, u_r](\mathbb{R}), \\ u_p(\xi_0) & \text{if } u_p(\xi_0) \notin \mathcal{RS}_p[\tilde{u}, u_r](\mathbb{R}), \end{cases}$$

and that $u_p$ is the juxtaposition of $\mathcal{RS}_p[u_\ell, \tilde{u}]$ and $\mathcal{RS}_p[\tilde{u}, u_r]$.

At last, the $L_{\text{loc}}$ continuity in $\Omega^2$ directly follows from the continuity of $\tilde{u}, \sigma, \lambda_1$ and $\lambda_2$. $\square$

5.2 Proof of Theorem 4.1

We split the proof of Theorem 4.1 into the following propositions.

Proposition 5.1. The coherence domain of $\mathcal{RS}_v$ is $\text{CH} = A \cup O_\Omega$.

Proof. Condition $(\text{ch}_v.0)$ holds true in $\Omega^2$ because $D_v = \Omega^2$; therefore, we are left to consider $(\text{ch}_v.1)$.

First, we prove that if $(u_\ell, u_r) \in A \cup O_\Omega$, then $(\text{ch}_v.1)$ holds. Assume that $(u_\ell, u_r) \in A$. In this case $u^- = u_\ell$ and $u^+ = u_r$. By (4.3) we have $\tilde{u}(u^-) = u^- = \tilde{u}_\ell$ and $\tilde{u}(u^+) = u^+ = \tilde{u}_r$; therefore $(u^-, u^+) \in A$, whence $(\text{ch}_v.1)$ holds true. If $(u_\ell, u_r) \in O_\Omega$, then it is sufficient to exploit the coherence of $\mathcal{RS}_p$.

Second, we prove that if $(u_\ell, u_r) \in O_A$ then $(\text{ch}_v.1)$ fails. Since $(u_\ell, u_r) \in O$, then $u_v \equiv u_p$, whence $u^- = u^+$; since $(u^-, u^+) \in A$, then by (pr.1) it follows

$$\mathcal{RS}_v[u^-, u^+](\xi) = \begin{cases} \mathcal{RS}_p[u^-, \tilde{u}(u^-)](\xi) & \text{if } \xi < 0, \\ \mathcal{RS}_p[\tilde{u}(u^+), u^+](\xi) & \text{if } \xi \geq 0. \end{cases}$$

Now, if by contradiction $(\text{ch}_v.1)$ holds, then we have

$$\mathcal{RS}_p[u^-, \tilde{u}(u^-)] \equiv u^- \quad \text{in } (-\infty, 0),$$

$$\mathcal{RS}_p[\tilde{u}(u^+), u^+] \equiv u^+ \quad \text{in } [0, \infty).$$

It follows that $u^- = \tilde{u}(u^-)$ and $u^+ = \tilde{u}(u^+)$; then $q_p(0\pm) = 0$, whence $u^- = u^+$ because $u_p$ cannot perform a stationary shock between states with zero flow by (2.4). Then it is not difficult to see that $\tilde{u} = u_p(0)$, whence $\tilde{q} = 0$ and therefore $\tilde{u}_\ell = \tilde{u} = \tilde{u}_r$. This contradicts the assumption $(u_\ell, u_r) \in O$, that is $|\tilde{p}_r - \tilde{p}_\ell| > M$. $\square$

Proposition 5.2. The consistence domain of $\mathcal{RS}_v$ is $\text{CN} = \text{CN}_1 \cup \text{CN}_2$.

Proof. Since $D_v = \Omega^2$, we have that $\text{CN} = \text{CN}_1 \cup \text{CN}_2$, where

$$\text{CN}_1 = \{(u_\ell, u_r) \in A_1: (u_\ell, u_r) \text{ satisfies (cn}_v.1)\}, \quad \text{CN}_2 = \{(u_\ell, u_r) \in A_1^\gamma: (u_\ell, u_r) \text{ satisfies (cn}_v.1)\}.$$
By Proposition 3.5 we have

\[
\begin{align*}
\text{CN}_1' & \equiv \left\{ (u_\ell, u_r) \in A_1 : \begin{cases} (u_\ell, u_\nu(\xi_o)) \in A_1^\ell \text{ and } \hat{u}(u_\nu(\xi_o)) = \hat{u}_\ell, & \text{for any } \xi_o < 0 \end{cases} \right\} \\
\text{CN}_2' & \equiv \left\{ (u_\ell, u_r) \in A_1^2 : (u_\ell, u_\nu(\xi_o)), (u_\nu(\xi_o), u_r) \in A_1^\xi, \text{ for any } \xi_o \in \mathbb{R} \right\}.
\end{align*}
\]

Clearly CN_2' = CN_2 and CN_1' \subseteq CN_1. Hence, we are left to prove that CN_1' \supseteq CN_1. Let (u_\ell, u_r) \in CN_1. If \xi_o < 0 (the case \xi_o \geq 0 is analogous), then

\[
q_\ell \geq 0 \quad \Rightarrow \quad \hat{u}_\ell \in S_1^{u_\ell} \quad \Rightarrow \quad u_\nu(\xi_o) \in \{ u_\ell, \hat{u}_\ell \},
\]

\[
q_\ell < 0 \quad \Rightarrow \quad \hat{u}_\ell \in R_4^{u_\ell} \quad \Rightarrow \quad q_\nu(\xi_o) \in [q_\ell, 0], \quad R_4^{\nu(\xi_o)} = R_4^{u_\ell}.
\]

As a consequence \hat{u}(u_\nu(\xi_o)) = \hat{u}_\ell, therefore (u_\ell, u_r) \in CN_1'.

\[\Box\]

\textbf{Proposition 5.3.} The consistence domain of \(\mathcal{RS}_\nu\) is \(\text{CN} = \text{CN}_0 \cup \text{CN}_A\).

\textbf{Proof.} It is sufficient to prove that \(\text{CN} \cap A = \text{CN}_A\) and \(\text{CN} \cap O = \text{CN}_O\). In the following we use Proposition 3.5 several times without any explicit mention.

We first prove that \(\text{CN} \cap A = \text{CN}_A\). Clearly \(\text{CN}_A = \bigcup_{i=1}^4 \text{CN}_A^i\), where

\(\text{CN}_A^1 = \{ (u_\ell, u_r) \in A : q_\ell > 0 > q_r, (u_\ell, u_\ell) \in O, (u_r, u_r) \in O \}\)

\(\text{CN}_A^2 = \{ (u_\ell, u_r) \in A : q_\ell > 0 > q_r, (u_\ell, u_r) \in O \} = \{ (u_\ell, u_r) \in A : q_\ell = 0, p_\ell - p_r > M \},\)

\(\text{CN}_A^3 = \{ (u_\ell, u_r) \in A : q_\ell > 0 > q_r, (u_\ell, u_r) \in O \} = \{ (u_\ell, u_r) \in A : p_\ell - p_r > M, q_r = 0 \},\)

\(\text{CN}_A^4 = \{ (u_\ell, u_r) \in A : q_\ell = 0 = q_r \}.
\]

\(\text{CN}_A^i\): We prove that \((u_\ell, u_r) \in A\) with \(q_\ell > 0 > q_r\) belongs to \(\text{CN}\) if and only if \((u_\ell, u_\ell), (u_r, u_r) \in O\).

\(\text{If} \ (u_\ell, u_r) \in A_1\), then \(u_\nu\) performs two shocks and an under-compressive shock, hence \((u_\ell, u_\nu(\xi^-))\), \((u_\nu(\xi^-), u_r) \in \{ (u_\ell, u_r), (\hat{u}_\ell, u_r), (\hat{u}, u_r), (u_\ell, u_r) \}\) for any \(\xi^- < 0 \leq \xi^+_o\). Obviously \((u_\ell, \hat{u}_\ell), (\hat{u}_\ell, u_r) \in A_1\) and \((u_\ell, u_\ell), (u_r, u_r) \in A_1\). Therefore \((u_\ell, u_\ell), (u_r, u_r) \in A\) if and only if \((u_\ell, u_\ell), (u_r, u_r) \in A\).

\(\text{If} \ (u_\ell, u_r) \in A_2\), then \(u_\nu\) coincides with \(u_\ell\) and performs two shocks, hence \((u_\ell, u_\nu(\xi)), (u_\nu(\xi), u_r) \in \{ (u_\ell, u_r), (u_\ell, \hat{u}), (\hat{u}, u_r), (u_\ell, u_r) \}\) for any \(\xi_o \in \mathbb{R}\). Since \(\hat{u}_\ell = \hat{u} = \hat{u}_r\), we have \((u_\ell, \hat{u}), (\hat{u}, u_r) \in A_1\); moreover by assumption \((u_\ell, u_\ell), (u_\ell, u_r) \in A_1\) and \((u_r, u_r) \in A_1\). Therefore \((u_\ell, u_\ell) \in \text{CN}_2\) if and only if \((u_\ell, u_\ell), (u_r, u_r) \in A\).

\(\text{CN}_2^3\): We prove that \((u_\ell, u_r) \in A\) with \(q_\ell = 0 > q_r\) belongs to \(\text{CN}\) if and only if \((u_r, u_r) \in O\).

\(\text{If} \ (u_\ell, u_r) \in A_1\), then \(u_\nu\) performs an under-compressive shock and a 2-shock, hence \((u_\ell, u_\nu(\xi^-))\), \((u_\nu(\xi^-), u_r) \in \{ (u_\ell, u_r), (\hat{u}_\ell, u_r), (\hat{u}_\ell, u_r), (u_\ell, u_r) \}\) for any \(\xi^- \leq \xi^+_o\). Obviously \((u_\ell, \hat{u}_\ell), (\hat{u}_\ell, u_r) \in A_1\) and \((u_r, u_r) \in A_1\). Therefore \((u_\ell, u_\ell), (u_r, u_r) \in \text{CN}_1\) if and only if \((u_\ell, u_\ell), (u_r, u_r) \in \text{CN}_1\).

\(\text{If} \ (u_\ell, u_r) \in A_2\), then \(u_\nu\) coincides with \(u_\ell\) and performs a 2-shock, hence \((u_\ell, u_\nu(\xi)), (u_\nu(\xi), u_r) \in \{ (u_\ell, u_r), (u_\ell, u_r), (u_\ell, u_r) \}\) for any \(\xi_o \in \mathbb{R}\). By assumption \((u_\ell, u_\ell), (u_\ell, u_r) \in A_1\) and \((u_r, u_r) \in A_1\). Therefore \((u_\ell, u_\ell), (u_r, u_r) \in \text{CN}_2\) if and only if \((u_r, u_r) \in O\).

\(\text{CN}_2^3\): Analogously to the previous item, it is possible to prove that \((u_\ell, u_r) \in A\) with \(q_\ell > 0 = q_r\) belongs to \(\text{CN}\) if and only if \((u_\ell, u_r) \in O\).

\(\text{CN}_2^3\): We prove that any \((u_\ell, u_r) \in A\) with \(q_\ell = 0 = q_r\) belongs to \(\text{CN}\).

\(\text{If} \ (u_\ell, u_r) \in A_1\), then \(u_\nu\) performs an under-compressive shock, hence \((u_\ell, u_\nu(\xi^-))\), \((u_\nu(\xi^-), u_r) \in \{ (u_\ell, u_r), (\hat{u}_\ell, u_r), (\hat{u}_\ell, u_r) \}\) for any \(\xi^- \leq \xi^+_o\). Obviously \((u_\ell, \hat{u}_\ell), (\hat{u}_\ell, u_r) \in A_1\) and \((u_\ell, u_\ell) \in A_1\).

\(\text{If} \ (u_\ell, u_r) \in A_2\), then \(u_\ell = u_r\) and \(u_\ell \equiv u_\ell \equiv u_\ell\), hence \((u_\ell, u_\nu(\xi)), (u_\nu(\xi), u_r) \in \{ (u_\ell, u_r) \}\) for any \(\xi_o \in \mathbb{R}\). By assumption \((u_\ell, u_\ell) \in A_1\) and therefore \((u_\ell, u_\ell) \in \text{CN}_2\).

To complete the proof that \(\text{CN} \cap A = \text{CN}_A\) it remains to prove that \(\text{CN} \cap \{ (u_\ell, u_r) : q_\ell < 0 \text{ or } q_r > 0 \} = \emptyset\). Assume by contradiction that there exists \((u_\ell, u_r) \in A \cap \text{CN} \) with \(q_\ell < 0\). Then \(u_\nu\) performs a
1-rarefaction \((u_\ell, \hat{u}_\ell)\). Clearly \(u_\ell(\xi_o) = \hat{u}_\ell\) with \(\xi_o = \lambda_1(\hat{u}_\ell) < 0\) and \(\hat{p}_\ell = \hat{p}(u_\ell(\xi_o))\). Hence there exists \(\varepsilon > 0\) sufficiently small such that \(0 < \hat{p}(u_\ell(\xi_o - \varepsilon)) - \hat{p}_\ell < M\), namely \((u_\ell, u_\ell(\xi_o - \varepsilon)) \in A_1\). On the other hand \((u_\ell, u_\ell) \in A \cap CN \subset CN_1 \cup CN_2\) implies that \((u_\ell, u_\ell(\xi)) \in A_1^2\) for any \(\xi < 0\), a contradiction. The case \(q_\ell > 0\) is dealt analogously.

We now prove that

\[
CN_2 \cap O = CN_O \cap \{ (u_\ell, u_r) \in O : \begin{array}{l}(u_\ell, u_\ell), (u_\ell, u_r), (u_\ell, \hat{u}), (\hat{u}, u_r) \in A_1^2, \\
\text{and } q_\ell \neq 0 \text{ along any rarefaction}
\end{array}\}. 
\]

“\(\subseteq\)” Let \((u_\ell, u_r) \in CN_2 \cap O\). By definition of \(CN_2\) we have \((u_\ell, u_{p}(\xi_o)), (u_p(\xi_o), u_r) \in A_1^2\), for any \(\xi_o \in \mathbb{R}\), because \(u_\ell \equiv u_p\). As a consequence \((u_\ell, u_\ell), (u_\ell, u_r), (u_\ell, \hat{u}), (\hat{u}, u_r) \in A_1^2\). Assume by contradiction that \(u_p\) has a 1-rarefaction (the case of a 2-rarefaction is analogous) along which \(q_\ell\) vanishes; then \(\hat{q} \geq 0 \geq q_\ell\) and there exists \(\xi_o\) such that \(q_p(\xi_o) = 0\). Clearly \(\hat{p}_\ell = \hat{p}(u_\ell(\xi_o))\), hence there exists \(\varepsilon \neq 0\) sufficiently small such that \(0 < |\hat{p}_\ell - p(u_\ell(\xi_o + \varepsilon))| < M\), namely \((u_\ell, u_p(\xi_o + \varepsilon)) \in A_1\), a contradiction.

“\(\supseteq\)” Let \((u_\ell, u_r) \in CN_O\). Clearly \(u_\ell \equiv u_p\). If \(u_p\) does not have rarefactions, then \((u_\ell, u_r) \in CN_2\) because \((u_\ell, u_{p}(\xi_o)), (u_{p}(\xi_o), u_r) \in \{(u_\ell, u_r), (u_r, u_r), (u_\ell, \hat{u}), (\hat{u}, u_r), (u_\ell, u_r)\} \subseteq A_1^2\) for any \(\xi_o \in \mathbb{R}\). If \(u_p\) has a 1-rarefaction with \(\bar{v} > v_\ell > 0\) and a (possibly null) 2-shock, then \((u_\ell, u_r) \in CN_2\) because \((u_\ell, u_{p}(\xi_o)), (u_{p}(\xi_o), u_r) \in \{(u_\ell, u_r) \times R_1([\bar{\rho}, \bar{\rho}], u_r)\} \cup \{R_1([\bar{\rho}, \bar{\rho}], u_\ell) \times (u_r, u_r)\} \subseteq A_1^2\) for any \(\xi_o \in \mathbb{R}\). Indeed, \((u_\ell, u_\ell), (\hat{u}, u_r) \in O\) (because \(q_\ell \neq 0 \neq \bar{q}\)) and for any \(u_r \in R_1([\bar{\rho}, \bar{\rho}], u_\ell)\) we have

\[
\hat{p}_\ell - \hat{p}(u_\ell) \geq \hat{p}_\ell - \hat{p}_\ell > M \Rightarrow (u_\ell, u_\ell) \in O, \quad \hat{p}(u_\ell) - \hat{p}_\ell > M \Rightarrow (u_\ell, u_\ell) \in O.
\]

The remaining cases can be treated analogously. \(\square\)

**Proposition 5.4.** The \(L^1_{loc}\)-continuity domain of \(RS_v\) is \(L = \{(u_\ell, u_r) \in \Omega^2 : |\hat{p}_\ell - \hat{p}_\ell| \neq M\}\).

**Proof.** By Proposition 2.5 we have that \(RS_v\) is \(L^1_{loc}\)-continuous in \(O\); in \(A \cap I\) it is sufficient to exploit the continuity of \(\dot{u}, \dot{u}, \sigma, \lambda_1\) and \(\lambda_2\). Hence \(RS_v\) is \(L^1_{loc}\)-continuous in \(L\). Assume now that \((u_\ell, u_r) \in L^\ell \equiv A \setminus L \subset A_1\). Clearly \(\hat{u}_\ell \neq \hat{u}_r\) and therefore \(RS_p[u_\ell, u_r] \neq RS_v[u_\ell, u_r]\). If \((u_r^\ell, u_r^r) \in O\) converges to \((u_\ell, u_r)\), then \(RS_v[u_r^\ell, u_r^r] = RS_p[u_r^\ell, u_r^r] = RS_p[u_r^\ell, u_r^r] \in L^1_{loc}\) to \(RS_p[u_\ell, u_r]\) and not to \(RS_v[u_\ell, u_r]\) by the \(L^1_{loc}\)-continuity of \(RS_p\). \(\square\)

**Proposition 5.5.** If \(u_0 \in \Omega\) is such that \(q_0 = 0\), then \(I_{u_0}\) defined by (2.7) is an invariant domain of \(RS_v\).

**Proof.** It is sufficient to recall that \(I_{u_0}\) is an invariant domain of \(RS_p\) and to observe that \(\hat{u}(u), \hat{u}(u) \in I_{u_0}\) for any \(u \in I_{u_0}\). \(\square\)

### 5.3 Proof of Proposition 4.2

In this subsection we completely characterize the states \((u_\ell, u_r) \in O_O\) by proving Proposition 4.2. Clearly, \((u_\ell, u_r) \notin A_N\), namely \(\bar{q} \neq 0\). Therefore, we have \(\hat{p} \notin \{\hat{p}_\ell, \hat{p}_r\}\).

We recall that \(\hat{u}_\ell, \hat{u}_r\) are given by (4.1),(4.2).

**Lemma 5.6.** We have, see Figure 14,

\[
O^\mathcal{D}_\ell \equiv \{(u_\ell, u_r) \in O : 0 < \hat{v} \leq u_\ell\} \subseteq O_O, \quad O^\mathcal{D}_\ell \equiv \{(u_\ell, u_r) \in O : \nu \leq \hat{v} < 0\} \subseteq O_O.
\]

**Proof.** Simple geometric arguments show that if \((u_\ell, u_r) \in O^\mathcal{D}_\ell \cup O^\mathcal{D}_\ell\), then

\[
|\hat{p}(u_\ell^+ - \hat{p}(u_\ell^-)| \geq \hat{p}_\ell - \hat{p}_\ell
\]

and therefore \((u_\ell, u_r) \in O_O\). Indeed, let \((u_\ell, u_r) \in O^\mathcal{D}_\ell\), the case \((u_\ell, u_r) \in O^\mathcal{D}_\ell\) is analogous; then \(q_\ell, \bar{q} > 0\) and so \(\hat{\nu} - \hat{\nu} < 0\).

(A) Assume that \(\nu < \hat{\nu} < \hat{\nu} < \hat{\nu} < \hat{\nu} < \hat{\nu}\), see Figure 15. In this case \(u_\ell^+ = \hat{u}\) and (5.1) holds true because \(\hat{\mu}(u_\ell^+) = \hat{\mu}(\hat{u}) \leq \hat{\mu}_\ell < \hat{\mu}_\ell < \hat{\mu}(\hat{u}) = \hat{\mu}(u_\ell^-)\).
We recall that (\(\mu\), \(\nu\))

To prove the lemma it is sufficient to show

\[\text{Proof.} \]

We have

Lemma 5.7.

Hence, the following lemma completes the proof of Proposition 4.2.

By the previous lemma we have that

\[O_A \subseteq \{(u_\ell, u_r) \in O : \nu > \max\{0, \nu_\ell\}\} \cup \{(u_\ell, u_r) \in O : \nu < \min\{0, \nu_r\}\}.\]

Hence, the following lemma completes the proof of Proposition 4.2.

Lemma 5.7. We have

\[\{(u_\ell, u_r) \in O : \nu > \max\{0, \nu_\ell\}\} = O_\nu^1, \quad \{(u_\ell, u_r) \in O : \nu < \min\{0, \nu_r\}\} = O_\nu^2.\]

Proof. To prove the lemma it is sufficient to show

\[\{(u_\ell, u_r) \in O : 1 \leq \nu_\ell < \hat{\nu}\} = \{(u_\ell, u_r) \in O : 1 \leq \nu_\ell < \hat{\nu}, \Phi(-\nu_\ell) > M e^{-\mu_\ell - \nu_\ell}\}, \quad (5.2)\]

\[\{(u_\ell, u_r) \in O : \nu_\ell < 1 < \hat{\nu}\} = \{(u_\ell, u_r) \in O : \nu_\ell < 1 < \hat{\nu}, \Phi(-1) > M e^{-\mu_\ell - \nu_\ell}\}, \quad (5.3)\]

\[\{(u_\ell, u_r) \in O : \max\{0, \nu_\ell\} < \hat{\nu} \leq 1\} = \{(u_\ell, u_r) \in O : \max\{0, \nu_\ell\} < \hat{\nu} \leq 1, \Phi(-\hat{\nu}) > M e^{-\mu_\ell - \nu_\ell}\}, \quad (5.4)\]

\[\{(u_\ell, u_r) \in O : \nu < \nu_r \leq -1\} = \{(u_\ell, u_r) \in O : \nu < \nu_r \leq -1, \Phi(\nu_r) > M e^{\nu_r - \mu_\ell}\}, \quad (5.5)\]

\[\{(u_\ell, u_r) \in O : \nu < -1 < \nu_r\} = \{(u_\ell, u_r) \in O : \nu < -1 < \nu_r, \Phi(-1) > M e^{\nu_r - \mu_\ell}\}, \quad (5.6)\]

\[\{(u_\ell, u_r) \in O : -1 \leq \hat{\nu} < \min\{0, \nu_r\}\} = \{(u_\ell, u_r) \in O : -1 \leq \hat{\nu} < \min\{0, \nu_r\}, \Phi(\hat{\nu}) > M e^{\nu_r - \mu_\ell}\}. \quad (5.7)\]

We recall that \((u_\ell, u_r) \in O\) if and only if \((u_\ell, u_r) \in O\) and by (pr.2)

\[|\hat{\rho}(u_\ell^+) - \hat{\rho}(u_r^-)| > M. \quad (5.8)\]
We prove (5.2)–(5.4); the proof of (5.5)–(5.7) is analogous.

If \((u_\ell, u_r) \in \mathcal{O}\) satisfies \(1 \leq \nu_\ell < \nu\), then \(u^\pm_p = u_\ell\) and (5.8) is equivalent to
\[
a^2 \left[ e^{\hat{\mu}_\ell} - e^{\hat{\nu}_\ell} \right] = a^2 e^{\mu_\ell} \left[ e^{-\Xi^{-1}(\nu_\ell)} - e^{-\nu_\ell} \right] = e^{\mu_\ell + \nu_\ell} \Phi(-\nu_\ell) > M,
\]
because of (4.1),(4.2). Therefore (5.3) holds true.

If \((u_\ell, u_r) \in \mathcal{O}\) satisfies \(\nu_\ell < 1 < \nu\), then \(u^\pm_p = \tilde{u}_\ell\) and (5.8) is equivalent to
\[
a^2 \left[ e^{\hat{\mu}(\tilde{u}_\ell)} - e^{\hat{\nu}(\tilde{u}_\ell)} \right] = a^2 e^{\mu_\ell} \left[ e^{-\Xi^{-1}(\nu_\ell)} - e^{-\nu_\ell} \right] = e^{\mu_\ell + \nu_\ell} \Phi(-1) > M,
\]
because of (4.1),(4.2), \(\tilde{\mu}_\ell = \mu_\ell + \nu_\ell - 1\) and because \(\tilde{\nu}_\ell = 1\) by (2.6). Therefore (5.4) holds true.

If \((u_\ell, u_r) \in \mathcal{O}\) satisfies \(\max\{0, \nu_\ell\} < \tilde{\nu} \leq 1\), then \(u^\pm_p = \tilde{u}\) and (5.8) is equivalent to
\[
a^2 \left[ e^{\hat{\mu}(\tilde{u})} - e^{\hat{\nu}(\tilde{u})} \right] = a^2 e^{\mu_\ell} \left[ e^{-\Xi^{-1}(\tilde{\nu})} - e^{-\tilde{\nu}} \right] = e^{\mu_\ell + \nu_\ell} \Phi(-\tilde{\nu}) > M,
\]
because of (4.1),(4.2) and by \(\tilde{\mu} + \tilde{\nu} = \mu_\ell + \nu_\ell\). Therefore (5.5) holds true.

\[\square\]

6 Conclusions

In this paper we studied a mathematical model for the isothermal fluid flow in a pipe with a valve. The modeling of the flow through the valve has been based on the general definition of coupling Riemann solver; in turn, the specific properties of the valve impose the coupling condition and then the solver. Our aim was to understand to what extent the solver satisfies some crucial properties: coherence, consistence and continuity. Coherence, in particular, corresponds to the commuting (chatting) of the valve, a well-known issue in real applications. In the same time we also searched for invariant domains. To the best of our knowledge, the mathematical modeling of valves has never considered these aspects.

We focused on the case of a simple pressure-relief valve; the framework we proposed is however suitable to deal with other types of valves. Even in the simple case under consideration, a complete characterization of the states (density and velocity of the fluid) that share these properties is not trivial and requires a very detailed study of the solver. Nevertheless, we believe that our results are rather satisfactory.

Several issues now arise. On the one hand, we intend to test our method to other kind of valves in order to understand whether in some cases the analysis can be simplified. On the other hand, a natural question is how to circumvent these difficulties. This can be done in several ways: for instance, either by introducing a finite response time of the valve or by locating a pair of sensors sufficiently far from the valve, see [19, page 31]. A related important problem is the water-hammer effect [7], which is due to the sudden closure of a valve. Even further, the study of flows in networks in presence of valves appears extremely appealing, see [14, 15, 19, 25] and the references therein; owing to the complexity of this subject, this is why we kept our model as simple as possible, while however catching the most important features of the valves working. A last natural step would be toward optimization problems, see [2, 13, 16, 17] in the case of compressors and [19] for valves. We plan to treat these topics in forthcoming papers.
