#### Abstract

Consider a sample $X_{n}=\left\{X_{1}, \ldots, X_{n}\right\}$ of i.i.d variables drawn with a probability distribution $\mathbb{P}_{X}$ supported on a set $M \subset \mathbb{R}^{d}$. This article mainly deals with the study of a natural estimator for the geodesic distance on M. Under rather general geometric assumptions on $M$, a general convergence result is proved. Assuming $M$ to be a manifold of known dimension $d^{\prime} \leq d$, and under regularity assumptions on $\mathbb{P}_{X}$, an explicit convergence rate is given. In the case when $M$ has no boundary, the knwoldege of the dimension $d^{\prime}$ is unnecessary to obtain this convergence rate. The second part of the work consists in building an estimator for the Fréchet expectations on $M$, and proving its convergence under regularity conditions, applying the previous results.

Keywords: Geometric inference, Geodesic distance, Statistics on manifolds, Fréchet expectations

## 1 Introduction

Let $\mathbb{P}_{X}$ be a probability distribution supported on a set $M \subset \mathbb{R}^{d}, d \geq 2$, that is $M$ is the smallest closed set in $\mathbb{R}^{d}$ of probability 1 . Let $\mathcal{X}_{n}=\left\{X_{1}, \ldots, X_{n}\right\}$ be a sample of i.i.d variables drawn on $M$ with the distribution $\mathbb{P}_{X}$. The first

[^0]aim of this work is the study of a rather classical estimator of the geodesic distance on the unknown set $M$.

The way to build this estimator is quite intuitive (see e.g. [14]): given $r>0$, build a graph interconnecting all the pairs $\left(X_{i}, X_{j}\right)$ of the sample $X_{n}$ such that $\left\|X_{i}-X_{j}\right\| \leq r$. The geodesic distance between any two points $X_{k}$ and $X_{l}$ of the sample is then estimated by the length of the shortest path connecting $X_{k}$ and $X_{l}$ in the graph (see the Definition 1 for details). This path (and its length) can be computed with optimal complexity by using Dijkstra's algorithm (see for example [2] for a presentation of this algorithm). As usual in such problems $r=r_{n}$ must be a conveniently chosen sequence. First it must converge to 0 as $n \rightarrow \infty$. Moreover this convergence has to be slow enough for the path realizing the estimator to be smooth enough.

To our knowledge, the asymptotic behaviour of such an estimator has not been studied yet. We will show, under quite general assumptions on the support $M$, that choosing $r_{n}=d_{h}\left(X_{n}, M\right)^{2 / 3}$ appears to be convenient (Theorem 1). Assuming that $M$ is a $d^{\prime}$-manifold, $d^{\prime} \leq d$, and assuming some regularity for the distribution $\mathbb{P}_{X}$, it will be shown that $d_{h}\left(X_{n}, M\right)=$ $\mathcal{O}(\ln n / n)^{1 / d^{\prime}}$, allowing to give the convergence rate of our estimator when the dimension $d^{\prime}$ is known (Corollary 1). When $d^{\prime}$ is unknown, and $M$ is supposed to have no boundary, the Corollary 2 presents an estimator of $r_{n}$ which allows to obtain the same convergence rate.

Eventually we will apply these results to the estimation of the Fréchet expectations, as defined in [10], of the distribution $\mathbb{P}_{X}$ on $M$ (Theorem 2).

Using the estimated geodesic distance in place of the euclidean distance has become frequent in different fields of application, in order to take the nonlinearity of the data into account. In [14], the authors propose to apply the multidimensional scaling (see e.g. [6]) to the array of geodesic distances between points. This idea opened the way to the use of the geodesic distance in dimension reduction (see [7], [4], [8], [12] and [9]). In [5], the authors study the question of intrinsic dimension estimation. More precisely, they propose a generalization of the correlation dimension where the euclidean distance is replaced by the (estimated) geodesic distance. This approach has the advantage to be less sensitive to the (difficult) question of the choice of the parameter (see also [13]). In [10], the author rises the question of the generalization of classical statistical quantities (such as the mean and median) to the case of data supported on Riemanian manifolds.

The paper is organized as follows: in Section 2, the general framweork, main definitions and the results are stated. The first subsection presents the results concerning the estimation of the geodesic distance on the support $M$ (Theorem 1 and Corollaries 1 and 2), while the second states the Theorem for the Fréchet expectations estimator (Theorem 2). Section 3 is devoted to
the proofs of the results.

## 2 General framework and Main results

### 2.1 Estimating geodesic distances

Let us first start with the definition of our estimator.
Definition 1. Let $X_{n}=\left\{X_{1}, \ldots X_{n}\right\}$ be a set of $n$ i.i.d. random variables with distribution $\mathbb{P}_{X}$ supported on a compact set $M \subset \mathbb{R}^{d}, d \geq 2$. Let, $r_{n}>0$ being a given number, $\mathcal{G}_{r_{n}}\left(\mathcal{X}_{n}\right)$ be the graph which edges are the segments $\left[X_{i}, X_{j}\right]$ such that $\left\|X_{i}-X_{j}\right\| \leq r_{n}$.

For $(i, j) \in\{1, \ldots, n\}^{2}$, let $\hat{\gamma}_{r_{n}}\left(X_{i}, X_{j}\right)$ be the shortest path (in euclidean norm) connecting $X_{i}$ and $X_{j}$ in $\mathcal{G}_{r_{n}}\left(\mathcal{X}_{n}\right)$, and $\left|\hat{\gamma}_{r_{n}}\left(X_{i}, X_{j}\right)\right|$ its length.

We aim at proving, for a class of convenient compact sets in $\mathbb{R}^{d}$, that $\left|\hat{\gamma}_{r_{n}}\left(X_{i}, X_{j}\right)\right|$ is an estimator of the geodesic distance $\gamma\left(X_{i}, X_{j}\right)$ on $M$, with good convergence properties.

Definition 2. Let $M \subset \mathbb{R}^{d}$ be a compact set, $M$ is told to be $K_{M}$-geodesically smooth (later denoted as GS) for some positive number $K_{M}$ if:
(i) For all $(x, y) \in M^{2}$ there exits a geodesic path $\gamma_{x \rightarrow y}$ of class $\mathcal{C}^{1}$ that links $x$ to $y$;
(ii) Let then $\Gamma_{x \rightarrow y}:\left[0,\left|\gamma_{x \rightarrow y}\right|\right] \rightarrow \mathbb{R}^{d}$ be the parametrization of $\gamma_{x \rightarrow y}$ such that $\Gamma_{x \rightarrow y}(s)$ is the point of $\gamma_{x \rightarrow y}$ that is at a (curvilinear) distance $s$ from $x$. Then, for all $(x, y) \in M^{2}, \dot{\Gamma}_{x \rightarrow y}$ is $K_{M}$-Lipschitz continous.

A compact manifold of class $\mathcal{C}^{2}$ with no boundary satisfies the assumptions of the Definition 2, but one can build more general examples of such sets (that is compact sets with $\mathcal{C}^{1}$ geodesic curves which have $K_{M}$-Lipschitz tangent maps). As an example, the Figure 1 depicts two examples of GS-Sets (sets 1 and 2), and one which is not. Notice that the second set, however satisfying the GS property, is not a manifold.

Theorem 1. Let $\hat{\gamma}_{r_{n}}$ be the estimator introduced in the Definition 1. Assume that there exists a sequence $\rho_{n} \xrightarrow{\text { a.s. }} 0$ such $\rho_{n} \geq d_{h}\left(X_{n}, M\right)$ (e.a.s), and let $\left(r_{n}\right)$ be a sequence such that $\rho_{n} / r_{n} \rightarrow 0$. Then,

$$
\begin{equation*}
\max _{i, j}| | \hat{\gamma}_{r_{n}}\left(X_{i}, X_{j}\right)\left|-\left|\gamma_{X_{i} \rightarrow X_{j}}\right|\right|=\mathcal{O}\left(\max \left(r_{n}, \frac{\rho_{n}^{2}}{r_{n}^{2}}\right)\right) \text { e.a.s. } \tag{1}
\end{equation*}
$$

Figure 1: Two GS sets and one not GS

One would then assume the sequence $r_{n}=d_{h}\left(X_{n}, M\right)^{2 / 3}$ to be an optimal choice. However, even though it is known that $d_{h}\left(X_{n}, M\right) \rightarrow 0$ a.s. (see [3]), the rate of this convergence is unknown in general. Thus, in order to obtain a convergence rate for our estimator, we are going to make extra assumptions on the set $M$ and the random distribution $\mathbb{P}_{X}$.

Definition 3. Let $\delta>0$. A probability measure $\mathbb{P}_{X}$ supported on $M \subset \mathbb{R}^{d}$ is said to be $\delta$-standard with respect to a measure $\mu$ if there exists $\lambda>0$ such that $\mathbb{P}_{X}(\mathcal{B}(x, \varepsilon)) \geq \delta \mu(\mathcal{B}(x, \varepsilon))$ for all $x \in M$ and $\left.\left.\varepsilon \in\right] 0, \lambda\right]$.

We then have the following result:
Corollary 1. Let $M \subset \mathbb{R}^{d}, d \geq 2$ be a $d^{\prime}$-dimensional manifold of class $\mathcal{C}^{1}$ satisfying the GS property for some number $K_{M}>0$. Let $\mathbb{P}_{X}$ be a probability distribution on $M$. Assume, for some number $\delta>0$, that $\mathbb{P}_{X}$ is $\delta$-standard with respect to the measure induced on $M$ by the Lebesgue measure in $\mathbb{R}^{d}$.

If the sequence ( $r_{n}$ ) the Definition 1 is such that

$$
\left(A_{0} \frac{\ln n}{n}\right)^{2 / 3 d^{\prime}} \leq r_{n} \leq\left(A_{1} \frac{\ln n}{n}\right)^{2 / 3 d^{\prime}}
$$

with $A_{0}>0$ and $A_{1}>0$, then

$$
\max _{i, j}| | \hat{\gamma}_{r_{n}}\left(X_{i}, X_{j}\right)\left|-\left|\gamma_{X_{i} \rightarrow X_{j}}\right|\right|=\mathcal{O}\left(\left(\frac{\ln n}{n}\right)^{2 / 3 d^{\prime}}\right) \text { e.a.s. }
$$

As usual when dealing with estimation problems, the sequence of radii $\left(r_{n}\right)$ in the previous theorem remains abstract. In particular the dimension $d^{\prime}$ of the support is generally unknown. However, making extra assumptions on the support $M$ and the density of the distribution, we can accurately estimate the sequence of radii, with no need for estimating $d^{\prime}$. This last fact is indeed worth being stretched on, since the knowledge of the geodesic distance is known to be useful for a good estimation of the dimension of a manifold (see e.g. [5]).

Corollary 2. Let $M \in \mathbb{R}^{d}$, $d \geq 2$ be a $d^{\prime}$-dimensional manifold, $d^{\prime}<d$ of class $\mathcal{C}^{2}$ with no boundary and $\mathbb{P}_{X}$ be a probability distribution on $M$ with continuous probability density $f_{X} \geq f_{0}>0$. Then, for any $c>0$, setting $r_{n}=\left(c \max _{i}\left(\min _{j}\left\|X_{i}-X_{j}\right\|\right)\right)^{2 / 3}$ in the Definition 1, we have

$$
\max _{i, j}| | \hat{\gamma}_{r_{n}}\left(X_{i}, X_{j}\right)\left|-\left|\gamma_{X_{i} \rightarrow X_{j}}\right|\right|=\mathcal{O}\left(\left(\frac{\ln n}{n}\right)^{2 / 3 d^{\prime}}\right) \text { e.a.s. }
$$

The assumptions of this Corollary imply those of the Theorem 1 ; they allow to explicitly build a convenient sequence of radii $\left(r_{n}\right)$ only from the sample. To prove this Theorem we use a result by Penrose (see [11]) which applies only in the case when $M$ has no boundary. However, numerical simulations on $\mathcal{C}^{2}$ sets with boundary, satisfying the GS assumption, lead us to think that the result is also true for such sets.

### 2.2 Estimating Fréchet Expectations

In this section we assume the set $M$ to be a a compact $d^{\prime}$-manifold of class $\mathcal{C}^{2}$. Following the ideas of X. Pennec (see [10]), we consider the Fréchet expectations

$$
\begin{equation*}
\mathbb{E}_{k}^{\mathrm{Fr}}(X)=\operatorname{argmin}_{x \in M} \mathbb{E}\left(\left|\gamma_{x \rightarrow X}\right|^{k}\right), \quad k \in \mathbb{N}^{*}, \tag{2}
\end{equation*}
$$

which are generalizations of the expected value for $k=2$ and of the median (or depth) for $k=1$. As it is pointed out in [10], these expectations are not necessarily unique. For exemple, if $M$ is a sphere and $\mathbb{P}_{X}$ the uniform distribution, then obviously all the points of $M$ realize the minimum in (2) (for any $k \geq 1$ ).

To avoid dealing with such situations, we are going to make the following assumption, considering that $k$ is fixed:

$$
\left\{\begin{array}{l}
\Phi(x)=\mathbb{E}\left(\left|\gamma_{x \rightarrow X}\right|^{k}\right) \text { admits a unique minimum } x^{*} \in M,  \tag{3}\\
\Phi \text { is of class } \mathcal{C}^{2} \text { in a neighbourhood of } x^{*}, \\
H_{\Phi}\left(x^{*}\right) \text { is positive definite },
\end{array}\right.
$$

where $H_{\Phi}$ denotes the hessian matrix of $\Phi$.

Remark: It must be noted that $\Phi$ is a continuous fonction on $M$. Indeed the triangle and Minkowski inequalities give $\left|\Phi(x)^{1 / k}-\Phi(y)^{1 / k}\right| \leq\left|\gamma_{x \rightarrow y}\right|$, for any $(x, y) \in M^{2}$. The extra (local) regularity in the conditions (3) is required for the sake of simplicity, allowing to apply basic differential calculus results at the optimal point $x^{*}$.

The first part of this assumption is very strong, but the second part is not. For example, when $d^{\prime}=1$ and $M$ is homeomorphic to a segment, explicit computations show that (3) holds for $k=1$ iff $f_{X}\left(x^{*}\right) \neq 0$. For $k=2$, when $M$ is a bounded closed convex set of dimension $d$, the geodesic distance on $M$ coincides with the euclidean distance, the expectation $\mathbb{E}(X)$ lies in $M$, it minimises the function $\Phi(x)$ and the condition (3) is satisfied (with $H_{\Phi} \equiv 2 I_{d}$ ). This leads to think that, for $k=2$, this condition is general enough and may hold for a wide class of regular submanifolds of $\mathbb{R}^{d}$.

In this section we aim at studying the behaviour of the natural estimator of $\mathbb{E}_{k}^{\mathrm{Fr}}(X)$ :

$$
\begin{equation*}
\hat{\mathbb{E}}_{k, r_{n}}^{\mathrm{Fr}}\left(X_{n}\right)=\operatorname{argmin}_{X_{i} \in M} \frac{1}{n} \sum_{j}\left|\hat{\gamma}_{r_{n}}\left(X_{i}, X_{j}\right)\right|^{k} \tag{4}
\end{equation*}
$$

Theorem 2. Assume that $M \subset \mathbb{R}^{d}, d \geq 2$ is a $d^{\prime}$-dimensional manifold, $d^{\prime}<d$ of class $\mathcal{C}^{2}$ with no boundary and that $\mathbb{P}_{X}$ is a probability distribution on $M$ with continuous and bounded from below probability density $f_{X}$. Moreover, suppose that assumption (3) holds. Then, chosing $r_{n}=$ $c\left(\max _{i}\left(\min _{j}\left\|X_{i}-X_{j}\right\|\right)\right)^{2 / 3}$ in the definition of $\hat{\gamma}_{r_{n}}$, we have

$$
\left|\mathbb{E}_{k}^{F r}(X)-\hat{\mathbb{E}}_{k, r_{n}}^{F r}\left(X_{n}\right)\right|=\mathcal{O}\left(\left(\frac{\ln n}{n}\right)^{\min \left(1 / 4,1 / 3 d^{\prime}\right)}\right) \text { e.a.s. }
$$

## 3 Proofs of the results

Let us start with a result which is a direct consequence of the regularity of the set considered here.
Proposition 1. If $M \subset \mathbb{R}^{d}$ is $K_{M}$-geodesically smooth then, there exist $r_{M}>0$ and $A_{M}>0$, depending only on $M$, such that

$$
\forall(x, y) \in M^{2} ;\|x-y\| \leq r_{M}, \quad\left|\gamma_{x \rightarrow y}\right| \leq\|x-y\|+A_{M}\|x-y\|^{2} .
$$

The proof of this result is simple and left to the reader.

### 3.1 Proof of Theorem 1

Let $(i, j) \in\{1, \ldots n\}^{2}, i \neq j$, and let $\gamma_{i j}$ be the geodesic curve between $X_{i}$ and $X_{j}$. Consider a partition $\left\{x_{0}, \ldots, x_{K}\right\}$ of $\gamma_{i j}$ such that

$$
\begin{align*}
& x_{0}=X_{i}, x_{K}=X_{j},  \tag{5}\\
& K=\left[\left.\frac{\left|\gamma_{X_{i} \rightarrow X_{j}}\right|}{r_{n}-2 \rho_{n}} \right\rvert\,,\right.  \tag{6}\\
& \left|\gamma_{x_{k} \rightarrow x_{k+1}}\right|=\frac{\left|\gamma_{X_{i} \rightarrow X_{j}}\right|}{K}, \tag{7}
\end{align*}
$$

so that

$$
\begin{align*}
& \left|\gamma_{x_{k} \rightarrow x_{k+1}}\right|=r_{n}-2 \rho_{n}, \quad k=0, \ldots K-2,  \tag{8}\\
& \left|\gamma_{x_{K-1} \rightarrow x_{K}}\right|<r_{n}-2 \rho_{n} .
\end{align*}
$$

We have

$$
\begin{equation*}
\left|\gamma_{X_{i} \rightarrow X_{j}}\right|=\sum_{k=0}^{K-1} \gamma_{x_{k} \rightarrow x_{k+1}} \geq \sum_{k=0}^{K-1}\left\|x_{k}-x_{k+1}\right\| . \tag{9}
\end{equation*}
$$

From the definition of $\rho_{n}$, for any $k \in\{0, \ldots, K\}$, there exists $i_{k} \in\{1, \ldots n\}$ such that $\left\|X_{i_{k}}-x_{k}\right\| \leq \rho_{n}$. Let us denote, for the sake of simplicity,

$$
Y_{k}=X_{i_{k}}, \quad \varepsilon_{k}=Y_{k}-x_{k}, \quad U_{k}=\frac{x_{k}-x_{k+1}}{\left\|x_{k}-x_{k+1}\right\|} .
$$

Recall that

$$
\begin{equation*}
\left\|\varepsilon_{k}\right\| \leq \rho_{n}, k=0 \ldots K-1 \tag{10}
\end{equation*}
$$

We have,

$$
\left\|Y_{K-1}-Y_{K}\right\|=\left\|\left(x_{K-1}-x_{K}\right)-\left(\varepsilon_{K-1}-\varepsilon_{K}\right)\right\|,
$$

hence, applying the triangle inequality and in view of the Proposition 1 and (10),

$$
\begin{equation*}
\left\|Y_{K-1}-Y_{K}\right\| \leq r_{n} \tag{11}
\end{equation*}
$$

Now, for $k \in\{0, \ldots, K-2\}$,

$$
\begin{aligned}
\left\|Y_{k}-Y_{k+1}\right\|^{2} & =\left\|\varepsilon_{k}+\left(x_{k}-x_{k+1}\right)-\varepsilon_{k+1}\right\|^{2} \\
& =\left\|x_{k}-x_{k+1}\right\|^{2}+2\left\langle x_{k}-x_{k+1} \mid \varepsilon_{k}-\varepsilon_{k+1}\right\rangle+\left\|\varepsilon_{k}-\varepsilon_{k+1}\right\|^{2} \\
& =\left\|x_{k}-x_{k+1}\right\|^{2} \times\left(1+2 \frac{\left\langle U_{k} \mid \varepsilon_{k}-\varepsilon_{k+1}\right\rangle}{\left\|x_{k}-x_{k+1}\right\|}+\frac{\left\|\varepsilon_{k}-\varepsilon_{k+1}\right\|^{2}}{\left\|x_{k}-x_{k+1}\right\|^{2}}\right),
\end{aligned}
$$

that is, taking the square root of this equality, and noticing that $\sqrt{1+t} \leq$ $1+t / 2, t \geq-1$,

$$
\begin{aligned}
\left\|Y_{k}-Y_{k+1}\right\| & \leq\left\|x_{k}-x_{k+1}\right\| \times\left(1+\frac{\left\langle U_{k} \mid \varepsilon_{k}-\varepsilon_{k+1}\right\rangle}{\left\|x_{k}-x_{k+1}\right\|}+\frac{1}{2} \frac{\left\|\varepsilon_{k}-\varepsilon_{k+1}\right\|^{2}}{\left\|x_{k}-x_{k+1}\right\|^{2}}\right) \\
& \leq\left\|x_{k}-x_{k+1}\right\|+\left\langle U_{k} \mid \varepsilon_{k}-\varepsilon_{k+1}\right\rangle+\frac{1}{2} \frac{\left\|\varepsilon_{k}-\varepsilon_{k+1}\right\|^{2}}{\left\|x_{k}-x_{k+1}\right\|} .
\end{aligned}
$$

In view of (9), we thus have

$$
\begin{equation*}
\left|\gamma_{X_{i} \rightarrow X_{j}}\right| \geq \sum_{k=0}^{K-2}\left\|Y_{k}-Y_{k+1}\right\|-\frac{1}{2} S_{1}-S_{2}, \tag{12}
\end{equation*}
$$

with

$$
\begin{equation*}
S_{1}=\sum_{k=0}^{K-2} \frac{\left\|\varepsilon_{k}-\varepsilon_{k+1}\right\|^{2}}{\left\|x_{k}-x_{k+1}\right\|}, \quad S_{2}=\sum_{k=0}^{K-2}\left\langle U_{k} \mid \varepsilon_{k}-\varepsilon_{k+1}\right\rangle . \tag{13}
\end{equation*}
$$

Let us first study $S_{1}$. From (8) and the Proposition 1, we have, for $k \in\{0, \ldots, K-2\}$,

$$
\begin{equation*}
r_{n}-2 \rho_{n}-A_{M}\left(r_{n}-2 \rho_{n}\right)^{2} \leq\left\|x_{k}-x_{k+1}\right\| \leq r_{n}-2 \rho_{n} \leq r_{n}, \tag{14}
\end{equation*}
$$

with $A_{M}>0$ only depending on $M$.
Then,

$$
\frac{\left\|\varepsilon_{k}-\varepsilon_{k+1}\right\|^{2}}{\left\|x_{k}-x_{k+1}\right\|} \leq \frac{4 \rho_{n}^{2}}{r_{n}-2 \rho_{n}-A_{M}\left(r_{n}-2 \rho_{n}\right)^{2}} \leq \frac{4 \rho_{n}^{2}}{r_{n}}+o\left(\frac{\rho_{n}^{2}}{r_{n}}\right), \quad 0 \leq k \leq K-2
$$

The definition of $\rho_{n}$ implies that $r_{n}-2 \rho_{n} \sim r_{n}$. Moreover, since the set $M$ is compact and satisfies the GS assumption, $\gamma_{X_{i} \rightarrow X_{j}}$ is uniformly bounded for all $(i, j) \in\{1, \ldots n\}^{2}$. Hence, there exists $L_{M}>0$ such that

$$
\begin{equation*}
0<K \leq \frac{L_{M}}{r_{n}} \tag{15}
\end{equation*}
$$

where $K$ is defined by (6), and we have

$$
\begin{equation*}
S_{1} \leq L_{M}\left(\frac{4 \rho_{n}^{2}}{r_{n}^{2}}+o\left(\frac{\rho_{n}^{2}}{r_{n}^{2}}\right)\right) . \tag{16}
\end{equation*}
$$

Now, since the set $M$ is smooth we can write, for $k \in\{0, \ldots, K-2\}$,

$$
U_{k}=\dot{\Gamma}_{x_{0} \rightarrow x_{k}}\left(k\left(r_{n}-2 \rho_{n}\right)\right)+\mathcal{O}\left(\left\|x_{k}-x_{k+1}\right\|\right)=\dot{\Gamma}_{x_{0} \rightarrow x_{k}}\left(k\left(r_{n}-2 \rho_{n}\right)\right)+\mathcal{O}\left(r_{n}\right),
$$

and

$$
U_{k}-U_{k+1}=\dot{\Gamma}_{x_{0} \rightarrow x_{k}}\left(k\left(r_{n}-2 \rho_{n}\right)\right)-\dot{\Gamma}_{x_{0} \rightarrow x_{k}}\left((k+1)\left(r_{n}-2 \rho_{n}\right)\right)+\mathcal{O}\left(r_{n}\right) .
$$

Then, $\dot{\Gamma}$ being Lipschitz continuous,

$$
\begin{equation*}
\left\|U_{k}-U_{k+1}\right\|=\mathcal{O}\left(r_{n}\right) \tag{17}
\end{equation*}
$$

We can now rewrite $S_{2}$ as

$$
S_{2}=\sum_{k=1}^{K-2}\left\langle U_{k}-U_{k-1} \mid \varepsilon_{k}\right\rangle+\left\langle U_{0} \mid \varepsilon_{0}\right\rangle-\left\langle U_{K-2} \mid \varepsilon_{K-1}\right\rangle,
$$

hence, in view of (10), (14), (15), we have

$$
S_{2}=\mathcal{O}\left(\rho_{n}\right)
$$

Combining this last inequality with (12),(13),(16), and in wiew of (11), we obtain

$$
\begin{equation*}
\left|\gamma_{X_{i} \rightarrow X_{j}}\right| \geq \sum_{k=0}^{K-1}\left\|Y_{k}-Y_{k+1}\right\|-r_{n}-\mathcal{O}\left(\rho_{n}\right)-2 L_{M} \frac{\rho_{n}^{2}}{r_{n}^{2}}+o\left(\frac{\rho_{n}^{2}}{r_{n}^{2}}\right) . \tag{18}
\end{equation*}
$$

Now, considering (10) , (11), (14) and applying the triangle inequality, we deduce that $\left\|Y_{k}-Y_{k+1}\right\| \leq r_{n}$ for all $k$. Hence, in view of the definition 1 , we have

$$
\left|\widehat{\gamma}_{r_{n}}\left(X_{i}, X_{j}\right)\right| \leq \sum_{k=0}^{K-1}\left\|Y_{k}-Y_{k+1}\right\|,
$$

therefore, since $\rho_{n}=o\left(r_{n}\right)$ and in wiew of (18), we have

$$
\begin{equation*}
\left|\widehat{\gamma}_{r_{n}}\left(X_{i}, X_{j}\right)\right| \leq\left|\gamma_{X_{i} \rightarrow X_{j}}\right|+r_{n}+o\left(r_{n}\right)+2 L_{M} \frac{\rho_{n}^{2}}{r_{n}^{2}}+o\left(\frac{\rho_{n}^{2}}{r_{n}^{2}}\right) . \tag{19}
\end{equation*}
$$

We are now going to prove the following inequality :

$$
\begin{equation*}
\left|\widehat{\gamma}_{r_{n}}\left(X_{i}, X_{j}\right)\right| \geq\left|\gamma_{X_{i} \rightarrow X_{j}}\right|-2 A_{M} L_{M} r_{n} . \tag{20}
\end{equation*}
$$

For the sake of clarity, let us omit the superscripts in the definition 1 and denote $Z_{0}=X_{i}, Z_{1}, \ldots Z_{L_{1}}, Z_{L}=X_{j}$ the nodes of the graph $\mathcal{G}_{n}^{i, j}$ realizing the path $\widehat{\gamma}_{r_{n}}\left(X_{i}, X_{j}\right)$. Proposition 1 yields

$$
\left|\gamma_{X_{i} \rightarrow X_{j}}\right| \leq \sum_{k=0}^{L-1}\left|\gamma_{Z_{k} \rightarrow Z_{k+1}}\right| \leq \sum_{k=0}^{L-1}\left(\left\|Z_{k}-Z_{k+1}\right\|+A_{M}\left\|Z_{k}-Z_{k+1}\right\|^{2}\right)
$$

Noticing, from Definition 1, that $\left\|Z_{k}-Z_{k+1}\right\| \leq r_{n}$, we obtain

$$
\begin{equation*}
\left|\widehat{\gamma}_{r_{n}}\left(X_{i}, X_{j}\right)\right| \geq\left|\gamma_{X_{i} \rightarrow X_{j}}\right|-A_{M} L r_{n}^{2} . \tag{21}
\end{equation*}
$$

Let us now obtain a bound for the number of nodes $L$ in the path $\widehat{\gamma}_{r_{n}}\left(X_{i}, X_{j}\right)$. Necessarily, by construction, we have

$$
\begin{equation*}
\left\|Z_{k}-Z_{k+1}\right\|+\left\|Z_{k+1}-Z_{k+2}\right\|>r_{n}, \quad k=0, \ldots, L-2 \tag{22}
\end{equation*}
$$

Indeed, if it was not the case, we would have $\left\|Z_{k}-Z_{k+2}\right\| \leq r_{n}$, hence the path $\left\{Z_{k}, Z_{k+2}\right\}$ would be shorter in the graph $\mathcal{G}_{n}^{i, j}$ than the path $\left\{Z_{k}, Z_{k+1}, Z_{k+2}\right\}$
which is impossible. Therefore, summing up (22) for $k \in\{0, \ldots L-2\}$, we obtain

$$
L r_{n}^{2} \leq 2\left|\widehat{\gamma}_{r_{n}}\left(X_{i}, X_{j}\right)\right|+r_{n}^{2}
$$

hence, in view of (19), (21) and reminding that $\left|\gamma_{X_{i} \rightarrow X_{j}}\right|$ is uniformly bounded, we get (20).

This inequality and (19) finally imply

$$
\begin{equation*}
\left|\left|\widehat{\gamma}_{r_{n}}\left(X_{i}, X_{j}\right)\right|-\left|\gamma_{X_{i} \rightarrow X_{j}}\right|\right| \leq C_{M} \max \left(\frac{\rho_{n}^{2}}{r_{n}^{2}}, r_{n}\right), \tag{23}
\end{equation*}
$$

where the constant $C_{M}>0$ only depends on the manifold $M$. This yields the estimate (1) and concludes the proof.

### 3.2 Proof of Corollary 1

Reasoning as in [1], since $M$ is of class $\mathcal{C}^{1}$, one can cover $M$ with $\nu_{n} \leq C n$ (with $C>0$ ) deterministic balls of radius $\varepsilon_{n}=(1 / n)^{1 / d^{\prime}}$. Let $\omega_{d^{\prime}}$ be the volume of the $d^{\prime}$ - dimensional unit ball. We then classically have

$$
\mathbb{P}_{X}\left(d_{h}\left(\mathcal{X}_{n}, M\right) \geq\left(\frac{2 \lambda}{\delta \omega_{d^{\prime}}} \frac{\ln n}{n}\right)^{1 / d^{\prime}}\right) \leq C n^{1-2 \lambda+o(1)}
$$

for any $\lambda>0$.
Applying the Borel-Cantelli Lemma, we deduce that, for any $\lambda>1$,

$$
d_{h}\left(X_{n}, M\right) \leq\left(\frac{2 \lambda}{\delta \omega_{d^{\prime}}} \frac{\ln n}{n}\right)^{1 / d^{\prime}} \quad \text { e.a.s. }
$$

Applying the Theorem 1 then gives the result.

### 3.3 Proof of Corollary 2

Let

$$
t_{n}=\max _{i}\left(\min _{j}\left\|X_{i}-X_{j}\right\|\right)
$$

Applying the result of M.D. Penrose in [11], we have

$$
\frac{n \omega_{d^{\prime}} t_{n}^{d^{\prime}}}{\ln n} \xrightarrow{\text { a.s. }} f_{0}^{-1} .
$$

Therefore, one can easily deduce that

$$
\left(\frac{1}{2 f_{0} \omega_{d^{\prime}}} \frac{\ln n}{n}\right)^{1 / d^{\prime}} \leq t_{n} \leq\left(\frac{2}{f_{0} \omega_{d^{\prime}}} \frac{\ln n}{n}\right)^{1 / d^{\prime}} \quad \text { e.a.s. }
$$

Since we have $r_{n}=\left(c t_{n}\right)^{2 / 3}$, the assumptions of the Corollary 1 are fulfilled, which allows to conclude the proof.

### 3.4 Proof of Theorem 2

In view of (3) and (4), let us introduce the following estimators :

$$
\begin{align*}
& \bar{\Phi}(x)=\frac{1}{n} \sum_{i}\left(\left|\gamma_{x \rightarrow X_{i}}\right|^{k}\right), \\
& \hat{\Phi}(x)=\frac{1}{n} \sum_{i}\left(\left|\hat{\gamma}_{r_{n}}\left(x, X_{i}\right)\right|^{k}\right) . \tag{24}
\end{align*}
$$

At first, let us prove that there exits a deterministic constant $D>0$ such that

$$
\begin{equation*}
\max _{i}\left|\hat{\Phi}\left(X_{i}\right)-\Phi\left(X_{i}\right)\right|=D\left(\frac{\ln n}{n}\right)^{\min \left\{2 / 3 d^{\prime}, 1 / 2\right\}} \text { e.a.s } \tag{25}
\end{equation*}
$$

Indeed, the manifold $M$ being compact, one can apply the Hoeffding inequality and obtain that

$$
\forall x \in M, \quad \mathbb{P}_{X}\left(|\bar{\Phi}(x)-\Phi(x)| \geq \varepsilon_{n}\right) \leq 2 \exp \left(-2 n \varepsilon_{n}^{2} / L^{2 k}\right)
$$

$L>0$ being the constant introduced in the proof of Theorem 1. Hence,

$$
\mathbb{P}_{X}\left(\exists i \in\{1, \ldots, n\} ;\left|\bar{\Phi}\left(X_{i}\right)-\Phi\left(X_{i}\right)\right| \geq \varepsilon_{n}\right) \leq 2 n \exp \left(-2 n \varepsilon_{n}^{2} / L^{2 k}\right)
$$

Setting $\varepsilon_{n}=\sqrt{2} L^{k} \sqrt{\ln n / n}$ in this last inequality yields

$$
\mathbb{P}_{X}\left(\max _{i}\left|\bar{\Phi}\left(X_{i}\right)-\Phi\left(X_{i}\right)\right| \geq \varepsilon_{n}\right) \leq 2 n^{-3}
$$

so that the Borel-Cantelli Lemma allows to conclude that

$$
\begin{equation*}
\max _{i}\left|\bar{\Phi}\left(X_{i}\right)-\Phi\left(X_{i}\right)\right|=\mathcal{O}\left(\frac{\ln n}{n}\right)^{1 / 2} \text { e.a.s. } \tag{26}
\end{equation*}
$$

Now, noticing that the assumptions of Corollary 2 are fulfilled, we have

$$
\max _{i}\left|\hat{\Phi}\left(X_{i}\right)-\bar{\Phi}\left(X_{i}\right)\right|=\mathcal{O}\left(\frac{\ln n}{n}\right)^{2 / 3 d^{\prime}} \text { e.a.s. }
$$

Combining this with (26), we obtain (25).
Next, $\Phi$ being continuous on the compact set $M$, and in view of assumptions (3), the gradient of $\Phi$ vanishes at the (unique) minimum point $x^{*}$, hence there exist $r_{0}>0, c_{0}>0, c_{1}>0$ and $\varepsilon_{0}$ such that

$$
\begin{align*}
& \forall x \in M \cap B^{c}, \Phi(x) \geq \Phi\left(x^{*}\right)+\varepsilon_{0},  \tag{27}\\
& \forall x \in M \cap \bar{B}, c_{0}\left\|x-x^{*}\right\|^{2} \leq \Phi(x)-\Phi\left(x^{*}\right) \leq c_{1}\left\|x-x^{*}\right\|^{2}, \tag{28}
\end{align*}
$$

where $B=\mathcal{B}\left(x^{*}, r_{0}\right)$ is the open ball in $\mathbb{R}^{d}$ of center $x^{*}$ and radius $r_{0}$. The second inequality holds due to the positiveness of the Hessian matrix $H_{\Phi}\left(x^{*}\right)$.

Now, since the assumptions of Corollary 2 are satisfied, there exists $C>0$ such that $d_{h}\left(X_{n}, M\right) \leq C(\ln n / n)^{1 / d^{\prime}}$. Thus, e.a.s.

$$
\exists i_{0} \in\{1, \ldots, n\} ;\left\|X_{i_{0}}-x^{*}\right\| \leq C\left(\frac{\ln n}{n}\right)^{1 / d^{\prime}}
$$

For $n$ large enough, we have $r_{0}>C(\ln n / n)^{1 / d^{\prime}}$, hence, in view of (28), $X_{i_{0}}$ satisfies

$$
\Phi\left(X_{i_{0}}\right) \leq \Phi\left(x^{*}\right)+c_{1} C^{2}\left(\frac{\ln n}{n}\right)^{2 / d^{\prime}}
$$

and by (25):

$$
\hat{\Phi}\left(X_{i_{0}}\right) \leq \Phi\left(x^{*}\right)+c_{1} C^{2}\left(\frac{\ln n}{n}\right)^{2 / d^{\prime}}+D\left(\frac{\ln n}{n}\right)^{2 \alpha}
$$

with

$$
\alpha=\min \left\{\frac{1}{3 d^{\prime}}, \frac{1}{4}\right\},
$$

that is, for $n$ large enough, we have

$$
\begin{equation*}
\exists i_{0} \in\{1, \ldots, n\}, \quad \hat{\Phi}\left(X_{i_{0}}\right) \leq \Phi\left(x^{*}\right)+2 D\left(\frac{\ln n}{n}\right)^{2 \alpha} \tag{29}
\end{equation*}
$$

Assume now that $n$ is large enough so that that $\varepsilon_{0}>4 D(\ln n / n)^{2 \alpha}$. For any $i \in\{1, \ldots, n\}$ such that

$$
\left\|X_{i}-x^{*}\right\| \geq \frac{2 D}{\sqrt{c_{0}}}\left(\frac{\ln n}{n}\right)^{\alpha}
$$

in view of (27) and (28), this point satisfies

$$
\Phi\left(X_{i}\right) \geq \Phi\left(x^{*}\right)+4 D\left(\frac{\ln n}{n}\right)^{2 \alpha}
$$

Thus, in view of (25), we have

$$
\begin{equation*}
\left\|X_{i}-x^{*}\right\| \geq \frac{2 D}{\sqrt{c_{0}}}\left(\frac{\ln n}{n}\right)^{\alpha} \Rightarrow \hat{\Phi}\left(X_{i}\right) \geq \Phi\left(x^{*}\right)+3 D\left(\frac{\ln n}{n}\right)^{2 \alpha} \tag{30}
\end{equation*}
$$

Finally, let $i^{*} \in\{1, \ldots, n\}$ such that $X_{i^{*}}$ realizes the minimum (4). From (24) and (29), it is clear that

$$
\hat{\Phi}\left(X_{i^{*}}\right) \leq \Phi\left(x^{*}\right)+2 D\left(\frac{\ln n}{n}\right)^{2 \alpha}
$$

and (30) allows to conclude the proof.
