HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

NOTES ON RANDOM WALKS IN THE CAUCHY DOMAIN OF ATTRACTION

QUENTIN BERGER

ABSTRACT. The goal of these notes is to fill some gaps in the literature about random walks in the Cauchy domain of attraction, which has often been left aside because of its additional technical difficulties. We prove here several results in that case: a Fuk-Nagaev inequality and a local version of it; a large deviation theorem; two types of local large deviation theorems. We also derive two important applications of these results: a sharp estimate of the tail of the first ladder epochs, and renewal theorems. Most of our techniques carry through to the case of random walks in the domain of attraction of an α -stable law with $\alpha \in (0, 2)$, so we also present results in that case—some of them are improvement of the existing literature.

Keywords: Random Walk, Cauchy Domain of Attraction, Stable Distribution, Local Large Deviations, Ladder Epochs, Renewal Theorem, Fuk-Nagaev Inequalities.

1. INTRODUCTION

This paper initiated when, consulting some colleagues about random walks in the Cauchy domain of attraction, they all shared the same observation that this case was often left aside in the literature, and that many very natural results were not proven (to the best of our knowledge). These notes therefore aim at filling as many gaps as possible.

1.1. Setting and first notations. Let $(X_i)_{i \geq 1}$ be a sequence of i.i.d. \mathbb{Z} -valued random variables. We denote $S_n := \sum_{i=1}^n X_i$, and $M_n := \max_{1 \leq i \leq n} \{X_i\}$. We assume that $(S_n)_{n \geq 0}$ is in the domain of attraction of an α -stable distribution, with $\alpha \in (0, 2)$. We will put emphasis on the case $\alpha = 1$, but we introduce notations in the general case.

We assume that there is some $\alpha \in (0, 2)$ and some slowly varying function $L(\cdot)$, such that as $x \rightarrow +\infty$, $\mathbf{P}(|X_1| > x) \sim L(x)x^{-\alpha}$ and

$$\mathbf{P}(X_1 > x) \sim pL(x)x^{-\alpha}, \quad \mathbf{P}(X_1 < -x) \sim qL(x)x^{-\alpha}, \quad (1.1)$$

with $p + q = 1$. If $p = 0$ (or $q = 0$), then we interpret (1.1) as $o(L(x)x^{-\alpha})$. We stress that the condition (1.1) is equivalent to $(S_n)_{n \geq 0}$ being in the domain of attraction of an α -stable distribution (see [14, IX.8, Eq. (8.14)])

We define a_n the scaling sequence, characterized up to asymptotic equivalence by the following relation ($\alpha \in (0, 2)$)

$$L(a_n)(a_n)^{-\alpha} \sim \frac{1}{n} \quad \text{as } n \rightarrow \infty. \quad (1.2)$$

We also define the centering sequence, that we denote b_n . We set $\mu := \mathbf{E}[X_1]$ if X_1 is integrable (if X_1 is not integrable we abbreviate it as $|\mu| = +\infty$), and we let

$$\begin{aligned} b_n &\equiv 0 & \text{if } \alpha \in (0, 1); & & b_n &= n\mu & \text{if } \alpha > 1; \\ b_n &= n\mu(a_n) & \text{with } \mu(x) = \mathbf{E}[X_1 \mathbf{1}_{\{|X_1| \leq x\}}] & & & \text{if } \alpha = 1. \end{aligned} \quad (1.3)$$

We then have that $(S_n - b_n)/a_n$ converges in distribution to a non-trivial α -stable distribution, see e.g. [14, IX.8] (in particular p. 315 (8.15) for the centering). We denote $g(\cdot)$ the density of the

limiting distribution, which is continuous and bounded. Under these assumptions, Gnedenko's local limit theorem gives (see e.g. [17, Ch. 9, §50]):

$$\sup_{x \in \mathbb{Z}^d} \left| a_n \mathbf{P}(S_n = x) - g\left(\frac{x - b_n}{a_n}\right) \right| \xrightarrow{n \rightarrow +\infty} 0. \quad (1.4)$$

This is sharp in the range when $|x - b_n|$ is of order a_n , but does not give much information when $|x - b_n|/a_n \rightarrow +\infty$: one aim of our paper is to provide large and local large deviations estimates, in particular in the case $\alpha = 1$ which was left aside in many cases.

1.2. Organization of the paper and outline of the results. Let us now present a brief overview of the paper.

In Section 2, we present large and local large deviation results. First, our Theorem 2.1 gives a standard large deviation estimate which seemed to be missing in the case $\alpha = 1$ in full generality. We provide a Fuk-Nagaev inequality and a local version of it (Theorem 2.2), which is a cornerstone of our paper. We derive a local large deviation Theorem 2.3 that extends Caravenna and Doney's result [6, Thm. 1.1] to the case $\alpha = 1$. Furthermore, with an additional locality assumption on the distribution of X_1 , we provide an improved local large deviation Theorem 2.4, extending that of Doney [12, Thm. A] to the case $\alpha \in [1, 2)$.

In Section 3, we give applications of these results. First, we consider the first descending ladder epoch $T_- = \inf\{n; S_n < 0\}$, and give a sharp asymptotic of $\mathbf{P}(T_- > n)$ in the case $\alpha = 1$ with infinite mean (Theorem 3.2). We also treat the finite mean case (Theorem 3.3, done in [11] for $\alpha \neq 1$). Some subtleties arise in the case $\alpha = 1$ with $\mu = 0$, that we collect in Theorem 3.4. Second, we consider renewal theorems for transient random walks: in the case $\alpha = 1$, we give sufficient conditions for the random walk to be transient, and we give the asymptotics of the Green function $G(x) = \sum_{n=0}^{+\infty} \mathbf{P}(S_n = x)$ as $x \rightarrow +\infty$, see Theorem 3.5 in the ‘‘centered’’ case $p = q$ and Theorem 3.6 in the infinite mean case with $p \neq q$. We also present the result in the case of finite non-zero mean (Theorem 3.7).

In Section 4, we develop further on the case $\alpha = 1$. In particular, we discuss the question of the transience/recurrence of the random walk when $|\mu| = +\infty$: this is actually quite subtle, since the random walk, even if it may go to $+\infty$ or $-\infty$ in probability, is shown not to drift to $+\infty$ or $-\infty$ (at least when $p, q \neq 0$, see Proposition 3.1). We give sufficient conditions for the random walk to be transient in the ‘‘centered’’ case $p = q$ (Proposition 4.1) or in the case $p \neq q$ (Proposition 4.2). We also provide useful estimates on slowly varying functions (more precisely de Haan functions) related to the case $\alpha = 1$.

All the proofs are collected in Sections 5-6-7-8. In Section 5 we state and prove Fuk-Nagaev inequalities, which are the central tool for proving the large and local large deviation estimates, that are derived in Section 6. In Section 7, we focus on the ladder epochs theorems in the case $\alpha = 1$ with $|\mu| = +\infty$ (and then adapt the proof to the case $\mu = 0$). In Section 8, we prove the renewal theorems, first in the case $\alpha = 1$ with infinite mean, and then in the finite mean case.

Remark 1.1. *Let us mention that the assumption that $X_1 \in \mathbb{Z}$ is not essential, but is used for the sake of the presentation (mostly for statements of local results such as (1.4)). For instance, if X_1 is non-lattice (i.e. if it is not supported by some lattice $a + b\mathbb{Z}$), then (1.4) is replaced by Stone's local limit theorem [22]: for any $h > 0$*

$$\sup_{x \in \mathbb{Z}^d} \left| \frac{a_n}{h} \mathbf{P}(S_n \in [x, x + h)) - g\left(\frac{x - b_n}{a_n}\right) \right| \xrightarrow{n \rightarrow +\infty} 0. \quad (1.5)$$

All the rest of the paper can therefore easily be adapted to the case of a non-lattice distribution, using (1.5) in place of (1.4)—the only results needing some adaptations are local results, for instance Theorem 2.2-(2.2), Theorems 2.3-2.4 or Theorems 3.5-3.6-3.7.

2. LARGE AND LOCAL LARGE DEVIATIONS

Let us begin by stating a large deviation theorem which is standard when $\alpha \neq 1$ (see [20] and references therein, also [8]), but appears to be missing in the case $\alpha = 1$.

Theorem 2.1. *Assume that (1.1) holds with $\alpha \in (0, 2)$, and define a_n as in (1.2) and b_n as in (1.3). Then,*

$$\begin{aligned} \mathbf{P}(S_n - b_n > x) &\sim npL(x)x^{-\alpha}, & \text{as } x/a_n \rightarrow +\infty, \\ \mathbf{P}(S_n - b_n < -x) &\sim nqL(x)x^{-\alpha}, & \text{as } x/a_n \rightarrow +\infty. \end{aligned}$$

(If $p = 0$ or $q = 0$, one interpret this as $o(nL(x)x^{-\alpha})$.)

This result asserts that the large deviation is realized by a so-called *one-jump* strategy (see [9] for a general setting). For the case $\alpha = 1$, [20] or [9] appear to be giving the correct behavior only when the step distribution is sufficiently centered, that is $\sup_n |b_n|/a_n < +\infty$ (see condition (27) in [9]), or when $x \geq \delta b_n$ for some $\delta > 0$. The contribution of Theorem 2.1 is therefore to extend the result in the case $\alpha = 1$ to the whole range $|x|/a_n \rightarrow +\infty$, without any restriction on b_n . In Section 5, we recall the central tool to prove this theorem, the so-called Fuk-Nagaev inequalities (we prove a new one in the case $\alpha = 1$): we then prove Theorem 2.1 as a simple consequence of these inequalities.

2.1. Local large deviations. As far as a local version of Theorem 2.1 is concerned, results can be found in [9, §9] in the “centered” case $\sup_n |b_n|/a_n < +\infty$. Recently, Caravenna and Doney [6, Thm. 1.1] gave an improved local limit estimate in the case $\alpha \in (0, 1) \cup (1, 2)$ (assuming $\mu = 0$ when $\alpha \in (1, 2)$): given $\gamma > 0$, they prove that there is some constant $C_0 = C_0(\gamma) < +\infty$ such that for all $x \geq 0$,

$$\mathbf{P}(S_n = x, M_n \leq \gamma x) \leq \frac{C_0}{a_n} (n\mathbf{P}(X_1 > x))^{[1/\gamma]}.$$

We extend their result to the case $\alpha = 1$: we give a Fuk-Nagaev inequality and a local version of it, which are new.

Theorem 2.2. *Assume that (1.1) holds with $\alpha = 1$. For every $\varepsilon > 0$ there exist constants $c_1, c_2, c_3 > 0$ such that for any $1 \leq y \leq x$ and $x \geq a_n$, we have*

$$\mathbf{P}(S_n - b_n \geq x; M_n \leq y) \leq e^{\frac{x}{y}} \left(1 + \frac{c_1 x}{nL(y)}\right)^{-(1-\varepsilon)\frac{x}{y}} + e^{-c_2(x/a_n)^{1/\varepsilon}} \quad (2.1)$$

$$c_3 a_n \times \mathbf{P}(S_n - \lfloor b_n \rfloor = x; M_n \leq y) \leq e^{\frac{x}{y}} \left(1 + \frac{c_1 x}{nL(y)}\right)^{-(1-\varepsilon)\frac{x}{2y}} + e^{-c_2(x/a_n)^{1/\varepsilon}}. \quad (2.2)$$

This can be improved if we assume that X_1 has a symmetric distribution (see (5.1)), or that $X_1 \geq 0$ (see Proposition 5.2).

The corresponding bounds hold in the case $\alpha \in (0, 1) \cup (1, 2)$, see Theorem 5.1 and Proposition 6.1. This has a simple consequence, which is an extension of the local limit theorem (1.4) to the case when $|x|/a_n \rightarrow +\infty$.

Theorem 2.3. *For any $\alpha \in (0, 2)$ (the case $\alpha \in (0, 1) \cup (1, 2)$ is in [6, Thm. 1.1.]), there exists a constant $C_0 > 0$ such that for any $x \in \mathbb{Z}$*

$$\mathbf{P}(S_n - \lfloor b_n \rfloor = x) \leq \frac{C_0}{a_n} nL(|x|)(1 + |x|)^{-\alpha}. \quad (2.3)$$

If $p = 0$ ($q = 0$ being symmetric), we get $\mathbf{P}(S_n - \lfloor b_n \rfloor = x) = o(\frac{1}{a_n} nL(x)x^{-\alpha})$ as $\frac{x}{a_n} \rightarrow +\infty$.

Let us underline that this statement is somehow optimal under the mere assumption (1.1): for any sequence $(\varepsilon_n)_{n \geq 0}$ with $\varepsilon_n \rightarrow 0$, one may find distributions verifying (1.1) and a sequence x_n such that $x_n/a_n \rightarrow +\infty$ with

$$\limsup_{n \rightarrow +\infty} \frac{a_n \mathbf{P}(S_n = x_n)}{\varepsilon_n n L(x_n) x_n^{-\alpha}} = +\infty. \quad (2.4)$$

2.2. Improved local large deviation. We may improve Theorem 2.3 if we assume that the (left or right) tail of the distribution of X_1 verifies a more local condition than (1.1), as considered for example by Doney in [12] in the case $\alpha \in (0, 1)$. A natural condition is that there exists a constant $C_1 > 0$ (resp. C_2) such that

$$\mathbf{P}(X_1 = x) \leq C_1 L(x) (1+x)^{-(1+\alpha)} \quad \text{for all } x \in \mathbb{N}, \quad (2.5)$$

$$\mathbf{P}(X_1 = -x) \leq C_2 L(x) (1+x)^{-(1+\alpha)} \quad \text{for all } x \in \mathbb{N}. \quad (2.6)$$

Another stronger assumption, analogous to Eq. (1.3) in [12], is that $\mathbf{P}(X_1 = x)$ (resp. $\mathbf{P}(X_1 = -x)$) is regularly varying, that is that

$$\mathbf{P}(X_1 = x) \sim p\alpha L(x) x^{-(1+\alpha)} \quad \text{as } x \rightarrow +\infty, \quad (2.7)$$

$$\mathbf{P}(X_1 = -x) \sim q\alpha L(x) x^{-(1+\alpha)} \quad \text{as } x \rightarrow +\infty. \quad (2.8)$$

(If $p = 0$ resp. $q = 0$, we interpret this as $o(L(x)x^{-(1+\alpha)})$.)

Theorem 2.4. *Assume that (1.1) holds with $\alpha \in (0, 2)$. If in addition we have (2.5), then there is a constant $C > 0$ such that for any $x \geq a_n$,*

$$\mathbf{P}(S_n - \lfloor b_n \rfloor = x) \leq C n L(x) x^{-(1+\alpha)} \sim \frac{C}{x} \frac{L(x)}{L(a_n)} \left(\frac{x}{a_n} \right)^{-\alpha}. \quad (2.9)$$

If we have (2.7), then as $n \rightarrow +\infty$, $x/a_n \rightarrow +\infty$

$$\mathbf{P}(S_n - \lfloor b_n \rfloor = x) \sim n p \alpha L(x) x^{-(1+\alpha)}. \quad (2.10)$$

The analogous conclusion to (2.9) (resp. (2.10)) holds for $\mathbf{P}(S_n - \lfloor b_n \rfloor = -x)$ if we assume (2.6) (resp. (2.8)).

3. APPLICATIONS: LADDER EPOCHS AND RENEWAL THEOREMS

In this section, we put more emphasis on the case $\alpha = 1$ (although we will also state results in the case $\alpha \in (1, 2)$). Slowly varying functions will be interpreted as functions of the integers as well as differentiable functions of positive real numbers. In the case $\alpha = 1$, we define

$$\ell(n) := \int_1^n \frac{L(u)}{u} du \quad \text{if } |\mu| = +\infty; \quad \ell^*(n) := \int_n^{+\infty} \frac{L(u)}{u} du \quad \text{if } |\mu| < +\infty. \quad (3.1)$$

We have that both $\ell(\cdot)$, $\ell^*(\cdot)$ are slowly varying function (in fact, de Haan functions), with $\ell(n) \rightarrow +\infty$, $\ell^*(n) \rightarrow 0$ as $n \rightarrow +\infty$, and also $\ell(n)/L(n)$, $\ell^*(n)/L(n) \rightarrow +\infty$, see [2, Prop. 1.5.9.a].

In the case $|\mu| = +\infty$, because of (1.1) we have $\mu(t) \stackrel{t \rightarrow +\infty}{\sim} (p-q)\ell(t)$ and $b_n \stackrel{n \rightarrow +\infty}{\sim} (p-q)n\ell(a_n)$. Similarly, in the case $|\mu| < +\infty$, we also get thanks to (1.1) that $\mu - \mu(t) \stackrel{t \rightarrow +\infty}{\sim} (p-q)\ell^*(t)$: we end up with $b_n \sim \mu n$ if $\mu \neq 0$, and $b_n \sim (q-p)n\ell^*(a_n)$ if $\mu = 0$. We therefore see that $|b_n|/a_n \rightarrow +\infty$ since $\ell(n)/L(n)$, $\ell^*(n)/L(n) \rightarrow +\infty$ (recall (1.2)), except possibly when $p = q$ and $\mu = 0$ or $\pm\infty$. In the case $p = q$ and $|\mu| = +\infty$ (resp. $\mu = 0$), we get that $b_n = o(n\ell(a_n))$ (resp. $b_n = o(n\ell^*(a_n))$), and the general study gets much more subtle since we do not have a priori the asymptotic behavior of b_n . We will sometimes consider the case $b_n/a_n \rightarrow b \in \mathbb{R}$.

3.1. Ladder epochs. Denote $T_- = \inf\{n; S_n < S_0 = 0\}$ and $T_+ = \inf\{n; S_n > S_0 = 0\}$ the first descending and ascending ladder epochs. A very natural question is first to know whether T_-, T_+ are defective (if so, then S_n is said to *drift* to $+\infty$, resp. $-\infty$), and to obtain the asymptotics of the tail probabilities $\mathbf{P}(T_- > n), \mathbf{P}(T_+ > n)$.

A crucial tool for this study is our Theorem 2.1, which gives as an easy consequence the following precise asymptotics (see Lemmas 7.1 and 7.3 below):

(i) in the case $\alpha = 1$ with $|\mu| = +\infty$, we have $b_n/a_n \rightarrow +\infty$ if $p > q$ and $b_n/a_n \rightarrow -\infty$ if $p < q$, so that

$$\mathbf{P}(S_n < 0) \sim \frac{q}{p-q} \frac{L(|b_n|)}{\ell(|b_n|)} \quad \text{if } p > q; \quad \mathbf{P}(S_n > 0) \sim \frac{p}{q-p} \frac{L(|b_n|)}{\ell(|b_n|)} \quad \text{if } p < q; \quad (3.2)$$

(ii) in the case $\alpha = 1$ with $\mu = 0$, we have $b_n/a_n \rightarrow -\infty$ if $p > q$ and $b_n/a_n \rightarrow +\infty$ if $p < q$, so that

$$\mathbf{P}(S_n > 0) \sim \frac{p}{p-q} \frac{L(|b_n|)}{\ell^*(|b_n|)} \quad \text{if } p > q; \quad \mathbf{P}(S_n < 0) \sim \frac{q}{q-p} \frac{L(|b_n|)}{\ell^*(|b_n|)} \quad \text{if } p < q. \quad (3.3)$$

(One may naturally find asymptotics in the general case $\alpha \in (0, 2)$.) From this, we may use Theorem 2 in [14, XII.7] and Lemma 4.4 below, to get the following.

Proposition 3.1. *Assume that (1.1) holds with $\alpha = 1$, and assume that $|\mu| = +\infty$. If $q \neq 0$ then*

$$\sum_{n=1}^{+\infty} \frac{1}{n} \mathbf{P}(S_n < 0) = +\infty,$$

and the random walk does not drift to $+\infty$, in the sense that $T_- < +\infty$ a.s. Analogously, if $p \neq 0$ then the random walk does not drift to $-\infty$, i.e. $T_+ < +\infty$ a.s.

Note that in the case of finite non-zero mean $\mu \neq 0$, the strong law of large numbers gives that $(S_n)_{n \geq 1}$ is transient, and drifts to $+\infty$ (resp. to $-\infty$) if $\mu > 0$ (resp. $\mu < 0$). In the case $\mu = 0$, it is known that $(S_n)_{n \geq 1}$ is recurrent, so $T_-, T_+ < +\infty$ a.s.

Proposition 3.1 tells that if $\alpha = 1$ with $|\mu| = +\infty$ and $q \neq 0$, then even if $b_n/a_n \rightarrow +\infty$ so that S_n goes to $+\infty$ in probability (more precisely S_n/b_n converges in probability to 1), the random walk does not drift to $+\infty$ (and $\liminf S_n = -\infty$ a.s.). This is due to the fact that even if the random walk is in probability “close” to $b_n \rightarrow +\infty$, once in a while a large jump to the left occurs (of length of order b_n), making $S_n < 0$ (and in fact, of order $-b_n$). We will see below in Section 4.1 that the random walk may still be transient (in the sense that 0 may be visited only a finite number of times), but that determining transience/recurrence is a more complicated matter.

As far as the asymptotics of $\mathbf{P}(T_- > n)$ are concerned (the estimates for T_+ are symmetric by considering $(-S_n)_{n \geq 0}$), we refer to the seminal papers of Rogozin [21] and of Doney [10, 11], and to [4] or [23] for more recent results. However, the case $\alpha = 1$ (to our knowledge) does not appear to have been treated in the literature, apart from the recent work of Budd, Curien and Marzouk [5, Prop. 1] where a rough estimate on $\mathbf{P}(T_- > n)$ is given in the case where $L(n)$ is constant. We shall give a sharp asymptotic, in the case of a general slowly varying function.

We give two levels of sharpness, depending on whether we assume that $L(\cdot)$ in (1.1) is slowly varying in the Flajolet-Odlyzko sense (see conditions V1-V2 in [15]), that is verifies:

- V1. there exists some $x_0 > 0$ and some $\phi \in (\pi/2, \pi)$ such that $L(z)$ is analytic in the region $\{z; \arg(z - x_0) \in [-\phi, \phi]\}$

V2. we have, for any $\theta \in [-\phi, \phi]$ and $x \geq x_0$

$$\left| \frac{L(xe^{i\theta})}{L(x)} - 1 \right| \leq \varepsilon(x), \quad \left| \frac{L(x \log x)}{L(x)} - 1 \right| \leq \varepsilon(x), \quad \text{for some } \varepsilon(x) \xrightarrow{x \rightarrow +\infty} 0.$$

This is satisfied for example if $L(x)$ is equal to $(\log x)^a$ or $(\log \log x)^a$ for some $a \in \mathbb{R}$, but we stress that V2 fails for instance if $L(x) = \exp((\log x)^b)$ for some $b \in (0, 1)$.

3.1.1. *Case* $\alpha = 1$, $|\mu| = +\infty$.

Theorem 3.2. *Assume that (1.1) holds with $\alpha = 1$ and $|\mu| = +\infty$. Recall the definitions of $b_n = n\mu(a_n)$ in (1.3) and of $\ell(\cdot)$ in (3.1).*

(i) *If $p = q$ and $b = \lim_{n \rightarrow +\infty} b_n/a_n$ exists, then there is a slowly varying $\varphi(\cdot)$ such that*

$$\mathbf{P}(T_- > n) = \varphi(n) n^{-\rho} \quad \text{with } \rho = \frac{1}{2} + \frac{1}{\pi} \arctan\left(\frac{2b}{\pi}\right).$$

(ii) *If $p < q$, then $b_n \sim -(q-p)n\ell(a_n) \rightarrow -\infty$ as $n \rightarrow +\infty$, and*

$$\mathbf{P}(T_- > n) = \frac{L(|b_n|)}{n} \ell(|b_n|)^{\frac{p}{q-p}-1+o(1)}.$$

(iii) *If $p > q$, then $b_n \sim (p-q)n\ell(a_n) \rightarrow +\infty$ as $n \rightarrow +\infty$, and*

$$\mathbf{P}(T_- > n) = \ell(b_n)^{-\frac{q}{p-q}+o(1)}.$$

If additionally V1-V2 above holds, then we can make the $o(1)$ in (ii) and (iii) more precise: in both cases there is a slowly varying $\tilde{L}(\cdot)$ such that $\ell(|b_n|)^{o(1)}$ can be replaced by $\tilde{L}(\ell(|b_n|))$.

We are also able to deal with the case $p = q = 1/2$ when $b_n/a_n \rightarrow +\infty$ but we did not state it here for conciseness, since it requires further notations: we refer to Section 7.5 for details, see in particular (7.22). After this article was complete, Kortchemski and Richier [19] proved a similar statement by replacing the $\ell(|b_n|)^{o(1)}$ by some slowly varying function $\Lambda(n)$, without assuming V1-V2, see [19, Prop. 12]. However, our statement under assumption V1-V2 is somehow stronger: it tells that $\Lambda(n)$ is of the form $\tilde{L}(\ell(|b_n|))$ with $\tilde{L}(\cdot)$ slowly varying.

As an application of Theorem 3.2, we improve Proposition 1 of [5] in the case $p \neq q$: if $L(n)$ is constant equal to c (and obviously verifies V1-V2), then $\ell(n) \sim c \log n$, $a_n \sim cn$, and $b_n \sim (p-q)cn \log n$. Hence, we obtain that there exist some slowly varying functions $\bar{L}(\cdot), \tilde{L}(\cdot)$ such that

$$\mathbf{P}(T_- > n) = \begin{cases} (\log n)^{-\frac{q}{p-q}} \bar{L}(\log n) & \text{if } p > q, \\ n^{-1} (\log n)^{\frac{p}{q-p}-1} \tilde{L}(\log n) & \text{if } p < q. \end{cases} \quad (3.4)$$

3.1.2. *Case* $|\mu| < +\infty$. In the finite mean case, estimates for $\mathbf{P}(T_- > n)$ can be found in [11] and in [3, 4], but again, the case $\alpha = 1$ appears to have been left aside. We stress that the proofs in [3, 4] rely on an asymptotic estimate of $\mathbf{P}(S_n < 0)$ (or $\mathbf{P}(S_n > 0)$) as $n \rightarrow +\infty$, that are given by Theorem 2.1. We state the results for the sake of completeness, leaving aside the case $\alpha = 1$, $\mu = 0$ for the moment.

Theorem 3.3 (cf. Theorems 0-I of [11] and Theorem 1 of [3]). *Assume that (1.1) holds with $\alpha \in [1, 2)$ and $|\mu| < +\infty$.*

(i) *If $\mu > 0$, then $\mathbf{P}(T_- = +\infty) = e^{-D_-} < 1$ with $D_- := \sum_{k=1}^{+\infty} k^{-1} \mathbf{P}(S_k < 0) < +\infty$. Moreover, if $q \neq 0$ we have*

$$\mathbf{P}(T_- = n) \stackrel{n \rightarrow +\infty}{\sim} \frac{q e^{-D_-}}{\mu^\alpha} L(n) n^{-\alpha}.$$

(ii) If $\mu < 0$ and $p \neq 0$, then we have $D_+ := \sum_{k=1}^{+\infty} \frac{1}{k} \mathbf{P}(S_k \geq 0) < +\infty$ and

$$\mathbf{P}(T_- > n) \stackrel{n \rightarrow +\infty}{\sim} \frac{p e^{D_+}}{|\mu|^\alpha} L(n) n^{-\alpha}.$$

(iii) If $\mu = 0$ and $\alpha \in (1, 2)$, then there exists a slowly varying function $\varphi(\cdot)$ such that

$$\mathbf{P}(T_- > n) = \varphi(n) n^{-\rho},$$

with $\rho := \frac{1}{2} + \frac{1}{\pi\alpha} \arctan((p - q) \tan(\pi\alpha/2))$.

The proof of items (i)-(ii) easily translates from [3, Thm. 1] to the case $\alpha = 1$ with a finite non-zero mean. For item (i), we simply use that in the case $\mu > 0$, we have $n^{-1} \mathbf{P}(S_n < 0) \sim qL(n)(\mu n)^{-\alpha}$ (from Theorem 2.1), which is regularly varying: the result then follows from Eq. (23) in [3] together with an application of [7, Thm. 1], using that $D_- := \sum_k k^{-1} \mathbf{P}(S_k > 0) < +\infty$. Item (ii) is similar. For (iii), we have that $b_n \equiv 0$, and we can use that $\mathbf{P}(S_k > 0) = \mathbf{P}(S_k/a_k > 0)$ converges to $\mathbf{P}(Y > 0)$ where Y has the limiting α -stable law, with skewness parameter $\beta = p - q$ (hence the formula for the positivity parameter $\rho := \mathbf{P}(Y > 0)$, see [28, Sec. 2.6]). This implies (see [21, 11]) that T_- is in the domain of attraction of a positive stable random variable with index ρ , and item (iii) follows.

3.1.3. *Case $\alpha = 1, \mu = 0$.* We left that case aside since it is not a straightforward adaptation of [3, Thm. 1], in particular because $\sum_k k^{-1} \mathbf{P}(S_k > 0) = +\infty$ (see Proposition 3.1).

Theorem 3.4. *Assume that (1.1) holds with $\alpha = 1$ and assume that $\mu = 0$. Then (recall the definition (3.1) of $\ell^*(\cdot)$),*

(i) *If $p > q$ we have $b_n \sim -(p - q)n\ell^*(a_n) \rightarrow -\infty$ as $n \rightarrow +\infty$, and*

$$\mathbf{P}(T_- > n) = \frac{L(|b_n|)}{n} \ell^*(|b_n|)^{-\frac{p}{p-q} - 1 + o(1)}.$$

(ii) *If $p < q$ we have $b_n \sim (q - p)n\ell^*(a_n) \rightarrow +\infty$ as $n \rightarrow +\infty$, and*

$$\mathbf{P}(T_- > n) = \ell^*(b_n)^{\frac{q}{q-p} + o(1)}.$$

If additionally $L(\cdot)$ verifies V1-V2 above, then in each case there is a slowly varying $\tilde{L}(\cdot)$ such that such that $\ell^(|b_n|)^{o(1)}$ can be replaced by $\tilde{L}(\ell^*(|b_n|))$.*

We prove this theorem in Section 7.6, where we discuss also the case $p = q$ —it is treated similarly to Theorem 3.2-(i), see in particular (7.24).

3.2. Renewal theorems. An interesting application of the local limit Theorems 2.3-2.4 is that we are able to obtain renewal theorems for transient random walks $(S_n)_{n \geq 1}$: we give the behavior, as $x \rightarrow +\infty$, of the Green function $G(x) = \sum_n \mathbf{P}(S_n = x)$.

When the step variable X_1 is positive, $(S_n)_{n \geq 0}$ is a renewal process, and we write $S = \{S_0, S_1, S_2, \dots\}$ the set of renewal points (with a slight abuse of notations). Then $G(x)$ is interpreted as the renewal mass function $\mathbf{P}(x \in S)$, and has been studied in a variety of papers. The well-known renewal theorem gives that whenever $X_1 > 0$ and $\mu = \mathbf{E}[X_1] < +\infty$, then $\mathbf{P}(x \in S) \rightarrow 1/\mu$ as $x \rightarrow +\infty$. Assuming additionally that (1.1) holds with $\alpha \in (0, 1]$ (and necessarily $p = 1, q = 0$ since $X_1 > 0$), then Garcia and Lamperti [16] showed the strong renewal theorem

$$\mathbf{P}(x \in S) \stackrel{x \rightarrow +\infty}{\sim} \frac{\alpha \sin(\pi\alpha)}{\pi} L(x)^{-1} x^{-(1-\alpha)} \quad \text{if } \alpha \in (1/2, 1); \quad (3.5)$$

Erickson [13] also proved that,

$$\mathbf{P}(x \in S) \underset{x \rightarrow +\infty}{\sim} \frac{1}{\mu(x)} \quad \text{if } \alpha = 1 \text{ with } |\mu| = +\infty. \quad (3.6)$$

Finally, Caravenna and Doney [6] gave very recently a necessary and sufficient condition for the above strong renewal theorem (3.5) to hold when $\alpha \in (0, 1/2]$.

When $(S_n)_{n \geq 1}$ is a (general) random walk rather than a renewal process, the Green function $G(x)$ has been considered in the case $\alpha \in (0, 1)$ for example in [6, 26], and when X_1 has a finite mean (see Theorem 3.7 below). We shall prove renewal theorems in the case $\alpha = 1$, under some specific assumptions that ensures the transience of the random walk. We comment further in Section 4 the particularity of the case $\alpha = 1$, $|\mu| = +\infty$, where even the question of recurrence/transience of $(S_n)_{n \geq 1}$ is subtle.

The first renewal theorem we get is in the ‘‘centered’’ case $p = q = 1/2$.

Theorem 3.5. *Assume that (1.1) holds with $\alpha = 1$ and $p = q = 1/2$, and that $b := \lim_{n \rightarrow +\infty} b_n/a_n$ exists, $b \in \mathbb{R}$. Assume also that $\sum_{n \geq 1} \frac{1}{nL(n)} < +\infty$. Then S_n is transient, and*

$$G(x) \underset{n \rightarrow +\infty}{\sim} \frac{2}{\pi(1 + (2b)^2)} \sum_{n > x} \frac{1}{nL(n)},$$

which is a slowly varying function vanishing as $x \rightarrow +\infty$.

In the case where (1.1) holds with $\alpha = 1$, $|\mu| = +\infty$ and $p \neq q$, we need the extra assumptions (2.5)-(2.6) to be able to derive a renewal theorem —otherwise it is not even clear if $(S_n)_{n \geq 0}$ is transient, see Proposition 4.2. Recall that in that case, we have $\mu(x) \sim (p - q)\ell(x)$ (and goes to $+\infty$ if $p > q$ and $-\infty$ if $p < q$).

Theorem 3.6. *Assume that (1.1) holds with $\alpha = 1$, $|\mu| = +\infty$, and $p \neq q$. Assume additionally that (2.5)-(2.6) hold. Then S_n is transient, and we have that $G(x) = O(1/|\mu(x)|)$ and also $\liminf G(x)/\mu(x) \geq 1$ if $p > q$.*

(i) *If $p > q$ and $\mathbf{P}(X_1 = -x) \underset{x \rightarrow +\infty}{\sim} qL(x)x^{-2}$ (if $q = 0$, we interpret this as $o(L(x)x^{-2})$), then*

$$G(x) \underset{x \rightarrow +\infty}{\sim} \frac{1 + q/(p - q)}{\mu(x)}. \quad (3.7)$$

(ii) *If $p < q$ and $\mathbf{P}(X_1 = x) \underset{x \rightarrow +\infty}{\sim} pL(x)x^{-2}$ (if $p = 0$, we interpret this as $o(L(x)x^{-2})$), then*

$$G(x) \underset{x \rightarrow +\infty}{\sim} \frac{p/(q - p)}{|\mu(x)|}. \quad (3.8)$$

We therefore recover Erickson’s result (3.6) in the case of general random walks, at the expense of assumptions (2.5)-(2.6) (in the case of renewals we get $q = 0$).

Let us make a short comment on (3.7). When $p > q$ (so that $b_n \rightarrow +\infty$) the behavior in (3.7) comes from two types of contribution to $G(x) = \sum_{k=1}^{+\infty} \mathbf{P}(S_k = x)$: when the number of steps is of the order of k_x verifying $b_{k_x} = x$ (so that S_{k_x} is approximately x), and when the number of steps is much larger (S_k is much larger than x , but large jumps to the left still occur). For the first part, we prove that it is asymptotic to $1/\mu(x)$. For the second part, we are able to prove that it is $O(1/\mu(x))$ under (2.6), and we can get its asymptotic behavior if $\mathbf{P}(X_1 = -x) \underset{x \rightarrow +\infty}{\sim} qL(x)x^{-2}$.

Finally, for the sake of completeness, we state a renewal theorem in the case of a finite non-zero mean. Recall that if X_1 is integrable with $\mu = 0$, then the walk is recurrent, *i.e.* $G(x) = +\infty$ for all $x \in \mathbb{Z}$.

Theorem 3.7. *Assume that X_1 is integrable, with $\mu = \mathbf{E}[X_1] \neq 0$.*

(i) *If $\mu > 0$, we have that $\lim_{x \rightarrow +\infty} G(x) = 1/\mu$.*

(ii) *If $\mu < 0$, let $S^* = \sup_{i \geq 0} S_i < +\infty$ and assume that $H(x) = \mathbf{P}(S^* \leq x)$ is subexponential (i.e. $\overline{H} * \overline{H}(x) \sim 2\overline{H}(x)$ as $x \rightarrow +\infty$, where $\overline{H} = 1 - H$). Then*

$$G(x) \stackrel{x \rightarrow +\infty}{\sim} \frac{1}{|\mu|} \mathbf{P}(S^* > x).$$

If the integrated distribution function $I(x) = (1 - \int_x^{+\infty} \mathbf{P}(X_1 > t) dt)_+$ is subexponential (as it is the case in (1.1)), Veraverbeke's theorem [24, 27] gives that $\mathbf{P}(S^ > x) \sim I(x)/|\mu|$.*

The case $\mu > 0$ can be found in [14, XI.9]. For the case $\mu < 0$, we were not aware of a reference (even if it must exist), so we prove it in Section 8.2, via elementary methods.

4. FURTHER DISCUSSION AND USEFUL ESTIMATES IN THE CASE $\alpha = 1$

In this section, we focus on the case $\alpha = 1$, and we discuss the subtleties that might arise. One of the main difficulty is that the recentering term b_n is not *homogeneous*: the *recentered* walk $S_n - b_n$ is a sum of i.i.d. *recentered* random variables, but that recentering depends on n : $S_n - b_n = \sum_{i=1}^n (X_i - \mu(a_n))$. Hence, we are not able to simplify the problem by studying a random walk with *centered* increments, as it is customary when $\alpha > 1$.

We focus on the case when $|\mu| = +\infty$ for a moment, for the simplicity of exposition (analogous reasoning holds when $\mu = 0$). Recall the definition (3.1) of $\ell(\cdot)$, and let us discuss the behavior of the centering constant b_n .

* If $p > q$, then $b_n \sim (p - q)n\ell(a_n)$: we get that $b_n/a_n \rightarrow +\infty$, since $\ell(x)/L(x) \rightarrow +\infty$ and $a_n \sim nL(a_n)$. Hence S_n/b_n converges in probability to 1, and S_n goes in probability to $+\infty$, even though Proposition 3.1 tells that S_n does not drift to $+\infty$.

* If $p = q$ then it is more tricky, and we can have a variety of possible behaviors: $b_n = o(a_n)$ (we may set $b_n \equiv 0$); $0 < \limsup_{n \rightarrow +\infty} |b_n|/a_n < +\infty$; $\lim_{n \rightarrow +\infty} b_n/a_n = +\infty$ (but still $b_n = o(n\ell(a_n))$); and it is not excluded that $\limsup_{n \rightarrow +\infty} b_n/a_n = +\infty$ and $\liminf_{n \rightarrow +\infty} b_n/a_n = +\infty$.

4.1. About the transience/recurrence of S_n . We recall that in the case of a finite mean, S_n is transient if $\mu \neq 0$ (by the strong law of large numbers), and recurrent if $\mu = 0$. In the case $\alpha = 1$ with $\mu = +\infty$ (and $p, q \neq 0$), the random walk is shown not to drift neither to $+\infty$ nor $-\infty$ (Proposition 3.1): the central (and subtle) question is therefore to know whether the random walk is transient or recurrent. Let us consider the Green function at 0, $G(0) := \sum_n \mathbf{P}(S_n = 0)$.

First case. If $\sup_n |b_n|/a_n < +\infty$, then $\mathbf{P}(S_n = 0)$ is of order $1/a_n$: by the local limit theorem (1.4) $a_n \mathbf{P}(S_n = 0) = (1 + o(1))g(-b_n/a_n)$, and it is therefore bounded away from 0 and infinity. We conclude that the walk is transient if and only if $\sum (a_n)^{-1} < +\infty$, and Wei [25] gives another characterization.

Proposition 4.1. *If (1.1) holds with $\alpha = 1$, and $\sup_n |b_n|/a_n < +\infty$ (necessarily $p = q$), then*

$$(S_n)_{n \geq 0} \text{ is transient} \iff \sum_{n=1}^{+\infty} \frac{1}{a_n} < +\infty \iff \sum_{n=1}^{+\infty} \frac{1}{nL(n)} < +\infty.$$

Second Case. If $\lim_{n \rightarrow +\infty} b_n/a_n \rightarrow +\infty$, we have that $S_n \rightarrow +\infty$ in probability, but we cannot conclude that S_n is transient, in particular because Proposition 3.1 tells that $\liminf S_n = -\infty$ a.s. We have $\mathbf{P}(S_n = 0) = \mathbf{P}(S_n - b_n = -b_n)$ and Theorem 2.3 gives that is is bounded by a

constant times $(a_n)^{-1}n\mathbf{P}(X_1 > b_n) \sim p(b_n)^{-1}L(b_n)/L(a_n)$. Hence, a sufficient condition for the walk to be transient is that

$$\sum_{n \geq 1} (b_n^{-1})L(b_n)/L(a_n) < +\infty.$$

However Theorem 2.3 does not provide a lower bound for $\mathbf{P}(S_n = 0)$, so the question of the recurrence/transience cannot be settled. We now give a simple sufficient condition for the transience of the random walk.

Proposition 4.2. *Assume that (1.1) holds with $\alpha = 1$, and assume that $|\mu| = +\infty$. If $p > q$ (we then have $b_n/a_n \rightarrow +\infty$) and if additionally (2.6) holds, then S_n is transient.*

Note that the local assumption (2.6) we need is only on the left tail of X_1 : since we already know that $S_n \rightarrow +\infty$ in probability when $p > q$, we simply need to control the (large) jumps to the left that might make the random walk visit 0.

Proof We use Theorem 2.4 to get that there is a constant C such that

$$\mathbf{P}(S_n = 0) = \mathbf{P}(S_n - \lfloor b_n \rfloor = -\lfloor b_n \rfloor) \leq Cnb_n^{-2}L(b_n).$$

Then, to show that $(S_n)_{n \geq 1}$ is transient, and since $b_n = n\mu(a_n) \sim (p-q)n\ell(a_n) \sim (p-q)n\ell(b_n)$ (see Lemma 4.3 below), it is therefore sufficient to show that

$$\sum_{n=1}^{+\infty} \frac{L(b_n)}{b_n\ell(b_n)} < +\infty \quad \iff \quad \sum_{k=1}^{+\infty} \frac{L(k)}{k\ell(k)^2} < +\infty.$$

The equivalence simply comes from a comparison of the sums with corresponding integral (we may work with differentiable slowly varying functions see [2, Th. 1.8.2]), and a change of variable $k = b_n$, $dk = (p-q)\ell(b_n)dn$. Then Lemma 4.4-(i) below (with $f(t) = 1/t^2$) shows the summability of the sum on the right-hand side, and concludes the proof. \square

Other cases. If for example $\limsup b_n/a_n = +\infty$ and $\liminf b_n/a_n < +\infty$, it is even less clear, and it seems hopeless to conclude anything without further assumptions.

4.2. Useful estimates on $\ell(\cdot), \ell^*(\cdot)$. We now collect a few estimates on the slowly varying function $\ell(\cdot), \ell^*(\cdot)$ defined in (3.1) (they are de Haan functions), which will be central in the proofs of Theorems 3.2 and 3.6.

Lemma 4.3. *Recall the definition (1.2) of a_n . We have that*

$$\ell(a_n) \sim \ell(n\ell(a_n)) \quad \text{as } n \rightarrow +\infty.$$

Similarly, we have $\ell^(a_n) \sim \ell^*(n\ell^*(a_n))$ as $n \rightarrow +\infty$.*

As a consequence, when $\alpha = 1$ with $|\mu| = +\infty$ (resp. $\mu = 0$) so that $b_n \sim (p-q)n\ell(a_n)$ (resp. $b_n \sim (q-p)n\ell^*(a_n)$), if $p \neq q$ we get that $\ell(a_n) \sim \ell(b_n)$ (resp. $\ell^*(a_n) \sim \ell^*(b_n)$). The proof of Lemma 4.3 is not difficult and can be found in [1], so we omit it.

The next lemma deals with sums that appear naturally in the course of the proofs.

Lemma 4.4. *Consider the case $\alpha = 1$, and recall the definitions (3.1) of $\ell(\cdot), \ell^*(\cdot)$. Let f be a non-increasing function $\mathbb{R}_+^* \rightarrow \mathbb{R}_+$.*

(i) If $|\mu| = +\infty$ then $\ell(n) \rightarrow +\infty$, and denoting $J = \int_1^{+\infty} f(t)dt$ we have as $n \rightarrow +\infty$

$$\text{if } J < +\infty, \quad \text{then} \quad \sum_{k=n}^{+\infty} \frac{L(k)}{k} f(\ell(k)) \sim \int_{\ell(n)}^{+\infty} f(t)dt \rightarrow 0;$$

$$\text{if } J = +\infty, \quad \text{then} \quad \sum_{k=1}^n \frac{L(k)}{k} f(\ell(k)) \sim \int_1^{\ell(n)} f(t)dt \rightarrow +\infty.$$

(ii) If $|\mu| < +\infty$ then $\ell^*(n) \rightarrow 0$, and denoting $K = \int_0^1 f(t)dt$ we have as $n \rightarrow +\infty$

$$\text{if } K < +\infty, \quad \text{then} \quad \sum_{k=n}^{+\infty} \frac{L(k)}{k} f(\ell^*(k)) \sim \int_0^{\ell^*(n)} f(t)dt \rightarrow 0;$$

$$\text{if } K = +\infty, \quad \text{then} \quad \sum_{k=1}^n \frac{L(k)}{k} f(\ell^*(k)) \sim \int_{\ell^*(n)}^1 f(t)dt \rightarrow +\infty.$$

We therefore have that $\sum_{k \geq 1} k^{-1}L(k)f(\ell(k))$ (resp. $\sum_{k \geq 1} k^{-1}L(k)f(\ell^*(k))$) is convergent if and only if $\int_1^{+\infty} f(t)dt$ (resp. $\int_0^1 f(t)dt$) is convergent.

Proof For (i), the asymptotic equivalence comes from a simple comparison of the sum with the following integral (since $k^{-1}L(k)f(\ell(k))$ is asymptotically non-increasing this is straightforward), which is computed explicitly thanks to a change of variable $t = \ell(u)$, $dt = L(u)u^{-1}du$ (recall $\ell(u) \rightarrow +\infty$ as $u \rightarrow +\infty$):

$$\int_n^{+\infty} \frac{L(u)}{u} f(\ell(u))du = \int_{\ell(n)}^{+\infty} f(t)dt; \quad \int_1^n \frac{L(u)}{u} f(\ell(u))du = \int_1^{\ell(n)} f(t)dt.$$

For (ii), the result is proven in a similar manner, using the change of variable $t = \ell^*(u)$, $dt = -L(u)u^{-1}du$ (recall $\ell^*(u) \rightarrow 0$ as $u \rightarrow +\infty$). \square

5. FUK-NAGAEV'S INEQUALITIES AND LOCAL LARGE DEVIATIONS

From now on, we use c, C, c', C', \dots as generic (universal) constants, and we will keep the dependence on parameters when necessary, writing for example $c_\varepsilon, C_\varepsilon$ for constants depending on a parameter ε .

5.1. Fuk-Nagaev inequalities. Let us first recall known Fuk-Nagaev inequalities—they are collected for example in [20], and are based on standard Cramér-type exponential moment calculations. Recall that $M_n = \max_{1 \leq i \leq n} \{X_i\}$.

Theorem 5.1. *Assume that (1.1) holds with $\alpha \in (0, 2)$. There exist a constant c such that for any $y \leq x$,*

(i) *If $\alpha < 1$,*

$$\mathbf{P}(S_n \geq x; M_n \leq y) \leq e^{\frac{x}{y}} \left(1 + \frac{cx}{ny^{1-\alpha}L(y)}\right)^{-\frac{x}{y}} \leq \left(ec^{-1} \frac{y}{x} nL(y)y^{-\alpha}\right)^{\frac{x}{y}}.$$

(ii) *If $\alpha > 1$,*

$$\mathbf{P}(S_n - \mu n \geq x; M_n \leq y) \leq \left(c \frac{y}{x} nL(y)y^{-\alpha}\right)^{-\frac{x}{y}}.$$

(iii) *If $\alpha = 1$, we have for any $y \leq x$,*

$$\mathbf{P}(S_n \geq x; M_n \leq y) \leq e^{\frac{x}{y}} \left(1 + \frac{cx}{nL(y)}\right)^{-\frac{x-n\mu(y)}{y}}.$$

The case $\alpha < 1$ is in [20, Thm 1.1] (take $t = 1$ so that $0 \leq A(1, Y) \leq c'ny^{1-\alpha}L(y)$). The case $\alpha = 1$ comes from [20, Thm 1.2] (take $t = 2$ so that $0 \leq A(2, Y) \leq c'ny^{2-\alpha}L(y)$). For $\alpha > 1$, [20, Thm 1.2] does not directly give item (ii), but

$$\mathbf{P}(S_n - \mu n \geq x; M_n \leq y) \leq e^{\frac{x}{y}} \left(1 + \frac{cx}{ny^{1-\alpha}L(y)}\right)^{-\frac{x}{y} + \frac{n(\mu(y) - \mu)}{y}}.$$

Then we can use that $|\mu(y) - \mu| = O(y^{1-\alpha}L(y))$, to get that

$$\mathbf{P}(S_n - \mu n \geq x; M_n \leq y) \leq e^{\frac{x}{y}} \left(1 + \frac{cx}{ny^{1-\alpha}L(y)}\right)^{-\frac{x}{y} (1 - c'ny^{1-\alpha}L(y)/x)}.$$

Then, there is some c'' such that $(1 + cu)^{1-c'/u} \geq c''u$ for all $u \geq 0$, so that we get Theorem 5.1(ii).

All these results remain valid if we only assume an upper bound $\mathbf{P}(|X_1| > x) \leq cL(x)x^{-\alpha}$. Also, the case $\alpha = 2$ (random walks in the Normal domain of attraction) can be dealt with, see Corollary 1.7 in [20]. For the case $\alpha = 1$, Theorem 5.1 gives some bound, but it is not optimal in general. However, if X_1 has a symmetric distribution, we have that $\mu(y) \equiv 0$ and $b_n \equiv 0$, so Theorem 5.1 yields immediately the inequality

$$\mathbf{P}(S_n - b_n \geq x; M_n \leq y) \leq e^{\frac{x}{y}} \left(1 + \frac{cx}{nL(y)}\right)^{-\frac{x}{y}}. \quad (5.1)$$

The general case needs more work: we need the following result for non-negative X_1 .

Proposition 5.2. *Assume that $X_1 \geq 0$ and that (1.1) holds with $\alpha = 1$. There exists a constant $c > 0$, and for every $\varepsilon > 0$ there is some $C_\varepsilon > 0$, such that for any $x \geq C_\varepsilon a_n$ and any $y \leq x$*

$$\begin{aligned} \mathbf{P}(S_n - b_n \geq x; M_n \leq y) &\leq e^{\frac{x}{y}} \left(1 + \frac{cx}{nL(y)}\right)^{-(1-\varepsilon)\frac{x}{y}}, \\ \mathbf{P}(S_n - b_n \leq -x) &\leq \exp\left(-\left(x/a_n\right)^{1/\varepsilon}\right). \end{aligned} \quad (5.2)$$

From Proposition 5.2, we obtain Theorem 2.2-(2.1), by separating the X_i 's into a positive and a negative part: $X_i^+ := X_i \mathbf{1}_{\{X_i > 0\}}$ and $X_i^- := -X_i \mathbf{1}_{\{X_i < 0\}}$, so that X_i^+, X_i^- are non-negative. Naturally, we also define $S_n^+ := \sum_{i=1}^n X_i^+$ and $S_n^- := \sum_{i=1}^n X_i^-$ so that $S_n = S_n^+ - S_n^-$; and also $b_n^+ := n\mathbf{E}[X_1^+ \mathbf{1}_{\{X_1^+ \leq a_n\}}]$ and $b_n^- := n\mathbf{E}[X_1^- \mathbf{1}_{\{X_1^- \leq a_n\}}]$, so that b_n^+ (resp. b_n^-) is a centering sequence for S_n^+ (resp. S_n^-), and $b_n = b_n^+ - b_n^-$. Then,

$$\begin{aligned} \mathbf{P}(S_n - b_n \geq x; M_n \leq y) &\leq \mathbf{P}(S_n^+ - b_n^+ \geq (1 - \varepsilon)x; \max_{1 \leq i \leq n} X_i^+ \leq y) \\ &\quad + \mathbf{P}(S_n^- - b_n^- \leq -\varepsilon x). \end{aligned} \quad (5.3)$$

Then, we may use (5.2) for both terms, and we obtain Theorem 2.2-(2.1), by possibly adjusting the constants (for instance to treat the case $x \geq a_n$ instead of $x \geq C_\varepsilon a_n$).

Note that in (2.1), the large deviation may come from two different possibilities: either the positive part makes a few jumps of length y (the number of such jumps is approximately $(1 - \varepsilon)x/y$), giving the first term; either the negative part makes a large deviation to lower its value, giving rise to the second term (which is not affected by the truncation $M_n \leq y$).

5.2. An easy consequence: Theorem 2.1. We now prove Theorem 2.1, as a consequence of the above Fuk-Nagaev inequalities. We write it only for large deviations to the right (*i.e.* $x/a_n \rightarrow +\infty$), the other case being symmetric. For any fixed $\varepsilon > 0$, we write

$$\mathbf{P}(S_n - b_n > x) = \mathbf{P}(S_n - b_n > x; M_n > (1 - \varepsilon)x) + \mathbf{P}(S_n - b_n > x; M_n \leq (1 - \varepsilon)x). \quad (5.4)$$

First term. It gives the main contribution. A lower bound is, by exchangeability and independence of the X_i 's

$$\begin{aligned} & \mathbf{P}(\exists i, X_i > (1 + \varepsilon)x, S_n - b_n > x) \\ & \geq n\mathbf{P}(X_1 > (1 + \varepsilon)x)\mathbf{P}(S_{n-1} - b_n > -\varepsilon x) - \mathbf{P}(\exists i \neq j, X_i, X_j > (1 + \varepsilon)x) \\ & \geq (1 - \varepsilon)n\mathbf{P}(X_1 > (1 + \varepsilon)x) - \binom{n}{2}\mathbf{P}(X_1 > (1 + \varepsilon)x)^2. \end{aligned}$$

The last inequality holds for n large enough: we used that $(S_{n-1} - b_n)/a_n$ converges in distribution and $x/a_n \rightarrow +\infty$. In the last line, the second term is negligible compared to the first one, since $n\mathbf{P}(X_1 > (1 + \varepsilon)x) \rightarrow 0$ as $x/a_n \rightarrow +\infty$.

For an upper bound, we use simply a union bound to get

$$\mathbf{P}(M_n > (1 - \varepsilon)x) \leq n\mathbf{P}(X_1 > (1 - \varepsilon)x).$$

Thanks to (1.1), the first term in (5.4) is therefore asymptotically bounded from below by $(1 - \varepsilon)(1 + \varepsilon)^{-\alpha}(p - \varepsilon)nL(x)x^{-\alpha}$ and from above by $(1 - \varepsilon)^{-\alpha}(p + \varepsilon)nL(x)x^{-\alpha}$.

Second term. It remains to prove that, for any arbitrary $\varepsilon > 0$, the second term in (5.4) is $o(nL(x)x^{-\alpha})$ as $x/a_n \rightarrow +\infty$. We decompose again this probability into two parts. The first part is

$$\mathbf{P}(S_n - b_n > x; M_n \in (x/8, (1 - \varepsilon)x]) \leq n\mathbf{P}(X_1 \geq x/8)\mathbf{P}(S_{n-1} - b_n > \varepsilon x) = o(nL(x)x^{-\alpha}).$$

The first inequality comes from the exchangeability and independence of the X_i 's, and the second one comes from the convergence in distribution of $(S_{n-1} - b_n)/a_n$ together with $x/a_n \rightarrow +\infty$. The last part ($M_n \leq x/8$) is controlled thanks to the above Fuk-Nagaev Theorems 2.2-5.1: we have that in any case, taking $\varepsilon = 1/2$ in (2.1), as $x/a_n \rightarrow +\infty$

$$\mathbf{P}(S_n - b_n > x; M_n \leq x/8) \leq (cnL(x)x^{-\alpha})^4 + e^{-c(x/a_n)^2} = o\left(\frac{L(x)}{L(a_n)}(x/a_n)^{-\alpha}\right),$$

where we used that $n \sim a_n^{-\alpha}L(a_n)$ (so that the last term is indeed $o(nL(x)x^{-\alpha})$).

In conclusion, since $\varepsilon > 0$ is arbitrary, we get Theorem 2.1. \square

5.3. Proof of Proposition 5.2. Recall that $X_1 \geq 0$, and that $\mu(y)$ is non-decreasing.

Proof of the first part of (5.2). We start from Theorem 5.1: for any $y \leq x'$ we have

$$\mathbf{P}(S_n \geq x'; M_n \leq y) \leq \left(1 + c \frac{x'}{nL(y)}\right)^{-\frac{x' - n\mu(y)}{y}}.$$

Plugging $x' = b_n + x = n\mu(a_n) + x$ in this inequality, we get that for any $y \leq x$

$$\mathbf{P}(S_n - b_n \geq x; M_n \leq y) \leq \left(1 + c \frac{n\mu(a_n) + x}{nL(y)}\right)^{-\frac{x}{y} + \frac{n(\mu(y) - \mu(a_n))}{y}}. \quad (5.5)$$

Then it is just a matter of comparing $n(\mu(y) - \mu(a_n))$ to x (with $x \geq y$).

First, when $y \leq a_n$, then $\mu(y) - \mu(a_n) \leq 0$ since X_1 is non negative, so that

$$\mathbf{P}(S_n - b_n \geq x; M_n \leq y) \leq \left(1 + \frac{cx}{nL(y)}\right)^{-\frac{x}{y}}.$$

When $y \geq a_n$, then we use the following claim (we prove it for $\ell(\cdot)$ defined in (3.1), but it obviously holds also for $\ell^*(c)$, and for $\mu(\cdot)$ in the case of a non-negative X_1).

Claim 5.3. For every $\delta > 0$, there is a constant c_δ s.t. for every $1 \leq u \leq v$ we have

$$\frac{1}{L(v)}(\ell(v) - \ell(u)) \leq c_\delta (u/v)^\delta. \quad (5.6)$$

Moreover, considering two sequences $(u_n), (v_n) \rightarrow +\infty$, if there is a constant $c > 0$ such that $u_n \leq v_n \leq cu_n$ for all n then we have

$$\frac{1}{L(u_n)}(\ell(v_n) - \ell(u_n)) \stackrel{n \rightarrow +\infty}{\sim} \log(v_n/u_n) \quad (5.7)$$

Proof of the Claim. We write

$$\frac{\ell(u) - \ell(v)}{L(v)} = \int_u^v \frac{L(t)t^{-1}}{L(v)} dt \leq c_\delta \left(\frac{u}{v}\right)^{\delta/2} \int_u^v \frac{dt}{t}$$

where we used Potter's bound (see [2]) to get that there is a constant c_δ such that uniformly for $t \geq v$ we have $L(t)/L(v) \leq c_\delta (t/v)^{\delta/2}$. Then, the last integral is equal to $\log(u/v) \leq c_\delta (u/v)^{\delta/2}$ so the first part of the claim is proven. For the second part, this is standard and comes from the same computation, together with the fact that $L(t)/L(v_n) \rightarrow 1$ uniformly for $t \in [u_n, v_n] \subset [u_n, cu_n]$:

$$\frac{\ell(v_n) - \ell(u_n)}{L(u_n)} = \int_{u_n}^{v_n} \frac{L(t)t^{-1}}{L(v_n)} dt = (1 + o(1)) \int_{u_n}^{v_n} \frac{dt}{t} \stackrel{n \rightarrow +\infty}{\sim} \log(v_n/u_n).$$

□

From Claim 5.3 (take $\delta = 1/2$) we get that, for any $y \geq a_n$, and since $x \geq y$

$$n(\mu(y) - \mu(a_n)) \leq c_\delta nL(a_n)(y/a_n)^{1/2} \leq c \frac{nL(a_n)}{a_n} (x/a_n)^{-1/2} \times x.$$

Therefore, by choosing $C_\varepsilon > 0$ large enough, we get that $n(\mu(y) - \mu(a_n)) \leq \varepsilon x$ provided that $x \geq C_\varepsilon a_n$, $a_n \leq y \leq x$. Plugged in (5.5), we get

$$\mathbf{P}(S_n - b_n \geq x; M_n \leq y) \leq e^{\frac{x}{y}} \left(1 + c \frac{n\mu(a_n) + x}{nL(y)}\right)^{-(1-\varepsilon)\frac{x}{y}} \leq e^{\frac{x}{y}} \left(1 + \frac{cx}{nL(y)}\right)^{-(1-\varepsilon)\frac{x}{y}}.$$

Hence, the first part of (5.2) is proven.

Proof of the second part of (5.2). We write, for any $t > 0$ and any $a_n \leq x \leq b_n$ (recall that $S_n - b_n \geq -b_n$)

$$\mathbf{P}(S_n - b_n \leq -x) \leq e^{-t(x-b_n)} \mathbf{E}[e^{-tX_1}]^n.$$

We also use that, because $X_1 \geq 0$ and thanks to (1.1), we have that there is a constant $c > 0$ such that for any $t \leq 1$

$$\mathbf{E}[e^{-tX_1}] - 1 + t\mu(1/t) \leq ctL(1/t). \quad (5.8)$$

Indeed, one simply writes that the absolute value of the left hand side is

$$\begin{aligned} & \left| \sum_{n=1}^{1/t} (1 - e^{-tn} - tn) \mathbf{P}(X_1 = n) + \sum_{n>1/t} (1 - e^{-tn}) \mathbf{P}(X_1 = n) \right| \\ & \leq \sum_{n=1}^{1/t} t^2 n^2 \mathbf{P}(X_1 = n) + \sum_{n>1/t} \mathbf{P}(X_1 = n) \\ & = t^2 \mathbf{E}[(X_1)^2 \mathbf{1}_{\{X_1 \leq 1/t\}}] + \mathbf{P}(X_1 > 1/t). \end{aligned}$$

Then, one easily get that both terms are $O(tL(1/t))$, using (1.1).

Thanks to (5.8), and using that $1 + x \leq e^x$, we get that for any $t \leq 1$

$$\begin{aligned} \mathbf{P}(S_n - b_n \leq -x) &\leq \exp\left(-t(x - b_n) - nt\mu(1/t) + cntL(1/t)\right) \\ &= \exp\left(-tx + nt\left[\mu(a_n) - \mu(1/t) + cL(1/t)\right]\right). \end{aligned} \quad (5.9)$$

Then, we fix $\varepsilon > 0$ and choose $t := (a_n)^{-1} \times (x/a_n)^{(1-\varepsilon)/\varepsilon}$. Since $a_n \leq x \leq b_n$, we have that $1 \leq (x/a_n)^{(1-\varepsilon)/\varepsilon} \leq (b_n/a_n)^{(1-\varepsilon)/\varepsilon}$, so that we indeed have $t \leq 1$, and also $1/t \leq a_n$. Thanks to Claim 5.3, we get that there is a constant c_ε such that $\mu(a_n) - \mu(1/t) \leq c_\varepsilon (ta_n)^\varepsilon L(a_n)$, and Potter's bound also gives that $L(1/t) \leq c_\varepsilon (ta_n)^\varepsilon L(a_n)$. We therefore get that the r.h.s. of (5.9) is bounded by

$$\exp\left(-tx + (1 + c_\varepsilon)nt(ta_n)^\varepsilon L(a_n)\right) \leq \exp\left(-\left(\frac{x}{a_n}\right)^{1/\varepsilon} + c'_\varepsilon \left(\frac{x}{a_n}\right)^{(1-\varepsilon^2)/\varepsilon}\right) \quad (5.10)$$

where we used the definition of t , together with the fact that $nL(a_n) \sim a_n$ for the second term in the exponential. Hence, there exists some $C_\varepsilon > 0$ such that provided that $x/a_n \geq C_\varepsilon$ we have

$$\mathbf{P}(S_n - b_n \leq -x) \leq \exp\left(-\frac{1}{2}\left(\frac{x}{a_n}\right)^{1/\varepsilon}\right),$$

which ends the proof of the second part of (5.2), the factor $1/2$ being irrelevant.

6. LOCAL LARGE DEVIATIONS

6.1. Local versions of Fuk-Nagaev inequalities. The following Proposition proves Theorem 2.2-(2.2), and together with a local version of Theorem 5.1.

Proposition 6.1. *Assume that (1.1) holds. There is a constant $C > 0$ such that for any $\varepsilon > 0$, there is some C_ε such that: for $x \geq C_\varepsilon a_n$ in the case $\alpha = 1$ and for $x \geq C_\varepsilon$ if $\alpha \neq 1$, for any $y \leq x$*

$$\mathbf{P}(S_n - \lfloor b_n \rfloor = x; M_n \leq y) \leq \frac{C}{a_n} \mathbf{P}\left(S_{\lfloor n/2 \rfloor} - b_{\lfloor n/2 \rfloor} \geq (1 - \varepsilon)\frac{x}{2}; M_{\lfloor n/2 \rfloor} \leq y\right).$$

An upper bound is then given by Theorem 2.2-(2.1) if $\alpha = 1$, or by Theorem 5.1 if $\alpha \neq 1$.

This result is similar to [6, Thm. 1.1], but here the estimate holds even when $y \ll x$ which is not the case in [6]. In view of Theorems 2.2, one obtains the upper bound $(cny^{1-\alpha}L(y)/x)^{(1-\varepsilon)^2x/2y}$ if $\alpha = 1$ for $x \geq C_\varepsilon a_n$ (the case $\alpha \neq 1$ is analogous): we might be able to improve the exponent to $\lceil x/y \rceil$ as in [6, Thm. 1.1] (at least when y is a constant times x), but we do not pursue this level of optimality here.

Proof Let us denote $\widehat{S}_n := S_n - \lfloor b_n \rfloor$ the ‘‘recentered’’ walk. We decompose $\mathbf{P}(\widehat{S}_n = x)$ according to whether $S_{\lfloor n/2 \rfloor} - \frac{1}{2}\lfloor b_n \rfloor \geq x/2$ or not, so that we obtain

$$\begin{aligned} \mathbf{P}(\widehat{S}_n = x; M_n \leq y) &\leq \mathbf{P}\left(\widehat{S}_n = x; S_{\lfloor n/2 \rfloor} - \frac{1}{2}\lfloor b_n \rfloor \geq x/2; M_{\lfloor n/2 \rfloor} \leq y\right) \\ &\quad + \mathbf{P}\left(\widehat{S}_n = x; S_n - S_{\lfloor n/2 \rfloor} - \frac{1}{2}\lfloor b_n \rfloor \geq x/2; \max_{\lfloor n/2 \rfloor < i \leq n} X_i \leq y\right). \end{aligned}$$

The two terms are treated similarly, so we only focus on the first one. We have

$$\begin{aligned}
& \mathbf{P}\left(\widehat{S}_n = x; S_{\lfloor n/2 \rfloor} - \frac{1}{2}\lfloor b_n \rfloor \geq x/2; M_{\lfloor n/2 \rfloor} \leq y\right) \\
&= \sum_{z \geq \frac{1}{2}\lfloor b_n \rfloor + x/2} \mathbf{P}(S_{\lfloor n/2 \rfloor} = z; M_{\lfloor n/2 \rfloor} \leq y) \mathbf{P}(S_n - S_{\lfloor n/2 \rfloor} = \lfloor b_n \rfloor + x - z) \\
&\leq \frac{C}{a_n} \sum_{z \geq \frac{1}{2}\lfloor b_n \rfloor + x/2} \mathbf{P}(S_{\lfloor n/2 \rfloor} = z; M_{\lfloor n/2 \rfloor} \leq y) \\
&= \frac{C}{a_n} \mathbf{P}\left(S_{\lfloor n/2 \rfloor} - \frac{1}{2}\lfloor b_n \rfloor \geq x/2; M_{\lfloor n/2 \rfloor} \leq y\right), \tag{6.1}
\end{aligned}$$

where we used Gnedenko's local limit theorem (1.4) to get that there is a constant $C > 0$ such that for any $k \geq 1$ and $y \in \mathbb{Z}$, we have $\mathbf{P}(S_k = y) \leq C/a_k$.

It remains to control $\frac{1}{2}\lfloor b_n \rfloor - b_{\lfloor n/2 \rfloor}$. When $\alpha \in (0, 1)$ we have that $b_n \equiv 0$ so this quantity is equal to 0, and when $\alpha > 1$ we have $b_k = k\mu$ in which case we get $\frac{1}{2}\lfloor b_n \rfloor - \lfloor b_{n/2} \rfloor \geq -|\mu|$. When $\alpha = 1$, this is more delicate but not too hard:

$$\begin{aligned}
\frac{1}{2}n\mu(a_n) - \lfloor n/2 \rfloor \mu(a_{\lfloor n/2 \rfloor}) &\geq \frac{n}{2} \left[\mu(a_n) - \mu(a_{\lfloor n/2 \rfloor}) \right] - |\mu(a_{\lfloor n/2 \rfloor})| \\
&\geq -c_0 nL(a_n) - |\mu(a_{\lfloor n/2 \rfloor})| \geq -2c_0 a_n.
\end{aligned}$$

For the second inequality we used Claim 5.3 (separating the positive and negative parts of X_1 , using also that $a_n/a_{\lfloor n/2 \rfloor}$ is bounded above by a constant), and for the last inequality we used the definition of a_n (and the fact that $|\mu(a_{\lfloor n/2 \rfloor})| = o(a_n)$). Therefore, provided that $x \geq C_\varepsilon a_n$ with some constant C_ε large enough in the case $\alpha = 1$ (if $\alpha \neq 1$, having $x \geq C_\varepsilon$ is enough), we get that $\frac{1}{2}\lfloor b_n \rfloor - b_{\lfloor n/2 \rfloor} \geq -\varepsilon x/2$. This concludes the proof. \square

6.2. Improved local large deviations: proof of Theorem 2.4. We only consider large deviations to the right, i.e. $x \geq a_n$, since the other case is symmetric. We give the proof of (2.9) and (2.10) together, the latter using the same estimates. We fix $\varepsilon > 0$ (we take $\varepsilon = 1/8$ when we prove (2.9), and we will choose ε arbitrarily small when we prove (2.10)), and we write (recall $\widehat{S}_n = S_n - \lfloor b_n \rfloor$)

$$\begin{aligned}
\mathbf{P}(\widehat{S}_n = x) &= \mathbf{P}(\widehat{S}_n = x, M_n \geq (1 - \varepsilon)x) \\
&\quad + \mathbf{P}(\widehat{S}_n = x, M_n \in (\varepsilon x, (1 - \varepsilon)x)) + \mathbf{P}(\widehat{S}_n = x, M_n \leq \varepsilon x). \tag{6.2}
\end{aligned}$$

The first term in (6.2) is also the main one: by exchangeability of the X_i 's, we get that

$$\begin{aligned}
\mathbf{P}(\widehat{S}_n = x, M_n \geq (1 - \varepsilon)x) &= \sum_{y \geq (1 - \varepsilon)x} \mathbf{P}(\widehat{S}_n = x, M_n = y) \\
&\leq \sum_{y \geq (1 - \varepsilon)x} n \mathbf{P}(X_1 = y) \mathbf{P}(S_{n-1} - \lfloor b_n \rfloor = x - y). \tag{6.3}
\end{aligned}$$

Bounding $\mathbf{P}(X_1 = y)$ by $\sup_{y \geq (1 - \varepsilon)x} \mathbf{P}(X_1 = y)$ and summing over y the last probability, we therefore get

$$\mathbf{P}(\widehat{S}_n = x, M_n \geq (1 - \varepsilon)x) \leq n \sup_{y \geq (1 - \varepsilon)x} \mathbf{P}(X_1 = y).$$

Then, if we assume (2.5), we obtain

$$\mathbf{P}(\widehat{S}_n = x, M_n \geq (1 - \varepsilon)x) \leq CnL(x)x^{-(1+\alpha)}. \tag{6.4}$$

If we assume (2.7), for any $\varepsilon > 0$ we have $\sup_{y \geq (1-\varepsilon)x} \mathbf{P}(X_1 = y) \leq (p + 3\varepsilon)L(x)x^{-(1+\alpha)}$, provided that x is large enough: we may replace the constant C in (6.4) by $(p + 3\varepsilon)$.

For the second term in (6.2), we have:

$$\begin{aligned} \mathbf{P}(\widehat{S}_n = x, M_n \in (\varepsilon x, (1-\varepsilon)x)) &= \sum_{y=\lfloor \varepsilon x \rfloor + 1}^{\lceil (1-\varepsilon)x \rceil - 1} \mathbf{P}(\widehat{S}_n = x, M_n = y) \\ &\leq \sum_{y=\lfloor \varepsilon x \rfloor + 1}^{\lceil (1-\varepsilon)x \rceil - 1} n \mathbf{P}(X_1 = y) \mathbf{P}(S_{n-1} - \lfloor b_n \rfloor = x - y) \\ &\leq C_\varepsilon n L(x) x^{-(1+\alpha)} \mathbf{P}(S_{n-1} - \lfloor b_n \rfloor \geq \varepsilon x), \end{aligned} \quad (6.5)$$

where we used (2.5) in the last inequality. Moreover, since $(S_n - b_n)/a_n$ converges in distribution, we get that $\mathbf{P}(S_{n-1} - \lfloor b_n \rfloor \geq \varepsilon x) \rightarrow 0$ if $x/a_n \rightarrow +\infty$, so the second term is $o(nL(x)x^{-(1+\alpha)})$.

For the last term in (6.2), we decompose it into two parts,

$$\mathbf{P}(\widehat{S}_n = x, M_n \leq \varepsilon x) \leq \mathbf{P}(\widehat{S}_n = x, M_n \leq ca_n) + \mathbf{P}(\widehat{S}_n = x, M_n \in (ca_n, \varepsilon x))$$

The first part is controlled thanks to the local Fuk-Nagaev inequalities Theorems 2.2-(2.2) (or Proposition 6.1 if $\alpha \neq 1$): using that $x \geq a_n$ and that $nL(a_n)a_n^{-\alpha} \rightarrow 1$, we get that

$$\mathbf{P}(\widehat{S}_n = x, M_n \leq ca_n) \leq \frac{C}{a_n} \left(\left(c' \frac{x}{a_n} \right)^{-c'x/a_n} + e^{-c_2(x/a_n)^2} \right) \leq \frac{c}{x} \times e^{-c'x/a_n}, \quad (6.6)$$

which is negligible compared to (6.4) (or (2.9)) as $x/a_n \rightarrow +\infty$. For the second part, we write

$$\begin{aligned} \mathbf{P}(\widehat{S}_n = x, M_n \in [ca_n, \varepsilon x)) &= \sum_{j=\log_2(1/\varepsilon)}^{\log_2(cx/a_n)-1} \mathbf{P}(\widehat{S}_n = x, M_n \in [2^{-(j+1)}, 2^{-j})x) \\ &\leq \sum_{j=\log_2(1/\varepsilon)}^{\log_2(cx/a_n)} \sum_{y \in [2^{-(j+1)}, 2^{-j})x} n \mathbf{P}(X_1 = y) \mathbf{P}(S_{n-1} - \lfloor b_n \rfloor = x - y, M_{n-1} \leq y) \\ &\leq C \sum_{j=\log_2(1/\varepsilon)}^{\log_2(cx/a_n)} n L(2^{-j}x) (2^{-j}x)^{-(1+\alpha)} \mathbf{P}(S_{n-1} - \lfloor b_n \rfloor \geq x/2, M_n \leq 2^{-j}x), \end{aligned} \quad (6.7)$$

where we used (2.5) to bound $\mathbf{P}(X_1 = y)$ uniformly for $y \in [2^{-(j+1)}, 2^{-j})x$. Then, we use Fuk-Nagaev's inequalities Theorem 5.1-Theorem 5.2—leave aside the case $\alpha = 1$ for the moment—to get that (replacing $S_{n-1} - \lfloor b_n \rfloor$ by $S_n - b_n$ for simplicity)

$$\mathbf{P}(S_n - b_n \geq x/2, M_n \leq 2^{-j}x) \leq \left(\frac{c2^j}{nL(2^{-j}x)(2^{-j}x)^{-\alpha}} \right)^{-2^{j-2}} \leq (c2^j)^{-2^{j-2}},$$

where we used that $2^{-j}x \geq a_n$ for the range considered, so $n\mathbf{P}(X_1 > 2^{-j}x) \leq n\mathbf{P}(X_1 > a_n)$ and is bounded above by a universal constant. Plugged in (6.7), and using Potter's bound to get that $L(2^{-j}x) \leq c2^j L(x)$ for all $j \geq 1$, we therefore get that

$$\begin{aligned} \mathbf{P}(\widehat{S}_n = x, M_n \in [ca_n, \varepsilon x)) &\leq CnL(x)x^{-(1+\alpha)} \sum_{j=\log_2(1/\varepsilon)}^{\log_2(cx/a_n)} 2^{(2+\alpha)j} (c2^j)^{-2^{j-2}} \\ &\leq c_\varepsilon nL(x)x^{-(1+\alpha)}, \end{aligned} \quad (6.8)$$

where the constant c_ε can be made arbitrarily small by choosing ε small. In the case $\alpha = 1$, Theorem 2.2 gives an additional $e^{-c_2(x/a_n)^2}$ in bounding $\mathbf{P}(S_n - b_n \geq x/2, M_n \leq 2^{-j}x)$ for any $j \leq \log_2(cx/a_n)$. Hence in (6.8) we obtain an additional

$$CnL(x)x^{-(1+\alpha)} \sum_{j=1}^{\log_2(cx/a_n)} 2^{(2+\alpha)j} e^{-c_2(x/a_n)^2} \leq CnL(x)x^{-(1+\alpha)} \times \left(\frac{x}{a_n}\right)^{3+\alpha} e^{-c_2(x/a_n)^2},$$

which is $o(nL(x)x^{-(1+\alpha)})$ as $x/a_n \rightarrow +\infty$.

In conclusion, combining (6.4)-(6.5)-(6.6)-(6.8), we proved that fixing $\varepsilon = 1/8$ we get (2.9). Assuming additionally (2.7), and in view of the remark made after (6.4), we obtain that for any $\eta > 0$ we can find $\varepsilon > 0$ (sufficiently small) such that, if n and x/a_n are large enough,

$$\mathbf{P}(S_n - b_n = x) \leq (p + \eta)nL(x)x^{-(1+\alpha)}.$$

This proves the upper bound part in Theorem 2.4.

To get the lower bound in (2.10), assume that $p > 0$ (otherwise there is nothing to prove), and write

$$\begin{aligned} \mathbf{P}(\widehat{S}_n = x) &\geq \mathbf{P}(\exists i \text{ s.t. } X_i \in ((1-\varepsilon)x, (1+\varepsilon)x); \forall j \neq i X_j \leq x/2; \widehat{S}_n = x) \\ &= \sum_{y=\lceil(1-\varepsilon)x\rceil}^{\lfloor(1+\varepsilon)x\rfloor} n\mathbf{P}(X_1 = y)\mathbf{P}(S_{n-1} - \lfloor b_n \rfloor = x - y; M_{n-1} \leq x/2) \\ &\geq (1 - 3\varepsilon)npL(x)x^{-(1+\alpha)}\mathbf{P}(S_{n-1} - b_n \in [-\varepsilon x, \varepsilon x]; M_{n-1} \leq x/2). \end{aligned}$$

We used that $\mathbf{P}(X_1 = y) \geq (1 - 3\varepsilon)pL(x)x^{-(1+\alpha)}$ uniformly for $y \in ((1-\varepsilon)x, (1+\varepsilon)x)$ and provided that x is large enough, because of (2.7). Then, the last probability converges to 1 as $n \rightarrow +\infty$ because $(S_{n-1} - \lfloor b_n \rfloor)/a_n$ and M_{n-1}/a_n both converge in distribution, and $x/a_n \rightarrow +\infty$. Hence we have that for any $\eta > 0$, we can find $\varepsilon > 0$ (sufficiently small) such that if n and x/a_n are large enough,

$$\mathbf{P}(S_n - \lfloor b_n \rfloor = x) \geq (1 - \eta)pnL(x)x^{-(1+\alpha)},$$

which concludes the proof. \square

7. LADDER EPOCHS: PROOF OF THEOREMS 3.2-3.4

To prove Theorem 3.2, a crucial identity follows from the Wiener-Hopf factorization (see e.g. Theorem 4 in [14, XII.7]). Set $p_k := \mathbf{P}(T_- > k)$ for every $k \geq 0$: for any $s \in [0, 1)$

$$p(s) := \sum_{k=0}^{+\infty} p_k s^k = \exp\left(\sum_{m=1}^{+\infty} \frac{s^m}{m} \mathbf{P}(S_m \geq 0)\right). \quad (7.1)$$

We present the proof in the case $\alpha = 1$ with infinite mean, *i.e.* Theorem 3.2 (it captures all the ideas needed), and then we adapt the proof to the case $\mu = 0$ (*i.e.* Theorem 3.4) in Section 7.6.

7.1. Preliminaries. Let us first give the following lemma, which is the core of our proofs.

Lemma 7.1. *Assume that (1.1) holds, with $\alpha = 1$ and $|\mu| = +\infty$. Recall the definition (3.1) of $\ell(\cdot)$ and (1.3) of b_n . If $p > q$, then $b_n \sim (p - q)n\ell(a_n) \rightarrow +\infty$ and*

$$\mathbf{P}(S_n < 0) \sim \frac{q}{p - q} \frac{L(b_n)}{\ell(b_n)} \quad \text{as } n \rightarrow +\infty.$$

Moreover we have that

$$\sum_{k=1}^n \frac{1}{k} \mathbf{P}(S_k < 0) \sim \frac{q}{p-q} \log \ell(b_n) \quad \text{as } n \rightarrow +\infty.$$

If $q = 0$, we interpret this as $o(\log \ell(b_n))$. The case $p < q$ is symmetric. If $p = q = 1/2$, then $b_n = o(n\ell(a_n))$ but if $b_n/a_n \rightarrow +\infty$ we have

$$\mathbf{P}(S_n < 0) \stackrel{n \rightarrow +\infty}{\sim} \frac{nL(b_n)}{2b_n}, \quad \sum_{k=1}^{+\infty} k^{-1} \mathbf{P}(S_k < 0) = +\infty.$$

Proof First, when $p > q$, we get thanks to Theorem 2.1 (since $b_n/a_n \rightarrow +\infty$) that

$$\mathbf{P}(S_n < 0) = \mathbf{P}(S_n - b_n < -b_n) \sim nqL(b_n)b_n^{-1} \sim \frac{q}{p-q} \frac{L(b_n)}{\ell(b_n)} \quad \text{as } n \rightarrow +\infty. \quad (7.2)$$

We used that $b_n = n\mu(a_n)$ with $\mu(a_n) \sim (p-q)\ell(a_n) \sim (p-q)\ell(b_n)$ for the last part (see Lemma 4.3). The first asymptotic equivalence remains true as soon as $b_n/a_n \rightarrow +\infty$.

Then, it remains to estimate the sum $\sum_{k=1}^n k^{-1} \mathbf{P}(S_k < 0)$ or, because of (7.2), of $q \sum_{k=1}^n L(b_k)/b_k$. By comparing with an integral, and using the function \tilde{b}_t such that $b_k \sim (p-q)\tilde{b}_k$ and $\partial_t \tilde{b}_t = \ell(\tilde{b}_t)$ (cf. (7.12) below, we may assume that we work with differentiable function, see [2, Thm. 1.8.2]), we obtain that

$$\sum_{k=1}^n \frac{L(b_k)}{b_k} \stackrel{n \rightarrow +\infty}{\sim} \int_{t=1}^n \frac{L(\tilde{b}_t)}{\tilde{b}_t} dt = \frac{1}{p-q} \int_{u=1}^{\tilde{b}_n} \frac{L(u)}{u\ell(u)} du \stackrel{n \rightarrow +\infty}{\sim} \frac{1}{p-q} \log \ell(b_n).$$

We used a change of variables $u = \tilde{b}_t$, $du = \ell(\tilde{b}_t) dt$, and then Lemma 4.4-(i) (with $f(t) = 1/t$) for the last identity.

In the case where $p = q = 1/2$ (so $b_k = o(k\ell(a_k))$) we use that according to (7.2) and provided that $b_n/a_n \rightarrow +\infty$, there is a constant $c > 0$ such that

$$k^{-1} \mathbf{P}(S_k < 0) \geq c \frac{L(b_k)}{b_k} \geq c' \frac{L(k\ell(a_k))}{k\ell(a_k)}.$$

And we proved just above that $\sum_{k=1}^{+\infty} \frac{L(k\ell(a_k))}{k\ell(a_k)} = +\infty$. \square

A simple consequence of Lemma 7.1 is Proposition 3.1 (in the case $|\mu| = +\infty$, the case $\mu = 0$ being treated in Lemma 7.3 below), thanks to [14, XII.7 Thm. 2]. Indeed, we get that $\sum_{k \geq 1} k^{-1} \mathbf{P}(S_k < 0) = +\infty$ as soon as $q \neq 0$: if $p > q$ or $p = q$ with $b_n/a_n \rightarrow +\infty$, this is directly Lemma 7.1; if $\sup_n |b_n|/a_n < +\infty$, then this is just a consequence of the convergence in distribution of $(S_n - b_n)/a_n$ to get that $\mathbf{P}(S_k < 0) = \mathbf{P}((S_k - b_k)/a_k < -b_k/a_k)$ is uniformly bounded away from 0, so that $\sum_{k \geq 1} k^{-1} \mathbf{P}(S_k < 0) = +\infty$; the general case when $p = q = 1/2$ can be dealt with similarly, by observing as above that there is a constant c such that $k^{-1} \mathbf{P}(S_k < 0) \geq c \frac{L(k\ell(a_k))}{k\ell(a_k)}$.

7.2. The case $\lim_{n \rightarrow +\infty} b_n/a_n = b$. This is case (i) in Theorem 3.2, which is standard, cf. Rogozin [21]. The sequence $\mathbf{P}(S_k > 0) = \mathbf{P}((S_k - b_k)/a_k > -b_k/a_k)$ converges to $\mathbf{P}(Y > -b)$, where Y is the limit in distribution of $(S_n - b_n)/a_n$, that is a symmetric Cauchy(1/2) distribution ($p = q = 1/2$), and $b = \lim_{n \rightarrow +\infty} b_n/a_n$. Note that we could also characterize b_n/a_n by $\mathbf{E}\left[\frac{X_1}{1+(X_1/a_n)^2}\right]$, see [2, Thm. 8.3.1]. We therefore get that

$$\lim_{n \rightarrow +\infty} \frac{1}{n} \sum_{k=1}^n \mathbf{P}(S_k > 0) = \mathbf{P}(Y > -b) =: \rho \in (0, 1),$$

with $\rho = \frac{1}{2} + \frac{1}{\pi} \arctan(2b/\pi)$. This is Spitzer's condition: from [2, Thm. 8.9.12], T_- is in the domain of attraction of a positive stable random variable with index ρ , and (i) follows.

7.3. The case $p < q$. We first prove the weak result with the $o(1)$ in the exponent, and then turn to the precise statement under assumptions V1-V2.

General Case. Denote

$$f(s) = \sum_{m=1}^{+\infty} \frac{s^m}{m} \mathbf{P}(S_m \geq 0), \quad f'(s) = \sum_{m=0}^{+\infty} s^m \mathbf{P}(S_{m+1} \geq 0). \quad (7.3)$$

We are able to obtain the behavior of $f(s)$ and $f'(s)$ as $s \uparrow 1$. For $p < q$, Lemma 7.1 gives

$$\sum_{k=1}^n k^{-1} \mathbf{P}(S_k \geq 0) \stackrel{n \rightarrow +\infty}{\sim} \frac{p}{q-p} \log \ell(|b_n|); \quad \sum_{k=1}^n \mathbf{P}(S_k \geq 0) \stackrel{n \rightarrow +\infty}{\sim} \frac{p}{q-p} \frac{nL(|b_n|)}{\ell(|b_n|)}, \quad (7.4)$$

(because $\mathbf{P}(S_k \geq 0) \sim \frac{p}{q-p} L(|b_k|)/\ell(|b_k|)$). Therefore, Corollary 1.7.3 in [2] gives that

$$f(s) \sim \frac{p}{q-p} \log \ell(|b_{1/(1-s)}|); \quad f'(s) \sim \frac{p}{q-p} \frac{1}{1-s} \frac{L(|b_{1/(1-s)}|)}{\ell(|b_{1/(1-s)}|)} \quad \text{as } s \uparrow 1. \quad (7.5)$$

The identity (7.1) gives that $p(s) = e^{f(s)}$ for any $s \in [0, 1)$ so that $p'(s) = f'(s)e^{f(s)}$: the estimates (7.5) allows us to derive that

$$p'(s) = \frac{L(|b_{1/(1-s)}|)}{1-s} \left(\ell(|b_{1/(1-s)}|) \right)^{\frac{p}{q-p} - 1 + o(1)} \quad \text{as } s \uparrow 1, \quad (7.6)$$

where the term $p/(q-p)$ has been absorbed in $\ell(|b_{1/(1-s)}|)^{o(1)}$. From this we would like to conclude that $\sum_{k=1}^n k p_k = nL(|b_n|) \ell(|b_n|)^{\frac{p}{q-p} - 1 + o(1)}$, but we cannot directly apply Corollary 1.7.3 in [2] since we do not have a proper asymptotic equivalence. We therefore prove it directly.

Upper bound. First, take $s = 1 - 1/n$ in (7.6), so that we get, as $n \rightarrow +\infty$

$$\sum_{k=0}^{+\infty} k p_k \left(1 - \frac{1}{n}\right)^{k-1} = nL(|b_n|) \ell(|b_n|)^{\frac{p}{q-p} - 1 + o(1)}. \quad (7.7)$$

Then, using that p_k is non-increasing, we can write that

$$\sum_{k=0}^{+\infty} k p_k \left(1 - \frac{1}{n}\right)^{k-1} \geq \sum_{k=0}^n k p_n \left(1 - \frac{1}{n}\right)^n \geq c n^2 p_n,$$

and we therefore get the upper bound

$$p_n \leq c \frac{1}{n} L(|b_n|) \ell(|b_n|)^{\frac{p}{q-p} - 1 + o(1)} = \frac{L(|b_n|)}{n} \ell(|b_n|)^{\frac{p}{q-p} - 1 + o(1)}. \quad (7.8)$$

Lower bound. The lower bound is a bit trickier. Let $\varepsilon > 0$, and define $t_n := \ell(|b_n|)^\varepsilon \rightarrow +\infty$ as $n \rightarrow +\infty$. Setting $s = 1 - 1/(nt_n)$ in (7.6), we get that for n sufficiently large

$$\begin{aligned} \sum_{k=0}^{+\infty} k p_k \left(1 - \frac{1}{nt_n}\right)^{k-1} &= nt_n L(|b_{n/t_n}|) \ell(|b_{n/t_n}|)^{\frac{p}{q-p} - 1 + o(1)} \\ &\geq nt_n^{1/2} L(|b_n|) \ell(|b_n|)^{\frac{p}{q-p} - 1 + o(1)}. \end{aligned} \quad (7.9)$$

For the second inequality, we used that $|b_{n/t_n}| \geq t_n^{-2} |b_n|$ for n large enough (since b_k is regularly varying with index -1), and then Potter's bound to get that $L(t_n^{-2} |b_n|) \leq t_n^{-1/4} L(|b_n|)$ and $\ell(t_n^{-2} |b_n|)^{\frac{p}{q-p} - 1 + o(1)} \leq t_n^{-1/4}$ for n large enough.

Now we may write, since p_k is non-increasing,

$$\sum_{k=0}^{+\infty} k p_k \left(1 - \frac{1}{nt_n}\right)^{k-1} \leq \sum_{k=0}^n k p_k + p_n \sum_{k=n+1}^{+\infty} k \left(1 - \frac{1}{nt_n}\right)^{k-1} \quad (7.10)$$

For the first sum, we get thanks to (7.8) that

$$\sum_{k=0}^n k p_k \leq c n L(|b_n|) (\ell(|b_n|))^{\frac{p}{q-p}-1+o(1)} = o(1) n t_n^{1/2} L(|b_n|) (\ell(|b_n|))^{\frac{p}{q-p}-1+o(1)},$$

where we used the definition of t_n , which is such that $\ell(|b_n|)^{o(1)} = o(t_n^{1/2})$. Now we have $\sum_{k \geq 1} k s^{k-1} = (1-s)^{-2}$, so that the second term in (7.10) is bounded by $p_n (nt_n)^2$. Hence, plugging (7.10) (and the subsequent estimates) in (7.9), we obtain that

$$n t_n^{1/2} L(|b_n|) (\ell(|b_n|))^{\frac{p}{q-p}-1+o(1)} \leq o\left(n t_n^{1/2} L(|b_n|) (\ell(|b_n|))^{\frac{p}{q-p}-1+o(1)}\right) + p_n (nt_n)^2,$$

so that we conclude that

$$p_n \geq \frac{c}{n t_n^{3/2}} L(|b_n|) (\ell(|b_n|))^{\frac{p}{q-p}-1+o(1)}.$$

Recalling that $t_n = \ell(|b_n|)^\varepsilon$, and since $\varepsilon > 0$ is arbitrary, we get that

$$p_n \geq \frac{L(|b_n|)}{n} (\ell(|b_n|))^{\frac{p}{q-p}-1+o(1)}. \quad (7.11)$$

Under assumption V1-V2. Let us first introduce some notations. We construct \tilde{b}_t an analytic function such that its derivative is given by $\ell(\tilde{b}_t)$. Define

$$H(x) = \left(\int_1^x \frac{dx}{\ell(x)} \right)^{-1}, \quad \text{and} \quad \tilde{b}_t = H^{-1}(1/t). \quad (7.12)$$

Then, it is easy to verify that $H'(x) = -H(x)/\ell(x)$, so that $\partial_t \tilde{b}_t = \ell(\tilde{b}_t)$ (using also that $H(\tilde{b}_t) = 1/t$). Notice that we also have easily that $H(x) \sim \ell(x)/x$ as $x \rightarrow +\infty$, so that $\tilde{b}_t \sim t\ell(\tilde{b}_t)$ as $t \rightarrow +\infty$. Thanks to Lemma 4.3 we get that $\tilde{b}_t \sim t\ell(a_t)$ as $t \rightarrow +\infty$, and therefore $b_n \sim -(q-p)\tilde{b}_n$. Let us define

$$g(s) := \log \ell\left(\tilde{b}_{\frac{1}{1-s}}\right).$$

Using that $\partial_t \tilde{b}_t = \ell(\tilde{b}_t)$, we get that

$$g'(s) = \frac{1}{(1-s)^2} \frac{L\left(\tilde{b}_{\frac{1}{1-s}}\right)}{\tilde{b}_{\frac{1}{1-s}}} \stackrel{s \uparrow 1}{\sim} \frac{1}{1-s} \frac{L\left(\tilde{b}_{\frac{1}{1-s}}\right)}{\ell\left(\tilde{b}_{\frac{1}{1-s}}\right)}.$$

Since $L(\cdot)$ satisfies V1-V2, so does $L\left(\tilde{b}_{\frac{1}{1-s}}\right)/\ell\left(\tilde{b}_{\frac{1}{1-s}}\right)$, and we may apply Theorem 5 in [15] to get that $g'(s) = \sum_{n=0}^{+\infty} a_n s^n$ with $a_n \sim L(\tilde{b}_n)/\ell(\tilde{b}_n)$ as $n \rightarrow +\infty$. We end up with

$$g(s) := \log \ell\left(\tilde{b}_{\frac{1}{1-s}}\right) = \sum_{n=1}^{+\infty} g_n s^n \quad \text{with} \quad g_n \sim \frac{L(\tilde{b}_n)}{n\ell(\tilde{b}_n)} \sim \frac{q-p}{p} \frac{\mathbf{P}(S_n \geq 0)}{n}. \quad (7.13)$$

In view of (7.3), we get that

$$f(s) = \frac{p}{q-p} g(s) + \sum_{n=1}^{+\infty} v_n s^n \quad \text{with} \quad v_n = o\left(\frac{L(\tilde{b}_n)}{n\ell(\tilde{b}_n)}\right), \quad (7.14)$$

so that

$$p'(s) = f'(s)\ell\left(\tilde{b}_{\frac{1}{1-s}}\right)^{\frac{p}{q-p}}\psi\left(\frac{1}{1-s}\right) \quad \text{with } \psi\left(\frac{1}{1-s}\right) := \exp\left(\sum_{n=1}^{+\infty} v_n s^n\right). \quad (7.15)$$

Lemma 7.2. *There exists some slowly varying function $\tilde{L}(\cdot)$ such that*

$$\psi\left(\frac{1}{1-s}\right) = \tilde{L}\left(\ell\left(\tilde{b}_{\frac{1}{1-s}}\right)\right).$$

With this lemma in hand, we get that $p'(s)$ is regularly varying with index -1 ,

$$p'(s) \sim \frac{L\left(\tilde{b}_{\frac{1}{1-s}}\right)}{1-s} \ell\left(\tilde{b}_{\frac{1}{1-s}}\right)^{\frac{p}{q-p}-1} \tilde{L}\left(\ell\left(\tilde{b}_{\frac{1}{1-s}}\right)\right) \quad \text{as } s \uparrow 1,$$

so that by Corollary 1.7.3 in [2] we get that

$$\sum_{k=1}^n k p_k \stackrel{n \rightarrow +\infty}{\sim} n L\left(\tilde{b}_n\right) \ell\left(\tilde{b}_n\right)^{\frac{p}{q-p}-1} \tilde{L}\left(\ell\left(\tilde{b}_n\right)\right).$$

The result follows by using the monotonicity of p_n (and the fact that $|b_n| \sim (q-p)\tilde{b}_n$).

Proof of Lemma 7.2 Set $Q(t) = \ell(\tilde{b}_t)$ for simplicity, which is an increasing function. We want to show that $\tilde{L}(t) := \psi(Q^{-1}(t))$ is slowly varying as $t \rightarrow +\infty$ ($t = (1-s)^{-1}$), *i.e.* denoting $R(t) = Q^{-1}(t)$ for simplicity ($R(t)$ is increasing and $R(t) \rightarrow +\infty$ as $t \rightarrow +\infty$), we need to show that for any $c > 1$,

$$\frac{\psi(R(ct))}{\psi(R(t))} = \exp\left(\sum_{n=1}^{+\infty} v_n \left[\left(1 - \frac{1}{R(ct)}\right)^n - \left(1 - \frac{1}{R(t)}\right)^n\right]\right) \rightarrow 1 \quad \text{as } t \rightarrow +\infty.$$

Since $v_n = o(L(\tilde{b}_n)/\tilde{b}_n)$, we write $v_n = \varepsilon_n L(\tilde{b}_n)/\tilde{b}_n$ with $\varepsilon_n \rightarrow 0$. In order to show that the sum in the exponential goes to 0 as $t \rightarrow +\infty$, we split it into three parts.

Part 1. For $n \leq R(t)$ we use that

$$\left(1 - \frac{1}{R(ct)}\right)^n - \left(1 - \frac{1}{R(t)}\right)^n \leq 1 - \left(1 - \frac{n}{R(t)}\right) = \frac{n}{R(t)}.$$

Hence the sum up to $n = R(t)$ is bounded by $\sum_{n=1}^{R(t)} n v_n / R(t)$, and since $n v_n \sim \varepsilon_n L(\tilde{b}_n) / \tilde{b}_n$ goes to 0 as $n \rightarrow +\infty$ (recall that $L(n)/\ell(n) \rightarrow 0$), we get that this first part goes to 0 as $t \rightarrow +\infty$.

Part 2. For $R(t) < n \leq R(2ct)$, we simply bound the sum by

$$\sum_{n=R(t)}^{R(2ct)} v_n \leq \sup_{n \geq R(t)} \varepsilon_n \times \int_{R(t)}^{R(2ct)} \frac{L(\tilde{b}_u)}{\tilde{b}_u} du. \quad (7.16)$$

Using that $Q(t) = \ell(\tilde{b}_t)$ we have that $Q'(t) = L(\tilde{b}_t)\ell(\tilde{b}_t)/\tilde{b}_t$, so that the integral is exactly $[\log Q(s)]_{R(t)}^{R(2ct)} = \log 2c$ (recall that $R = Q^{-1}$). Since $\varepsilon_n \rightarrow 0$, this second part also goes to 0 as $t \rightarrow +\infty$.

Part 3. For $n > R(2ct)$, we bound the sum by

$$\begin{aligned} & \sum_{k=1}^{+\infty} \sum_{n=R(2^k ct)}^{R(2^{k+1} ct)} \varepsilon_n \frac{L(\tilde{b}_n)}{\tilde{b}_n} \left(1 - \frac{1}{R(ct)}\right)^{R(2^k ct)} \\ & \leq \sup_{n \geq Q^{-1}(t)} \varepsilon_n \times \sum_{k=1}^{+\infty} e^{-R(2^k ct)/R(ct)} \int_{R(2^k ct)}^{R(2^{k+1} ct)} \frac{L(\tilde{b}_u)}{\tilde{b}_u} du. \end{aligned}$$

As above, the integral is equal to $\log 2$. Moreover, since $Q(\cdot)$ is slowly varying we get that for t large enough (recall $R = Q^{-1}$), by Potter's bound, for any $k \geq 1$

$$Q(2^k R(ct)) \leq 2^k Q(R(ct)) = Q(R(2^k ct)),$$

giving that $2^k R(ct) \leq R(2^k ct)$ since Q is increasing. Hence, for t large enough the third part is bounded by

$$\sup_{n \geq R(t)} \varepsilon_n \times \log 2 \sum_{k \geq 1} e^{-2^k},$$

which goes to 0 as $t \rightarrow +\infty$. \square

7.4. The case $p > q$. This case is similar to the case $p < q$. We only prove the general case (with the $o(1)$ in the exponent), the improvement under assumption V1-V2 being identical to what is done above.

Using the same definition of $f(s)$, and writing $\mathbf{P}(S_m \geq 0) = 1 - \mathbf{P}(S_m < 0)$, we get that

$$f(s) = \sum_{m=1}^{+\infty} \frac{s^m}{m} \mathbf{P}(S_m \geq 0) = \log \left(\frac{1}{1-s} \right) - h(s) \quad \text{with } h(s) = \sum_{m=1}^{+\infty} \frac{s^m}{m} \mathbf{P}(S_m < 0). \quad (7.17)$$

Then, Lemma 7.1 gives that $\sum_{k=1}^n k^{-1} \mathbf{P}(S_k < 0) \stackrel{n \rightarrow +\infty}{\sim} \frac{q}{p-q} \log \ell(b_n)$, and Corollary 1.7.3 in [2] gives that $h(s) \sim \frac{q}{p-q} \log \ell(b_{1/(1-s)})$ as $s \uparrow 1$.

Hence, we conclude thanks to (7.1) that

$$p(s) = \frac{1}{1-s} e^{-h(s)} = \frac{1}{1-s} \left(\ell(b_{1/(1-s)}) \right)^{-q/(p-q)+o(1)} \quad \text{as } s \uparrow 1,$$

and we deduce from this the behavior of p_n in the same way as above.

Upper bound. Taking $s = 1 - 1/n$, and using that p_k is non-increasing, we get that

$$n (\ell(b_n))^{-q/(p-q)+o(1)} = \sum_{k=0}^{+\infty} p_k \left(1 - \frac{1}{n}\right)^k \geq \sum_{k=0}^n p_n \left(1 - \frac{1}{n}\right)^k \geq cn p_n,$$

and therefore

$$p_n \leq c^{-1} (\ell(b_n))^{-q/(p-q)+o(1)} = (\ell(b_n))^{-q/(p-q)+o(1)}. \quad (7.18)$$

Lower bound. As above, we fix $\varepsilon > 0$ and define $t_n = \ell(b_n)^\varepsilon$. Taking $s = 1 - 1/(nt_n)$, we get as in (7.9) that for n large enough

$$\sum_{k=0}^{+\infty} p_k \left(1 - \frac{1}{nt_n}\right)^k = nt_n (\ell(b_{nt_n}))^{-q/(p-q)+o(1)} \geq nt_n^{1/2} (\ell(b_n))^{q/(p-q)+o(1)}. \quad (7.19)$$

On the other hand, as in (7.10), since p_k is non-increasing we have

$$\begin{aligned} \sum_{k=0}^{+\infty} p_k \left(1 - \frac{1}{nt_n}\right)^k &\leq \sum_{k=0}^n p_k + p_n \sum_{k \geq n+1} \left(1 - \frac{1}{nt_n}\right)^k \\ &= o\left(nt_n^{1/2} (\ell(b_n))^{-q/(p-q)+o(1)}\right) + nt_n p_n, \end{aligned}$$

where we used (7.18) for the first term, together with the fact that $\ell(b_n)^{o(1)} = o(t_n^{1/2})$, and a standard computation for the second term. Combining this with (7.19) we get that

$$p_n \geq t_n^{-1/2} (\ell(b_n))^{-q/(p-q)+o(1)},$$

and since $t_n = \ell(b_n)^\varepsilon$ with $\varepsilon > 0$ arbitrary, we get that $p_n \geq \ell(b_n)^{-q/(p-q)+o(1)}$.

7.5. Further remarks on the case $p = q$. When $p = q = 1/2$, then $b_n = o(n\ell(a_n))$. If $\lim_{n \rightarrow +\infty} b_n/a_n = b$, then Theorem 3.2 gives the correct asymptotic for $\mathbf{P}(T_- > n)$. In the case $\lim_{n \rightarrow +\infty} b_n/a_n = +\infty$ (the case where the limit is $-\infty$ is symmetric), then we still have as in (7.2) that

$$\mathbf{P}(S_n < 0) \sim \frac{1}{2} n L(b_n) (b_n)^{-1} \quad \text{as } n \rightarrow +\infty. \quad (7.20)$$

Since b_n is regularly varying with exponent -1 , we get that

$$r(n) := \sum_{k=1}^n \frac{1}{k} \mathbf{P}(S_k < 0) \stackrel{n \rightarrow +\infty}{\sim} \sum_{k=1}^n \frac{L(b_n)}{2b_n} \quad (7.21)$$

is slowly varying. Additionally, we get that $r(n) = o(\log n)$ (since $\mathbf{P}(S_n < 0) \rightarrow 0$), and also $r(n) \gg \log(\ell(a_n))$, in view of Lemma 7.1, since $b_n = o(n\ell(a_n))$. We therefore have

$$\ell(a_n)^{1/o(1)} \leq e^{r(n)} \leq n^{o(1)}.$$

Then, the same scheme of proof as above gives the behavior of $p(s)$ and $p'(s)$ and in turns those of p_n : we get that

$$\mathbf{P}(T_- > n) = e^{(1+o(1))r(n)} \quad \text{and} \quad \mathbf{P}(T_+ > n) = \frac{L(b_n)}{b_n} e^{(1+o(1))r(n)}. \quad (7.22)$$

Details are straightforward, and we do not develop further.

7.6. Case $\alpha = 1$, $\mu = 0$: proof of Theorem 3.4. First of all, let us state the analogues of Lemma 7.1 in the case $\alpha = 1$, $\mu = 0$.

Lemma 7.3. *Assume that (1.1) holds, with $\alpha = 1$ and $\mu = 0$. Recall the definition (3.1) of $\ell^*(\cdot)$ and (1.3) of b_n . Then, if $p > q$, $b_n \sim -(p-q)n\ell^*(a_n) \rightarrow -\infty$ and*

$$\mathbf{P}(S_n > 0) \sim \frac{p}{p-q} \frac{L(|b_n|)}{\ell^*(|b_n|)} \quad \text{as } n \rightarrow +\infty.$$

Moreover we have that (recall $\ell^*(n) \rightarrow 0$)

$$\sum_{k=1}^n \frac{1}{k} \mathbf{P}(S_k > 0) \stackrel{n \rightarrow +\infty}{\sim} -\frac{p}{p-q} \log \ell^*(|b_n|) \quad \text{as } n \rightarrow +\infty.$$

The case $p < q$ is symmetric.

We skip the proof here since it is identical to that of Lemma 7.1, using Lemma 4.4-(ii) in place of Lemma 4.4-(i). We now turn to the proof of Theorem 3.3, which is very similar to that of Theorem 3.2, the key identity being the Wiener-Hopf factorization (7.1).

(i) *The case $p > q$.* Denoting $f(s)$ as in (7.3), Lemma 7.3 and Corollary 1.7.3 in [2] give analogously to (7.5)

$$f(s) \sim \frac{-p}{p-q} \log \ell^*(|b_{1/(1-s)}|), \quad f'(s) \sim \frac{p}{p-q} \frac{1}{1-s} \frac{L(|b_{1/(1-s)}|)}{\ell^*(|b_{1/(1-s)}|)} \quad \text{as } s \uparrow 1. \quad (7.23)$$

Therefore,

$$p'(s) = f'(s)e^{f(s)} = \frac{L(|b_{1/(1-s)}|)}{1-s} \left(\ell^*(|b_{1/(1-s)}|) \right)^{-\frac{p}{p-q}-1+o(1)} \quad \text{as } s \uparrow 1,$$

which can be turned into $p_n = n^{-1}L(|b_n|)(\ell^*(b_n))^{-1-\frac{p}{p-q}+o(1)}$ as done in Section 7.3. Again, as in Section 7.3, the term $\ell^*(|b_n|)^{o(1)}$ can be replaced by $\tilde{L}(\ell^*(|b_n|))$ for some slowly varying function \tilde{L} , under the assumption V1-V2.

(ii) *The case $p < q$.* Here also, the method of Section 7.4 is easily adapted. Denote $h(s)$ as in (7.17). Then Lemma 7.3 gives that $\sum_{k=1}^n k^{-1}\mathbf{P}(S_k < 0) \sim -\frac{q}{q-p} \log \ell^*(b_n)$ as $n \rightarrow +\infty$, so that Corollary 1.7.3 in [2] gives that $h(s) \sim -\frac{q}{q-p} \log \ell^*(b_{1/(1-s)})$ as $s \uparrow 1$. Therefore, we get

$$p(s) = \frac{e^{-h(s)}}{1-s} = \frac{1}{1-s} \left(\ell^*(b_{1/(1-s)}) \right)^{q/(q-p)+o(1)},$$

which can be turned into $p_n = (\ell^*(b_n))^{q/(q-p)+o(1)}$ as done in Section 7.4. Here again, $\ell^*(|b_n|)^{o(1)}$ can be replaced by $\bar{L}(\ell^*(|b_n|))$ for some slowly varying function \bar{L} , under the assumption V1-V2.

(iii) *The case $p = q$.* In the case $\lim_{n \rightarrow +\infty} b_n/a_n = b \in \mathbb{R}$, the proof is identical to that of Section 7.2: we get that

$$\lim_{n \rightarrow +\infty} \frac{1}{n} \sum_{k=1}^n \mathbf{P}(S_k > 0) = \mathbf{P}(Y > -b) =: \rho \in (0, 1),$$

with $\rho = \frac{1}{2} + \frac{1}{\pi} \arctan(2b/\pi)$. This is Spitzer's condition, and [2, Thm. 8.9.12] implies that T_- is in the domain of attraction of a positive stable random variable with index ρ , so that there exists a slowly varying function $\varphi(\cdot)$ such that

$$\mathbf{P}(T_- > n) \stackrel{n \rightarrow +\infty}{\sim} \varphi(n)n^{-\rho}. \quad (7.24)$$

The case $\lim_{n \rightarrow +\infty} b_n/a_n = +\infty$ (or $-\infty$) can be treated similarly to Section 7.5: we get the same conclusion as in (7.22).

8. RENEWAL THEOREMS: PROOF OF THEOREMS 3.5-3.6-3.7

8.1. The case $\alpha = 1$ with infinite mean.

8.1.1. *The case $\lim_{n \rightarrow +\infty} b_n/a_n = b \in \mathbb{R}$.* Recall that we have $p = q = 1/2$ in that case. Let us set k_x an integer such that $a_{k_x} \sim x$. We fix $\varepsilon > 0$ such that $\sup_n |b_n|/a_n \leq 1/\sqrt{\varepsilon}$, and we write

$$G(x) := \left(\sum_{k \leq \frac{1}{\varepsilon} k_x} + \sum_{k > \frac{1}{\varepsilon} k_x} \right) \mathbf{P}(S_k = x). \quad (8.1)$$

The first term is estimated thanks to Theorem 2.3, which gives that there is a constant C such that for any $x \geq 1$ and any k , $\mathbf{P}(S_k = x) \leq C(a_k)^{-1}kL(x)x^{-1}$, so that

$$\sum_{k \leq \frac{1}{\varepsilon}k_x} \mathbf{P}(S_k = x) \leq C' \left(\frac{k_x}{\varepsilon} \right)^2 (a_{k_x/\varepsilon})^{-1} L(x)x^{-1} \leq \frac{C''}{\varepsilon} L(x)^{-1}. \quad (8.2)$$

where we used that $a_{k_x/\varepsilon} \sim \varepsilon^{-1}a_{k_x}$ and that $k_x \sim a_{k_x}L(a_{k_x})^{-1} \sim xL(x)^{-1}$.

The second term is in fact the main one. Thanks to the local limit theorem (1.4), for any $\eta > 0$ there is some k_0 such that for any $k \geq k_0$,

$$g((x - b_k)/a_k) - \eta \leq a_k \mathbf{P}(S_k = x) \leq g((x - b_k)/a_k) + \eta.$$

Then for any $\varepsilon > 0$ fixed, $|(x - b_k)/a_k - b| \leq |x/a_k| + |b_k/a_k - b| \leq 5\varepsilon$, provided that $k > \varepsilon^{-1}k_x$ and x is large enough. Indeed, since a_k is regularly varying with index -1 , for $k > \varepsilon^{-1}k_x$ we have $a_k \geq \frac{1}{2}\varepsilon^{-1}a_{k_x} \geq x/(4\varepsilon)$. Since $|b_k/a_k - b| \leq \varepsilon$ for k large enough, we obtain the above claim. Therefore, by continuity of g we get that, provided ε is small and x is large enough

$$g(-b) - 2\eta \leq a_k \mathbf{P}(S_k = x) \leq g(-b) + 2\eta \quad \text{for all } k \geq \varepsilon^{-1}k_x.$$

Since we are in the symmetric case, with $p = q = 1/2$, and by our definition (1.2) of a_n , $g(\cdot)$ is the density of a symmetric Cauchy(1/2) distribution, so that $g(-b) = \frac{2}{\pi(1+(2b)^2)}$.

Hence, for any $\eta' > 0$ and provided that ε is small enough and x large enough (so that $\varepsilon^{-1}k_x$ is large), the second sum in (8.1) is

$$\frac{2(1 - \eta')}{\pi(1 + (2b)^2)} \sum_{k > \frac{1}{\varepsilon}k_x} \frac{1}{a_k} \leq \sum_{k > \frac{1}{\varepsilon}k_x} \mathbf{P}(S_k = x) \leq \frac{2(1 + \eta')}{\pi(1 + (2b)^2)} \sum_{k > \frac{1}{\varepsilon}k_x} \frac{1}{a_k}.$$

We then estimate the last sum thanks to a comparison with the following (convergent) integral

$$\int_{k_x/\varepsilon}^{+\infty} \frac{dt}{at} \sim \int_{a_{k_x/\varepsilon}}^{+\infty} \frac{du}{uL(u)} \sim \int_{x/\varepsilon}^{+\infty} \frac{du}{uL(u)} \quad \text{as } x \rightarrow +\infty.$$

We used a change of variable $u = a_t$ so that $t \sim u/L(u)$ (see (1.2)) and $dt = L(u)^{-1}du$, and then used that $a_{k_x/\varepsilon} \sim \varepsilon^{-1}a_{k_x} \sim \varepsilon^{-1}x$. Since $v \mapsto \int_v^{+\infty} \frac{du}{uL(u)}$ is a slowly varying function (vanishing as $v \rightarrow +\infty$), we get that for $\varepsilon > 0$ small enough and x large enough (how large depends on ε)

$$\frac{2(1 - 2\eta')}{\pi(1 + (2b)^2)} \sum_{n > x} \frac{1}{nL(n)} \leq \sum_{k > \frac{1}{\varepsilon}k_x} \mathbf{P}(S_k = x) \leq \frac{2(1 + 2\eta')}{\pi(1 + (2b)^2)} \sum_{n > x} \frac{1}{nL(n)}. \quad (8.3)$$

In conclusion, combining (8.2) and (8.3), and since $L(x)^{-1} = o(\sum_{n > x} \frac{1}{nL(n)})$ and η' is arbitrary, we get that

$$G(x) \sim \frac{2}{\pi(1 + (2b)^2)} \sum_{n > x} \frac{1}{nL(n)} \quad \text{as } x \rightarrow +\infty.$$

8.1.2. *The case $p > q$.* Let k_x to be a solution of $b_{k_x} = k_x \mu(a_{k_x}) = x$ (in the following, we assume for simplicity of notation that k_x is an integer). Then we identify the range of k 's for which we may apply the local limit theorem (1.4) to $\mathbf{P}(S_k = x)$: they are the k 's such that $x - b_k$ is of order a_k , and we find that they are in the range $k = k_x + \Theta(a_{k_x}/\mu(a_{k_x}))$. Let us mention the results of [1, 18] where this heuristic is confirmed: if N_x the number of renewals before reaching x , it is shown that $(a_{k_x}/\mu(a_{k_x}))^{-1}(N_x - k_x)$ converges in distribution.

Let us stress right away that $\mu(a_{k_x}) \sim \mu(b_{k_x}) = \mu(x)$. Indeed, since $p > q$ we have that $\mu(x) \sim (p - q)\ell(x)$, and Lemma 4.3 gives that $\ell(a_n) \sim \ell(b_n)$.

We fix $\varepsilon > 0$ and decompose $G(x)$ into five sums

$$\begin{aligned} G(x) &= \left(\sum_{k < \frac{1}{2}k_x} + \sum_{k = \frac{1}{2}k_x}^{k_x - \frac{a_{k_x}}{\varepsilon\mu(x)}} + \sum_{k = k_x - \frac{a_{k_x}}{\varepsilon\mu(x)}}^{k_x + \frac{a_{k_x}}{\varepsilon\mu(x)}} + \sum_{k_x + \frac{a_{k_x}}{\varepsilon\mu(x)}}^{2k_x} + \sum_{k > 2k_x} \right) \mathbf{P}(S_k = x) \\ &=: \text{I} + \text{II} + \text{III} + \text{IV} + \text{V}. \end{aligned} \quad (8.4)$$

The main contributions are the sums III and V, so we start by estimating those terms.

Term III. By the local limit theorem (1.4), we get that as $x \rightarrow +\infty$ (so $k_x \rightarrow +\infty$)

$$\text{III} = (1 + o(1)) \sum_{k = k_x - \frac{a_{k_x}}{\varepsilon\mu(x)}}^{k_x + \frac{a_{k_x}}{\varepsilon\mu(x)}} \frac{1}{a_k} g\left(\frac{x - k\mu(a_k)}{a_k}\right).$$

Then, we use the fact that a_{k_x} is negligible compared to $b_{k_x} = k_x\mu(a_{k_x}) \sim k_x\mu(x)$: we get that uniformly for the k 's in the range considered, we have $k = (1 + o(1))k_x$ so that $a_k = (1 + o(1))a_{k_x}$. Setting $j = k - k_x$, we also have that for the range of k considered (using also $\mu(a_{k_x}) \sim \mu(x)$), since $x = k_x\mu(a_{k_x})$

$$\frac{x - k\mu(a_k)}{a_k} = (1 + o(1)) \frac{j\mu(x)}{a_{k_x}} + \frac{k_x(\mu(a_{k_x}) - \mu(a_k))}{(1 + o(1))a_{k_x}} = (1 + o(1)) \frac{j\mu(x)}{a_{k_x}} + o(1). \quad (8.5)$$

For the second identity, we used Claim 5.3 to get that $|\mu(a_{k_x}) - \mu(a_k)| = o(L(a_{k_x})) = o(a_{k_x}/k_x)$. In the end, and since g is continuous, we get that

$$\text{III} = (1 + o(1)) \sum_{j = -\frac{a_{k_x}}{\varepsilon\mu(x)}}^{\frac{a_{k_x}}{\varepsilon\mu(x)}} \frac{1}{a_{k_x}} g\left(j \times \frac{\mu(x)}{a_{k_x}}\right) = \frac{1 + o(1)}{\mu(x)} \int_{-1/\varepsilon}^{1/\varepsilon} g(u) du, \quad (8.6)$$

where we used a Riemann sum approximation in the last identity. Since $\int_{-\infty}^{+\infty} g(u) du = 1$, we then get that for any $\eta > 0$ we can choose $\varepsilon > 0$ such that for all sufficiently large x (how large depend on ε)

$$\frac{1 - \eta}{\mu(x)} \leq \text{III} \leq \frac{1 + \eta}{\mu(x)}. \quad (8.7)$$

Term V. For the last term in (8.4), we use (2.6): Theorem 2.4 gives that for $k \geq 2k_x$

$$\mathbf{P}(S_k = x) = \mathbf{P}(S_k - b_k = x - b_k) \leq CkL(b_k)b_k^{-(1+\alpha)},$$

where we used that $b_k \geq b_{2k_x} \geq \frac{3}{2}b_{k_x} = \frac{3}{2}x$ provided that x is large enough, so that $|x - b_k| \geq \frac{1}{2}b_k \gg a_k$. Then we get that (we have $\alpha = 1$)

$$\text{V} \leq C \int_{k_x}^{+\infty} \frac{uL(b_u)}{b_u^2} du \leq C' \int_x^{+\infty} \frac{L(t)}{t\ell(t)^2} dt = \frac{C'}{\ell(x)}, \quad (8.8)$$

where we used a change of variable $t = b_u \sim (p - q)u\ell(b_u)$ (using also $dt \sim (p - q)\ell(b_u)du$ and $b_{k_x} = x$), and then Lemma 4.4-(i).

If one has additionally that $\mathbf{P}(X_1 = -x) \sim qL(x)x^{-2}$, then we write for any $\varepsilon \in (0, 1/2)$

$$\text{V} = \sum_{k=2k_x}^{\frac{1}{\varepsilon}k_x} \mathbf{P}(S_k = x) + \sum_{k > \frac{1}{\varepsilon}k_x} \mathbf{P}(S_k = x).$$

As above, the first term is comparable to $\int_{2k_x/\varepsilon}^{k_x/\varepsilon} \frac{uL(b_u)}{b_u^2} du \leq C \int_x^{x/\varepsilon} \frac{L(t)}{t\ell(t)^2} dt$, which is $o(1/\ell(x))$ because of Lemma 4.4 and since $\ell(x)$ is slowly varying (so $\ell(x/\varepsilon) \sim \ell(x)$). For the second term, we use Theorem 2.4 which gives that for any $\eta > 0$, and provided that ε is fixed small enough and that x is large enough, we have for all $k \geq \varepsilon^{-1}k_x$ (so $x = b_{k_x} \leq \frac{1}{2\varepsilon}b_k$)

$$\mathbf{P}(S_k = x) = \mathbf{P}(S_k - b_k = x - b_k) \begin{cases} \leq (q + \eta)kL(b_k)b_k^{-2}, \\ \geq (q - \eta)kL(b_k)b_k^{-2}. \end{cases}$$

Moreover, by a change of variable $t = b_u$ ($dt \sim (p - q)\ell(b_u)du$) we get

$$\int_{k_x/\varepsilon}^{+\infty} \frac{uL(b_u)}{b_u^2} du \sim \int_{x/\varepsilon}^{+\infty} \frac{1}{(p - q)^2} \frac{L(t)}{t\ell(t)^2} dt = \frac{1}{(p - q)^2} \frac{1}{\ell(x/\varepsilon)} \sim \frac{1}{(p - q)\mu(x)}, \quad (8.9)$$

where we used that $b_{k_x/\varepsilon} \sim b_{k_x}/\varepsilon = x/\varepsilon$ and that $\ell(\cdot)$ is slowly varying, with $\mu(x) \sim (p - q)\ell(x)$. In the end, and since η is arbitrary, we get that as $x \rightarrow +\infty$,

$$\mathbf{V} = (1 + o(1)) \frac{q}{p - q} \frac{1}{\mu(x)}. \quad (8.10)$$

To conclude the proof of the statement, we need to show that the terms I, II and IV are negligible compared to $1/\mu(x)$ (or $1/\ell(x)$).

Term I. Thanks to (2.5) and Theorem 2.4, we obtain that there is a constant $C > 0$ such that for any $k \leq k_x/2$ (so that $x \geq \frac{2}{3}b_k \gg a_k$ provided that x is large enough) we have $\mathbf{P}(S_k = x) \leq CkL(x)x^{-2}$. Then the first term in (8.4) is bounded by a constant times

$$\sum_{k=1}^{k_x/2} kL(x)x^{-2} \leq k_x^2 L(x)x^{-2} \leq \frac{c}{\ell(x)} \frac{L(x)}{\ell(x)}. \quad (8.11)$$

For the last inequality, we used that $k_x \sim \frac{1}{p-q}x\ell(x)^{-1}$ as $x \rightarrow +\infty$. (Indeed $x = b_{k_x} \sim (p - q)k_x\ell(b_{k_x})$.) Now, because $L(x)/\ell(x) \rightarrow 0$, we get that I = $o(1/\ell(x))$.

Term II. We set $j = k_x - k$. Then, the range of k considered corresponds to $j \in [\frac{a_{k_x}}{\varepsilon\mu(x)}, \frac{1}{2}k_x]$, and for that range we have similarly to (8.5)

$$\frac{x - b_k}{a_k} = \frac{k_x\mu(a_{k_x}) - (k_x - j)\mu(a_{k_x-j})}{a_k} \geq \frac{k_x}{a_k} |\mu(a_{k_x}) - \mu(a_{k_x-j})| + j \frac{\mu(x)}{2a_k}. \quad (8.12)$$

We used that $\mu(a_{k_x-j}) \sim \mu(a_{k_x}) \sim \mu(x)$ (since $j \leq k_x/2$ and $\mu(\cdot)$ is slowly varying). Then, we may use Claim 5.3 to get that

$$|\mu(a_{k_x}) - \mu(a_{k_x-j})| \leq cL(a_{k_x}) \log(a_{k_x}/a_{k_x-j}) \leq c'L(a_{k_x})j/k_x,$$

where in the second inequality we used that there is a constant $c > 0$ such that uniformly for $j \in [k/2, k]$, $a_k/a_{k-j} \leq 1 + cj/k$ (using that a_k is regularly varying with index 1). Plugging this in (8.12), and since $L(a_{k_x}) = o(\mu(a_{k_x})) = o(\mu(x))$, we get that

$$x - b_k \geq \frac{1}{4}j\mu(x), \quad \text{for } j := k_x - k \in \left[\frac{a_{k_x}}{\varepsilon\mu(x)}, \frac{1}{2}k_x \right]. \quad (8.13)$$

Then, since we have here $j\mu(x) \geq \varepsilon^{-1}a_{k_x}$ we get that $x - b_k \geq \frac{1}{4}j\mu(x) \geq a_k$ ($k \geq k_x/2$), so that we may apply Theorem 2.4. We therefore obtain, for $j := k_x - k \in [\frac{a_{k_x}}{\varepsilon\mu(x)}, \frac{1}{2}k_x]$

$$\begin{aligned} \mathbf{P}(S_k = x) &= \mathbf{P}(S_k - b_k = x - b_k) \leq CkL(x - b_k)(x - b_k)^{-2} \\ &\leq Ck_x L(j\mu(x))(j\mu(x))^{-2}. \end{aligned} \quad (8.14)$$

Overall, we get that

$$\begin{aligned} \text{II} &= \sum_{k=\frac{1}{2}k_x}^{k_x - \frac{a_{k_x}}{\varepsilon\mu(x)}} \mathbf{P}(S_k = x) \leq Ck_x \int_{\frac{a_{k_x}}{\varepsilon\mu(x)}}^{\frac{1}{2}k_x} \frac{L(j\mu(x))}{(j\mu(x))^2} dj \\ &\leq C \frac{k_x}{\mu(x)} \int_{\varepsilon^{-1}a_{k_x}}^{+\infty} \frac{L(t)}{t^2} dt \leq C \frac{k_x}{\mu(x)} \frac{L(\varepsilon^{-1}a_{k_x})}{\varepsilon^{-1}a_{k_x}}, \end{aligned}$$

where in the second inequality we made a change of variable $t = j\mu(x)$. Now, since $L(\cdot)$ is slowly varying, and because of the definition (1.2) of a_n , we get that $k_x L(\varepsilon^{-1}a_{k_x})/a_{k_x} \rightarrow 1$ as $x \rightarrow +\infty$. Hence, there exists a constant $C > 0$ (independent of ε) such that for x sufficiently large (how large depends on ε) we have

$$\text{II} \leq \frac{C\varepsilon}{\mu(x)}. \quad (8.15)$$

Term IV. It is treated similarly to the term II. Setting $j = k - k_x$, one gets exactly as in (8.13) that provided that x is large enough,

$$x - b_k \leq -\frac{1}{4}j\mu(x), \quad \text{for } j := k - k_x \in \left[\frac{a_{k_x}}{\varepsilon\mu(x)}, 2k_x \right]. \quad (8.16)$$

Then, we may apply Theorem 2.4 (we have that $|x - b_k| \geq a_k$ for the range considered) to get analogously to (8.14) that there is some C such that for any $j := k - k_x \in \left[\frac{a_{k_x}}{\varepsilon\mu(x)}, 2k_x \right]$

$$\mathbf{P}(S_k = x) = \mathbf{P}(S_k - b_k = x - b_k) \leq Ck_x L(j\mu(x))(j\mu(x))^2.$$

Therefore, we can bound the term IV

$$\text{IV} = \sum_{k=k_x + \frac{a_{k_x}}{\varepsilon\mu(x)}}^{2k_x} \mathbf{P}(S_k = x) \leq Ck_x \sum_{j=\frac{a_{k_x}}{\varepsilon\mu(x)}}^{2k_x} \frac{L(j\mu(x))}{(j\mu(x))^2}.$$

Then as for the term II, we get that there is a constant C (independent of ε) such that for x sufficiently large

$$\text{IV} \leq \frac{C\varepsilon}{\mu(x)}. \quad (8.17)$$

Conclusion. Assuming (2.5)-(2.6), we get from (8.7)-(8.8) and (8.11)-(8.15)-(8.17) that there is a constant C such that $G(x) \leq C/\mu(x)$ holds for x sufficiently large.

If we additionally assume that $\mathbf{P}(X_1 = -x) \sim qL(x)x^{-1}$ as $x \rightarrow +\infty$, we can use (8.10) instead of (8.8). According to (8.7)-(8.15)-(8.17) and to (8.10), we find that for every $\eta > 0$, we can choose $\varepsilon > 0$ small enough, such that for x sufficiently large we get

$$\frac{1-\eta}{\mu(x)} + (1+o(1))\frac{q}{p-q}\frac{1}{\mu(x)} \leq G(x) \leq \frac{1+3\eta}{\mu(x)} + (1+o(1))\frac{q}{p-q}\frac{1}{\mu(x)}. \quad (8.18)$$

Since $\eta > 0$ is arbitrary, we get (3.7).

8.1.3. *The case $p < q$.* Here, we have that $b_k = k\mu(a_k) \rightarrow -\infty$ as a regularly varying function, since $\mu(k) \sim (p-q)\ell(k)$. We define k_x to verify $b_{k_x} = -x$. Let us fix $\varepsilon > 0$, and split the sum in $G(x)$ into two parts this time.

$$G(x) = \left(\sum_{k=1}^{\frac{1}{\varepsilon}k_x} + \sum_{k > \frac{1}{\varepsilon}k_x} \right) \mathbf{P}(S_k = x) =: \text{I} + \text{II}. \quad (8.19)$$

Term I. Since $x - b_k \geq -b_k = |b_k|$ with $|b_k| \geq a_k$, we may use (2.5) to get thanks to Theorem 2.4 that

$$\mathbf{P}(S_k = x) = \mathbf{P}(S_k - b_k = x - b_k) \leq Ck \frac{L(x - b_k)}{(x - b_k)^2}. \quad (8.20)$$

Then, since $x - b_k \geq x$ (except possibly for finitely many k 's for which b_k is positive), we get that $\mathbf{P}(S_k = x) \leq CkL(x)x^{-2}$ for all $k \leq \varepsilon^{-1}k_x$ (and k larger than a constant). Hence, we get that the term I in (8.19) is bounded by

$$\text{I} \leq C(k_x/\varepsilon)^2 L(x)x^{-2} \leq C'\varepsilon^{-2} \frac{L(x)}{\ell(x)^2}, \quad (8.21)$$

where we used for the second inequality that $k_x \sim \frac{1}{q-p}x\ell(x)^{-1}$ (as for (8.11)). Then, since $L(x)/\ell(x) \rightarrow 0$ as $x \rightarrow +\infty$, we get that $\text{I} = o(1/\ell(x))$.

Term II. Again, (8.20) is valid. Here, we use that $x - b_k \geq |b_k|$ to get that $\mathbf{P}(S_k = x) \leq CkL(|b_k|)|b_k|^2$. Then, we obtain that

$$\text{II} \leq C \sum_{k \geq \frac{1}{\varepsilon}k_x} k \frac{L(|b_k|)}{|b_k|^2} \leq \frac{C}{\ell(x)} \quad (8.22)$$

where we used the same calculation as in (8.9), with $|b_k| \sim (q-p)k\ell(|b_k|)$.

Hence we proved that also in that case there is some $C > 0$ such that $G(x) \leq C/|\mu(x)|$ (since $|\mu(x)| \sim -(q-p)\ell(x)$).

Let us now obtain the right asymptotic equivalence, assuming (2.7). We may use Theorem 2.4 to obtain that for any $\eta > 0$, we can choose $\varepsilon > 0$ so that if x is large enough we get for any $k \geq \varepsilon^{-1}k_x$ we have $|b_k| \leq x - b_k \leq (1 + 2\varepsilon)|b_k|$ and then

$$\mathbf{P}(S_k = x) = \mathbf{P}(S_k = b_k = x - b_k) \begin{cases} \leq (p + \eta)kL(|b_k|)|b_k|^{-2}, \\ \geq (p - \eta)kL(|b_k|)|b_k|^{-2}. \end{cases}$$

The same calculation as in (8.9) then gives that

$$\sum_{k > \frac{1}{\varepsilon}k_x} \frac{kL(|b_k|)}{|b_k|^2} \sim \frac{1}{(q-p)|\mu(x)|}, \quad (8.23)$$

using that $|b_k| \sim (q-p)k\ell(|b_k|)$ and $|\mu(x)| \sim (q-p)\ell(x)$. Since η is arbitrary, we get that as $x \rightarrow +\infty$

$$\text{V} = \sum_{k > \varepsilon^{-1}k_x} \mathbf{P}(S_k = x) \stackrel{x \rightarrow +\infty}{\sim} \frac{p}{q-p} \frac{1}{|\mu(x)|}. \quad (8.24)$$

8.2. The finite mean case: proof of Theorem 3.7. We only have to treat the case $\mu < 0$. Recall that $S^* = \sup_{i \geq 0} S_i$, and for $x > 0$ let $\tau_x = \inf\{n \geq 1, S_n \geq x\}$. Then, using Markov's property, we have that

$$G(x) = \sum_{k=1}^{+\infty} \sum_{y=x}^{+\infty} \mathbf{P}(\tau_x = k, S_{\tau_x} = y) G(y, x)$$

with $G(y, x) = \sum_{n=0}^{+\infty} \mathbf{P}(y + S_n = x) = G(x - y)$. The renewal theorem (Theorem 3.7-(i)) gives that $G(x - y) \rightarrow 1/|\mu|$ as $x - y \rightarrow -\infty$, and also $G(y - x) \leq C$ for all $y \geq x$. Then, we take some

$\varepsilon_x > 0$ with $\varepsilon_x \rightarrow 0$ and $x\varepsilon_x \rightarrow +\infty$, and we split the sum according to whether $y \in [x, (1 + \varepsilon_x)x]$ or $y > (1 + \varepsilon_x)x$. The first term is

$$\begin{aligned} \sum_{k=1}^{+\infty} \sum_{y \in [x, (1 + \varepsilon_x)x]} \mathbf{P}(\tau_x = k, S_{\tau_x} = y) G(x - y) &\leq C \sum_{k=1}^{+\infty} \sum_{y \in [x, (1 + \varepsilon_x)x]} \mathbf{P}(\tau_x = k, S_{\tau_x} = y) \\ &= C \mathbf{P}(S^* \in [x, (1 + \varepsilon)x]). \end{aligned}$$

The second term deals with $y > (1 + \varepsilon_x)x$, so $x - y \rightarrow -\infty$: it is

$$\begin{aligned} \sum_{k=1}^{+\infty} \sum_{y > (1 + \varepsilon_x)x} \mathbf{P}(\tau_x = k, S_{\tau_x} = y) G(x - y) &= \sum_{k=1}^{+\infty} \sum_{y > (1 + \varepsilon_x)x} \mathbf{P}(\tau_x = k, S_{\tau_x} = y) \frac{1 + o(1)}{|\mu|} \\ &= \frac{1 + o(1)}{|\mu|} \mathbf{P}(S^* > (1 + \varepsilon_x)x). \end{aligned}$$

As a consequence, we get that

$$G(x) = (1 + o(1)) \frac{1}{|\mu|} \mathbf{P}(S^* > x) + O\left(\mathbf{P}(S^* > x) - \mathbf{P}(S^* > (1 + \varepsilon_x)x)\right). \quad (8.25)$$

Since $\mathbf{P}(S^* > x)$ is subexponential, the second term is negligible compared to the first one. \square

Acknowledgements: I am most grateful to Vitali Wachtel for his comments and his suggestions for the improvement of Theorem 3.2, and also to I. Kortchemski and L. Richier for attracting my attention to some subtleties of Theorem 3.4 (and to their article [19]). I thank the referees for their remarks and suggestions, in particular for pointing out references (and an elementary proof) for Theorem 3.7. I am grateful to Thomas Duquesne and Francesco Caravenna for the many discussions we had on this (and related) topic(s), and I also thank Cyril Marzouk for telling me about the reference [5].
