Abstract

Stability of spatially inhomogeneous stationary solutions to the Vlasov equation for multi-dimensional systems is investigated. The formal stability criterion taking into account all of the Casimir invariants is derived in an explicit form without use of the angle-action variables of a single particle's Hamiltonian associated with a stationary solutions to the Vlasov equation, when biorthogonal basis can be defined.

1 Introduction

Temporal evolution of systems with long range interaction (LRI) is approximately described by the Vlasov equation (also called the collisionless Boltzmann equation) which is an evolution equation of a single particle density function, when the number of particles are large enough [1–5]. This approximation gets to be exact when one takes a large population limit (mean-field limit) [6–8]. This equation is hence a basic tool for analyzing mesoscopic dynamics of Hamiltonian systems with LRI, for example, plasmas [4] and self-gravitating systems [5]. One of remarkable phenomena observed in the LRI systems is existence of long-lasting out-of-equilibrium stationary states called quasistationary states (QSSs) and slowly equilibration in the relaxation process. The QSSs are regarded as stable stationary solutions to the Vlasov equation [9–12]. The LRI system is often trapped in a QSS and its duration diverges as the number N of elements consisting the system. After that, the finite N effect appears and the temporal evolution is no longer described by the Vlasov equation and is described by the kinetic equation such as Balescu-Lenard equation [1–4]. Then, the system leaves the QSS and relaxes to the thermal equilibrium state. Such a relaxation process is directly observed in the N body simulations for the Hamiltonian mean field (HMF) model (globally coupled XY model with inertial terms) [13] in Refs. [9, 14, 15] and for the α -HMF model with $\alpha \leq 1$ (the coupling constant decays as $r^{-\alpha}$ where r denotes distance between lattice points) [16] in Refs. [17, 18]. The duration τ_{QSS} of QSS diverges as, for instance, $\tau_{\text{QSS}} \sim N^\nu$ with $\nu > 0$ for the HMF model and the α -HMF model with $\alpha < 1$ [9, 10, 14, 15, 18], $\tau_{\text{QSS}} \sim \ln N$ for the α -HMF model with $\alpha = 1$ [18], and $\tau_{\text{QSS}} \sim N/\ln N$ for self-gravitating systems [5].

The stability analysis for the Vlasov equation is considered to be a first step of study on QSSs because it clarifies which kind of solutions can be QSSs. For the spatially homogeneous stationary solutions, the simple criteria of formal and spectral stability have been already derived in Refs. [9, 19–22]. It is shown rigorously that some stable homogeneous states are valid for the finite N system within a time scale $\tau_{\text{st}} \sim N^{1/8}$ [12]. The asymptotic stability in the nonlinear regime is rigorously shown for the Vlasov-Poisson system in the study on nonlinear Landau damping [23].

The aim of this article is to derive a precise formal stability criterion for spatially inhomogeneous stationary solutions to the Vlasov equation in an explicit form. The stability of inhomogeneous states has been investigated in the context of astrophysics for a long time [5, 24–27], and it has been investigated for

*shun.ogawa@riken.jp

simple systems with long-range interaction [28, 29]. The nonlinear (orbital) stability is rigorously investigated recently for the spherical gravitating systems [30] and for the HMF model [31].

The spectral stability has been investigated by use of the Nyquist methods [19–22]. In these works the background stationary state is assumed to be spatially homogeneous, and an explicit form of the plasmas dispersion function is required. Thus it is difficult to look into stability of spatially inhomogeneous states by using the Nyquist method. There exists another way to derive a stability criterion for spatially inhomogeneous states of the HMF model [28], and the explicit form of dispersion function is necessary in this procedure too, so that it cannot be applied for stationary states whose effective Hamiltonian is non-integrable.

In this article, the formal stability [9, 28, 29, 32, 33] is investigated. Let f_0 be a stationary solution to the Vlasov equation and also be a critical point of some invariant functional (The detail is exhibited in Sec. 3.). A solution f_0 is said to be formally stable when a second variation (“Hessian”) of the invariant functional around f_0 is positive or negative definite. In this case, L^2 -like-norm of perturbation given by this “Hessian” is an invariant of the linearized Vlasov equation, so that the formally stable solution is linearly stable.

The Vlasov equation has infinitely many constraint conditions coming from the Casimir invariant functionals. Then a physically relevant perturbation satisfies these constraint conditions within a linear order. The problem of dealing these constraints appeared in a stability analysis of perfect fluid flows [33, 34]. More recently, this is a main problem to derive the asymptotic form of the linear response of the Vlasov systems around spatially inhomogeneous states [14, 35, 36]. The QSSs are looked as stable fixed points on a constraint “surface” and these constraints prevent systems relaxing to the equilibrium state [14], and the solution to the linearized Vlasov equation around f_0 should be on the tangent “plane” at f_0 in a constraint “surface.” When f_0 is spatially homogeneous [9] or is inhomogeneous whose effective single particle Hamiltonian is integrable [28], the formal stability criterion taking into account all the Casimir constraints is derived. Stationary states with nonintegrable effective Hamiltonians are out of scope in these previous studies. However, for a system in two or three dimensional spaces, the effective Hamiltonians are nonintegrable in general. In Ref. [29], the linear stability is investigated without use of the angle-action variables, and less-refined formal stability criteria taking into account a finite number of invariants have been derived. But the formal stability criterion taking into account all of the Casimir constraints has not been derived, because it requires to determine an infinite number of Lagrangian multipliers associated with the Casimir constraints [29], and it is impossible in general.

Some stationary states are stable against the perturbation violating some Casimir constraints. For instance, if an only normalization condition is taken into account, the inhomogeneous thermal equilibria are judged to be stable in the HMF model [29]. On the other hand, some perturbation violating the constraint conditions can bring about instability. For instance, if one does not take into account any constraint condition, all equilibria in the ordered phase are not judged to be stable in the HMF model [29]. Further, as shown in Ref. [28], some inhomogeneous solutions are not judged to be stable when one use the stability criterion taking into account only normalization of density functions, even though this is formally stable. Thus, it is important in practice to derive the stability criterion taking into account infinitely many Casimir invariants without use of the angle-action variables.

We then derive the formal stability criterion without use of the angle-action variables by expressing the constraint conditions in a simpler manner as in Ref. [36] (a similar formula is found in Ref. [25, 30]). The formal stability criterion is explicitly written in terms of the positive or negative definiteness of a matrix in a similar manner with the previous result [28]. Everything is given *a priori* in this matrix, so that we can judge the stability of f_0 by substituting it into the criterion, in principle. When this formula is applied for the one-dimensional (1d) systems, this matrix coincides with the dispersion matrix [5, 37] with null frequency. For the multi-dimensional systems, the inverse matrix appears in the linear response and the zero-field susceptibility diverges when the matrix has a null eigenvalue [36]. The marginally formally stable solutions are the marginally spectrally stable ones not only in the 1d systems but also in the multi-dimensional systems.

The rest part of this article is organized as follows: We introduce the Vlasov equation and the constraint conditions of Vlasov dynamics in Sec. 2. In Sec. 3, we exhibit a definition of formal stability and

derive its criterion. We check the present result includes the previous one for the 1d HMF model, and derive the stability criterion for the 2d HMF model. The article is summarized in Sec. 4.

2 Vlasov equation

2.1 Model

A model dealt in this article is an N -body system with Hamiltonian, in the d dimensional real space,

$$H_N = \sum_{i=1}^N \frac{\|\mathbf{p}_i\|^2}{2} + \frac{1}{2N} \sum_{i,j=1}^N V(\mathbf{q}_i - \mathbf{q}_j), \quad (1)$$

where $\mathbf{q}_i \in \mathbb{D}^d \subset \mathbb{R}^d$ and its conjugate momentum $\mathbf{p}_i \in \mathbb{R}^d$, for $i = 1, 2, \dots, N$. We assume that the domain \mathbb{D}^d is bounded and the potential V is smooth. In the limit $N \rightarrow \infty$, the temporal evolution is well described by the Vlasov equation [6–8],

$$\begin{aligned} \frac{\partial f}{\partial t} + \{\mathcal{H}[f], f\} &= 0, \quad \mathcal{H}[f] = \frac{\|\mathbf{p}\|^2}{2} + \mathcal{V}[f](\mathbf{q}), \\ \mathcal{V}[f] &= \iint V(\mathbf{q} - \mathbf{q}') f(\mathbf{q}', \mathbf{p}', t) d\mathbf{q}' d\mathbf{p}', \end{aligned} \quad (2)$$

where $f(\mathbf{q}, \mathbf{p}, t)$ is a single particle density function, and the Poisson bracket is given by $\{a, b\} = \frac{\partial a}{\partial \mathbf{p}} \cdot \frac{\partial b}{\partial \mathbf{q}} - \frac{\partial a}{\partial \mathbf{q}} \cdot \frac{\partial b}{\partial \mathbf{p}}$. The Vlasov equation has infinitely many stationary solutions, and we here deal mainly with a stationary solution f_0 depending only on the one particle effective Hamiltonian \mathcal{H}_0 ,

$$f_0(\mathbf{q}, \mathbf{p}) = F_0(\mathcal{H}_0(\mathbf{q}, \mathbf{p})), \quad \mathcal{H}_0(\mathbf{q}, \mathbf{p}) = \mathcal{H}[f_0], \quad (3)$$

where F_0 is a monotonically decreasing function. In the similar manner, we can deal with a stationary solution f_0 depending on two integrals as follows

$$f_0(\mathbf{q}, \mathbf{p}) = F_0(\mathcal{H}_0(\mathbf{q}, \mathbf{p}) + \bar{v}L(\mathbf{q}, \mathbf{p})), \quad \mathcal{H}_0(\mathbf{q}, \mathbf{p}) = \mathcal{H}[f_0], \quad (4)$$

where L is an additional invariant of the Hamiltonian system with \mathcal{H}_0 , and where F_0 is monotonic with respect to $\mathcal{H}_0 + \bar{v}L$ where \bar{v} is a constant. The stationary solution f_0 is assumed to depend on a linear combination of two integrals because we focus on the stationary solution f_0 which is also a solution to the optimization problem with some constraint conditions in the present article.

We additionally assume that biorthogonal basis can be defined in this model, and this is introduced in a forthcoming section.

2.2 Casimir invariants

The Vlasov equation has infinitely many constraint conditions coming from Casimir functionals,

$$\mathcal{C}[f] = \iint c(f(\mathbf{q}, \mathbf{p}, t)) d\mathbf{q} d\mathbf{p}, \quad (5)$$

which are conserved in the temporal evolution for any smooth function c . Then solutions to the linearized Vlasov equation around f_0 should be on the tangent “plane” at f_0 on the iso-Casimirs “surface,” so that the physically relevant perturbation δf satisfies, within a linear order,

$$\iint c'(f_0(\mathbf{q}, \mathbf{p})) \delta f(\mathbf{q}, \mathbf{p}) d\mathbf{q} d\mathbf{p} = 0, \quad (6)$$

for any c , where $c'(x) = dc/dx$. Since $f_0 = F_0(\mathcal{H}_0)$ is assumed to be monotonic with respect to \mathcal{H}_0 , it is shown that this constraint condition is equivalent to the condition:

$$\iint R(\mathcal{H}_0(\mathbf{q}, \mathbf{p})) \delta f(\mathbf{q}, \mathbf{p}) d\mathbf{q} d\mathbf{p} = 0 \quad (7)$$

for any function R [28]. This is equivalent to the condition:

$$\iint R(\mathcal{H}_0(\mathbf{q}, \mathbf{p})) \langle \delta f(\mathbf{q}, \mathbf{p}) \rangle_{\mathcal{H}_0} d\mathbf{q} d\mathbf{p} = 0 \quad (8)$$

(see A for the derivation). The constraint condition are expressed as follows:

$$\langle \delta f \rangle_{\mathcal{H}_0} = 0, \quad (9)$$

for almost every \mathcal{H}_0 , where $\langle \bullet \rangle_{\mathcal{H}_0}$ denotes the average over the iso- \mathcal{H}_0 set. Thus, the accessible perturbation can be written as

$$\delta f(\mathbf{q}, \mathbf{p}) = g(\mathbf{q}, \mathbf{p}) - \langle g \rangle_{\mathcal{H}_0(\mathbf{q}, \mathbf{p})}. \quad (10)$$

It should be remarked that the condition (6)-(9) is not for the initial state of the perturbation $\delta f(t = 0)$ but for the relevant dynamical part of the perturbation whose constrained on a constraint surface. Even if the $\delta f(t = 0)$ does not satisfies the constraint condition (9), the linearized dynamics should be constrained on a tangent plane of the constraint surface and the directions that are not parallel to the tangent plane are not accessible. Thus, it is worthwhile to check the formal stability to show the linear stability of the stationary solution f_0 .

When the system has an additional invariant L , we should find a condition likes Eq. (9) for each steady state. If the stationary solution f_0 depends on only \mathcal{H}_0 , the physically relevant perturbation satisfies Eq. (9). When f_0 is written as Eq. (4), the accessible perturbation satisfies

$$\langle \delta f \rangle_{\mathcal{H}_0 + \bar{v}L} = 0. \quad (11)$$

Then the stability criterion for f_0 in Eq. (4) is derived as done for the stationary solution depending only \mathcal{H}_0 by replacing \mathcal{H}_0 with $\mathcal{H}_0 + \bar{v}L$.

3 Formal stability

3.1 Definition of formal stability

The concept of the formal stability [32] is introduced here. Let us consider the stationary solution f_0 to the Vlasov equation, which is a solution to an optimization problem with constraints, normalization and energy conservation;

$$\begin{aligned} \text{maximizing } \mathcal{S}[f] &= \iint s(f) d\mathbf{q} d\mathbf{p}, \\ \text{subject to } \mathcal{N}[f] &= \iint f d\mathbf{q} d\mathbf{p} = 1, \\ \mathcal{E}[f] &= \iint \frac{\|\mathbf{p}\|^2}{2} f d\mathbf{q} d\mathbf{p} + \frac{1}{2} \iint \mathcal{V}[f] f d\mathbf{q} d\mathbf{p} = E, \end{aligned} \quad (12)$$

where s is a strictly concave function. This is similar to the maximizing entropy principle. A solution to the optimization problem (12) is

$$f_0 = (s')^{-1}(\beta \mathcal{H}_0 + \alpha), \quad (13)$$

where $s'(x) = ds/dx$, and α and β are Lagrangian multipliers corresponding to the normalization and the energy conservation respectively. Since s is concave, f_0 satisfies the condition (3) when $\beta > 0$. Taking the second variation of the functional $\mathcal{F} = \mathcal{S} - \alpha \mathcal{N} - \beta \mathcal{E}$ around f_0 , we have

$$\delta^2 \mathcal{F}[f_0][\delta f, \delta f^*] = \beta \iint \left(\frac{|\delta f|^2}{\gamma(\mathcal{H}_0)} - \delta f^* \mathcal{V}[\delta f] \right) d\mathbf{q} d\mathbf{p}, \quad (14)$$

where z^* denotes complex conjugate of $z \in \mathbb{C}$ and $\gamma(\mathcal{H}_0) = \beta/s''(f_0) = df_0/d\mathcal{H}_0$. The functional (14) is an invariant of the linearized Vlasov dynamics. When the quadratic form (14) is negative for any perturbations δf satisfying Eq. (9), the stationary solution f_0 is said to be formally stable. The formally stable solution is linearly stable [32].

Let us consider the case that there is an additional invariant,

$$\mathcal{L}[f] = \iint L(\mathbf{q}, \mathbf{p}) f d\mathbf{q} d\mathbf{p} = \bar{L}. \quad (15)$$

The solution to the optimization problem is $f_0 = (s')^{-1}(\beta\Psi + \alpha)$, where $\Psi = \mathcal{H}_0 + vL/\beta$ and v is a Lagrangian multiplier associated with the condition (15). The second variation of the functional (15) is zero, so that it does not appear in Eq. (14). Then, we just put $\gamma(\mathcal{H}_0, L) = df_0/d\Psi$ in Eq. (14) instead of $\gamma(\mathcal{H}_0)$.

3.2 Bi-orthogonal basis

A useful tool for analyzing perturbations of the Vlasov systems are biorthogonal basis, $\{d_i(\mathbf{q})\}_{i \in \mathbb{I}}$ and $\{u_i(\mathbf{q})\}_{i \in \mathbb{I}'}$, where $\mathbb{I}' \subset \mathbb{I} \subset \mathbb{Z}$, and we assume a number of elements of \mathbb{I}' , $\#\mathbb{I}' < \infty$ [5, 37, 42, 43]. Any spatial density perturbations $\delta\rho(\mathbf{q}) = \int \delta f(\mathbf{q}, \mathbf{p}) d\mathbf{p}$ is spanned with $\{d_i(\mathbf{q})\}_{i \in \mathbb{I}}$, and $\{u_i(\mathbf{q})\}_{i \in \mathbb{I}'}$ are given by

$$u_i(\mathbf{q}) = (V * d_i)(\mathbf{q}) \equiv \int V(\mathbf{q} - \mathbf{q}') d_j(\mathbf{q}') d\mathbf{q}'. \quad (16)$$

They are supposed to satisfy

$$\int u_i^*(\mathbf{q}) d_j(\mathbf{q}) d\mathbf{q} = \lambda_i \delta_{ij}, \quad (17)$$

where $\lambda_i \neq 0$ for $i \in \mathbb{I}'$ and $\lambda_i = 0$ for $i \in \mathbb{I} \setminus \mathbb{I}'$. By use of the biorthogonal basis, we can express the second term of right hand side in Eq. (14) as

$$\iint \delta f^* \mathcal{V}[\delta f] d\mathbf{q} d\mathbf{p} = \sum_{i \in \mathbb{I}'} \frac{1}{\lambda_i} \left| \iint u_i^* \delta f d\mathbf{q} d\mathbf{p} \right|^2. \quad (18)$$

The derivation is exhibited in B.

3.3 Formal stability criterion

Let us derive the formal stability criterion explicitly. We suppose that the single particle Hamiltonian \mathcal{H}_0 has only one integral, \mathcal{H}_0 *per se*. Substituting Eq. (10) into Eq. (14), we express the formal stability condition as

$$\mathcal{G}[g, g^*] = \delta^2 \mathcal{F}[f_0] [g - \langle g \rangle_{\mathcal{H}_0}, g^* - \langle g^* \rangle_{\mathcal{H}_0}] / \beta < 0, \quad (19)$$

for any g . Our strategy is to find a g_{\max} maximizing \mathcal{G} under a constraint,

$$\mathcal{M}[g, g^*] = \sum_{i \in \mathbb{I}'} \left| \iint u_i^*(g - \langle g \rangle_{\mathcal{H}_0}) d\mathbf{q} d\mathbf{p} \right|^2 = 1, \quad (20)$$

and to derive the condition so that $\mathcal{G}[g_{\max}, g_{\max}^*] < 0$ which is equivalent to Eq. (19). The value 1 itself in the right hand side of Eq. (20) is not important. The condition $\mathcal{M}[g, g^*] > 0$ is really important. This is because the rescaling $g \mapsto cg$ with a constant c just changes the values of functionals as $\mathcal{G} \mapsto |c|^2 \mathcal{G}$ and $\mathcal{M} \mapsto |c|^2 \mathcal{M}$ and it does not affect the sign of \mathcal{G} . When $\mathcal{M}[g, g^*] = 0$, then $\mathcal{G}[g, g^*] < 0$ because $\gamma(\mathcal{H}_0) < 0$. Thus such a perturbation does not bring about instability. By using a vector $\boldsymbol{\xi} = (\xi_i)_{i \in \mathbb{I}'}$ given by

$$\xi_i[g] = \iint u_i^*(g - \langle g \rangle_{\mathcal{H}_0}) d\mathbf{q} d\mathbf{p}, \quad (21)$$

the constraint (20) is expressed as $\|\xi\| = 1$, where $\|\bullet\|$ denotes Euclidean norm. We write $\xi_i[g_{\max}] = \bar{\xi}_i$ and $\xi[g_{\max}] = \bar{\xi}$. Let \hat{A}^\dagger denote the Hermitian conjugate of a matrix \hat{A} and $\mathbf{a}^\dagger = (\mathbf{a}^*)^\top$ where the superscript T denotes transposition. By use of the equality (see A for the derivation),

$$\iint a \langle b \rangle_{\mathcal{H}_0} d\mathbf{q} d\mathbf{p} = \iint \langle a \rangle_{\mathcal{H}_0} b d\mathbf{q} d\mathbf{p}, \quad (22)$$

for any functions a and b for which the integrals are defined, we have g_{\max} holding $\delta\mathcal{G}/\delta g - \eta\delta\mathcal{M}/\delta g = 0$ as

$$g_{\max}^* - \langle g_{\max}^* \rangle_{\mathcal{H}_0} = \gamma(\mathcal{H}_0) \sum_{i \in \mathbb{V}'} \left(\frac{1}{\lambda_i} + \eta \right) \bar{\xi}_i^* (u_i^* - \langle u_i^* \rangle_{\mathcal{H}_0}), \quad (23)$$

where η is a Lagrangian multiplier with respect to the constraint condition (20). Let $\zeta_i = (\lambda_i^{-1} + \eta)\bar{\xi}_i$ and $\zeta = (\zeta_i)_{i \in \mathbb{V}'}$. Substituting Eq. (23) into Eq. (19), we have the condition of the formal stability of f_0 as

$$\sum_{i,j \in \mathbb{V}'} \zeta_i^* \zeta_j \iint \gamma(\mathcal{H}_0) (u_i^* u_j - \langle u_i^* \rangle_{\mathcal{H}_0} \langle u_j \rangle_{\mathcal{H}_0}) d\mathbf{q} d\mathbf{p} - \sum_{i \in \mathbb{V}'} \lambda_i^{-1} |\bar{\xi}_i|^2 < 0. \quad (24)$$

This inequality is similar to Eq. (1.26) in Ref. [30]. For simplicity, we introduce several notations;

$$F_{ij} = \iint \gamma(\mathcal{H}_0) (u_i^* u_j - \langle u_i^* \rangle_{\mathcal{H}_0} \langle u_j \rangle_{\mathcal{H}_0}) d\mathbf{q} d\mathbf{p}, \quad (25)$$

$\hat{F} = (F_{ij})_{(i,j) \in \mathbb{V}' \times \mathbb{V}'}$, and $\hat{\Lambda} = \text{diag}(\lambda_1, \lambda_2, \dots, \lambda_{\#\mathbb{V}'})$. By use of them, a relation $\bar{\xi} = \hat{F}\zeta$ is derived from Eq. (23). We thus have the formal stability condition as $\zeta^\dagger \hat{F} (\hat{\mathbb{1}} - \hat{\Lambda}^{-1} \hat{F}) \zeta < 0$, where $\hat{\mathbb{1}} \in \mathbb{C}^{\#\mathbb{V}' \times \#\mathbb{V}'}$ is the unit matrix and we have used the fact $\hat{F} = \hat{F}^\dagger$. The matrix \hat{F} is negative definite, because

$$F_{ij} = \iint \gamma(\mathcal{H}_0) (\langle u_i^* u_j \rangle_{\mathcal{H}_0} - \langle u_i^* \rangle_{\mathcal{H}_0} \langle u_j \rangle_{\mathcal{H}_0}) d\mathbf{q} d\mathbf{p}, \quad (26)$$

the matrix $(\langle u_i^* u_j \rangle_{\mathcal{H}_0} - \langle u_i^* \rangle_{\mathcal{H}_0} \langle u_j \rangle_{\mathcal{H}_0})_{(i,j) \in \mathbb{V}' \times \mathbb{V}'}$ is positive definite, and $\gamma(\mathcal{H}_0) < 0$. It is therefore shown the main claim of this article.

Main Claim Let $f_0 = F_0(\mathcal{H}_0)$ ($F_0'(\mathcal{H}_0) < 0$) be a stationary solution to the Vlasov equation and \mathcal{H}_0 have only one integral of motion, \mathcal{H}_0 itself. A stationary solution f_0 to the Vlasov equation is formally stable if and only if the matrix $\hat{D}[f_0] = \hat{\mathbb{1}} - \hat{\Lambda}^{-1} \hat{F}$ is positive definite. ■

It should be remarked that the matrix $\hat{D}[f_0]$ is the matrix form of dispersion functions with null frequency when the spatial dimension $d = 1$ [5,37,42]. Further, the inverse matrix of $\hat{D}[f_0]$ appears in a linear response formula for the 1d and multi-dimensional systems [36,38]. Thus, the zero minimum eigenvalue of $\hat{D}[f_0]$ might also correspond to the marginal spectral stability, because the zero field susceptibility diverges when $\det \hat{D}[f_0] = 0$.

We mention the relation between the present main claim and the classical results on the spherical stellar system. The Antonov's variational principle [5] says: For the stellar system in the state $f_0 = F_0(\mathcal{H}_0)$ ($F_0' < 0$) is stable if and only if

$$\mathcal{W}_A[f_0][h] \equiv -\delta^2 \mathcal{F} [\{h, f_0\}, \{h, f_0\}] / \beta > 0, \quad (27)$$

for any $h(\mathbf{q}, \mathbf{p})$. Furthermore, it is shown that $F_0(\mathcal{H}_0)$ with $F_0' < 0$ is stable by showing $\mathcal{W}_A[f_0][h] > 0$ [5]. We call this statement the classical statement. Let us recall that $f_0 = F_0(\mathcal{H}_0)$ ($F_0' < 0$) is formally stable if and only if (Eq. (19))

$$-\mathcal{G}[g, g^*] = -\delta^2 \mathcal{F} [g - \langle g \rangle_{\mathcal{H}_0}, g^* - \langle g^* \rangle_{\mathcal{H}_0}] / \beta > 0.$$

This is similar to Eq. (27). Let \mathbb{W} and \mathbb{G} be sets of δf such that

$$\exists h(\mathbf{q}, \mathbf{p}), \quad \text{s.t. } \delta f = \{h, f_0\}, \quad (28)$$

$$\exists g(\mathbf{q}, \mathbf{p}), \quad \text{s.t. } \delta f = g - \langle g \rangle_{\mathcal{H}_0}, \quad (29)$$

respectively. Since $\langle \{h, f_0\} \rangle_{\mathcal{H}_0} = 0$, we have $\mathbb{W} \subset \mathbb{G}$. It is hence shown that $W_A[f_0][h] > 0$ for any h and Antonov's variational principle holds true, when Eq. (19) holds, or equivalently, $\hat{D}[f_0]$ is positive definite. If there exists h satisfying

$$F'_0(\mathcal{H}_0)\{h, \mathcal{H}_0\} = g - \langle g \rangle_{\mathcal{H}_0}, \quad (30)$$

for each g , we have $\mathbb{W} = \mathbb{G}$. Thus, the positive definiteness of $\hat{D}[f_0]$ is equivalent to the condition (27) and we have: For the spherical stellar system, if $F_0(\mathcal{H}_0)$ satisfies $F'_0(\mathcal{H}_0) < 0$ for all \mathcal{H}_0 , then $\hat{D}[f_0]$ is positive definite. On the other hand, $F'_0(\mathcal{H}_0) < 0$ is assumed in our main claim, so that the present criterion is not so powerful for the spherical stellar systems, when $\mathbb{W} = \mathbb{G}$.

The set \mathbb{I}' is assumed to be a finite set in the present section. One problem is that the matrix $\hat{D}[f_0]$ becomes infinite matrix, *i. e.* \mathbb{I}' is not a finite set in general. Thus, some truncation or approximation of the model $V(\mathbf{q} - \mathbf{q}') = \sum_{i \in \mathbb{I}'} u_i(\mathbf{q}) u_i^*(\mathbf{q}')$ is necessary. When the biorthogonal basis are the Fourier modes, and V is smooth enough, it may be possible to truncate the matrix elements $D[f_0]_{ij}$ for large i or j when one computes the determinant. We do not deal with this problem in this article. In the precedence subsections, two examples are exhibited, in which $\#\mathbb{I}' < \infty$, the 1d and two dimensional (2d) HMF models [13, 39, 40]. Both of them are out of scope of the classical statement. The 2d one is out of scope of the previous paper [28], because the angle-action variables are not constructed.

3.4 One-dimensional Hamiltonian mean-field model

Let us examine the obtained criterion includes the one obtained in the previous article [28], the formal stability criterion for the HMF model whose Hamiltonian is

$$H = \sum_{i=1}^N \frac{p_i^2}{2} - \frac{1}{2N} \sum_{i \neq j} \cos(q_i - q_j) - h \sum_{i=1}^N \cos q_i, \quad (31)$$

where h is an external field, $p_i \in \mathbb{R}$, $q_i \in [-\pi, \pi)$ for $i = 1, 2, \dots, N$. The effective Hamiltonian \mathcal{H}_0 of the stationary state $f_0 = F_0(\mathcal{H}_0)$ is

$$\mathcal{H}_0 = \frac{p^2}{2} - \iint \cos(q - q') f_0(q', p') dq' dp' - h \cos q. \quad (32)$$

In this case, $\mathbb{I} = \mathbb{N}$, $\mathbb{I}' = \{1, 2\}$ and d_i and u_i are given respectively by $d_{2k} = \pi^{-1} \cos(kq)$, $d_{2k-1} = \pi^{-1} \sin(kq)$, $u_1 = -\sin q$, and $u_2 = -\cos q$, and $\lambda_1 = \lambda_2 = -1$. Substituting them into the general form (26) of the matrix $\hat{D} = (D_{ij})_{(i,j) \in \{1,2\}^2}$, we have $D_{12} = D_{21} = 0$ [41], and

$$\begin{aligned} D_{11} &= 1 + \iint \frac{dF_0(\mathcal{H}_0)}{d\mathcal{H}_0} \left(\sin^2 q - \langle \sin q \rangle_{\mathcal{H}_0(q,p)}^2 \right) dq dp, \\ D_{22} &= 1 + \iint \frac{dF_0(\mathcal{H}_0)}{d\mathcal{H}_0} \left(\cos^2 q - \langle \cos q \rangle_{\mathcal{H}_0(q,p)}^2 \right) dq dp. \end{aligned} \quad (33)$$

The stationary solution f_0 is formally stable if and only if $D_{11} > 0$ and $D_{22} > 0$. Using the angle-action variables, one shows that these coincide with the dispersion function (also called a dielectric function in the context of plasma physics) with null frequency. This criterion is hence the same with the one obtained in the previous study [28], and with the criterion of the orbital stability [31].

3.5 Two-dimensional Hamiltonian mean-field model

The 2d HMF model is out of scope of the previous study [28], because it is impossible to construct the angle-action variables for the effective Hamiltonian of the inhomogeneous stationary states. The N -body Hamiltonian of this model is

$$\begin{aligned} H &= \sum_{i=1}^N \frac{\|\mathbf{p}_i\|^2}{2} - h_x \sum_{i=1}^N \cos x_i - h_y \sum_{i=1}^N \cos y_i \\ &\quad - \frac{1}{2N} \sum_{i \neq j} \left[\cos(x_i - x_j) + \cos(y_i - y_j) + \cos(x_i - x_j) \cos(y_i - y_j) \right], \end{aligned} \quad (34)$$

where $\mathbf{p}_i = (p_{xi}, p_{yi}) \in \mathbb{R}^2$ and $\mathbf{q}_i = (x_i, y_i) \in [-\pi, \pi]^2$ for $i = 1, 2, \dots, N$ [39, 40]. The effective Hamiltonian for the stationary state with the external field $h_x = h_y = h$ is

$$\mathcal{H}_0 = \frac{p_x^2 + p_y^2}{2} + \mathcal{V}(x, y), \quad (35)$$

$$\mathcal{V}(x, y) = -(M + h) \cos x - (M + h) \cos y - P_{cc} \cos x \cos y,$$

where we assume that the stationary state $f_0(\mathbf{q}, \mathbf{p}) = F_0(\mathcal{H}_0)$ is symmetric with respect to both x and y , and we define the order parameters in the stationary state f_0 as $M = \iint \cos x f_0 d\mathbf{q} d\mathbf{p} = \iint \cos y f_0 d\mathbf{q} d\mathbf{p}$ and $P_{cc} = \iint \cos x \cos y f_0 d\mathbf{q} d\mathbf{p}$. We chose $\{u_i\}_{i \in \{1, 2, \dots, 8\}}$ as

$$\begin{aligned} u_1 &= \cos x, & u_2 &= \cos y, & u_3 &= \cos x \cos y, \\ u_4 &= \sin x, & u_5 &= \sin x \cos y, \\ u_6 &= \sin y, & u_7 &= \cos x \sin y, \\ u_8 &= \sin x \sin y. \end{aligned} \quad (36)$$

For the symmetric potential \mathcal{V} , we have $\langle u_i \rangle_{\mathcal{H}_0} = 0$, for $i = 4, 5, \dots, 8$, and $F_{ij} = 0$ when $u_i u_j$ is odd with respect to x or y . Let $0_{m,n}$ be an $m \times n$ null matrix. In the similar manner in Ref. [36], we explicitly write the matrix $\hat{D} = (D_{ij})_{(i,j) \in \{1, 2, \dots, 8\}^2}$ as

$$\hat{D} = \begin{pmatrix} \hat{D}_e & 0_{3,4} & 0_{3,1} \\ 0_{4,3} & \hat{D}_o & 0_{2,2} & 0_{4,1} \\ 0_{1,3} & 0_{1,4} & D_{88} \end{pmatrix} = \text{diag}(\hat{D}_e, \hat{D}_o, \hat{D}_o, D_{88}), \quad (37)$$

where $\hat{D}_e \in \mathbb{R}^{3 \times 3}$, $\hat{D}_o \in \mathbb{R}^{2 \times 2}$, and D_{88} are respectively

$$\begin{aligned} \hat{D}_e &= \begin{pmatrix} 1 + G_1^e & G_2^e & G_3^e \\ G_2^e & 1 + G_1^e & G_3^e \\ G_3^e & G_3^e & 1 + G_4^e \end{pmatrix}, \\ \hat{D}_o &= \begin{pmatrix} 1 + G_1^o & G_2^o \\ G_2^o & 1 + G_3^o \end{pmatrix}, \\ D_{88} &= 1 + \iint \frac{dF_0(\mathcal{H}_0)}{d\mathcal{H}_0} \sin^2 x \sin^2 y d\mathbf{q} d\mathbf{p}, \end{aligned} \quad (38)$$

and where

$$\begin{aligned} G_1^e &= \iint \frac{dF_0(\mathcal{H}_0)}{d\mathcal{H}_0} (\cos^2 x - \langle \cos x \rangle_{\mathcal{H}_0}^2) d\mathbf{q} d\mathbf{p}, \\ G_2^e &= \iint \frac{dF_0(\mathcal{H}_0)}{d\mathcal{H}_0} (\cos x \cos y - \langle \cos x \rangle_{\mathcal{H}_0} \langle \cos y \rangle_{\mathcal{H}_0}) d\mathbf{q} d\mathbf{p}, \\ G_3^e &= \iint \frac{dF_0(\mathcal{H}_0)}{d\mathcal{H}_0} (\cos^2 x \cos y - \langle \cos x \rangle_{\mathcal{H}_0} \langle \cos x \cos y \rangle_{\mathcal{H}_0}) d\mathbf{q} d\mathbf{p}, \\ G_4^e &= \iint \frac{dF_0(\mathcal{H}_0)}{d\mathcal{H}_0} (\cos^2 x \cos^2 y - \langle \cos x \cos y \rangle_{\mathcal{H}_0}^2) d\mathbf{q} d\mathbf{p}, \end{aligned} \quad (39)$$

(see Appendix of Ref. [36] for a way to compute numerically them.) and

$$\begin{aligned} G_1^o &= \iint \frac{dF_0(\mathcal{H}_0)}{d\mathcal{H}_0} \sin^2 x d\mathbf{q} d\mathbf{p}, \\ G_2^o &= \iint \frac{dF_0(\mathcal{H}_0)}{d\mathcal{H}_0} \sin^2 x \cos y d\mathbf{q} d\mathbf{p}, \\ G_3^o &= \iint \frac{dF_0(\mathcal{H}_0)}{d\mathcal{H}_0} \sin^2 x \cos^2 y d\mathbf{q} d\mathbf{p}, \end{aligned} \quad (40)$$

Thus, for the 2d HMF model, F_0 is formally stable if and only if \hat{D}_e and \hat{D}_o is positive definite and $D_{88} > 0$. The matrix \hat{D}_e appears in the linear response formula [36] and if one of its eigenvalues is 0, the response diverges. Thus, the marginally formally stable solution f_0 is the marginally spectrally stable solution.

4 Summary

The formal stability criterion of stationary solutions to the Vlasov equation for systems in multi-dimensional space is derived in an explicit form, where the biorthogonal basis can be defined. This criterion takes into account all of the Casimir invariants.

The practical usefulness of the refined criterion has been already mentioned in the previous paper [28]. The less refined criteria taking into account on the finite numbers of invariants cannot be used when the stationary state is close to the marginal stable one with spatial inhomogeneity. Furthermore, we overcome a weak point of the result obtained in Ref. [28]; the criteria has been derived only for the HMF model or its generalized ones such as α -HMF model [16, 17]. We have checked that our general result includes what is obtained in the previous study for the HMF model [28], and the matrix $\hat{D}[f_0]$ coincides with the dispersion matrix when the system is in 1d real space.

For the 1d systems the minimum eigenvalue of $\hat{D}[f_0]$ is 0 if and only if the operator $\hat{L}[f_0]$ in the linearized Vlasov equation $\partial_t \delta f = \hat{L}[f_0][\delta f]$ around f_0 has an (embedded) eigenvalue 0. Thus, the marginally formally stable solution f_0 is also the marginally spectrally stable solution. In the multi-dimensional systems, although the dispersion relation for the non-zero frequency has not been derived, we can obtain the same statement as follows: The matrix $\hat{D}[f_0]^{-1}$ appears in the linear response formula [36]. Thus, the linear response diverges when $\hat{D}[f_0]$ has a null eigenvalue, and the marginally formally stable f_0 is the marginally spectrally stable. It should be noted that the spectral stability criterion is not obtained and this is an open problem. It should be noted that when the matrix $\hat{D}[f_0]$ is not positive definite, and has both positive and negative eigenvalues, it is possible that a growing (unstable) mode exists around f_0 .

A Derivation of Eq. (22)

We exhibit a derivation of Eq. (22). $\langle X \rangle_{\mathcal{H}_0}$ is explicitly written as

$$\langle X \rangle_{\mathcal{H}_0} = \frac{1}{S(\mathcal{H}_0)} \iint X(\mathbf{q}, \mathbf{p}) \delta(\mathcal{H}_0 - \mathcal{H}_0(\mathbf{q}, \mathbf{p})) d\mathbf{q} d\mathbf{p}, \quad (41)$$

where S denotes a measure of iso- \mathcal{H}_0 in the μ -space, the phase space of single particle,

$$S(E) = \iint \delta(E - \mathcal{H}_0(\mathbf{q}, \mathbf{p})) d\mathbf{q} d\mathbf{p}. \quad (42)$$

We assume that $\|\nabla \mathcal{H}_0\| \neq 0$, so that the iso- \mathcal{H}_0 sets are null sets in $2d$ -dimensional μ space for each level. Hereafter, for any function $X(\mathbf{q}, \mathbf{p})$, X , X' , and X'' denote $X(\mathbf{q}, \mathbf{p})$, $X(\mathbf{q}', \mathbf{p}')$, and $X(\mathbf{q}'', \mathbf{p}'')$ respectively. The primes do not mean derivatives hereafter. The equation (22) is shown as follows: The right hand side in Eq. (22) is equal to

$$\iint a \left[\iint \frac{b' \delta(\mathcal{H}_0 - \mathcal{H}'_0)}{S(\mathcal{H}'_0)} d\mathbf{q}' d\mathbf{p}' \right] d\mathbf{q} d\mathbf{p} = \iint b' \left[\iint \frac{a \delta(\mathcal{H}_0 - \mathcal{H}'_0)}{S(\mathcal{H}'_0)} d\mathbf{q} d\mathbf{p} \right] d\mathbf{q}' d\mathbf{p}', \quad (43)$$

and this is the same with the left hand side in Eq. (22). We have used the fact, for functions $f \in \mathbb{R}$ and G ,

$$\iint \delta(f - f') G(f') d\mathbf{q}' d\mathbf{p}' = G(f) \iint \delta(f - f') d\mathbf{q}' d\mathbf{p}', \quad (44)$$

where the range of f is in \mathbb{R} and $\iint \delta(f - f') d\mathbf{q}' d\mathbf{p}' < \infty$.

B Derivation of Eq. (18)

The Eq. (18) is shown as follows: The spatial density perturbation is

$$\delta\rho(\mathbf{q}) = \int \delta f(\mathbf{q}, \mathbf{p}) d\mathbf{p} = \sum_{i \in \mathbb{I}} a_i d_i(\mathbf{q}). \quad (45)$$

We firstly show that

$$\iint \delta f^* \mathcal{V}[\delta f] d\mathbf{q} d\mathbf{p} = \int \delta\rho^*(V * \delta\rho) d\mathbf{q} = \sum_{i \in \mathbb{I}'} a_i \int \delta\rho^* u_i d\mathbf{q} = \sum_{i \in \mathbb{I}'} \lambda_i |a_i|^2. \quad (46)$$

It is also shown that

$$\sum_{i \in \mathbb{I}'} \frac{1}{\lambda_i} \left| \int u_i^* \delta f d\mathbf{q} d\mathbf{p} \right|^2 = \sum_{i \in \mathbb{I}'} \left| \int u_i^* \delta\rho d\mathbf{q} \right|^2 = \sum_{i \in \mathbb{I}'} \lambda_i |a_i|^2. \quad (47)$$

We therefore have Eq. (18).
