**Abstract.** Security properties of cryptographic protocols are typically expressed as reachability or equivalence properties. Secrecy and authentication are examples of reachability properties while privacy properties such as untraceability, vote secrecy, or anonymity are generally expressed as behavioural equivalence in a process algebra that models security protocols.

Our main contribution is to reduce the search space for attacks for reachability as well as equivalence properties. Specifically, we show that if there is an attack then there is one that is well-typed. Our result holds for a large class of typing systems, a family of equational theories that encompasses all standard primitives, and a large class of deterministic security protocols. For many standard protocols, we deduce that it is sufficient to look for attacks that follow the format of the messages expected in an honest execution, therefore considerably reducing the search space.

## 1 INTRODUCTION

Formal methods have been very successful for the analysis of security protocols and many decision procedures and tools (e.g. [24, 35, 36]) have been proposed. Two main families of security properties are typically considered: trace or accessibility properties, as well as equivalence properties. The former are used to express the most standard properties such as secrecy and authentication: for any execution of the protocol, an attacker should not learn the secret nor get authenticated without the server having accepted her request. The later model privacy properties such as untraceability, vote secrecy, or anonymity (e.g. [8, 15]). For example, the anonymity of Bob is typically expressed by the fact that an adversary should not distinguish between the situation where Bob is present and the situation where Alice is present. Formally, the behaviour of a protocol can be modelled through a process algebra such as CSP or the pi calculus, enriched with terms to represent cryptographic messages. Then indistinguishability can be modelled through various behavioral equivalences. In contrast, secrecy or authentication are typically expressed by requesting that some bad event never occurs or that some event (e.g. Bob is logged) is always preceded by another one (e.g. the server granted access to Bob). Then checking for privacy amounts into checking for trace equivalence between processes, while checking for secrecy amounts into checking that a process never reaches a certain state. Both properties are undecidable in general [29]. Many results have been developed in the context of reachability properties. For an unbounded number of sessions, several decidable classes have been identified (e.g. bounding the size of messages [29] or the number of variables [23]). Tools like ProVerif [11] or Tamarin [38] do not try to *decide* security:

---

instead they propose sound procedures, incomplete but that work well in practice. Tamarin also supports user guidance through lemmas and direct interactions. The case of a bounded number of sessions is known to be (co)-NP-complete [37] and several tools aim at developing efficient decision procedures in practice, like AVISPA [7], or Scyther [27] (that can also handle an unbounded number of sessions). Results for equivalence properties are more rare. Even in the case of a bounded number of sessions, there are few decidability results and the associated decision procedures are complex [10, 17, 39].

*Our contribution.* We consider here a different approach. Instead of trying directly to decide security, we develop a simplification result. Our main contribution reduces the search space for attacks: if there is an attack, then there exists a well-typed attack. More formally, we show that if there is a witness (*i.e.* a trace) that  $P \not\approx Q$  then there exists a witness which is well-typed w.r.t.  $P$  or  $Q$ , provided that  $P$  and  $Q$  are deterministic processes (intuitively, at any time, no two messages may be emitted or received on the same channel). Similarly for reachability, for any trace of  $P$ , we show that there is a well-typed trace of  $P$  that follows the same sequence of inputs and outputs, on the same channels, hence preserving secrecy or authentication violations. We can consider arbitrary processes and a large family of equational theories that can express most standard primitives: randomized and deterministic asymmetric and symmetric encryptions, signatures, hash, MACs, and even some form of threshold encryption (1 out of  $n$  keys or  $n$  out of  $n$ ). These results hold for any typing system provided that any two unifiable encrypted subterms of  $P$  (or  $Q$ ) are of the same type. It is then up to the user to adjust the typing system such that this hypothesis holds for the protocols under consideration. The finer the typing system is, the more our typing result restricts the attack search. One way to enforce our assumption is to consider the class of tagged protocols introduced by Blanchet and Podelski [14]. An easy way to achieve this in practice is by labelling encryption and is actually a good protocol design principle [2, 30].

We extend here a preliminary result presented at Concur'14 [20]. Compared to [20], we considerably enrich the class of cryptographic primitives since [20] considers (deterministic) symmetric encryption only. Moreover, we provide a small attack property for equivalence as well as reachability properties while [20] focuses on equivalence. The reachability case is somehow an intermediary step of the equivalence case. Therefore the reachability case was in some sense contained in [20] but not formally stated as an independent result. The simplification result of [20], that we extend, has already been used in several contexts.

- First, in [20] itself, the small attack property is shown to imply decidability for an unbounded number of sessions but for protocols with no fresh nonces nor fresh keys. Such a decidability result should probably extend to our novel class of primitives but we chose to focus here on the small attack property.
- [21] establishes the first decidability result for equivalence of protocols *with* fresh nonces and keys. It uses as a preliminary that only well-typed traces need to be considered.
- SAT-Equiv [25] is a new and efficient tool for deciding trace equivalence for a bounded number of sessions. Thanks to the small attack property, trace equivalence is reduced to finite model-checking and SAT-Equiv adapts standard model-checking techniques, namely graph planning.

Of course, due to the limitations of [20], these three results hold for protocols with symmetric key only. Our extension of the small attack property to a general class of primitives opens the way to new decidability results or more efficient procedures for more general primitives.

*Related work.* Formal methods have been very successful for the analysis of security protocols and many decision procedures and tools (*e.g.* [24, 35, 36]) have been proposed. Most of these results

focus on reachability properties such as confidentiality or authentication. Much fewer results exist for behavioral equivalences. Based on a procedure proposed by Baudet [10], a first decidability result has been proposed for deterministic processes without else branches, and for equational theories that capture most standard primitives [18]. Then Tiu and Dawson [39] have designed and implemented a procedure for open bisimulation, a notion of equivalence stronger than the standard notion of trace equivalence. Cheval *et al* [17] have proposed and implemented a procedure for processes with else branches and standard primitives. The tool AkisS [16] is also dedicated to trace equivalence but is not guaranteed to terminate. All these results focus on a bounded number of sessions. The tools ProVerif [13] and Tamarin [38] can handle equivalence properties for an unbounded number of sessions. They actually reason on a stronger notion of equivalence (which may turn to be too strong in practice) and are not guaranteed to terminate. For an unbounded number of sessions, a few results have been established [19–21].

Our goal here is not to decide equivalence or reachability properties but to restrict the search space for attacks. As already discussed, our result extends the preliminary result of [20] to a wide class of cryptographic primitives and to reachability properties. In terms of proof techniques, we completely reshaped the proof. [20] relies on the fact that reachability is decidable for a bounded number of sessions, builds a decision algorithm for equivalence, for a bounded number of sessions, and then use this algorithm to show that, from any witness of non equivalence, it is possible to construct a well-typed witness. Our proof here directly builds a well-typed witness, without the need of decision algorithms. Moreover, the fact that [20] considers symmetric key only simplifies the proof as an attacker never needs to construct when it tries to learn new information. This is no longer true for example with asymmetric encryption or hashes where the attacker may need to encrypt and hash to compare values.

Our proof technique is inspired from the approach developed by Arapinis *et al* [6] for bounding the size of messages of an attack for the reachability case. Specifically, they show for some class of tagged protocols, that whenever there is an attack, there is a well-typed attack (for a particular typing system). We extend their approach to trace equivalence, for more general typing systems, and more general cryptographic primitives. One of the first small model properties has been established by Lowe [34]. It shows that it is sufficient to consider a finite number of roles, but assumes that messages are strongly typed: agents expects messages that follows a given (fixed) format and may never accept e.g. an arbitrary message instead of a nonce. Heather *et al* [31] provide a result for limiting attacks to well-typed ones, assuming a strong labelling scheme and no blind copies. Ramanujam and Suresh [36] also show some kind of typing result, assuming an even stronger labeling scheme, with fresh nonces, and use it to establish a decidability result for protocols with nonces, with no blind copies and the standard primitives. Again for reachability, Mödersheim *et al* [3, 32] establish a typing result similar to our result, for a flexible class of primitives (but incomparable to ours). The type-compliance notion is more restrictive since even pairs of terms of a protocol should be non unifiable (or have the same type).

## 2 MODEL

### 2.1 Term algebra

Private data are represented through an infinite set of *names*  $\mathcal{N}$ . Names can model e.g. long-term and short-term keys, or nonces. We consider an infinite set  $\Sigma_0^-$  of constants to represent public data, or any data known by the attacker, such as agent names or attacker’s nonces or keys. We also consider two additional infinite sets of constants  $\Sigma_{\text{fresh}}^{\text{atom}}$  and  $\Sigma_{\text{fresh}}^{\text{bitstring}}$  on which we will rely on for our technical development. We write  $\Sigma_{\text{fresh}} = \Sigma_{\text{fresh}}^{\text{atom}} \uplus \Sigma_{\text{fresh}}^{\text{bitstring}}$ , and  $\Sigma_0^+ = \Sigma_0^- \uplus \Sigma_{\text{fresh}}$ . Lastly, we consider two sets of *variables*  $\mathcal{X}$  and  $\mathcal{W}$ . Variables in  $\mathcal{X}$  typically model arbitrary data expected

by the protocol, while variables in  $\mathcal{W}$  are used to store messages learnt by the attacker. All these sets are assumed to be pairwise disjoint. A *data* is either a constant, a variable, or a name.

We model messages exchanged on the network and computations of the attacker by *terms*. A *signature*  $\Sigma$  is a set of function symbols with their arity. We distinguish between *constructor* symbols, like encryption, in  $\Sigma_c$  and *destructor* symbols, like decryption, in  $\Sigma_d$ , i.e.  $\Sigma = \Sigma_c \uplus \Sigma_d$ . Given a signature  $\mathcal{F}$ , the set of terms built from  $\mathcal{F}$  and a set of data  $D$  is denoted  $\mathcal{T}(\Sigma, D)$ . *Constructor terms* on  $D$  are terms in  $\mathcal{T}(\Sigma_c, D)$ . We use the usual terminology on terms, that we recall here. We denote  $\text{vars}(u)$  the set of variables that occur in a term  $u$ . A term is *ground* if it contains no variable. The application of a substitution  $\sigma$  to a term  $u$  is written  $u\sigma$ . We denote  $\text{dom}(\sigma)$  its *domain* and  $\text{img}(\sigma)$  its *image*. The *positions* of a term are defined as usual. Given a term  $t$ , we denote  $\text{root}(t)$  the function symbol occurring at position  $\epsilon$  in  $t$ , and  $\text{St}(t)$  its set of *subterms*. Two terms  $u_1$  and  $u_2$  are *unifiable* when there exists a substitution  $\sigma$  such that  $u_1\sigma = u_2\sigma$ .

We consider two *sorts*: *atom* and *bitstring*. *atom* represents atomic data like nonces or keys while *bitstring* models arbitrary messages. Names in  $\mathcal{N}$ , as well as constants in  $\Sigma_0^-$  and  $\Sigma_{\text{fresh}}^{\text{atom}}$  have sort *atom*, whereas constants in  $\Sigma_{\text{fresh}}^{\text{bitstring}}$  have sort *bitstring*. The constants of sort *atom*, i.e. those in  $\Sigma_0^-$  and  $\Sigma_{\text{fresh}}^{\text{atom}}$ , are called *atomic constants*. Any constructor  $f$  comes with its sort, i.e.  $f : (s_1 \times \dots \times s_n) \rightarrow s_0$  where  $n$  is the arity of  $f$ ,  $s_0 = \text{bitstring}$ , and  $s_i \in \{\text{atom}; \text{bitstring}\}$  for  $0 \leq i \leq n$ . Given a constructor term  $t \in \mathcal{T}(\Sigma_c, \Sigma_0^+ \uplus \mathcal{X})$ ,  $p$  is a *key position* of  $t$  if it corresponds to a position where an atom is expected, that is,

$$p = p'.i, \quad t|_{p'} = f(t_1, \dots, t_n) \text{ for some } f \in \Sigma_c : (s_1 \times \dots \times s_n) \rightarrow s_0, \text{ and } s_i = \text{atom}.$$

We say that  $t$  is *well-sorted* if any of its subterm is of the right sort, that is,  $t|_p \in \Sigma_0^- \uplus \Sigma_{\text{fresh}}^{\text{atom}} \uplus \mathcal{X}$  for any key position  $p$  of  $t$ .

We consider theories where, intuitively, each symbol corresponds to a particular function that may be applied only in one particular context. For example, if asymmetric encryption is represented by  $\text{aenc}(m, \text{pk}(k))$  then it should not be applied to other keys, such as  $\text{vk}(k)$ . To each constructor function symbol  $f$ , we associate a *linear* term  $f(u_1, \dots, u_n) \in \mathcal{T}(\Sigma_c, \mathcal{X})$  denoted  $\text{sh}_f$  which is called the *shape* of  $f$ . Shapes have to be *compatible*, that is, fixed for a given function symbol. Formally, for any  $f(t_1, \dots, t_n)$  occurring in a shape, we have that  $f(t_1, \dots, t_n) = \text{sh}_f$ . A term is *well-shaped* if it complies with the shapes, that is, any subterm of  $t$ , heading with a constructor symbol  $f$  is an instance of the shape of  $f$ . More formally, a constructor term  $t \in \mathcal{T}(\Sigma_c, \Sigma_0^+ \uplus \mathcal{X})$  is well-shaped if for any  $t' \in \text{St}(t)$  such that  $\text{root}(t') = f$ , we have that  $t' = \text{sh}_f\sigma$  for some substitution  $\sigma$ . Given  $D \subseteq \Sigma_0^+ \uplus \mathcal{X}$ , we denote  $\mathcal{T}_0(\Sigma_c, D)$  the subset of ground constructor terms on  $D$  that are well-shaped and well-sorted. Given a set  $\Sigma_0$  of constants (typically  $\Sigma_0^-$  or  $\Sigma_0^+$ ),  $\Sigma_0$ -messages are terms in  $\mathcal{T}_0(\Sigma_c, \mathcal{N} \uplus \Sigma_0)$ .

*Example 2.1.* Randomized asymmetric encryption, pairs, and triples are typically modelled by the following signature

$$\Sigma^{\text{ex}} = \{\text{raenc}, \text{pub}, \text{radec}, \langle \rangle, \langle \rangle^3, \text{fst}, \text{snd}, \text{proj}_1^3, \text{proj}_2^3, \text{proj}_3^3\}$$

with  $\Sigma_c^{\text{ex}} = \{\text{raenc}, \text{pub}, \langle \rangle, \langle \rangle^3\}$ , and  $\Sigma_d^{\text{ex}} = \{\text{radec}, \text{fst}, \text{snd}, \text{proj}_1^3, \text{proj}_2^3, \text{proj}_3^3\}$ .

The symbols  $\text{raenc}$  (arity 3) and  $\text{radec}$  (arity 2) represent resp. randomized asymmetric encryption and decryption. The symbol  $\text{pub}$  is a key function that models the public key associated to a given private key. Pairing is modelled using  $\langle \rangle$  of arity 2, whereas associated projection functions are denoted  $\text{fst}$  and  $\text{snd}$  (both of arity 1). We also model triples by  $\langle \rangle^3$  of arity 3. Projection functions  $\text{proj}_i^3$  ( $i \in \{1; 2; 3\}$ ) are of arity 1 and retrieve the component  $x_i$  of the triple  $\langle x_1, x_2, x_3 \rangle^3$ . The

sort of our constructors and their shapes are as follows:

$$\begin{array}{ll}
\text{raenc} : \text{bitstring} \times \text{bitstring} \times \text{atom} \rightarrow \text{bitstring} & sh_{\text{raenc}} = \text{raenc}(x_1, \text{pub}(x_2), x_3) \\
\text{pub} : \text{atom} \rightarrow \text{bitstring} & sh_{\text{pub}} = \text{pub}(x_2) \\
\langle \rangle : \text{bitstring} \times \text{bitstring} \rightarrow \text{bitstring} & sh_{\langle \rangle} = \langle x_1, x_2 \rangle \\
\langle \rangle^3 : \text{bitstring} \times \text{bitstring} \times \text{bitstring} \rightarrow \text{bitstring} & sh_{\langle \rangle^3} = \langle x_1, x_2, x_3 \rangle^3
\end{array}$$

For example, the term  $\text{raenc}(m, \text{pub}(k), r)$  represents the encryption of  $m$  with the public key  $\text{pub}(k)$  and randomness  $r$ . We chose to model randomness as an atom to reflect that randomness are typically non composed messages. However, we could consider the function symbol  $\text{raenc}$  with sort:  $\text{bitstring} \times \text{bitstring} \times \text{bitstring} \rightarrow \text{bitstring}$  as well.

Let  $a, b \in \Sigma_0^-$  and  $sk_0, r_0 \in \mathcal{N}$  (all of sort atom), the term  $\text{raenc}(\langle a, b \rangle, \text{pub}(sk), r_0)$  is a constructor term whose key positions are  $p_1 = 2.1$  and  $p_2 = 3$ . Actually this is a  $\Sigma_0^-$  message. We may note that it is well-sorted since  $sk$  and  $r_0$  are of sort atom, and well-shaped. The constructor term  $\text{raenc}(a, sk, r_0)$  is well-sorted but it is *not* well-shaped. Note that we will require protocols to only process messages, which enforces that terms are well-sorted and well-shaped.

The properties of cryptographic primitives are represented through a set  $\mathcal{R}$  of rewriting rules. We consider rewriting rules that apply a destructor on top of constructor terms that are linear, well-sorted, and well-shaped. We strictly control the non-linearity of our rules, and we assume the standard subterm property. More formally, for each destructor symbol  $\text{des} \in \Sigma_d$ , there is exactly one rule of the form  $\ell_{\text{des}} \rightarrow r_{\text{des}}$  such that:

- (1)  $\ell_{\text{des}} = \text{des}(t_1, \dots, t_n)$  where each  $t_i$  is either a variable, or equal to  $sh_{\text{root}(t_i)}$  up to a bijective renaming of variables;
- (2)  $r_{\text{des}} \in \mathcal{T}_0(\Sigma_c, \emptyset) \cup St(t_1)$ . In case  $r_{\text{des}}$  is not a fixed constructor term, for simplicity and readability in our technical developments, we assume that  $r_{\text{des}}$  occurs in  $t_1$ . Of course, our results easily extend to the case where the arguments of a destructor symbol are written in a different order;
- (3) either  $\ell_{\text{des}}$  is a linear term, or there is a unique variable  $x$  with several occurrences in  $\ell_{\text{des}}$  and such that  $x$  occurs exactly once at a key position in  $t_1$ ;

Moreover, we assume the existence of at least one non linear rule in our set  $\mathcal{R}$  of rewriting rules.

Given a set  $\mathcal{R}$  of rewriting rules, a term  $u$  can be rewritten in  $v$  using  $\mathcal{R}$  if there is a position  $p$  in  $u$ , and a rewriting rule  $g(t_1, \dots, t_n) \rightarrow t$  in  $\mathcal{R}$  such that  $u|_p = g(t_1, \dots, t_n)\theta$  for some substitution  $\theta$ , and  $v = u[t\theta]_p$ , i.e.  $u$  in which the subterm at position  $p$  has been replaced by  $t\theta$ . Moreover, we assume that  $t_1\theta, \dots, t_n\theta$  as well as  $t\theta$  are  $\Sigma_0^+$ -messages, in particular they do not contain destructor symbols. We consider sets of rewriting rules that yield a convergent rewriting system. As usual, we denote  $\rightarrow^*$  the reflexive-transitive closure of  $\rightarrow$ , and  $u\downarrow$  the normal form of a term  $u$  (it is well defined as our rewriting system is convergent by unicity of the rule associated to each destructor).

*Example 2.2.* The properties of the primitives given in Example 2.1 are reflected through the following rewriting rules.

$$\begin{array}{ll}
\text{fst}(\langle x, y \rangle) \rightarrow x & \text{radec}(\text{raenc}(x, \text{pub}(y), z), y) \rightarrow x \\
\text{snd}(\langle x, y \rangle) \rightarrow y & \text{proj}_i^3(\langle x_1, x_2, x_3 \rangle_3) \rightarrow x_i \quad \text{with } i \in \{1; 2; 3\}
\end{array}$$

They satisfy all the requirements stated above.

Our class of rewriting rules is flexible enough to represent most of the standard primitives as illustrated in the following example. However, we cannot model for instance a decryption algorithm that never fails and always returns a bitstring (e.g.  $\text{sdec}(m, k)$ ). Indeed, such a term is not a message and will not be accepted as input or output of a protocol.

*Example 2.3.* We may consider symmetric encryption (randomized or not) using the signature  $\Sigma^{\text{senc}} = \{\text{senc}, \text{rsenc}, \text{sdec}, \text{rsdec}\}$  and the rewriting rules:

$$\begin{aligned} \text{senc} &: \text{bitstring} \times \text{atom} \rightarrow \text{bitstring} & sh_{\text{rsenc}} &= \text{senc}(x_1, x_2) \\ \text{rsenc} &: \text{bitstring} \times \text{atom} \times \text{atom} \rightarrow \text{bitstring} & sh_{\text{rsenc}} &= \text{rsenc}(x_1, x_2, x_3) \\ \text{sdec}(\text{senc}(x, y), y) &\rightarrow x & \text{rsdec}(\text{rsenc}(x, y, z), y) &\rightarrow x \end{aligned}$$

Of course, we may consider non randomized asymmetric encryption as well. We can also model signature, and hash function through the signature  $\Sigma^{\text{sign}} = \{\text{sign}, \text{getmsg}, \text{check}, \text{vk}, \text{ok}, \text{hash}\}$ :

$$\begin{aligned} \text{ok} &: \rightarrow \text{bitstring} & sh_{\text{ok}} &= \text{ok} \\ \text{sign} &: \text{bitstring} \times \text{atom} \rightarrow \text{bitstring} & sh_{\text{sign}} &= \text{sign}(x_1, x_2) \\ \text{vk} &: \text{atom} \rightarrow \text{bitstring} & sh_{\text{vk}} &= \text{vk}(x_1) \\ \text{hash} &: \text{bitstring} \rightarrow \text{bitstring} & sh_{\text{hash}} &= \text{hash}(x_1) \\ \text{getmsg}(\text{sign}(x, y)) &\rightarrow x & \text{check}(\text{sign}(x, y), \text{vk}(y)) &\rightarrow x \end{aligned}$$

We may also represent more exotic theory like 1 out of  $n$  encryption (that is, one key among  $n$  suffices to decrypt) and  $n$  out of  $n$  encryption (that is, the  $n$  shares of the key are needed to decrypt) through the signature  $\Sigma^{\text{shamir}} = \{k_1, k_2, \text{reveal}, \text{get}_1, \text{get}_2, \text{onekey}, \text{allkeys}\}$ :

$$\begin{aligned} k_i &: \text{atom} \rightarrow \text{bitstring} & sh_{k_i} &= k_i(x_1); \\ \text{onekey} &: \text{bitstring} \times \text{atom} \times \text{atom} & sh_{\text{onekey}} &= \text{onekey}(x_1, x_2, x_3); \\ \text{allkeys} &: \text{bitstring} \times \text{atom} & sh_{\text{allkeys}} &= \text{allkeys}(x_1, x_2); \\ \text{get}_i(\text{onekey}(x, y_1, y_2), y_i) &\rightarrow x \text{ with } i \in \{1, 2\} & \text{reveal}(\text{allkeys}(x, y), k_1(y), k_2(y)) &\rightarrow x \end{aligned}$$

We can also model tuples of various size in a similar fashion than triples in Example 2.1. Another theory of interest is when it is possible to check whether two ciphertexts have been encrypted with the same key. This can be modeled by adding the destructor symbol `samekey` to  $\Sigma^{\text{senc}}$  and the rewrite rule

$$\text{samekey}(\text{senc}(x_1, y), \text{senc}(x_2, y)) \rightarrow \text{ok}$$

An attacker builds his own messages by applying public function symbols to terms he already knows and that are available through variables in  $\mathcal{W}$ . Formally, given a set  $\Sigma_0$  of constants (typically  $\Sigma_0^-$  or  $\Sigma_0^+$ ), a computation done by the attacker is a  $\Sigma_0$ -*recipe*, i.e. a term in  $\mathcal{T}(\Sigma, \mathcal{W} \uplus \Sigma_0)$ .

## 2.2 Process algebra

Our process algebra is inspired from the applied pi calculus [1]. We do not consider else branches. Actually we do not have conditional. Instead, equality tests are performed through pattern-matching. We do not consider replication but our typing result easily extend to processes with replication as explained in [20]. Indeed, our key result shows how to build a well-typed trace from an arbitrary one. This holds for traces obtained from finite processes as well as traces from replicated processes.

Let  $Ch$  be an infinite set of *channels*. We consider processes built using the following grammar:

$$\begin{array}{ll} P, Q := & 0 & \text{null process} \\ & | \text{in}(c, u).P & \text{input} \\ & | \text{out}(c, u).P & \text{output} \\ & | (P \mid Q) & \text{parallel} \\ & | i : P & \text{phase} \end{array}$$

where  $u \in \mathcal{T}_0(\Sigma_c, \Sigma_0^- \uplus \mathcal{N} \uplus \mathcal{X})$ , and  $c \in Ch$ .

The process 0 does nothing. The process  $\text{in}(c, u).P$  expects a message  $m$  of the form  $u$  on channel  $c$  and then behaves like  $P\sigma$  where  $\sigma$  is a substitution such that  $m = u\sigma$ . The process  $\text{out}(c, u).P$

emits  $u$  on channel  $c$ , and then behaves like  $P$ . The variables that occur in  $u$  are instantiated when the evaluation takes place. The process  $P \mid Q$  runs  $P$  and  $Q$  in parallel. Our calculus also introduces a phase instruction, in the spirit of [13], denoted  $i : P$ . Some protocols like e-voting protocols may proceed in phase. More generally, phases are particularly useful to model security requirements, for example in case the attacker interacts with the protocol before being given some secret.

For the sake of clarity, we may omit the null process. We also assume that processes are *variable distinct*, i.e. any variable is at most bound once. We write  $fv(P)$  for the set of *free variables* that occur in  $P$ , i.e. the set of variables that are not in the scope of an input.

*Example 2.4.* We consider a variant of the Needham Schroeder Lowe public key protocol [33] with randomized encryption. The protocol aims at ensuring mutual authentication through the secrecy of the nonces  $N_a$  and  $N_b$  that are exchanged during an execution. It can be described informally as follows:

1.  $A \rightarrow B$  :  $\text{raenc}(\langle A, N_a \rangle, \text{pub}(B), r_1)$
2.  $B \rightarrow A$  :  $\text{raenc}(\langle N_a, \langle N_b, B \rangle \rangle, \text{pub}(A), r_2)$
3.  $A \rightarrow B$  :  $\text{raenc}(N_b, \text{pub}(B), r_3)$

where  $A$  and  $B$  are agents trying to authenticate each other,  $\text{pub}(A)$  (resp.  $\text{pub}(B)$ ) is the public key of  $A$  (resp.  $B$ ),  $N_a$  and  $N_b$  (as well as  $r_1$ ,  $r_2$ , and  $r_3$ ) are nonces generated by  $A$  and  $B$ . This is a slight variant of the original protocol [33] proposed by J. Millen: in the second message, the identity of  $B$  is placed at the end of the message, instead of the beginning of the message. This variant is subject to a type-flaw attack (discovered by J. Millen) as we shall explain in the next section.

We model the Needham Schroeder Lowe protocol in our formalism through the process  $P_{\text{NSL}}$  that results from the composition of the process  $P_A$  representing the role of  $A$  and the process  $P_B$  representing the role of  $B$ .

$$P_{\text{NSL}} = P_A \mid P_B$$

with  $P_A$  and  $P_B$  defined as follows.

$$\begin{aligned} P_A = & \text{out}(c_A, \text{raenc}(\langle a, n_a \rangle, \text{pub}(sk_b), r_1)). & P_B = & \text{in}(c_B, \text{raenc}(\langle a, y_1 \rangle, \text{pub}(sk_b), y_2)). \\ & \text{in}(c_A, \text{raenc}(\langle n_a, \langle x_1, b \rangle \rangle, \text{pub}(sk_a), x_2)). & & \text{out}(c_B, \text{raenc}(\langle y_1, \langle n_b, b \rangle \rangle, \text{pub}(sk_a), r_2)). \\ & \text{out}(c_A, \text{raenc}(x_1, \text{pub}(sk_b), r_3)) & & \text{in}(c_B, \text{raenc}(n_b, \text{pub}(sk_b), y_3)). \end{aligned}$$

where  $sk_a, sk_b, n_a, n_b, r_1, r_2$ , and  $r_3$  are names, whereas  $a$  and  $b$  are constants from  $\Sigma_0^-$ .

In order to model a richer scenario, we may want to consider in addition the process  $P'_B$  that corresponds to the role  $B$  played by agent  $a$  interacting with a dishonest agent  $c$ . Below,  $r'_3, n'_b \in \mathcal{N}$  whereas  $c, sk_c \in \Sigma_0^-$  (so that they are implicitly given to the attacker). We write  $\overline{P}_{\text{NSL}} = P_B \mid P'_B$

$$\begin{aligned} P'_B = & \text{in}(c'_B, \text{raenc}(\langle c, y'_1 \rangle, \text{pub}(sk_a), y'_2)). \\ & \text{out}(c'_B, \text{raenc}(\langle y'_1, \langle n'_b, a \rangle \rangle, \text{pub}(sk_c), r'_2)). \\ & \text{in}(c'_B, \text{raenc}(n'_b, \text{pub}(sk_a), y'_3)). \end{aligned}$$

The initial knowledge of the attacker will be specified later.

### 2.3 Semantics.

The operational semantics of a process is defined using a relation over configurations. Configurations are parameterized by a set of constants  $\Sigma_0$  (typically  $\Sigma_0^-$  or  $\Sigma_0^+$ ). A  $\Sigma_0$ -configuration is a tuple  $(\mathcal{P}; \phi; \sigma; i)$  with  $i \in \mathbb{N}$  and such that:

- $\mathcal{P}$  is a multiset of processes (not necessarily ground);
- $\phi = \{w_1 \triangleright m_1, \dots, w_n \triangleright m_n\}$  is a  $\Sigma_0$ -frame, i.e. a substitution where  $w_1, \dots, w_n$  are variables in  $\mathcal{W}$ , and  $m_1, \dots, m_n$  are  $\Sigma_0$ -messages;

IN	$(i : \text{in}(c, u).P \cup \mathcal{P}; \phi; \sigma; i)$	$\xrightarrow{\text{in}(c, R)}$	$(i : P \cup \mathcal{P}; \phi; \sigma \uplus \sigma_0; i)$ where $R$ is a $\Sigma_0$ -recipe such that $R\phi\downarrow$ is a $\Sigma_0$ -message, and $R\phi\downarrow = (u\sigma)\sigma_0$ for $\sigma_0$ with $\text{dom}(\sigma_0) = \text{vars}(u\sigma)$ .
OUT	$(i : \text{out}(c, u).P \cup \mathcal{P}; \phi; \sigma; i)$	$\xrightarrow{\text{out}(c, w)}$	$(i : P \cup \mathcal{P}; \phi \cup \{w \triangleright u\sigma\}; \sigma; i)$ with $w$ a fresh variable from $\mathcal{W}$ , and $u\sigma$ is a $\Sigma_0$ -message.
MOVE	$(\mathcal{P}; \phi; \sigma; i)$	$\xrightarrow{\text{phase } i'}$	$(\mathcal{P}; \phi; \sigma; i')$ with $i' > i$ .
PHASE	$(i : i' : P \cup \mathcal{P}; \phi; \sigma; i)$	$\xrightarrow{\tau}$	$(i' : P \cup \mathcal{P}; \phi; \sigma; i)$
CLEAN	$(i : P \cup \mathcal{P}; \phi; \sigma; i')$	$\xrightarrow{\tau}$	$(\mathcal{P}; \phi; \sigma; i')$ when $i' > i$ .
NULL	$(i : 0 \cup \mathcal{P}; \phi; \sigma; i)$	$\xrightarrow{\tau}$	$(\mathcal{P}; \phi; \sigma; i)$
PAR	$(i : (P \mid Q) \cup \mathcal{P}; \phi; \sigma; i)$	$\xrightarrow{\tau}$	$(i : P \cup i : Q \cup \mathcal{P}; \phi; \sigma; i)$

Fig. 1. Semantics for processes w.r.t.  $\Sigma_0$

- $\sigma$  is a substitution such that  $\text{dom}(\sigma) = \text{fv}(P)$ , and  $\text{img}(\sigma)$  are  $\Sigma_0$ -messages.

A  $\Sigma_0$ -configuration  $(\mathcal{P}; \phi; \sigma; i)$  such that  $\sigma = \emptyset$  is said *initial*.

Intuitively,  $\mathcal{P}$  represents the processes that still remain to be executed;  $\phi$  represents the sequence of messages that have been learnt so far by the attacker, and  $\sigma$  stores the value of the variables that have already been instantiated. We often write  $i : P$  instead of  $(P; \emptyset; i)$ ,  $P$  instead of  $0 : P$  and  $P \uplus \mathcal{P}$  instead of  $\{P\} \uplus \mathcal{P}$ . The operational semantics of a  $\Sigma_0$ -configuration is induced by the relation  $\xrightarrow{\alpha}$  w.r.t.  $\Sigma_0$  over  $\Sigma_0$ -configurations defined in Figure 1.

The first rule (IN) allows the attacker to send to some process a term built from publicly available terms and symbols. The second rule (OUT) corresponds to the output of a term by some process: the corresponding term is added to the frame of the current configuration, which means that the attacker can now access the sent term. Note that the term is outputted provided that it is a message. Regarding phases (rules MOVE, PHASE, and CLEAN), the attacker may move to a subsequent phase whenever he wants, while processes may move to the next phase when they are done or simply disappear if the phase is over. The two remaining rules NULL and PAR are quite standard and are unobservable ( $\tau$  action) from the point of view of the attacker.

The relation  $\xrightarrow{\alpha_1 \dots \alpha_n}$  w.r.t.  $\Sigma_0$  between  $\Sigma_0$ -configurations (where  $\alpha_1 \dots \alpha_n$  is a sequence of actions) is defined as the transitive closure of  $\xrightarrow{\alpha}$  w.r.t.  $\Sigma_0$ . Given a sequence of observable actions  $\text{tr}$ , and two  $\Sigma_0$ -configurations  $\mathcal{K}$  and  $\mathcal{K}'$ , we write  $\mathcal{K} \xrightarrow{\text{tr}} \mathcal{K}'$  w.r.t.  $\Sigma_0$  when there exists a sequence  $\alpha_1 \dots \alpha_n$  such that  $\mathcal{K} \xrightarrow{\alpha_1 \dots \alpha_n} \mathcal{K}'$  w.r.t.  $\Sigma_0$  and  $\text{tr}$  is obtained from  $\alpha_1 \dots \alpha_n$  by erasing all occurrences of  $\tau$ .

*Definition 2.5.* Given a  $\Sigma_0$ -configuration  $\mathcal{K} = (\mathcal{P}; \phi; \sigma; i)$ , we denote  $\text{trace}_{\Sigma_0}(\mathcal{K})$  the set of traces defined as follows:

$$\text{trace}_{\Sigma_0}(\mathcal{K}) = \{(\text{tr}, \phi') \mid \mathcal{K} \xrightarrow{\text{tr}} (\mathcal{P}; \phi'; \sigma'; i') \text{ w.r.t. } \Sigma_0 \text{ for some } \Sigma_0\text{-configuration } (\mathcal{P}; \phi'; \sigma'; i')\}.$$

Given a  $\Sigma_0$ -configuration  $\mathcal{K}$ , we may note that, by definition of  $\text{trace}_{\Sigma_0}(\mathcal{K})$ ,  $\text{tr}\phi\downarrow$  only contains  $\Sigma_0$ -messages.

*Example 2.6.* Continuing Example 2.4, consider the initial configuration  $\mathcal{K}_{\text{NSL}} = (\bar{P}_{\text{NSL}}; \phi_0; \emptyset; 0)$  with initial knowledge  $\phi_0 = \{w_a \triangleright \text{pub}(sk_a), w_b \triangleright \text{pub}(sk_b)\}$ . This models that the attacker initially

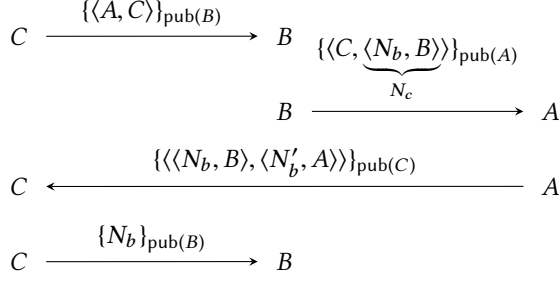

Fig. 2. Attack trace.

knows the public keys of a and b. Note that the private key of c,  $sk_c$ , is a public constant and is thus also initially known to the attacker.

As mentioned in Example 2.4, this variant of the Needham Schroeder Lowe protocol is subject to a type flaw attack depicted in Figure 2. The attack relies on the fact that agent  $A$  may accept the pair  $\langle N_b, B \rangle$  as a nonce  $N_C$  coming from  $C$  and agent  $B$  may confuse the identity  $C$  with a nonce. In this attack, a dishonest agent  $C$  initiates a session with agent  $B$  but writes his identity  $C$  instead of a nonce.  $B$  replies as expected by  $\{C, N_b, B\}_{\text{pub}(A)}$ . This message is then accepted by  $A$  (playing the responder role).  $A$  thinks she is contacted by  $C$  and replies with  $\{N_b, B, N'_b, A\}_{\text{pub}(C)}$ . Therefore the attacker learns  $N_b$  and may impersonate  $A$  w.r.t.  $B$ . This attack is reflected by the following sequence  $\text{tr}$ :

$$\text{in}(c_B, \text{raenc}(\langle a, c \rangle, w_b, r_0)).\text{out}(c_B, w_1).\text{in}(c'_B, w_1).\text{out}(c'_B, w_2).\text{in}(c_B, \text{raenc}(R, w_b, r'_0))$$

where  $R = \text{fst}(\text{fst}(\text{radec}(w_2, sk_c)))$  and  $r_0, r'_0 \in \Sigma_0^-$ . This sequence of actions yields the frame  $\phi$  defined as follows:

$$\phi = \phi_0 \uplus \{w_1 \triangleright \text{raenc}(\langle c, \langle n_b, b \rangle \rangle, \text{pub}(sk_a), r_2), w_2 \triangleright \text{raenc}(\langle \langle n_b, b \rangle, \langle n'_b, a \rangle \rangle, \text{pub}(sk_c), r'_2)\}.$$

We have that  $(\text{tr}, \phi) \in \text{trace}(\mathcal{K}_{\text{NSL}})$ .

## 2.4 Action-determinism

As mentioned in introduction, we require processes to be deterministic. We consider a definition similar to the one introduced in [9]. Intuitively, no two inputs nor two outputs should occur on the same channel at a concurrent time.

*Definition 2.7.* A configuration  $\mathcal{K}$  is *action-deterministic* if whenever  $\mathcal{K} \xrightarrow{\text{tr}} (\mathcal{P}; \phi; \sigma; i)$ , and  $\alpha.P$  and  $\beta.Q$  are two elements of  $\mathcal{P}$  with  $\alpha, \beta$  instructions of the form  $\text{in}(c, u)$ ,  $\text{out}(c', u)$  then  $c \neq c'$  or the instructions are not of the same nature (that is,  $\alpha, \beta$  are not both an input, nor both an output).

This condition is actually stronger than the one considered in our preliminary results [20]. In [20], we consider instead *determinate* processes, as introduced in [16]. Intuitively, a process is determinate as soon as all executions corresponding to one trace yield equivalent frames. However, this condition is insufficient for the proof of [20] that assumes a unique frame once a trace has been fixed. For action-deterministic protocols, the attacker knowledge is entirely determined by its interaction with the protocol.

**LEMMA 2.8.** *Let  $\mathcal{K}$  be an action-deterministic configuration such that  $\mathcal{K} \xrightarrow{\text{tr}} \mathcal{K}_1$  and  $\mathcal{K} \xrightarrow{\text{tr}} \mathcal{K}_2$  for some  $\text{tr}$ ,  $\mathcal{K}_1 = (\mathcal{P}_1; \phi_1; \sigma_1; i_1)$ , and  $\mathcal{K}_2 = (\mathcal{P}_2; \phi_2; \sigma_2; i_2)$ . We have that  $\phi_1 = \phi_2$ ,  $\sigma_1 = \sigma_2$ , and  $i_1 = i_2$ .*

## 2.5 Trace equivalence

Many privacy properties such as vote-privacy or untraceability are expressed as trace equivalence [5, 28]. Intuitively, two configurations are trace equivalent if an attacker cannot tell with which of the two configurations he is interacting. We first introduce a notion of equivalence between frames.

Intuitively, an attacker can see the difference between two sequences of messages if he is able to perform some computation that succeeds in  $\phi_1$  and fails in  $\phi_2$ ; or if he can build a test that leads to an equality in  $\phi_1$  and not in  $\phi_2$  (or conversely).

*Definition 2.9.* Two  $\Sigma_0$ -frames  $\phi_1$  and  $\phi_2$  are in *static inclusion* w.r.t.  $\Sigma_0$ , written  $\phi_1 \sqsubseteq_s \phi_2$  w.r.t.  $\Sigma_0$ , when  $\text{dom}(\phi_1) = \text{dom}(\phi_2)$ , and:

- for any  $\Sigma_0$ -recipe  $R$ , we have that  $R\phi_1\downarrow$  is  $\Sigma_0$ -message implies that  $R\phi_2\downarrow$  is  $\Sigma_0$ -message; and
- for any  $\Sigma_0$ -recipes  $R, R'$  such that  $R\phi_1\downarrow, R'\phi_1\downarrow$  are  $\Sigma_0$ -messages, we have that:  $R\phi_1\downarrow = R'\phi_1\downarrow$  implies  $R\phi_2\downarrow = R'\phi_2\downarrow$ .

They are in *static equivalence* w.r.t.  $\Sigma_0$ , written  $\phi_1 \sim_s \phi_2$  w.r.t.  $\Sigma_0$ , if  $\phi_1 \sqsubseteq_s \phi_2$  and  $\phi_2 \sqsubseteq_s \phi_1$ .

In the remaining of this paper,  $\Sigma_0$  will be either  $\Sigma_0^-$  or  $\Sigma_0^+$ , and we sometimes omit to mention it when it is clear from the context.

*Example 2.10.* Continuing Example 2.6, we consider the two following  $\Sigma_0^-$ -frames:

- $\phi_1 = \phi \uplus \{w_3 \triangleright n_b\}$ ; and
- $\phi_2 = \phi \uplus \{w_3 \triangleright k\}$ .

We have that  $R\phi_1\downarrow = w_3\phi_1\downarrow$  where  $R = \text{fst}(\text{fst}(\text{radec}(w_2, sk_c)))$ . This equality does not hold in  $\phi_2$ , hence  $\phi_1$  and  $\phi_2$  are not in static equivalence.

Trace equivalence is the active counterpart of static equivalence. Two configurations are trace equivalent if, however the attacker behaves, the resulting sequences of messages observed by the attacker are in static equivalence.

*Definition 2.11.* A  $\Sigma_0$ -configuration  $\mathcal{K}$  is trace included (w.r.t.  $\Sigma_0$ ) in a  $\Sigma_0$ -configuration  $\mathcal{K}'$ , written  $\mathcal{K} \sqsubseteq_t \mathcal{K}'$  w.r.t.  $\Sigma_0$ , if for every  $(\text{tr}, \phi) \in \text{trace}_{\Sigma_0}(\mathcal{K})$ , there exist  $(\text{tr}', \phi') \in \text{trace}_{\Sigma_0}(\mathcal{K}')$  such that  $\text{tr} = \text{tr}'$ , and  $\phi \sqsubseteq_s \phi'$  w.r.t.  $\Sigma_0$ . They are in trace equivalence, written  $\mathcal{K} \approx_t \mathcal{K}'$  w.r.t.  $\Sigma_0$ ,  $\mathcal{K} \sqsubseteq_t \mathcal{K}'$  and  $\mathcal{K}' \sqsubseteq_t \mathcal{K}$  w.r.t.  $\Sigma_0$ .

Note that two trace equivalent configurations are necessarily at the same phase.

This notion of trace equivalence slightly differs from the one used in [20], where the frames are required to be in static equivalence  $\phi \sim_s \phi'$  instead of static inclusion  $\phi \sqsubseteq_s \phi'$ . Actually, these two notions of equivalence coincide for action-deterministic protocols [16]. Moreover, we will actually prove a finer result, showing the existence of a well-typed witness (when a witness exists) for this trace inclusion notion.

*Example 2.12.* Continuing Example 2.4, we consider the protocol  $\overline{P}_{\text{NSL}}$  that models two roles of  $B$ : one played by  $B$  responding to  $A$ , and the other one played by  $A$  responding to  $C$ . To model the fact that the nonce  $n_b$  sent by  $B$  for  $A$  should remain secret, we define *strong secrecy* of  $n_b$  by requiring that  $n_b$  remains indistinguishable from a fresh value. Formally, we extend the process  $P_B$  modeling agent  $B$  responding to  $A$  with either the output of the true nonce  $n_b$  or the output of a fresh value  $k \in \mathcal{N}$ , yielding the following two processes.

$$\begin{aligned}
 P_B^1 &= \text{in}(c_B, \text{raenc}(\langle a, y_1 \rangle, \text{pub}(sk_b), y_2)). \\
 &\quad \text{out}(c_B, \text{raenc}(\langle y_1, \langle n_b, b \rangle \rangle, \text{pub}(sk_a), r_2)). \\
 &\quad \text{in}(c_B, \text{raenc}(n_b, \text{pub}(sk_b), y_3)). \\
 &\quad 1 : \text{out}(c_B, n_b) \\
 P_B^2 &= \text{in}(c_B, \text{raenc}(\langle a, y_1 \rangle, \text{pub}(sk_b), y_2)). \\
 &\quad \text{out}(c_B, \text{raenc}(\langle y_1, \langle n_b, b \rangle \rangle, \text{pub}(sk_a), r_2)). \\
 &\quad \text{in}(c_B, \text{raenc}(n_b, \text{pub}(sk_b), y_3)). \\
 &\quad 1 : \text{out}(c_B, k)
 \end{aligned}$$

The corresponding overall processes are  $\bar{P}_{\text{NSL}}^1 = P'_B \mid P_B^1$  and  $\bar{P}_{\text{NSL}}^2 = P'_B \mid P_B^2$ , and we consider the initial frame  $\phi_0$  as given in Example 2.6 and the initial configurations  $\mathcal{K}_1 = (\bar{P}_{\text{NSL}}^1; \phi_0; \emptyset; 0)$  and  $\mathcal{K}_2 = (\bar{P}_{\text{NSL}}^2; \phi_0; \emptyset; 0)$ . Then, we can show that  $\mathcal{K}_1 \not\sqsubseteq_t \mathcal{K}_2$  since  $n_b$  is not strongly secret due to the attack depicted in Figure 2. This is exemplified by the trace

$$\text{tr} = \text{in}(c_B, R_1).\text{out}(c_B, w_1).\text{in}(c'_B, w_1).\text{out}(c'_B, w_2).\text{in}(c_B, R_2).\text{out}(c_B, w_3)$$

with  $R_1 = \text{raenc}(\langle a, c \rangle, w_b, r_0)$  and  $R_2 = \text{raenc}(\text{fst}(\text{fst}(\text{radec}(w_2, sk_c))), w_b, r'_0)$ , where  $r_0, r'_0 \in \Sigma_0^-$ . Indeed, consider now

$$\phi = \phi_0 \uplus \{w_1 \triangleright \text{raenc}(\langle c, \langle n_b, b \rangle \rangle, \text{pub}(sk_a), r_2), w_2 \triangleright \text{raenc}(\langle \langle n_b, b \rangle, \langle n'_b, a \rangle \rangle, \text{pub}(sk_c), r'_2)\}$$

and  $\phi_1 = \phi_0 \uplus \{w_3 \triangleright n_b\}$ ,  $\phi_2 = \phi_0 \uplus \{w_3 \triangleright k\}$ . We have  $(\text{tr}, \phi_1) \in \text{trace}_{\Sigma_0^-}(\mathcal{K}_1)$  and  $(\text{tr}, \phi_2) \in \text{trace}_{\Sigma_0^-}(\mathcal{K}_2)$ . Now consider the equality  $w_3 = \text{fst}(\text{fst}(\text{radec}(w_2, sk_c)))$ . It holds in  $\phi_1$  but not in  $\phi_2$  hence we have that  $\mathcal{K}_1 \not\sqsubseteq_t \mathcal{K}_2$ .

Consider now a variant  $P'_{\text{NSL}}$  where the second message  $\{\langle N_a, \langle N_b, B \rangle \rangle\}_{\text{pub}(A)}$  is no longer encoded using two nested pairs but using a triple instead, that is,  $\{\langle N_a, N_b, B \rangle^3\}_{\text{pub}(A)}$ . This transformation yields the process

$$\begin{aligned} Q_B = & \text{in}(c_B, \text{raenc}(\langle a, y_1 \rangle, \text{pub}(sk_b), y_2)). \\ & \text{out}(c_B, \text{raenc}(\langle y_1, n_b, b \rangle^3, \text{pub}(sk_a), r_2)). \\ & \text{in}(c_B, \text{raenc}(n_b, \text{pub}(sk_b), y_3)) \end{aligned}$$

instead of  $P_B$ . The use of triples rules out the type flaw attack and the resulting processes are in trace equivalence.

### 3 OUR TYPING RESULTS

Even when considering finite processes (i.e. processes without replication), the problem of checking trace equivalence is difficult due to several sources of unboundedness. One of them is the arbitrarily large size of messages that can be forged by an attacker. We propose here a simplification result that reduces the search space for attacks. Roughly, if there is an attack, then there is a well-typed attack, for a flexible notion of type that can be adapted depending on the desired result. We establish this result both for trace properties and equivalence properties (trace equivalence). Compared to the initial work of [20], we extend the result from a fixed, simple signature (symmetric encryption) to a large class of cryptographic primitives that encompasses all the standard ones. Moreover, [20] only applies to trace equivalence. Intuitively, proving the small attack property for trace equivalence requires to first show how to reduce the attack on a single trace. This yields a reduction result for reachability properties, such as authentication or confidentiality, which is of independent interest.

#### 3.1 Typing system

We consider any type system that is consistent with substitution and unification.

*Definition 3.1.* A *typing system* is a pair  $(\mathcal{T}, \delta)$  where  $\mathcal{T}$  is a set of elements called *types* and  $\delta$  is a function mapping terms  $t \in \mathcal{T}_0(\Sigma_c, \Sigma_0^+ \cup \mathcal{N} \cup \mathcal{X})$  to types in  $\mathcal{T}$  such that:

- If  $t$  is a term of type  $\tau$  and  $\sigma$  is a well-typed substitution, then  $t\sigma$  is of type  $\tau$ .
- For any unifiable terms  $t$  and  $t'$  with the same type, i.e.  $\delta(t) = \delta(t')$ , their most general unifier  $\text{mgu}(t, t')$  is well-typed.

Consider a configuration  $\mathcal{K}$  and a typing system  $(\mathcal{T}, \delta)$ , an execution  $\mathcal{K} \xrightarrow{\text{tr}} (\mathcal{P}; \phi; \sigma; i)$  is *well-typed* if  $\sigma$  is a well-typed substitution, i.e. every variable of its domain has the same type as its image.

Some interesting typing systems are *structure-preserving* typing systems, that is typing system that preserve the structure of terms. They are defined as follows:

*Definition 3.2.* A *structure-preserving typing system* is a pair  $(\mathcal{T}_{\text{init}}, \delta)$  where  $\mathcal{T}_{\text{init}}$  is a set of elements called *initial types*, and  $\delta$  is a function mapping data in  $\Sigma_0^+ \uplus \mathcal{N} \uplus \mathcal{X}$  to types  $\tau$  generated using the following grammar:

$$\tau, \tau_1, \tau_2 = \tau_0 \mid f(\tau_1, \dots, \tau_n) \text{ with } f \in \Sigma_c \text{ and } \tau_0 \in \mathcal{T}_{\text{init}}$$

Then,  $\delta$  is extended to constructor terms as follows:

$$\delta(f(t_1, \dots, t_n)) = f(\delta(t_1), \dots, \delta(t_n)) \text{ with } f \in \Sigma_c.$$

The following lemma proves that structure-preserving typing systems are typing systems as defined in Definition 3.1.

**LEMMA 3.3.** *Let  $(\mathcal{T}_{\text{init}}, \delta)$  be a structure-preserving typing system. Then  $(\mathcal{T}_0(\Sigma, \mathcal{T}_{\text{init}}), \delta)$  is a typing system as in Definition 3.1.*

**PROOF.** We have to prove the two following items:

- (1) If  $t$  is a term and  $\sigma$  is a well-typed substitution, then  $\delta(t\sigma) = \delta(t)$ .
- (2) For any unifiable terms  $t$  and  $t'$  with the same type, i.e.  $\delta(t) = \delta(t')$ , their most general unifier  $\text{mgu}(t, t')$  is well-typed.

We prove item (1) by induction on  $t$ . If  $t$  is a name or a constant, then  $t\sigma = t$  and the result trivially holds. If  $t$  is a variable, then  $\delta(t\sigma) = \delta(t)$  as  $\sigma$  is well-typed. Now, if  $t = f(t_1, \dots, t_n)$ , then  $\delta(t\sigma) = f(\delta(t_1\sigma), \dots, \delta(t_n\sigma))$  as  $(\mathcal{T}_{\text{init}}, \delta)$  is structure-preserving. By induction hypothesis, we have that  $\delta(t_i\sigma) = \delta(t_i)$  for  $i \in \{1, \dots, n\}$ , and we get that  $\delta(t\sigma) = f(\delta(t_1), \dots, \delta(t_n))$ . As  $\delta$  is structure-preserving, we have that  $\delta(t) = f(\delta(t_1), \dots, \delta(t_n))$ , and this allows us to conclude.

We now prove item (2). Given a set  $\Gamma$  of well-typed equations, we denote  $\#vars(\Gamma)$  the number of variables occurring in  $\Gamma$ , and  $|\Gamma|$  its size, i.e.  $\sum_{t=t' \in \Gamma} (|t| + |t'|)$  where  $|t|$  denotes the number of symbols occurring in  $t$ . Our measure  $\|\Gamma\|$  is determined by these two elements, in lexicographic order. We prove the result by induction on  $\|\Gamma\|$  relying on this measure.

*Base case:*  $\|\Gamma\| = (0, 0)$ , i.e.  $\Gamma = \emptyset$ , and thus the result trivially holds.

*Induction step:*  $\Gamma = \Gamma' \uplus \{t = t'\}$ . We distinguish several cases:

- In case  $t$  or  $t'$  is a variable. We assume w.l.o.g. that  $t$  is a variable  $x$ . In such a case, let  $\sigma = \{x \mapsto t'\}$ . We have that  $\sigma$  is well-typed. Moreover, applying our induction hypothesis on  $\Gamma'$ , we deduce that  $\text{mgu}(\Gamma')$  is well-typed, and thus  $\{x \mapsto t' \text{mgu}(\Gamma')\}$  is well-typed, and  $\text{mgu}(\Gamma) = \text{mgu}(\Gamma') \uplus \{x \mapsto t' \text{mgu}(\Gamma')\}$  is well-typed.
- Otherwise, assume that  $t$  is an atom (but not a variable). In such a case, we have that  $t'$  is also an atom (and not a variable due to the previous case). Therefore, since  $t$  and  $t'$  are unifiable, we have that  $t = t'$ , and  $\text{mgu}(\Gamma) = \text{mgu}(\Gamma')$ . Since  $\|\Gamma'\| < \|\Gamma\|$ , we have that  $\text{mgu}(\Gamma')$  is well-typed by induction hypothesis, and this allows us to conclude.
- Now, we assume that  $t = f(t_1, \dots, t_k)$ . In such a case, we have that  $t' = f(t'_1, \dots, t'_k)$  since  $t'$  is not a variable and we know that  $t$  and  $t'$  are unifiable. We have that  $\text{mgu}(\Gamma) = \text{mgu}(\Gamma'')$  where  $\Gamma'' = \Gamma' \uplus \{t_1 = t'_1, \dots, t_k = t'_k\}$ . Note that  $\Gamma''$  is a set of well-typed equations,  $\|\Gamma''\| < \|\Gamma\|$  and thus  $\text{mgu}(\Gamma'')$  is well-typed by induction hypothesis.

This concludes the proof. □

We further assume the existence of an infinite number of constants in  $\Sigma_0$  (resp.  $\Sigma_{\text{fresh}}^{\text{atom}}, \Sigma_{\text{fresh}}^{\text{bitstring}}$ ) of any type.

*Example 3.4.* Let's continue our running example, with the processes  $\overline{P}_{\text{NSL}}^1$  and  $\overline{P}_{\text{NSL}}^2$ , as defined in Example 2.12. We consider the structure preserving typing system generated from the set  $\overline{\mathcal{T}}_{\text{NSL}} = \{\tau_a, \tau_b, \tau_c, \tau_{na}, \tau_{nb}, \tau_r, \tau_{sk}, \tau_k\}$  of initial types, and the function  $\delta_{\text{NSL}}$  that associates the expected type to each constant/name ( $\delta_{\text{NSL}}(a) = \tau_a$ ,  $\delta_{\text{NSL}}(b) = \tau_b$ , etc.), and the following type to the variables:

$$\delta_{\text{NSL}}(y_1) = \delta_{\text{NSL}}(y'_1) = \tau_{na}, \text{ and } \delta_{\text{NSL}}(y_2) = \delta_{\text{NSL}}(y_3) = \delta_{\text{NSL}}(y'_2) = \delta_{\text{NSL}}(y'_3) = \tau_r.$$

The goal of our main results is to be able to consider only execution traces that comply with a given type, like this one.

### 3.2 Type compliance

Our main assumption on the typing of protocols is that any two unifiable encrypted subterms are of the same type. The goal of this part is to state this hypothesis formally. For this, we need to define the notion of *encrypted subterms*.

Among the constructor symbols in  $\Sigma_c$ , we distinguish those that are *transparent*. They intuitively correspond to constructors that can be freely opened by the attacker, such as pairs, tuples, or lists. A constructor symbol  $f$  of arity  $n$  is *transparent* if there exists a term  $f(R_1^f, \dots, R_n^f) \in \mathcal{T}(\Sigma, \square)$  such that for any term  $t \in \mathcal{T}_0(\Sigma, \Sigma_0^+ \uplus \mathcal{N} \uplus \mathcal{X})$  such that  $\text{root}(t) = f$ , we have that  $f(R_1^f, \dots, R_n^f)\{\square \rightarrow t\} \downarrow = t$ . We denote  $C_f$  such a term, and write  $C_f[t]$  the term obtained by replacing each occurrence of the hole with  $t$ .

We write  $Est(t)$  for the set of *encrypted subterms* of  $t$ , i.e. the set of subterms that are not headed by a transparent function.

$$Est(t) = \{u \in St(t) \mid u \text{ is of the form } f(u_1, \dots, u_n) \text{ and } f \text{ is not transparent}\}$$

*Example 3.5.* Going back to the signature  $\Sigma^{\text{ex}}$  introduced in Example 2.1, the symbols  $\langle \rangle$  and  $\langle \rangle^3$  are transparent: the contexts  $C_{\langle \rangle} = \langle \text{fst}(\square), \text{snd}(\square) \rangle$  and  $C_{\langle \rangle^3} = \langle \text{proj}_1^3(\square), \text{proj}_2^3(\square), \text{proj}_3^3(\square) \rangle^3$  satisfy the requirements.

A configuration  $\mathcal{K} = (\mathcal{P}; \phi; \emptyset; i)$  is type-compliant if two unifiable encrypted subterms occurring in  $\mathcal{K}$  (i.e. either in  $\mathcal{P}$  or in  $\phi$ ) have the same type. Formally, we use the definition given in the preliminary result [20], which is similar to the one originally introduced by B. Blanchet and A. Podelski in [14].

*Definition 3.6.* A configuration  $\mathcal{K}$  is type-compliant w.r.t. a typing system  $(\overline{\mathcal{T}}_{\text{init}}, \delta)$  if for every  $t, t' \in Est(\mathcal{K})$  we have that:  $t$  and  $t'$  unifiable implies that  $\delta(t) = \delta(t')$ .

*Example 3.7.* Continuing our running example with  $\mathcal{K}_{\text{NSL}} = (P_{\text{NSL}}; \phi_0; \emptyset; 0)$ , we have that  $\mathcal{K}_{\text{NSL}}$  is *not* type-compliant w.r.t. the typing system given in Example 3.4. Indeed, the encrypted subterms are:

- $t_1 = \text{raenc}(\langle a, y_1 \rangle, \text{pub}(sk_b), y_2)$  and  $t'_1 = \text{raenc}(\langle c, y'_1 \rangle, \text{pub}(sk_a), y'_2)$ ;
- $t_2 = \text{raenc}(\langle y_1, \langle n_b, b \rangle \rangle, \text{pub}(sk_a), r_2)$  and  $t'_2 = \text{raenc}(\langle y'_1, \langle n'_b, a \rangle \rangle, \text{pub}(sk_c), r'_2)$ ;
- $t_3 = \text{raenc}(n_b, \text{pub}(sk_b), y_3)$  and  $t'_3 = \text{raenc}(n'_b, \text{pub}(sk_a), y_3)$ ;
- $t_A = \text{pub}(sk_a)$  and  $t_B = \text{pub}(sk_b)$ .

Actually, we have that  $t_2$  and  $t'_1$  are unifiable with  $\sigma = \{y_1 \rightarrow c, y'_1 \rightarrow \langle n_b, b \rangle, y'_2 \rightarrow r_2\}$ , but we have that:

- $\delta_{\text{NSL}}(t_2) = \text{raenc}(\langle \tau_{na}, \langle \tau_{nb}, \tau_b \rangle \rangle, \text{pub}(\tau_{sk}), \tau_r)$ , whereas
- $\delta_{\text{NSL}}(t'_1) = \text{raenc}(\langle \tau_c, \tau_{na} \rangle, \text{pub}(\tau_{sk}), \tau_r)$ .

Actually,  $\mathcal{K}_{\text{NSL}}$  is type-compliant when considering a typing system such that  $\delta_{\text{NSL}}(y'_1) = \langle \tau_{nb}, \tau_b \rangle$ ,  $\delta_{\text{NSL}}(y_1) = \tau_c$ , and keeping the others elements as defined in the typing system introduced in Example 3.4. Note that, w.r.t. this typing system, the attack trace trace  $\text{tr}$  given in Example 2.6 is well-typed.

Consider now the variant  $P'_{\text{NSL}}$ , as sketched in Example 2.12, where a triple is used instead of two pairs, that is replacing messages  $t_2$  and  $t'_2$  by  $s_2 = \text{raenc}(\langle y_1, n_b, b \rangle^3, \text{pub}(sk_a), r_2)$  and  $s'_2 = \text{raenc}(\langle y'_1, n'_b, a \rangle^3, \text{pub}(sk_c), r'_2)$ . Then the corresponding configuration  $\mathcal{K}'_{\text{NSL}} = (P'_{\text{NSL}}; \phi_0; \emptyset; 0)$  is type-compliant w.r.t. the typing system given in Example 3.4.

### 3.3 Reduction results

Our main result consists in showing that whenever there is an attack, then there is an attack that is well-typed. This holds for reachability properties as well as equivalence properties.

**3.3.1 Reachability.** We first prove that for any execution trace, there is a well-typed execution that follows the same sequence of input and output, on the same channels. Formally, we define  $\overline{\text{tr}}$  obtained from  $\text{tr}$  by replacing any action  $\text{in}(c, R)$  by  $\text{in}(c, \_)$ , any  $\text{out}(c, w)$  by  $\text{out}(c, \_)$ , while phase  $i'$  is left unchanged. Intuitively,  $\overline{\text{tr}}$  only remembers the type of actions, and on which channel.

**THEOREM 3.8.** *Let  $\mathcal{K}_P$  be a  $\Sigma_0^-$ -configuration type-compliant w.r.t.  $(\mathcal{T}_0, \delta_0)$ . If  $\mathcal{K}_P \xrightarrow{\text{tr}} (\mathcal{P}; \phi; \sigma; i)$  w.r.t.  $\Sigma_0^-$  then there exists a well-typed execution  $\mathcal{K}_P \xrightarrow{\text{tr}'} (\mathcal{P}; \phi'; \sigma'; i)$  w.r.t.  $\Sigma_0^+$  such that  $\overline{\text{tr}'} = \overline{\text{tr}}$ .*

*Conversely, if  $\mathcal{K}_P \xrightarrow{\text{tr}'} (\mathcal{P}; \phi'; \sigma'; i)$  is a well-typed execution w.r.t.  $\Sigma_0^+$ , then there exists  $\mathcal{K}_P \xrightarrow{\text{tr}} (\mathcal{P}; \phi; \sigma; i)$  w.r.t.  $\Sigma_0^-$  such that  $\overline{\text{tr}} = \overline{\text{tr}'}$ .*

This shows that for any property that can be expressed as a reachability property, it is sufficient to consider well-typed attacks. For example, secrecy of a data  $s$  can easily be encoded by adding a witness process of the form  $\text{in}(c, s).\text{out}(c_{\text{secret-violated}}, s)$ . Then the secret of  $s$  is preserved if and only if there is no trace that contains  $c_{\text{secret-violated}}$ . Similarly, we can consider any property that expresses that some state should never be reached. The second part of Theorem 3.8 can be established by mapping constants from  $\Sigma_{\text{fresh}}$  on a constant  $a \in \Sigma_0^-$ . Such a mapping transform non-atomic data on atomic ones, and may create equalities. Since our process algebra does not feature disequality tests, the resulting trace, i.e. the one obtained by applying the mapping, is still a valid execution trace. The first and main part of this theorem is proved in Section 4.

**LEMMA 3.9.** *Let  $\mathcal{K}_P$  be a  $\Sigma_0^-$ -configuration type-compliant w.r.t.  $(\mathcal{T}_0, \delta_0)$ . If  $\mathcal{K}_P \xrightarrow{\text{tr}'} (\mathcal{P}; \phi'; \sigma'; i)$  is an execution w.r.t.  $\Sigma_0^+$ , then there exists  $\mathcal{K}_P \xrightarrow{\text{tr}} (\mathcal{P}; \phi; \sigma; i)$  w.r.t.  $\Sigma_0^-$  such that  $\overline{\text{tr}} = \overline{\text{tr}'}$ .*

**PROOF.** The result is a direct consequence of Lemma A.1 considering the substitution  $\theta$  defined as follows:  $\theta(c) = a \in \Sigma_0^-$  for any  $c \in \Sigma_{\text{fresh}}$ .  $\square$

**3.3.2 Equivalence.** Similarly to reachability, we show that whenever two processes are not in trace equivalence, then there is a well-typed witness of non equivalence. Actually, we prove this result for trace inclusion. Formally, assume given two  $\Sigma_0^-$ -configurations  $\mathcal{K}_P$  and  $\mathcal{K}_Q$  with  $\mathcal{K}_Q$  action-deterministic, and such that  $\mathcal{K}_P \not\sqsubseteq_t \mathcal{K}_Q$  w.r.t.  $\Sigma_0^-$ . A *witness of non-inclusion* is a trace  $(\text{tr}, \phi) \in \text{trace}_{\Sigma_0^-}(\mathcal{K}_P)$  such that:

- either there is no  $\psi$  such that  $(\text{tr}, \psi) \in \text{trace}_{\Sigma_0^-}(\mathcal{K}_Q)$ ;
- or such  $\psi$  exists but  $\phi \not\sqsubseteq_s \psi$  w.r.t.  $\Sigma_0^-$ .

Note that when a configuration is action-deterministic, once the sequence  $\text{tr}$  is fixed, there is a unique frame reachable through  $\text{tr}$ , which ensures the unicity of  $\psi$ .

**THEOREM 3.10.** *Let  $\mathcal{K}_P$  be a  $\Sigma_0^-$ -configuration type-compliant w.r.t.  $(\mathcal{T}_0, \delta_0)$  and  $\mathcal{K}_Q$  be an action-deterministic  $\Sigma_0^-$ -configuration. We have that  $\mathcal{K}_P \not\sqsubseteq_t \mathcal{K}_Q$  w.r.t.  $\Sigma_0^-$  if, and only if, there exists a witness  $(\text{tr}, \phi) \in \text{trace}_{\Sigma_0^+}(\mathcal{K}_P)$  of this non-inclusion such that its underlying execution  $\mathcal{K}_P \xrightarrow{\text{tr}} (\mathcal{P}; \phi; \sigma; i)$  w.r.t.  $\Sigma_0^+$  is well-typed.*

The main part of the theorem is proved in Section 5. Here, we simply prove that the existence of a witness w.r.t.  $\Sigma_0^+$  can be turned into a witness w.r.t.  $\Sigma_0^-$ . Actually, similarly to the reachability case, the idea is to replace any symbol from  $\Sigma_{\text{fresh}}$  by a symbol of  $\Sigma_0^-$ . However, creating more equalities is problematic when the witness of non-inclusion is an equality test that holds in  $\mathcal{K}_P$  but not in  $\mathcal{K}_Q$ . Therefore, we use here a bijective renaming. Moreover, replacing non atomic constants from  $\Sigma_{\text{fresh}}^{\text{bitstring}}$  by atomic constants may enable more executions and non trace inclusion may be lost. Therefore, sometimes, we emulate constants from  $\Sigma_{\text{fresh}}^{\text{bitstring}}$  by a message  $t_0$  of sort `bitstring`. Note that such a  $t_0$  exists since our theory contains a non-linear rule  $\text{des}(t_1, \dots, t_n) \rightarrow r_{\text{des}}$  with a key position in  $t_1$ , and thus  $t_1\delta$  where  $\delta$  maps any variable occurring in  $t_1$  to a constant  $a \in \Sigma_0^-$  is a message of sort `bitstring`.

**LEMMA 3.11.** *Let  $\mathcal{K}_P$  be a  $\Sigma_0^-$ -configuration type-compliant w.r.t.  $(\mathcal{T}_0, \delta_0)$  and  $\mathcal{K}_Q$  be an action-deterministic  $\Sigma_0^-$ -configuration. If  $\mathcal{K}_P \not\sqsubseteq_t \mathcal{K}_Q$  w.r.t.  $\Sigma_0^+$  then  $\mathcal{K}_P \not\sqsubseteq_t \mathcal{K}_Q$  w.r.t.  $\Sigma_0^-$ .*

**PROOF.** By hypothesis on our theory, we know the existence of a message  $t_0$  of sort `bitstring`. We consider a minimal (in length) witness of non-inclusion, i.e. a trace  $(\text{tr}_S, \phi_S) \in \text{trace}_{\Sigma_0^+}(\mathcal{K}_P)$  such that:

- (1) either  $(\text{tr}_S, \psi_S) \notin \text{trace}_{\Sigma_0^+}(\mathcal{K}_Q)$  for any  $\psi_S$ ; or
- (2)  $(\text{tr}_S, \psi_S) \in \text{trace}_{\Sigma_0^+}(\mathcal{K}_Q)$  but  $\phi_S \not\sqsubseteq_S \psi_S$ .

We consider two substitutions:

- $\theta$  which is an injective renaming from  $\Sigma_{\text{fresh}}$  to constants in  $\Sigma_0^-$  that have not been used along the execution under study.
- $\theta'$  which is an injective renaming from  $\Sigma_{\text{fresh}}^{\text{atom}}$  to  $\Sigma_0^-$ , and which maps constants from  $\Sigma_{\text{fresh}}^{\text{bitstring}}$  to  $t_0$ . Note that  $\theta'$  preserves atomicity, i.e.  $\theta'(c)$  is an atom if, and only if,  $c \in \Sigma_{\text{fresh}}^{\text{atom}}$ .

*Case 1:*  $\text{tr}_S = \text{tr}_S^- . \alpha_S$  does not pass in  $\mathcal{K}_Q$ . In such a case, we have that:

- $\mathcal{K}_P \xrightarrow{\text{tr}_S^-} (\mathcal{P}_S^-; \phi_S^-; \sigma_P^-; i_P^-) \xrightarrow{\alpha_S} (\mathcal{P}_S; \phi_S; \sigma_P; i_P)$ ;
- $\mathcal{K}_Q \xrightarrow{\text{tr}_S^-} (\mathcal{Q}_S^-; \psi_S^-; \sigma_Q^-; i_Q^-)$ ; and
- $\phi_S^- \sqsubseteq_S \psi_S^-$ .

Relying on Lemma A.1, we have that  $(\text{tr}_S^- \theta, \psi_S^- \theta) \in \text{trace}_{\Sigma_0^-}(\mathcal{K}_Q)$ . More precisely, we have that

$\mathcal{K}_Q \xrightarrow{\text{tr}_S^- \theta} (\mathcal{Q}_S^-; \psi_S^- \theta; \sigma_Q^- \theta; i_Q^-)$ . The same holds regarding the substitution  $\theta'$ . Note that the first-order substitution associated to  $\theta$  (resp.  $\theta'$ ) through  $\psi_S^-$  is  $\theta$  (resp.  $\theta'$ ) itself. Thus, to conclude, it remains to justify that either  $\alpha_S \theta$  can not be triggered from  $(\mathcal{Q}_S^-; \psi_S^- \theta; \sigma_Q^- \theta; i_Q^-)$ , or  $\alpha_S \theta'$  can not be triggered from  $(\mathcal{Q}_S^-; \psi_S^- \theta'; \sigma_Q^- \theta'; i_Q^-)$ . We consider three cases depending on the action  $\alpha_S$ .

- (1)  $\alpha_S = \text{phase } i$ . We have that  $i > i_P^-$  but  $i \leq i_Q^-$ , and thus “phase  $i$ ” can still not be triggered from  $(\mathcal{Q}_S^-; \psi_S^- \theta; \sigma_Q^- \theta; i_Q^-)$ . Thus,  $\text{tr}_S \theta$  is a witness of non-inclusion w.r.t.  $\Sigma_0^-$ .
- (2)  $\alpha_S = \text{out}(c, w)$  with  $\mathcal{P}_S^- = \text{out}(c, u_S) . P \uplus \mathcal{P}$ , then either  $\mathcal{Q}_S^-$  is not ready to perform an output on channel  $c$ , and thus this is the case for  $(\mathcal{Q}_S^-; \psi_S^- \theta; \sigma_Q^- \theta; i_Q^-)$ , and we are done. Otherwise, we have that  $\mathcal{Q}_S^- = \text{out}(c, v_S) . Q \uplus \mathcal{Q}$  but  $v_S \sigma_Q^-$  is not a  $\Sigma_0^+$ -message. If  $v_S \sigma_Q^-$  is not well-shaped,

then we consider  $\theta$ . We have that  $(v_S \sigma_Q^-) \theta = v_S(\sigma_Q^- \theta)$  since  $v_S$  does not contain constants from  $\Sigma_{\text{fresh}}$ , and  $v_S(\sigma_Q^- \theta)$  is not well-shaped, and thus not a  $\Sigma_0^-$ -message. If  $v_S \sigma^- Q$  is not well-sorted, then we consider  $\theta'$ . We have that  $(v_S \sigma_Q^-) \theta' = v_S(\sigma_Q^- \theta')$  since  $v_S$  does not contain constants from  $\Sigma_{\text{fresh}}$ , and  $v_S(\sigma_Q^- \theta)$  is not well-sorted since  $\theta'$  preserves atomicity.

- (3)  $\alpha_S = \text{in}(c, R)$  with  $\mathcal{P}_S^- = \text{in}(c, u_S).P \uplus \mathcal{P}$ , then either  $Q_S^-$  is not ready to perform an input on channel  $c$ , and thus  $(Q_S^-; \psi_S^- \theta; \sigma_Q^-; i_Q^-)$  is not ready to perform an input on channel  $c$ , and we are done. Otherwise, since  $\phi_S^- \sqsubseteq_s \psi_S^-$ , and  $R\phi_S^- \downarrow$  is a message, we deduce that  $R\psi_S^- \downarrow$  is a message, and we have that  $R\psi_S^- \downarrow \theta = (R\psi_S^-) \theta \downarrow = R(\psi_S^- \theta) \downarrow$  is a  $\Sigma_0^-$ -message. Hence, since the input can not be triggered, this is due to a problem of filtering, there does not exist  $\tau_S$  such that  $(v_S \sigma_Q^-) \tau = R\psi_S^- \downarrow$ . By contradiction, assume that there exists  $\tau'$  such that  $(v_S(\sigma_Q^- \theta)) \tau' = R(\psi_S^- \theta) \downarrow$ , then  $[(v_S(\sigma_Q^- \theta)) \tau'] \theta^{-1} = (R(\psi_S^- \theta) \downarrow) \theta^{-1}$ , i.e.  $(v_S \sigma_Q^-) (\tau' \theta^{-1}) = R\psi_S^- \downarrow$ . Contradiction.

*Case 2:* We have that  $(\text{tr}_S, \phi_S) \in \text{trace}_{\Sigma_0^+}(\mathcal{K}_P)$ ,  $(\text{tr}_S, \psi_S) \in \text{trace}_{\Sigma_0^+}(\mathcal{K}_Q)$ , and  $\phi_S \not\sqsubseteq_s \psi_S$ . Thanks to Lemma A.1, we know that  $(\text{tr}_S \theta, \phi_S \theta) \in \text{trace}_{\Sigma_0^+}(\mathcal{K}_P)$  and  $(\text{tr}_S \theta, \psi_S \theta) \in \text{trace}_{\Sigma_0^+}(\mathcal{K}_Q)$ , and similarly considering  $\theta'$ . To conclude, it remains to show that either  $\phi_S \theta \not\sqsubseteq_s \psi_S \theta$ , or  $\phi_S \theta' \not\sqsubseteq_s \psi_S \theta'$ . We distinguish two cases depending on the form of the test. We consider a test of minimal size regarding the number of symbols.

- (1) We have that  $R\phi_S \downarrow$  and  $R'\phi_S \downarrow$  are both messages such that  $R\phi_S \downarrow = R'\phi_S \downarrow$ . By minimality of our witness, we know that  $R\psi_S \downarrow$  and  $R'\psi_S \downarrow$  are messages. However,  $R\psi_S \downarrow \neq R'\psi_S \downarrow$ . In such a case, consider  $\theta$ . We have that  $R\phi_S \downarrow \theta = R(\phi_S \theta) \downarrow$  (similarly for  $R'$ ), and  $R\psi_S \downarrow \theta = R(\psi_S \theta) \downarrow$  (similarly for  $R'$ ). Now, assume that  $R(\psi_S \theta) \downarrow = R'(\psi_S \theta) \downarrow$ , i.e.  $(R\psi_S \downarrow) \theta = (R'\psi_S \downarrow) \theta$ , and thus applying  $\theta^{-1}$ , we deduce that  $R\psi_S \downarrow = R'\psi_S \downarrow$ , leading to a contradiction.
- (2) We have that  $R\phi_S \downarrow$  is a message whereas  $R\psi_S \downarrow$  is not. First, we may note that  $R$  can not be reduced to a variable  $w$ , a name, or a constant. Therefore, we have that  $R = g(R_1, \dots, R_k)$ , and by minimality of our test, we know that  $R_i \phi_S \downarrow$  is a message. We first consider the case where  $g \in \Sigma_c$ . Since  $R\psi_S \downarrow$  is not a message whereas  $R_1 \psi_S \downarrow, \dots, R_k \psi_S \downarrow$  are, it means that either  $R_i \psi_S \downarrow$  is not an atom whereas an atom was expected at the  $i^{\text{th}}$  position or  $R\phi_S$  is not well-shaped. In the first case, we know that  $R_i \phi_S \downarrow$  is an atom. In such a case, we consider  $\theta'$ , and relying on this test, we can see that  $\phi_S \theta' \not\sqsubseteq_s \psi_S \theta'$ . In case  $R\psi_S \downarrow$  is not a message due to a problem of shape, we consider  $\theta$ , and relying on this test, we can see that  $\phi_S \theta \not\sqsubseteq_s \psi_S \theta$ . □

### 3.4 Tightness of our model

In this subsection, we give examples of theories that do not satisfy the hypothesis of the model and for which Theorem 3.10 no longer holds, exhibiting processes that do have well-typed witnesses of attacks. This shows that our hypotheses are rather tight.

In this subsection we assume  $n, m \in \mathcal{N}$  and  $a, b \in \Sigma_0^-$ .

**Well-shapedness.** We first show why we need our assumption on the existence of a shape of each constructor symbol. Consider the processes:

$$\begin{aligned} P &= \text{in}(c, x).\text{out}(c, \text{aenc}(\langle a, n \rangle, x)) \\ Q &= \text{in}(c, x).\text{out}(c, \text{hash}(n)) \end{aligned}$$

$P$  is not a process according to our grammar since it involves a term that is not well-shaped. Indeed  $x$  appears in key position while a term of the form  $\text{pub}(t)$  is expected. The trace  $\text{tr} = \text{in}(c, \text{pub}(a)).\text{out}(c, w)$  is a trace of non-inclusion as  $R = \text{adec}(w, a)$  gives a message in the  $P$  side but not in the  $Q$  side.

If we define a structure preserving typing system where  $\delta(x) = \tau$  with  $\tau$  an initial type, then  $P$  is type-compliant as there is only one encrypted subterm in  $P$ . However, there is no well-typed attack. Indeed, note first that we can not have  $x\sigma = \text{pub}(t)$  for  $\sigma$  well-typed since  $\delta(x) = \delta(x\sigma) = \delta(\text{pub}(t)) = \text{pub}(\delta(t))$  which is not an initial type. The term  $\text{aenc}(\langle a, n \rangle, x\sigma)$  cannot be built by any other recipe as  $n$  is unknown from the attacker, and it cannot be opened as  $x\sigma$  is not a key. Therefore, it is indistinguishable from  $\text{hash}(n)$ .

**Subterm property.** Consider the theory  $\text{des}(f(x)) \rightarrow g(x)$  where  $g$  is a free symbol. This theory does not satisfy the subterm property and actually violates our main theorem. Consider the processes

$$\begin{aligned} P &= \text{in}(c, x).\text{in}(c, y).\text{out}(c, f(\langle n, x \rangle)).\text{out}(c, g(\langle n, y \rangle)) \\ Q &= \text{in}(c, x).\text{in}(c, y).\text{out}(c, f(\langle n, x \rangle)).\text{out}(c, g(\langle m, y \rangle)) \end{aligned}$$

Then  $\text{tr} = \text{in}(c, a).\text{in}(c, a).\text{out}(c, w_1).\text{out}(c, w_2)$  is a trace of non-inclusion of  $P$  in  $Q$ , as exemplified by the recipes  $R_1 = \text{des}(w_1)$ ,  $R_2 = w_2$  and the test  $R_1 = R_2$ .

Then  $P$  is type-compliant even if we chose  $\delta(x) \neq \delta(y)$  but then for any well-typed substitution  $\sigma$ ,  $x\sigma \neq y\sigma$ . Thus the equality  $R_1 = R_2$  does not hold on  $P$  side, and there is no way to compare  $g(\langle n, y\sigma \rangle)$  to anything the attacker may build, as he does not know  $n$ . This kind of theories would require to extend the notion of subterm to allow for some variations, relying for example on some form of locality.

**Each  $t_i$  is linear in  $\text{des}(t_1, \dots, t_n) \rightarrow t_0$ .** Consider the rule  $\text{des}(f(x, x, y)) \rightarrow \text{ok}$ , with non linear term  $f(x, x, y)$ , and the processes:

$$\begin{aligned} P &= \text{in}(c, x).\text{in}(c, y).\text{out}(c, f(x, y, m)) \\ Q &= \text{in}(c, x).\text{in}(c, y).\text{out}(c, f(x, n, m)) \end{aligned}$$

Then  $\text{tr} = \text{in}(c, a).\text{in}(c, a).\text{out}(c, w)$  is a trace of non-inclusion. Indeed, after executing  $\text{tr}$ , the test  $\text{des}(w)$  yields a message on  $P$  side, but not on  $Q$  side.

As there is only one encrypted subterm  $f(x, y, m)$  in  $P$ ,  $P$  is type-compliant for any typing system. So we chose  $\delta(x) = \tau$  and  $\delta(y) = \tau'$  where  $\tau \neq \tau'$ . Then, again, for any well-typed substitution,  $x\sigma \neq y\sigma$  so  $\text{des}(f(x, y, m))\sigma$  is not a message, and it is quite clear we cannot build  $f(x\sigma, y\sigma, m)$  to compare it with  $f(x\sigma, n, m)$  as  $m$  is private.

**At most one non-linear variable in a rule.** Consider the rule  $\text{des}(f(x, y), g(x, y)) \rightarrow \text{ok}$ , with non linear variables  $x$  and  $y$ , and the processes:

$$\begin{aligned} P &= \text{in}(c, x).\text{in}(c, y).\text{out}(c, f(x, n)).\text{out}(c, g(y, n)) \\ Q &= \text{in}(c, x).\text{in}(c, y).\text{out}(c, f(x, n)).\text{out}(c, g(y, m)) \end{aligned}$$

Then  $\text{tr} = \text{in}(c, a).\text{in}(c, a).\text{out}(c, w_1).\text{out}(c, w_2)$  is a trace of non inclusion. Indeed, the recipe  $R = \text{des}(w_1, w_2)$  yields a message on  $P$  side, but not on  $Q$  side.

There is no unifiable encrypted subterm in  $P$ , so  $P$  is type compliant even if  $\delta(x) \neq \delta(y)$ . But then for any well-typed substitution, we have  $x\sigma \neq y\sigma$  and so  $R$  is not a message in the  $P$  side anymore. Moreover, in this example  $n, m$  are secret so they cannot be reused to rebuild the messages by the attacker. Therefore there is no well-typed witness of non trace inclusion.

#### 4 TYPING RESULT FOR REACHABILITY

The goal of this section is to provide the main ingredients of the proof of Theorem 3.8. Some of the lemmas are also useful for the proof of Theorem 3.10 on equivalence.

We first define a notion of simple recipes and we explain how we can restrict ourselves to simple recipes (see Section 4.1). Second, our proof crucially relies on a crafted measure on recipes that we

introduce in Section 4.2. A witness of reachability, minimal w.r.t. this measure, will be shown to satisfy some good properties, used to derive a well-typed trace.

#### 4.1 Some preliminaries

We introduce the notion of *forced normal form*, denoted  $u \downarrow$ . This is the normal form obtained when applying rewrite rules as soon as the destructor and the constructor match, for example decrypting a message even with a wrong key. Formally, we define the forced rewriting system associated to a set  $\mathcal{R}$  of rewriting rules.

*Definition 4.1.* Given a rewriting rule of the form  $\ell_{\text{des}} \rightarrow r_{\text{des}}$  as defined in Section 2.1, its associated forced rewriting rule is  $\ell'_{\text{des}} \rightarrow r_{\text{des}}$  where  $\ell'_{\text{des}}$  is obtained from  $\ell_{\text{des}}$  by keeping only the path to  $r_{\text{des}}$  in  $\ell_{\text{des}}$ . Formally,  $\ell'_{\text{des}}$  is defined as follows:

- (1)  $\ell'_{\text{des}} = \text{des}(x_1, \dots, x_n)$  when  $r_{\text{des}}$  is a ground term;
- (2) otherwise denoted  $p_0$  the unique position of  $\ell_{\text{des}}$  such that  $\ell_{\text{des}}|_{p_0} = r_{\text{des}}$  and  $p_0 = 1.p'_0$ , we have that  $\ell'_{\text{des}}$  is the linear term such that:
  - for any position  $p'$  prefix of  $p_0$ , we have that  $\text{root}(\ell'_{\text{des}}|_{p'}) = \text{root}(\ell_{\text{des}}|_{p'})$ ;
  - $\ell'_{\text{des}}|_{p_0} = r_{\text{des}}$ ;
  - for any other position  $p'$  of  $\ell'_{\text{des}}$ , we have that  $\ell'_{\text{des}}|_{p'}$  is a variable.

We may note that the forced rewriting system associated to a rewriting system as defined in Section 2.1 is well-defined. In particular, given a rewriting rule  $\text{des}(t_1, \dots, t_n) \rightarrow r_{\text{des}}$  such that  $r_{\text{des}}$  is a non ground term, there exists a unique position  $p'_0$  in  $t_1$  such that  $t_1|_{p'_0} = r_{\text{des}}$ . This comes from the fact that  $r_{\text{des}} \in \text{St}(t_1)$ , and the variable occurring in  $r_{\text{des}}$  has a unique occurrence in  $t_1$  which is a linear term.

*Example 4.2.* Going back to our running example, we have that the forced rewriting system  $\mathcal{R}_f^{\text{ex}}$  associated to  $\mathcal{R}^{\text{ex}}$  is:

$$\text{radec}(\text{raenc}(x, y_1, z), y_2) \rightarrow x \quad \text{fst}(\langle x, y \rangle) \rightarrow x \quad \text{snd}(\langle x, y \rangle) \rightarrow y$$

Regarding symmetric encryption and signature as introduced in Example 2.3, we get:

$$\text{sdec}(\text{senc}(x, y_1), y_2) \rightarrow x \quad \text{getmsg}(\text{sign}(x, y)) \rightarrow x \quad \text{check}(x_1, x_2) \rightarrow \text{ok}$$

Then, given a set  $\mathcal{R}_f$  of rewriting rules, a term  $u$  can be rewritten in  $v$  using  $\mathcal{R}_f$  if there is a position  $p$  in  $u$ , and a rewriting rule  $g(t_1, \dots, t_n) \rightarrow t$  in  $\mathcal{R}_f$  such that  $u|_p = g(t_1, \dots, t_n)\theta$  for some substitution  $\theta$ , and  $v = u[t\theta]_p$ . As usual, we denote  $\rightarrow^*$ , the reflexive-transitive closure of  $\rightarrow$ . We may note that such a rewriting system is confluent as it terminates and has no critical pair. As usual, the normal form of a term  $u$  is denoted  $u \downarrow$ .

The forced rewriting system allows more rewriting steps than the original one. We will apply it on recipes to simplify them and avoid detours. The following lemma ensures that the term deduced (in a given frame  $\phi$ ) through the recipe  $R$  would be the same as the one deduced relying on  $R \downarrow$  as soon as we know that  $R\phi \downarrow$  is a message.

**LEMMA 4.3.** *Let  $\phi$  be a  $\Sigma_0$ -frame,  $R$  a  $\Sigma_0$ -recipe such that  $R\phi \downarrow$  is a  $\Sigma_0$ -message, and  $R'$  be such that  $R \rightarrow R'$ . We have that  $R'$  is a  $\Sigma_0$ -recipe, and  $R'\phi \downarrow = R\phi \downarrow$ .*

In our development, we will consider recipes that have a simple form: they are built using constructor symbols on top of recipes that necessarily extract a subterm of the frame (roughly a recipe made of destructors).

*Definition 4.4.* A  $\Sigma_0$ -recipe  $R$  is a *subterm  $\Sigma_0$ -recipe* if for any  $\Sigma_0$ -frame  $\phi$  such that  $R\phi \downarrow$  is a  $\Sigma_0$ -message, we have that  $R\phi \downarrow \in \text{St}(\phi)$ . We say that  $R$  is a *simple  $\Sigma_0$ -recipe* if  $R = C[R_1, \dots, R_k]$  for

some context  $C$  built using symbols from  $\Sigma_c \uplus \Sigma_0$ , and each  $R_i$  is a subterm  $\Sigma_0$ -recipe such that  $\text{root}(R_i) \notin \Sigma_c$ .

Simple recipes can be obtained through normalization w.r.t. our forced rewriting system.

LEMMA 4.5. *Let  $\theta$  be a substitution with  $\text{dom}(\theta) \subseteq \Sigma_{\text{fresh}}$  and whose image contains  $\Sigma_0^-$ -recipes. Let  $R$  be a  $\Sigma_0^+$ -recipe in normal form w.r.t.  $\rightarrow$  such that  $(R\theta)\phi\downarrow$  is a  $\Sigma_0^+$ -message for some  $\Sigma_0^-$ -frame  $\phi$ . We have that  $R'$  is a simple  $\Sigma_0^+$ -recipe for any  $R' \in \text{St}(R)$ .*

## 4.2 Our measure

One key step of the proof is to design a measure that reflects how to transform a trace into a well-typed one. Our transformation will proceed by modifying the recipes used by the attacker to forge messages: instead of sending arbitrarily large messages, he should send only small, well-typed messages. The transformation depends on the trace and the frame  $\phi_S$  under consideration and therefore our measure is parameterized by  $\phi_S$ . Finally, the measure of a recipe will be determined by three elements, in lexicographic order.

- First, the size of the term computed by  $R$ , that is  $R\phi_S\downarrow$ ;
- Second, the recipe  $R$  should be headed by as much constructor terms as possible. In particular, we will prefer the recipe  $\langle \text{fst}(w), \text{snd}(w) \rangle$  over  $w$  itself;
- Finally, the size of  $R$  itself.

The rest of this section is devoted to the definition of our measure and the establishment of a couple of its properties.

Given a term  $t \in \mathcal{T}(\Sigma, \Sigma_0^+ \uplus \mathcal{N})$ , we denote  $\text{Multi}(t)$ , the multiset of elements from  $\Sigma \uplus \Sigma_0^+ \uplus \mathcal{N}$  defined as follows:

- $\text{Multi}(a) = \{a\}$  when  $a \in \Sigma_0^+ \uplus \mathcal{N}$ , and
- $\text{Multi}(f(t_1, \dots, t_n)) = \{f\} \uplus \text{Multi}(t_1) \uplus \dots \uplus \text{Multi}(t_n)$  when  $f \in \Sigma$ .

Given a set  $D$  of data and a term  $t \in \mathcal{T}(\Sigma, D)$ , the size of  $t$ , denote  $|t|$ , is the number of function symbols occurring in it. The hat of  $t$  is the constructor context  $R$  (i.e. a term built on  $\Sigma_c$  with some holes) such that  $t = R[t_1, \dots, t_n]$  with  $\text{root}(t_1), \dots, \text{root}(t_n) \notin \Sigma_c$ . We denote it  $\hat{t}$ .

Given a  $\Sigma_0^-$ -frame  $\phi_S$  together with an ordering  $<$  on  $\Sigma_{\text{fresh}}$  (typically the one corresponding to the order of appearance of these constants in the underlying trace  $\text{tr}_S$  associated to  $\phi_S$ ), the measure  $\mu_{\phi_S}$  associated to a  $\Sigma_0^+$ -recipe  $R$  is defined as follows (using the lexicographic ordering):

- (1)  $\mu_{\phi_S}^1(R) = \text{Multi}(R\phi_S\downarrow)$  where elements of the multisets are ordered as follows ( $c_{\min} \in \Sigma_0^-$ ):

$$c_{\min} < \Sigma_0^- \setminus \{c_{\min}\} \uplus \Sigma_c < \Sigma_{\text{fresh}} < \Sigma_d$$

and for elements in  $\Sigma_{\text{fresh}}$ , we have that  $c < c'$  when  $c < c'$ .

- (2)  $\mu_{\phi_S}^2(R) = |R\phi_S\downarrow| - |\hat{R}|$ .
- (3)  $\mu_{\phi_S}^3(R) = |R|$ .

Note that  $c_{\min} \in \Sigma_0^-$  is the minimal  $\Sigma_0^-$ -recipe according to this measure.

We start by establishing some properties regarding this measure. First, we may note that the measure  $\mu_{\phi_S}^2$  remains positive since, intuitively, the hat of a term can never disappear by rewriting. (this result is formally stated and proved in Appendix B.2 - see Lemma B.1).

Then we can show that if a recipe  $R_2$  is greater than a recipe  $R_1$  and does not yield a message, then  $R_0[R_2]$  is greater than  $R_0[R_1]$ . This technical lemma will be used very often in our proofs, when reasoning about some reduction that failed inside a bigger term.

LEMMA 4.6. *Let  $<$  be an ordering on  $\Sigma_{\text{fresh}}$ ,  $\phi_S$  be a  $\Sigma_0^+$ -frame,  $R_1, R_2$  be two  $\Sigma_0^+$ -recipes such that  $R_2\phi_S\downarrow$  is not a  $\Sigma_0^+$ -message, and  $\mu_{\phi_S}^1(R_1) < \mu_{\phi_S}^1(R_2)$ . Let  $R_0$  be a  $\Sigma_0^+$ -recipe, and  $p$  a position in  $R_0$ . We have that:*

$$\mu_{\phi_S}^1(R_0[R_1]_p) < \mu_{\phi_S}^1(R_0[R_2]_p).$$

The proof of Lemma 4.6 is given in Appendix B.2. It relies on the fact that  $R_0[R_1]$  may only reduce more than  $R_0[R_2]$ .

The measure decreases when applying forced reduction.

LEMMA 4.7. *Let  $<$  be an ordering on  $\Sigma_{\text{fresh}}$ ,  $\phi_S$  be a  $\Sigma_0^+$ -frame, and  $R, R'$  be two  $\Sigma_0^+$ -recipes such that  $R \twoheadrightarrow R'$ . We have that  $\mu_{\phi_S}(R') < \mu_{\phi_S}(R)$ .*

The proof of Lemma 4.7 is given in Appendix B.2. Intuitively, if  $R \twoheadrightarrow R'$  then we consider the instantiated rule  $\ell_{\text{des}}\theta \twoheadrightarrow r_{\text{des}}\theta$  that has been applied. Either  $\ell_{\text{des}}\theta\phi_S\downarrow$  is a message. Then both  $R$  and  $R'$  yield the same term, that is  $R\phi_S\downarrow = R'\phi_S\downarrow$ . The two first items of the measure are unchanged and we conclude thanks to the third item since  $R'$  is smaller than  $R$ . In case  $\ell_{\text{des}}\theta\phi_S\downarrow$  is not a message, we conclude by Lemma 4.6.

### 4.3 Completeness

We are now ready to prove the core part of Theorem 3.8.

THEOREM 3.8. *Let  $\mathcal{K}_P$  be a  $\Sigma_0^-$ -configuration type-compliant w.r.t.  $(\mathcal{T}_0, \delta_0)$ . If  $\mathcal{K}_P \xrightarrow{\text{tr}} (\mathcal{P}; \phi; \sigma; i)$  w.r.t.  $\Sigma_0^-$  then there exists a well-typed execution  $\mathcal{K}_P \xrightarrow{\text{tr}'} (\mathcal{P}'; \phi'; \sigma'; i)$  w.r.t.  $\Sigma_0^+$  such that  $\overline{\text{tr}'} = \overline{\text{tr}}$ .*

*Conversely, if  $\mathcal{K}_P \xrightarrow{\text{tr}'} (\mathcal{P}'; \phi'; \sigma'; i)$  is a well-typed execution w.r.t.  $\Sigma_0^+$ , then there exists  $\mathcal{K}_P \xrightarrow{\text{tr}} (\mathcal{P}; \phi; \sigma; i)$  w.r.t.  $\Sigma_0^-$  such that  $\overline{\text{tr}} = \overline{\text{tr}'}$ .*

Given a trace  $\mathcal{K}_P \xrightarrow{\text{tr}} (\mathcal{P}; \phi; \sigma; i)$ , we need to build a well-typed trace  $\mathcal{K}_P \xrightarrow{\text{tr}_S} (\mathcal{P}; \phi_S; \sigma_S; i)$  such that  $\overline{\text{tr}_S} = \overline{\text{tr}}$ . This is done inductively in the number of execution steps, by modifying the recipes used by the adversary: given a recipe  $R$ , some parts of  $R$  will be replaced by fresh constants from  $\Sigma_{\text{fresh}}$ . Roughly, we will show that  $\text{tr}$  is actually an instance of  $\text{tr}_S$  in which the fresh constants of  $\text{tr}_S$  are replaced by recipes over the current frame  $\phi_S$ .

We first note that once the recipes are fixed (by  $\theta$  in the following lemma), the underlying terms - computed by the recipes - are entirely determined.

LEMMA 4.8. *Let  $\phi_S$  be a  $\Sigma_0^+$ -frame together with  $<$  a total ordering on  $\text{dom}(\phi_S)$ . Let  $\theta$  be a substitution such that  $\text{dom}(\theta) \subseteq \Sigma_{\text{fresh}}$ , and for any  $c \in \Sigma_{\text{fresh}}$  occurring in  $\phi_S$  we have that  $c \in \text{dom}(\theta)$  and  $c\theta \in \mathcal{T}(\Sigma, \Sigma_0^- \uplus \text{dom}(\phi_S))$ . Moreover, we assume that in case  $c \in \Sigma_{\text{fresh}}$  occurs in  $w\phi_S$ , then  $w' < w$  for any  $w' \in \text{vars}(c\theta)$ . We consider the substitution  $\lambda$  whose domain is  $\text{dom}(\theta)$ , and such that:*

$$c\lambda = (c\theta)(\phi_S\lambda)\downarrow \text{ for any } c \in \text{dom}(\lambda).$$

*The substitution  $\lambda$  is well-defined. Moreover, if  $(c\theta)\phi_S\downarrow$  is a  $\Sigma_0^+$ -message for each  $c \in \text{dom}(\theta)$ , and  $(c\theta)\phi_S\downarrow$  is an atomic  $\Sigma_0^+$ -message when  $c \in \Sigma_{\text{fresh}}^{\text{atom}}$ , then  $c\lambda$  is a  $\Sigma_0^-$ -message for each  $c \in \text{dom}(\lambda)$ , and  $c\lambda$  is an atomic  $\Sigma_0^-$ -message when  $c \in \Sigma_{\text{fresh}}^{\text{atom}}$ .*

*We call  $\lambda$  the first-order substitution associated to  $\theta$  through  $\phi_S$ .*

The fact that  $\lambda$  is well-defined comes from the recursive application of the recipes defined by  $\theta$ , thanks to the order on the variables. This lemma is formally proved in Appendix B.3.

The relation  $c\lambda = (c\theta)(\phi_S\lambda)\downarrow$  established by Lemma 4.8 can be generalized to arbitrary recipes  $R$ .

LEMMA 4.9. Let  $\phi_S$  be a  $\Sigma_0^+$ -frame together with  $<$  a total ordering on  $\text{dom}(\phi_S)$ . Let  $\theta$  be a substitution such that  $\text{dom}(\theta) \subseteq \Sigma_{\text{fresh}}$ , and for any  $c \in \Sigma_{\text{fresh}}$  occurring in  $\phi_S$  we have that  $c \in \text{dom}(\theta)$  and  $c\theta \in \mathcal{T}(\Sigma, \Sigma_0^- \uplus \text{dom}(\phi_S))$ . Moreover, we assume that in case  $c \in \Sigma_{\text{fresh}}$  occurs in  $w\phi_S$ , then  $w' < w$  for any  $w' \in \text{vars}(c\theta)$ . Let  $\lambda$  be the first-order substitution associated to  $\theta$  through  $\phi_S$ .

Assume that for any  $c \in \text{dom}(\lambda)$ , we have that  $c\lambda$  is a  $\Sigma_0^-$ -message. Moreover,  $c\lambda$  is an atomic  $\Sigma_0^-$ -message when  $c \in \Sigma_{\text{fresh}}^{\text{atom}}$ . Let  $R \in \mathcal{T}(\Sigma, \Sigma_0^- \uplus \text{dom}(\theta) \uplus \text{dom}(\phi_S))$  such that  $R\phi_S \downarrow$  is a  $\Sigma_0^+$ -message. We have that  $(R\theta)(\phi_S\lambda) \downarrow = (R\phi_S \downarrow)\lambda$ .

The proof follows from an induction on  $R$ . The base case is ensured by Lemma 4.8. A formal proof is given in Appendix B.3.

We also note that execution traces do not introduce new encrypted subterms: they are all instances of the initial encrypted subterms.

LEMMA 4.10. Let  $\mathcal{K}_0 = (\mathcal{P}_0; \phi_0; \emptyset; 0)$  be an initial  $\Sigma_0$ -configuration and  $\mathcal{K} = (\mathcal{P}; \phi; \sigma; i)$  be a  $\Sigma_0$ -configuration such that  $\mathcal{K}_0 \xrightarrow{\text{tr}} \mathcal{K}$  for some  $\text{tr}$  w.r.t.  $\Sigma_0$ .

(1) We have that  $\text{Est}(\mathcal{K}\sigma) \subseteq \text{Est}(\mathcal{K}_0\sigma)$ .

(2) Moreover, in case  $\sigma$  is an mgu between pairs of terms occurring in  $\text{Est}(\mathcal{K}_0)$ , then we have that  $\text{Est}(\mathcal{K}\sigma) \subseteq \text{Est}(\mathcal{K}_0)\sigma$ .

The first property follows from the definition: the processes of  $\mathcal{K}$  are included in those of  $\mathcal{K}_0$  and the output terms stored in the frame  $\phi$  of  $\mathcal{K}$  appear initially in the processes of  $\mathcal{K}_0$ . The second property comes from the fact that unification does not create new encrypted subterm. A formal proof is given in Appendix B.3.

Given  $\mathcal{K}_0 = (\mathcal{P}_0; \phi_0; \emptyset; \emptyset)$  be an initial  $\Sigma_0^-$ -configuration and  $(\text{tr}_S, \phi_S) \in \text{trace}_{\Sigma_0^+}(\mathcal{K}_0)$ , we consider the order  $<$  induced by  $\text{tr}_S$ . It is defined on the subset of  $\mathcal{W} \uplus \Sigma_{\text{fresh}}$  that correspond to elements that occur in  $\text{tr}_S$  and  $\phi_S$  as follows:

$$u < v \Leftrightarrow \begin{cases} \text{either } u \in \text{dom}(\phi_0) \text{ and } v \notin \text{dom}(\phi_0) \\ \text{or } u \text{ occurs in } \text{tr}_S \text{ before the first occurrence of } v \text{ in } \text{tr}_S. \end{cases}$$

We are now ready to state how we transform a trace  $(\text{tr}, \phi)$  into a well-typed trace  $(\text{tr}_S, \phi_S)$ .

PROPOSITION 4.11. Let  $\mathcal{K}_P = (\mathcal{P}_0; \phi_0; \emptyset; i_0)$  be an initial  $\Sigma_0^-$ -configuration, and  $(\text{tr}, \phi) \in \text{trace}_{\Sigma_0^-}(\mathcal{K}_P)$  with underlying substitution  $\sigma$ . Then, there exists  $(\text{tr}_S, \phi_S) \in \text{trace}_{\Sigma_0^+}(\mathcal{K}_P)$  with underlying substitution  $\sigma_S$  with  $\text{dom}(\sigma_S) = \text{dom}(\sigma)$  such that  $\sigma_S = \text{mgu}(\Gamma)\rho$ , as well as two substitutions  $\lambda$  and  $\theta$  such that:

- $\Gamma = \{(u, v) \mid u, v \in \text{Est}(\mathcal{K}_P) \text{ such that } u\sigma = v\sigma\}$ .
- $\rho$  is a bijective renaming from variables in  $\text{dom}(\sigma) \setminus \text{dom}(\text{mgu}(\Gamma))$  to constants in  $\Sigma_{\text{fresh}}$  such that  $x\rho \in \Sigma_{\text{fresh}}^{\text{atom}}$  if, and only if,  $x\sigma$  is an atomic  $\Sigma_0^-$ -message.
- $\text{dom}(\theta) \subseteq \Sigma_{\text{fresh}}$ , for any  $c \in \Sigma_{\text{fresh}}$  occurring in  $\text{tr}_S$ , we have that  $c \in \text{dom}(\theta)$ ,  $c\theta \in \mathcal{T}(\Sigma, \Sigma_0^- \uplus \text{dom}(\phi_S))$ , and  $w' < c$  for any  $w' \in \text{vars}(c\theta)$  (where  $<$  is the ordering induced by  $\text{tr}_S$ ).
- for any  $c \in \text{dom}(\theta)$ ,  $(c\theta)\phi_S \downarrow$  is a  $\Sigma_0^+$ -message and it is an atom when  $c \in \Sigma_{\text{fresh}}^{\text{atom}}$ .
- $\lambda$  is the first-order substitution associated to  $\theta$  through  $\phi_S$ .
- $\phi = \phi_S\lambda$ ,  $\sigma = \sigma_S\lambda$ , and  $(\text{tr}_S\theta)\phi \downarrow = \text{tr}\phi \downarrow$ .

The fact that  $(\text{tr}_S, \phi_S)$  is well typed is ensured by  $\sigma_S = \text{mgu}(\Gamma)\rho$ . Indeed, since  $\Gamma$  is a set of unifiable encrypted subterms of the protocol, we know that  $\text{mgu}(\Gamma)$  is well-typed (by assumption on the protocol). Hence  $\sigma_S$  is well-typed. Therefore Theorem 3.8 is a direct consequence of Proposition 4.11 (the details are provided in Appendix B.3).

The proof of Proposition 4.11 is the key step for proving the existence of a well-typed trace. We provide here a detailed sketch of proof while the full proof can be found in Appendix B.3. We

omit here the subtleties between  $\Sigma_0^+$  and  $\Sigma_0^-$ . Proposition 4.11 is proved by induction. Consider an execution trace

$$\mathcal{K}_P \xrightarrow{\text{tr}^-} (\mathcal{P}; \phi^-; \sigma^-; i^-) \xrightarrow{\alpha} (\mathcal{P}; \phi; \sigma; i)$$

By induction, there exist  $\phi_S^-$ , and  $\sigma_S^-$  such that

$$\mathcal{K}_P \xrightarrow{\text{tr}_S^-} (\mathcal{P}; \phi_S^-; \sigma_S^-; i^-)$$

with corresponding  $\lambda^-$ , and  $\theta^-$  as specified in the proposition. We consider the transition  $\alpha$ .

- The case of a phase is immediate:  $(\text{tr}_S^-, \phi_S^-)$  can be easily extended.
- The case of an output, i.e.  $\alpha = \text{out}(c, w)$  with a corresponding process  $\text{out}(c, u).P$  ready to emit, is relatively simple. We simply need to guarantee that  $u\sigma_S^-$  is a message, which follows from the fact that  $u\sigma^-$  is a message and  $\sigma^- = \sigma_S^- \lambda^-$ .
- The difficult case is the input case:  $\alpha = \text{in}(c, R)$ , with a corresponding process  $\text{in}(c, u).P$  ready to receive. We have that  $R\phi^- \downarrow = u\sigma$ . We are looking for  $R_S$  such that

$$(R_S \theta^-) \phi^- \downarrow = u\sigma$$

Such a  $R_S$  exists since we could take  $R$ . We consider the minimal  $R_S$ , w.r.t. our measure, that satisfies this property.

**Step 1** We first prove that  $R_S \phi_S \downarrow$  is a message: if this is not the case, we show that this contradicts the minimality of  $R_S$  w.r.t. the measure.

**Step 2** We then show that  $R_S = C[R_1, \dots, R_n]$  where  $C$  is a context of constructors and  $R_i \phi_S \downarrow$  are encrypted subterms. Indeed, if  $R_i \phi_S \downarrow$  was headed by a transparent function, we could push it into the context  $C$  and obtain a smaller  $R_S$  (w.r.t. item 2 of the measure). In other words, we show that  $R_S$  is a simple recipe.

**Step 3**  $R_S$  still does not satisfy the requirements of Proposition 4.11. It could still be a “big” recipe, that does not satisfy the relation

$$R_S \phi_S \downarrow = u\sigma_S$$

needed to pass the input action. Intuitively, we build  $\overline{R}_S$  from  $R_S$  by “cutting” the parts that go beyond  $u\sigma_S$ . By Lemma 4.9, we have that  $(R_S \phi_S \downarrow) \lambda = u\sigma_S \lambda$ . Let’s consider a leaf  $c$  of  $R_S$  that goes beyond  $u\sigma_S$ . If  $R_S \phi_S \downarrow \neq u\sigma_S$ , we can show that

- either  $c$  appears in the context  $C$ , then we simply cut this part from the context  $C$ .
- or  $c$  belongs to one of the  $R_i$ . Then,  $R_i \phi_S \downarrow$  is an encrypted subterm of  $\phi_S$  which is equal to an encrypted subterm of  $u\sigma_S$ . By Lemma 4.10, they are subterms of  $\Gamma$  and therefore, thanks to the application of the mgu, they are equal (thus there is no need to “cut”).

These three steps are highlighted in the detailed proof.

## 5 EQUIVALENCE

We now show how to extract a well-typed witness of non trace inclusion  $\mathcal{K}_P \not\sqsubseteq_t \mathcal{K}_Q$  from an arbitrary witness. Compared with the proof for reachability, the proof starts similarly: from a trace  $(\text{tr}, \phi) \in \mathcal{K}_P$ , we build a well-typed trace  $(\text{tr}_S, \phi_S) \in \mathcal{K}_P$ . However, an additional work is needed to show that the corresponding trace  $(\text{tr}_S, \psi_S)$  in  $\mathcal{K}_Q$  is indeed a witness of non trace inclusion, that is,  $\phi_S \not\sqsubseteq_s \psi_S$ . This requires to further show that any test  $T$  witness of non static inclusion for  $\phi \not\sqsubseteq_s \psi$  can be transformed into a witness of non static inclusion for  $\phi_S \not\sqsubseteq_s \psi_S$ .

## 5.1 Some preliminaries

We introduce a slightly different notion of static inclusion where the attacker is also given the ability to check whether a message is atomic, i.e. a name in  $\mathcal{N}$ , a constant in  $\Sigma_0^- \uplus \Sigma_{\text{fresh}}^{\text{atom}}$ , or a constant in  $\Sigma$  of sort `atom`. This new equivalence actually coincides with the original one.

*Definition 5.1.* Let  $\phi_1$ , and  $\phi_2$  be two  $\Sigma_0$ -frames. We write  $\phi_1 \sqsubseteq_s^{\text{atom}} \phi_2$  w.r.t.  $\Sigma_0$  when  $\text{dom}(\phi_1) = \text{dom}(\phi_2)$ , and:

- for any  $\Sigma_0$ -recipe  $R$ , we have that  $R\phi_1\downarrow$  is a  $\Sigma_0$ -message implies that  $R\phi_2\downarrow$  is a  $\Sigma_0$ -message;
- for any  $\Sigma_0$ -recipe  $R$ , we have that  $R\phi_1\downarrow$  is an atomic  $\Sigma_0$ -message, implies that  $R\phi_2\downarrow$  is an atomic  $\Sigma_0$ -message; and
- for any  $\Sigma_0$ -recipes  $R, R'$  such that  $R\phi_1\downarrow, R'\phi_1\downarrow$  are  $\Sigma_0$ -messages, we have that:  $R\phi_1\downarrow = R'\phi_1\downarrow$  implies  $R\phi_2\downarrow = R'\phi_2\downarrow$ .

*Example 5.2.* To illustrate the definition above and its difference with the original definition of static equivalence, we consider  $\Sigma^{\text{sign}}$  as described in Example 2.3. Let  $\phi = \{w \triangleright n\}$  and  $\psi = \{w \triangleright \text{hash}(n)\}$  where  $n \in \mathcal{N}$ .

We have that  $\phi \not\sqsubseteq_s^{\text{atom}} \psi$ . Indeed, we have that  $w\phi\downarrow$  is an atomic message, whereas  $w\psi\downarrow$  is not. Such a test is not possible when considering  $\sqsubseteq_s$ . However, relying on a non-linear rule of our rewriting system, here  $\text{check}(\text{sign}(x, y), \text{vk}(y)) \rightarrow \text{ok}$ , we can consider another test that will witness this non-inclusion, namely  $\text{check}(\text{sign}(w, w), \text{vk}(w)) = \text{ok}$ . Indeed such a test holds in  $\phi$  but not in  $\psi$ .

More generally, we can show that  $\sqsubseteq_s^{\text{atom}}$  coincides with  $\sqsubseteq_s$ .

**LEMMA 5.3.** *Let  $\phi_1$  and  $\phi_2$  be two  $\Sigma_0$ -frames. We have that  $\phi_1 \sqsubseteq_s \phi_2$  if, and only if,  $\phi_1 \sqsubseteq_s^{\text{atom}} \phi_2$ .*

**PROOF.** The proof of the lemma relies on the fact that the attacker may always emulate the atomicity test using one of the non-linear rules, as illustrated in Example 5.2. In case  $\phi_1 \sqsubseteq_s^{\text{atom}} \phi_2$ , it is easy to see that  $\phi_1 \sqsubseteq_s \phi_2$ . Therefore, we consider the other implication. Let  $\phi_1$  and  $\phi_2$  be two  $\Sigma_0$ -frames such that  $\phi_1 \sqsubseteq_s \phi_2$ , we have to establish that  $\phi_1 \sqsubseteq_s^{\text{atom}} \phi_2$ . Let  $R$  be a  $\Sigma_0$ -recipe such that  $R\phi_1\downarrow$  is an atomic  $\Sigma_0$ -message. We have to show that  $R\phi_2\downarrow$  is an atomic  $\Sigma_0$ -message. By hypothesis, we know that there exists  $\ell_{\text{des}} \rightarrow r_{\text{des}} \in \mathcal{R}$  with  $\ell_{\text{des}}$  non-linear, i.e. several occurrences of a variable  $x$  with at least one occurring at a key position. Let  $\sigma$  be the substitution with  $\text{dom}(\sigma) = \text{vars}(\ell_{\text{des}})$ , and  $\text{img}(\sigma) = \{R\}$ , and  $R' = \ell_{\text{des}}\sigma$ . We have that  $R'$  is a  $\Sigma_0$ -recipe such that  $R'\phi_1\downarrow$  is a  $\Sigma_0$ -message. Indeed, the rewriting rule applies since the same atomic message occurs at each key position.

Relying on our hypothesis  $\phi_1 \sqsubseteq_s \phi_2$ , we know that both  $R\phi_2\downarrow$  and  $R'\phi_2\downarrow$  are  $\Sigma_0$ -message. In particular, we have that  $(\ell_{\text{des}}\sigma)\phi_2\downarrow$  reduces using  $\ell_{\text{des}} \rightarrow r_{\text{des}}$  meaning that atomic messages occur at each key position, and thus  $R\phi_2\downarrow$  is an atomic  $\Sigma_0$ -message.  $\square$

Note that this lemma crucially relies on our assumption that our set of rewriting rules contains at least one non-linear rule.

**Our measure.** We extend our measure to tests, as considered for checking static inclusion. Formally, a test  $T$  is either a single recipe  $R$ , or a pair  $R, R'$  of two recipes. In such a case, i.e. when  $T$  is a pair  $R, R'$ , we define:

$$\mu_{\phi_S}(T) = (\mu_{\phi_S}^1(R) \uplus \mu_{\phi_S}^1(R'), \mu_{\phi_S}^2(R) \uplus \mu_{\phi_S}^2(R'), \mu^3(R) \uplus \mu^3(R')).$$

## 5.2 Completeness

The equivalence counterpart of Proposition 4.11 is the following proposition, that states that we can transform a witness of non trace inclusion into a well-typed one.

PROPOSITION 5.4. Let  $\mathcal{K}_P$  and  $\mathcal{K}_Q$  be two initial  $\Sigma_0^-$ -configurations such that  $\mathcal{K}_Q$  is action-deterministic, and  $\mathcal{K}_P \not\sqsubseteq_t \mathcal{K}_Q$  w.r.t.  $\Sigma_0^-$ . Let  $(\text{tr}, \phi) \in \text{trace}_{\Sigma_0^-}(\mathcal{K}_P)$  with underlying substitution  $\sigma$  be a witness of non-inclusion of minimal length. Then, there exists  $(\text{tr}_S, \phi_S) \in \text{trace}_{\Sigma_0^+}(\mathcal{K}_P)$  a witness of this non-inclusion with underlying substitution  $\sigma_S$  such that  $\sigma_S = \text{mgu}(\Gamma)\rho$ , as well as two substitutions  $\lambda_P$  and  $\theta$  such that:

- $\Gamma = \{(u, v) \mid u, v \in \text{ESt}(\mathcal{K}_P) \text{ such that } u\sigma = v\sigma\}$ .
- $\rho$  is a bijective renaming from variables in  $\text{dom}(\sigma) \setminus \text{dom}(\text{mgu}(\Gamma))$  to constants in  $\Sigma_{\text{fresh}}$  such that  $x\rho \in \Sigma_{\text{fresh}}^{\text{atom}}$  if, and only if,  $x\sigma$  is an atomic  $\Sigma_0^-$ -message.
- $\text{dom}(\theta) \subseteq \Sigma_{\text{fresh}}$ , for any  $c \in \Sigma_{\text{fresh}}$  occurring in  $\text{tr}_S$ , we have that  $c \in \text{dom}(\theta)$ ,  $c\theta \in \mathcal{T}(\Sigma, \Sigma_0^- \uplus \text{dom}(\phi_S))$ , and  $w' < c$  for any  $w' \in \text{vars}(c\theta)$  (where  $<$  is the ordering induced by  $\text{tr}_S$ ).
- for any  $c \in \text{dom}(\theta)$ ,  $(c\theta)\phi_S\downarrow$  is a  $\Sigma_0^+$ -message and it is an atom when  $c \in \Sigma_{\text{fresh}}^{\text{atom}}$ .
- $\lambda_P$  is the first-order substitution associated to  $\theta$  through  $\phi_S$ .
- $\phi = \phi_S\lambda_P$ ,  $\sigma = \sigma_S\lambda_P$ , and  $(\text{tr}_S\theta)\phi\downarrow = \text{tr}\phi\downarrow$ .

Exactly like for the reachability case, the fact that  $(\text{tr}_S, \phi_S)$  is well typed is ensured by  $\sigma_S = \text{mgu}(\Gamma)\rho$ . Indeed, since  $\Gamma$  is a set of unifiable encrypted subterms of  $\mathcal{K}_P$ , we know that  $\text{mgu}(\Gamma)$  is well-typed (by assumption on the protocol). Hence  $\sigma_S$  is well-typed. Therefore Theorem 3.10 is a direct consequence of Proposition 5.4 (the details are provided in Appendix C).

We provide here a detailed sketch of proof of Proposition 5.4, leaving the full proof in Appendix C. Consider  $(\text{tr}, \phi) \in \text{trace}_{\Sigma_0^-}(\mathcal{K}_P)$  with underlying substitution  $\sigma$  be a witness of non-inclusion of minimal length. We explain how to build a well-typed witness of non inclusion. Thanks to Proposition 4.11, there exists a well-typed trace  $(\text{tr}_S, \phi_S) \in \text{trace}_{\Sigma_0^+}(\mathcal{K}_P)$  with underlying substitution  $\sigma_S$  such that  $\sigma_S = \text{mgu}(\Gamma)\rho$ , and  $\lambda_P$  and  $\theta$  satisfying the conditions of Proposition 4.11. We would like to show that  $(\text{tr}_S, \phi_S)$  is a witness of non-inclusion. There must exist a trace  $(\text{tr}_S, \psi_S) \in \text{trace}_{\Sigma_0^+}(\mathcal{K}_Q)$  otherwise we can already conclude that  $(\text{tr}_S, \phi_S)$  is a witness of non trace inclusion. For the same reason, we must have  $\phi_S \sqsubseteq_s \psi_S$ . Then the first step of the proof consists in showing that we can instantiate  $(\text{tr}_S, \psi_S)$  by  $\theta$  and  $\lambda_Q$  such that  $\psi = \psi_S\lambda_Q$ ,  $\text{tr}\psi\downarrow = (\text{tr}_S\theta)\psi\downarrow$ , and  $(\text{tr}, \psi) \in \text{trace}_{\Sigma_0^-}(\mathcal{K}_Q)$ . We also show that  $\psi$  satisfies the assumptions of Propositions 4.8 and 4.9.

In a second step of the proof, we show that  $\phi_S \sqsubseteq_s \psi_S$  implies  $\phi \sqsubseteq_s \psi$ , hence a contradiction. More specifically, we show by induction on  $\mu_{\phi_S}(T)$ , that:

$$\text{for any test } T, \text{ if } T\theta \text{ holds for } \phi \text{ then it holds for } \psi. \quad (*)$$

This allows us to conclude that any test  $T$  that holds in  $\phi$  also holds in  $\psi$  since we may simply consider tests without constants in  $\text{dom}(\theta)$ . Hence  $\phi \sqsubseteq_s \psi$ .

We consider all the tests defined by the static inclusion  $\sqsubseteq_s^{\text{atom}}$ . In particular, the attacker can test directly whether a message is an atom or not, which avoids to consider a “big” recipe of the form  $\text{check}(\text{sign}(R, R), \text{vk}(R)) = \text{ok}$  instead of simply  $R$ . We show (\*) by induction on our measure. Therefore let’s assume that (\*) holds for any test  $T'$  such that  $\mu_{\phi_S}(T') < \mu_{\phi_S}(T)$ . We consider the three possible cases for  $T$ .

- Either  $T$  checks whether the term induced by  $R$  is a message. We need to show that  $(R\theta)\phi\downarrow$  is a message implies  $(R\theta)\psi\downarrow$  is a message. If  $R\phi_S\downarrow$  is a message then so is  $R\psi_S\downarrow$  by static inclusion and we can rather easily conclude that  $(R\theta)\psi\downarrow$  is a message. If  $R\phi_S\downarrow$  is not a message, similarly to the reachability case, we can build smaller tests, apply the induction hypothesis and reconstruct  $R$ . An additional difficulty comes from the fact that we now also need to transfer the properties on  $\psi$ .
- Or  $T$  checks whether the term induced by  $R$  is atomic. We need to show that  $(R\theta)\phi\downarrow$  is atomic implies  $(R\theta)\psi\downarrow$  is atomic. Thanks to the previous case, we already know that  $(R\theta)\psi\downarrow$  is a message. Actually,  $R\phi_S\downarrow$  must be atomic because  $(R\theta)\phi\downarrow = R\phi_S\downarrow\lambda_P$  is atomic and due to

the constraints on  $\lambda_P$ . We deduce that  $R\psi_S\downarrow$  is atomic by static inclusion, and thus  $(R\theta)\psi_S\downarrow = R\psi_S\downarrow\lambda_Q$  is atomic since  $\lambda_Q$  preserves atomicity.

- Or  $T$  is an equality test  $\bar{R} = R'$ . If  $R$  and  $R'$  are headed by the same constructor symbol, we may simply open each recipe and apply the induction hypothesis. Therefore, we may assume that  $R = C[R_1, \dots, R_n]$  and  $R'$  is headed by a destructor. As for the reachability case, we can show that the  $R_i$  as well as  $R'$  are subterm recipes yielding an encrypted subterm. We have that  $R\phi_S\downarrow$  and  $R'\phi_S\downarrow$  are messages. Either  $R\phi_S\downarrow = R'\phi_S\downarrow$ . Then this holds for  $\psi_S$  as well and therefore for  $\psi$ . Or  $R\phi_S\downarrow \neq R'\phi_S\downarrow$  and yet  $(R\phi_S)\downarrow\lambda_P = (R'\phi_S)\downarrow\lambda_P$ . Let's consider a leaf position  $p$  on which the two terms differ, i.e.  $p$  exits in both  $R\phi_S\downarrow$  and  $R'\phi_S\downarrow$ , but  $R\phi_S\downarrow|_p \neq R'\phi_S\downarrow|_p$ . We assume that  $p$  is a leaf of  $R'\phi_S\downarrow$ , and since  $\lambda_P$  makes these two terms equal, we know that  $R'\phi_S\downarrow = c \in \Sigma_{\text{fresh}}$  (the case where  $p$  is a leaf of  $R\phi_S$  is actually simpler).
  - either  $p$  belongs to one of the  $R_i\phi_S\downarrow$ . Then, as for the reachability case,  $R_i\phi_S\downarrow$  is an encrypted subterm of  $\phi_S$  which is equal to an encrypted subterm of  $R'\phi_S\downarrow$ , and thus an encrypted subterm of  $\phi_S$  since  $R'$  is a subterm recipe. By Lemma 4.10, they are subterms of  $\Gamma$  and therefore, thanks to the application of the mgu, they are equal.
  - or  $p$  belongs to the context  $C$ , then we build  $\bar{C}$  from  $C$  by replacing  $C|_p$  by  $c$  for all such  $c$ . Consider the corresponding recipe  $\bar{R} = \bar{C}[R_1, \dots, R_n]$ . We show that the equality  $\bar{R} = R'$  holds in  $\phi_S$  since we have removed all the differences. Therefore we have that  $\bar{R} = R'$  holds in  $\psi_S$ . Moreover, the equality  $\bar{R} = R$  holds relying on our induction hypothesis.

## 6 EXAMPLES

We review several protocols of the literature and identify whether our main results can be applied, that is, we identify when the protocols satisfy the type-compliance condition. We first discuss which scenario is considered.

### 6.1 Complete scenario

We explain which scenario and which security property we consider, illustrated on the NSL protocol. As presented in Example 2.4 and Example 2.12, we may need to consider a rich scenario when searching for attacks. In the case of a 2-agent protocol, like the Needham-Schroeder-Lowe protocol, we wish to instantiate the roles  $P_A$  and  $P_B$  with different combinations of honest and dishonest agents. We consider  $a$  and  $b$  to be two honest agents, whereas  $c$  is dishonest, and denote by  $P_A(z_A, z_B)$  (resp.  $P_B(z_B, z_A)$ ) the role  $P_A$  (resp.  $P_B$ ) played by agents  $z_A$  and  $z_B$ . Then we consider the following:

$$P_{\text{NSL}}^{\text{semi}} = P_A(a, b) \mid P_B(b, a) \mid P_A(a, c) \mid P_B(b, c) \mid P_A(b, a) \mid P_B(a, b) \mid P_A(b, c) \mid P_B(a, c)$$

$P_{\text{NSL}}^{\text{semi}}$  considers all possible combinations of  $a, b, c$  within  $P_A$  and  $P_B$ , except that we exclude the processes  $P_A(c, a)$  and  $P_A(c, b)$  as well as  $P_B(c, b)$  and  $P_B(c, a)$ . Indeed, these four processes describe the behaviour of a dishonest agent  $c$ , which is already included within the semantics of our model.  $P_{\text{NSL}}^{\text{semi}}$  models the possible two-way interactions between honest agents, and between honest agents willing to establish a session with an attacker. Note that processes  $P_A(a, b)$ ,  $P_B(a, b)$  and  $P_B(a, c)$  correspond respectively to  $P_A$ ,  $P_B$  and  $P'_B$  in Example 2.4.  $P_{\text{NSL}}^{\text{semi}}$  models a complete scenario with one session only of each possible instantiation of a role. Even though our calculus does not contain replication, type-compliance and well-typedness can easily be lifted to protocols with replication, provided we account for issues arising from the generation of new renamed copies of our processes. In a slightly different setting, [20] has established that type compliance is guaranteed for an unbounded number of sessions as soon as a protocol is type-compliant when 2

sessions are considered for each role and each possible choice of agents. For this reason, we consider a complete protocol  $P_{\text{NSL}}^{\text{complete}} = P_{\text{NSL}}^{\text{semi}} \mid P_{\text{NSL}}^{\prime\text{semi}}$  where  $P_{\text{NSL}}^{\prime\text{semi}}$  is a copy of  $P_{\text{NSL}}^{\text{semi}}$  alpha-renamed to ensure names and variables are all distinct in  $P_{\text{NSL}}^{\text{complete}}$ , and the same type is given to names and variables that have been alpha-renamed. This scenario is complete in the sense that, according to the approach of [20], a richer scenario derived from this one by adding more copies of a process will still be type-compliant according to our definition (note that no more encrypted subterms will be introduced).

For the security property, we consider the secrecy of a key or a nonce, where secrecy is encoded as a combination of key usability and “which key-concealing”. For NSL, we consider secrecy of the nonce  $n_b$  as received by  $P_A(a, b)$ . To that end we consider two variants of  $P_A(a, b)$ : in the first one, we add a final action  $\text{out}(c_A, \text{senc}(m_1, n_b))$ , whereas we add  $\text{out}(c_A, \text{senc}(m_2, k))$  in the second, where  $k$  is a fresh nonce, and  $m_1$  and  $m_2$  are two publicly known constants. However, for NSL, the resulting protocols are not type-compliant. Indeed, there is an encrypted subterm  $\text{aenc}(x_1, \text{pub}(sk_b), r_3)$  in  $P_A$  (Example 2.4) which can be unified with other encrypted subterm from the protocol. Note that the scenario we consider is richer than the scenario from Example 3.7, which explains why the typing system considered is not enough to make the entire protocol type-compliant. To ensure type-compliance, we need here to consider a tagged version of the protocol where a public constant is appended to each plaintext in the specification. The informal specification is given below.

$$\begin{aligned} A \rightarrow B &: \{1, N_a, A\}_{\text{pub}(B)} \\ B \rightarrow A &: \{2, N_a, N_b, B\}_{\text{pub}(A)} \\ A \rightarrow B &: \{3, N_b\}_{\text{pub}(B)} \end{aligned}$$

## 6.2 Review of key-exchange protocols

We consider several protocols from the literature and investigate their type-compliance for the complete scenario. As well as for the Needham-Schroeder-Lowe protocol, the security property we consider is the secrecy of secret (nonce or session key) exchanged between two honest agents  $a$  and  $b$ , encoded as a combination of key usability and “which key-concealing”. Tuples are encoded directly, without using nested pairs.

The complete scenario for a 3-party protocol with a trusted server  $S$  is somewhat more complex than for a 2-party protocol. We need to consider a server  $S$  willing to establish a session between all pairs of agents in  $\{a, b, c\}$ , in addition of the usual interactions between  $a, b$  and  $c$ . Each of the protocols is thus modelled as 14 processes, leading to 28 processes after duplication.

Type-compliance of the protocols has been verified automatically. In some cases, we needed to tag the protocol to ensure type compliance, as for the case of the NSL protocol. Our findings are summarized in Figure 3, which describes which protocol is type-compliant, with or without tags. We discuss below each protocol individually.

**Wide Mouth Frog.** The Wide Mouth Frog protocol can be informally described as follows.

$$\begin{aligned} A \rightarrow S &: A, \{B, K_{ab}\}_{K_{as}} \\ S \rightarrow B &: \{A, K_{ab}\}_{K_{bs}} \end{aligned}$$

Here we verify the strong secrecy of  $K_{ab}$  as received by  $B$ . We consider a structure-preserving typing system which associates the type agent to agents  $a, b, c$  and  $S$ , the type session to negotiated keys between the agents such as  $K_{ab}$  and the type longterm to long-term keys  $K_{as}, K_{bs}$  and  $K_{cs}$ . The constants  $m_1$  and  $m_2$  occurring in the security property (as for the NSL protocol) are typed with a type constant. This protocol is type-compliant, without requiring any additional tagging, as every encrypted subterm is of the form  $\text{senc}(\langle \text{agent}, \text{session} \rangle, \text{longterm})$ , except for the terms

	Type-compliance with tuples	Type-compliance with tagging
Needham-Schroeder-Lowe	×	✓

Active authentication	✓	✓

Fig. 3. Type-compliance of protocols for Sections 6.2 and 6.3.

that come from the encoding of the security property, which use a constant as plaintext and thus cannot be unified with other ciphertext.

**Denning Sacco with shared keys.** The Denning Sacco protocol can be informally described as follows.

$$\begin{aligned}
A \rightarrow S &: A, B \\
S \rightarrow A &: \{B, K_{ab}, \{K_{ab}, A\}_{K_{bs}}\}_{K_{as}} \\
A \rightarrow B &: \{K_{ab}, A\}_{K_{bs}}
\end{aligned}$$

We consider the same typing system as for the Wide Mouth Frog protocol. This protocol is type-compliant, without requiring any additional tagging. The difference in the arity of the plaintexts in the protocol specification ensures all possible unifications between encrypted subterms occur between encrypted subterms of the same type.

**Needham-Schroeder with shared keys.** The Needham-Schroeder symmetric key protocol can be informally described as follows.

$$\begin{aligned}
A \rightarrow S &: A, B, N_a \\
S \rightarrow A &: \{B, N_a, K_{ab}, \{A, K_{ab}\}_{K_{bs}}\}_{K_{as}} \\
A \rightarrow B &: \{A, K_{ab}\}_{K_{bs}} \\
B \rightarrow A &: \{\text{req}, N_b\}_{K_{ab}} \\
A \rightarrow B &: \{\text{rep}, N_b\}_{K_{ab}}
\end{aligned}$$

This protocol is type-compliant, without requiring any additional tagging, using the same structure-preserving typing system as before.

**Yahalom-Lowe.** The Yahalom-Lowe protocol can be informally described as follows.

$$\begin{aligned}
A \rightarrow B &: A, N_a \\
B \rightarrow S &: \{A, N_a, N_b\}_{K_{bs}} \\
S \rightarrow A &: \{B, K_{ab}, N_a, N_b\}_{K_{as}} \\
S \rightarrow B &: \{A, K_{ab}\}_{K_{bs}} \\
A \rightarrow B &: \{A, B, S, N_b\}_{K_{ab}}
\end{aligned}$$

This protocol is type-compliant, without requiring any additional tagging, using the same structure-preserving typing system as before. Note that type-compliance depends on the encoding of tuples: when considered as nested pairs, type-compliance is not guaranteed, as more encrypted subterms become unifiable.

**Yahalom-Paulson.** The Yahalom-Paulson protocol can be informally described as follows.

$$\begin{aligned}
A \rightarrow B &: A, N_a \\
B \rightarrow S &: B, N_b, \{A, N_a\}_{K_{bs}} \\
S \rightarrow A &: N_b, \{B, K_{ab}, N_a\}_{K_{as}}, \{A, B, K_{ab}, N_b\}_{K_{bs}} \\
A \rightarrow B &: \{A, B, K_{ab}, N_b\}_{K_{bs}}, \{N_b\}_{K_{ab}}
\end{aligned}$$

This protocol is not type-compliant. Indeed its formal specification contains a term  $\text{senc}(x_{nb}, x_{Kab})$ , in the encrypted subterms of  $A$ , which can be unified with any other encrypted subterm from the protocol, such as subterms encrypted with long-term keys  $K_{as}$  and  $K_{bs}$ . To ensure type-compliance with a non-trivial typing system, we consider a tagged version of the protocol.

$$\begin{aligned}
A \rightarrow B &: A, N_a \\
B \rightarrow S &: B, N_b, \{1, A, N_a\}_{K_{bs}} \\
S \rightarrow A &: N_b, \{2, B, K_{ab}, N_a\}_{K_{as}}, \{3, A, B, K_{ab}, N_b\}_{K_{bs}} \\
A \rightarrow B &: \{3, A, B, K_{ab}, N_b\}_{K_{bs}}, \{4, N_b\}_{K_{ab}}
\end{aligned}$$

**Otway-Rees.** The Otway-Rees protocol can be informally described as follows.

$$\begin{aligned}
A \rightarrow B &: M, A, B, \{N_a, M, A, B\}_{K_{as}} \\
B \rightarrow S &: M, A, B, \{N_a, M, A, B\}_{K_{as}}, \{N_b, M, A, B\}_{K_{bs}} \\
S \rightarrow B &: M, \{N_a, K_{ab}\}_{K_{as}}, \{N_b, K_{ab}\}_{K_{bs}} \\
B \rightarrow A &: M, \{N_a, K_{ab}\}_{K_{as}}
\end{aligned}$$

This protocol is type-compliant, without requiring any additional tagging, using the same structure-preserving typing system as before. As for the Yahalom-Lowe protocol, type-compliance relies here on the direct encoding of tuples, and would not hold with nested pairs. Actually, we can also consider a different typing system which consists of typing the variables used to model ciphertext forwarding using a constant. This does not correspond to the expected type in a normal execution, but we can show that the protocol is type-compliant. This yields an interesting property w.r.t. attack search. Namely, we deduce that it is useless to instantiate these variables with complex terms when looking for an attack.

**Denning Sacco with signature.** This protocol, presented in [12], can be seen as a simplified version of the Denning Sacco protocol. It can be informally described as follows.

$$\begin{aligned}
A \rightarrow B &: A, B, \{\text{sign}(\langle A, B, k \rangle, skA)\}_{\text{pub}(B)} \\
B \rightarrow A &: \{m\}_k
\end{aligned}$$

This protocol is type-compliant, without requiring any additional tagging, using the same structure-preserving typing system as before.

### 6.3 E-passport protocols

We also consider two authentication protocols used in the e-passport application, namely the passive authentication (PA) protocol and the active authentication (AA) protocol. These protocols enable a reader (agent  $R$  in the following informal specifications) to authenticate a passport (agent  $P$ ). The two agents already possess sessions keys thanks to a prior execution of a key-exchange protocol. For this reason, the security property we want to verify here is a variant of unlinkability: we want to model the inability for an attacker to distinguish between a scenario involving Passport 1 and two sessions of Passport 2, and a scenario involving two copies of Passport 1 and only one session of Passport 2. This models the inability for the attacker to link two sessions of a same passport together. We then investigate the type-compliance of the resulting configurations, and summarize the results in Figure 3. Similarly to the key-exchange protocols, we consider a version

of the protocol where each session has been duplicated, to ensure all possible unifications are observed.

**Passive authentication.** This protocol can be informally described as follows.

$$\begin{aligned} R \rightarrow P &: \{read\}_{k_{senc}}, \text{mac}(\{read\}_{k_{senc}}, k_{mac}) \\ P \rightarrow R &: \{data_P\}_{k_{senc}}, \text{mac}(\{data_P\}_{k_{senc}}, k_{mac}) \end{aligned}$$

where  $data_P = \langle dg_P, \text{sign}(\text{hash}(dg_P), sk_{DS}), \text{hash}(dg_P) \rangle$ . This protocol is type-compliant, without requiring any additional tagging, using the same structure-preserving typing system as before. Type-compliance arises here from the fact that encrypted subterms in the formal specification of the protocol use a fixed key, the session key shared between the reader and the passport, preventing unification between messages other than the honest execution of the protocol.

**Active authentication.** This protocol can be informally described as follows.

$$\begin{aligned} R \rightarrow P &: \{init, r\}_{k_{senc}}, \text{mac}(\{init, r\}_{k_{senc}}, k_{mac}) \\ P \rightarrow R &: \{\text{sign}(\langle n, r \rangle, sk_P)\}_{k_{senc}}, \text{mac}(\{\text{sign}(\langle n, r \rangle, sk_P)\}_{k_{senc}}, k_{mac}) \end{aligned}$$

This protocol is type-compliant, without requiring any additional tagging, using the same structure-preserving typing system as before, and following the same argument as for the PA protocol.

## 7 CONCLUSION

We have established a simplification result for both reachability and equivalence properties: if there is an attack, then there is a well-typed attack, which reduces the search space. Our result holds for a large class of cryptographic primitives, that encompasses asymmetric encryption, signatures, and hashes, and for a flexible notion of typing system, provided the underlying protocol is type-compliant: any two unifiable encrypted subterms have the same type.

The natural next step would be to extend results that rely on the previous small attack result [20], limited to symmetric encryption. For example, we could probably establish a novel decidability result for protocols with nonces, for an unbounded number of sessions, for a large class of cryptographic primitives, generalizing the approach of [21]. Similarly, we plan to extend the tool SAT-Equiv [25] that (efficiently) decides trace equivalence for a bounded number of sessions. SAT-Equiv is currently limited to symmetric encryption as it relies on [20]. The extension to asymmetric encryption, signatures and hashes will require further (provably correct) optimizations, in order to preserve the efficiency of the tool.

Finally, typing results can potentially be used for composition results. Given two secure protocols  $P$  and  $Q$ , they can be safely composed if, intuitively, the execution of  $P$  does not interfere with the execution of  $Q$  (and conversely). Such composition results have been established for trace properties [3, 22, 26] as well as equivalence properties [4]. We could probably use our typing result to establish composition for equivalence properties and a larger class of primitives and protocols, assuming that protocols have disjoint types, which can be typically enforced by tagging.

## A SOUNDNESS PROOFS OF SECTION 3.

This Lemma may seem too precise when we want to prove the soundness part of Theorem 3.8. It will be used with its complete power when proving the completeness of Theorem 3.10. See the proof of Proposition 5.4 in Appendix C.

LEMMA A.1. *Let  $\mathcal{K}_Q = (Q_0; \psi_0; \sigma_0; i_0)$  be a  $\Sigma_0^-$ -configuration, and  $(\text{tr}_S, \psi_S) \in \text{trace}_{\Sigma_0^+}(\mathcal{K}_Q)$ . Let  $\theta$  be a substitution such that  $\text{dom}(\theta) \subseteq \Sigma_{\text{fresh}}$ , for any  $c \in \Sigma_{\text{fresh}}$  occurring in  $\text{tr}_S$ , we have that  $c \in \text{dom}(\theta)$ ,  $c\theta \in \mathcal{T}(\Sigma, \Sigma_0^- \uplus \text{dom}(\psi_S))$ , and  $w' < c$  for any  $w' \in \text{vars}(c\theta)$  (where  $<$  is the ordering induced by  $\text{tr}_S$ ). We also assume that  $(c\theta)\psi_S \downarrow$  is a  $\Sigma_0^+$ -message for any  $c \in \text{dom}(\theta)$  and an atomic one in case  $c \in \Sigma_{\text{fresh}}^{\text{atom}}$ . We have that  $(\text{tr}_S\theta, \psi_S\lambda) \in \text{trace}_{\Sigma_0^-}(\mathcal{K}_Q)$  where  $\lambda$  is the first-order substitution associated to  $\theta$  through  $\psi_S$ .*

PROOF. Since  $(\text{tr}_S, \psi_S) \in \text{trace}_{\Sigma_0^+}(\mathcal{K}_Q)$ , we know that  $\mathcal{K}_Q = (Q_0; \psi_0; \sigma_0; i_0) \xrightarrow{\text{tr}_S} (Q_S; \psi_S; \sigma_S; i_S)$ .

Given  $\theta$  and  $\lambda$  as defined in the lemma, we establish that:  $\mathcal{K}_Q = (Q_0; \psi_0; \sigma_0; i_0) \xrightarrow{\text{tr}_S\theta} (Q; \psi; \sigma; i)$  where  $Q = Q_S$ ,  $\phi = \psi_S\lambda$ ,  $\sigma = \sigma_S\lambda$ , and  $i = i_S$ . We show this result by induction on the length of the trace.

*Base case:*  $\text{tr}$  is empty. Let  $(Q; \psi; \sigma; i) = \mathcal{K}_Q$ . Since  $\mathcal{K}_Q$  is a  $\Sigma_0^-$ -configuration, we have that  $\psi\lambda = \psi$ , and  $\sigma\lambda = \sigma$ . Therefore, the result trivially holds.

*Inductive case:*  $\text{tr} = \text{tr}^- . \alpha_S$ . In such a case, we have that:

$$\mathcal{K}_Q = (Q_0; \psi_0; \sigma_0; i_0) \xrightarrow{\text{tr}_S} (Q_S^-; \psi_S^-; \sigma_S^-; i_S^-) \xrightarrow{\alpha_S} (Q_S; \psi_S; \sigma_S; i_S)$$

Thanks to our induction hypothesis applied on  $\text{tr}^-$ , we know that:

$$\mathcal{K}_Q = (Q_0; \psi_0; \sigma_0; i_0) \xrightarrow{\text{tr}_S\theta} (Q^-; \psi^-; \sigma^-; i^-)$$

with  $Q^- = Q_S^-$ ,  $\psi^- = \psi_S^- \lambda$ ,  $\sigma^- = \sigma_S^- \lambda$ , and  $i^- = i_S^-$ . We distinguish three cases depending on  $\alpha_S$ .

- *Case  $\alpha_S = \text{phase } j$  for some integer  $j$ .* In such a case, we have that  $Q_S = Q_S^-$ ,  $\psi_S = \psi_S^-$ ,  $\sigma_S = \sigma_S^-$ , and  $i_S = j > i_S^-$ . Let  $Q = Q^-$ ,  $\psi = \psi^-$ ,  $\sigma = \sigma^-$ ,  $i = j$ . Since  $i^- = i_S^- < j$ . We have that:

$$(Q^-; \psi^-; \sigma^-; i^-) \xrightarrow{\text{phase } j} (Q^-; \psi^-; \sigma^-; j) = (Q; \psi; \sigma; i)$$

We have that  $Q = Q_S$ ,  $\psi = \psi_S\lambda$ ,  $\sigma = \sigma_S\lambda$ , and  $i = i_S$ . It gives us the result.

- *Case  $\alpha_S = \text{in}(c, R)$  for some  $\Sigma_0^+$ -recipe  $R$ .* In such a case, we have that  $Q_S^- = \{\text{in}(c, u).Q_c\} \uplus \mathcal{P}$ , and we have also that  $u\sigma_S^-$  and  $R\psi_S^- \downarrow$  (ground term) are unifiable with some substitution  $\tau$ , and we have that  $\sigma_S = \sigma_S^- \uplus \tau$ . Thanks to Lemma 4.8, we can apply Lemma 4.9, and thus we have:

$$(R\theta)\psi^- \downarrow = (R\theta)(\psi_S\lambda) \downarrow = (R\psi_S^- \downarrow)\lambda = [(u\sigma_S^-)\tau]\lambda = u(\sigma_S^- \uplus \tau)\lambda = (u(\sigma_S^- \lambda))(\tau\lambda).$$

Let  $Q = \{Q_c\} \uplus \mathcal{P}$ ,  $\psi = \psi^-$ ,  $\sigma = \sigma^- \uplus \tau\lambda$ , and  $i = i^-$ . We have that:

$$(\{\text{in}(c, u).Q_c\} \uplus \mathcal{P}; \psi^-; \sigma^-; i^-) \xrightarrow{\text{in}(c, R\theta)} (\{Q_c\} \uplus \mathcal{P}; \psi^-; \sigma^- \uplus \tau\lambda; i^-) = (Q; \psi; \sigma; i)$$

We have that  $Q = Q_S$ ,  $\psi = \psi_S\lambda$ ,  $i = i_S$ , and  $\sigma = \sigma^- \uplus \tau\lambda = \sigma_S^- \lambda \uplus \tau\lambda = (\sigma_S^- \uplus \tau)\lambda = \sigma_S\lambda$ . It gives us the result.

- *Case  $\alpha_S = \text{out}(c, w)$ .* In such a case, we have that  $Q_S^- = Q^- = \{\text{out}(c, u).Q_c\} \uplus \mathcal{P}$ , and we have that  $\psi_S = \psi_S^- \uplus \{w \triangleright u\sigma_S^-\}$ . Let  $Q = \{Q_c\} \uplus \mathcal{P}$ ,  $\psi = \psi^- \uplus \{w \triangleright u\sigma^-\}$ ,  $\sigma = \sigma^-$ , and  $i = i^-$ . We now show that  $u\sigma^- = u\sigma_S^- \lambda$  is a  $\Sigma_0^-$ -message. We know that  $u\sigma_S^-$  is a  $\Sigma_0^+$ -message. Moreover, thanks to Lemma 4.8, we know that  $c\lambda$  is a  $\Sigma_0^-$ -message for each  $c \in \text{dom}(\lambda)$ , and  $c\lambda$  is atomic

when  $c \in \Sigma_{\text{fresh}}^{\text{atom}}$ . This allows us to conclude that  $u\sigma^- = u\sigma_S^- \lambda$  is a  $\Sigma_0^-$ -message. Therefore, we have that:

$$(\{\text{out}(c, u).Q_c\} \uplus \mathcal{P}; \psi^-; \sigma^-; i^-) \xrightarrow{\text{out}(c, w)} (\{Q_c\} \uplus \mathcal{P}; \psi^- \uplus \{w \triangleright u\sigma^-\}; \sigma^-; i^-) = (Q; \psi; \sigma; i).$$

We have that  $Q = Q_S$ ,  $\sigma = \sigma_S \lambda$ ,  $i = i_S$ , and  $\psi = \psi_S \lambda$  since  $\sigma_S^- \lambda = \sigma^-$  by induction hypothesis. It gives us the result.

We may note that the resulting trace  $\text{tr}_S \theta$  only contains  $\Sigma_0^-$ -recipes: constants from  $\Sigma_{\text{fresh}}$  occurring in  $\text{tr}_S$  have been replaced by  $\theta$ . Hence, the result.  $\square$

## B PROOFS OF SECTION 4

### B.1 Some preliminaries

LEMMA 4.3. *Let  $\phi$  be a  $\Sigma_0$ -frame,  $R$  a  $\Sigma_0$ -recipe such that  $R\phi\downarrow$  is a  $\Sigma_0$ -message, and  $R'$  be such that  $R \rightarrow R'$ . We have that  $R'$  is a  $\Sigma_0$ -recipe, and  $R'\phi\downarrow = R\phi\downarrow$ .*

PROOF. Since  $R \rightarrow R'$ , we know that there exists a position  $p$  in  $R$ , a rewriting rule  $\ell' \rightarrow r$  associated to  $\ell \rightarrow r \in \mathcal{R}$ , and a substitution  $\sigma$  such that  $R|_p = \ell'\sigma$ , and  $R' = R[r\sigma]_p$ . Since  $R\phi\downarrow$  is a  $\Sigma_0$ -message, we know that  $(\ell'\sigma)\phi\downarrow$  is a  $\Sigma_0$ -message. Let  $t'_1, \dots, t'_k$  and  $\text{des} \in \Sigma_d$  be such that  $\ell' = \text{des}(t'_1, \dots, t'_n)$ . We have that  $(\ell'\sigma)\phi = \text{des}((t'_1\sigma)\phi, \dots, (t'_k\sigma)\phi)$ . As  $(\ell'\sigma)\phi\downarrow$  is a  $\Sigma_0$ -message, it means that  $\ell \rightarrow r$  applies as it is the only rule reducing  $\text{des}$ . Hence, we have that  $\text{des}((t'_1\sigma)\phi\downarrow, \dots, (t'_k\sigma)\phi\downarrow) \rightarrow (r\sigma)\phi\downarrow$ . We deduce that  $(\ell'\sigma)\phi\downarrow = (r\sigma)\phi\downarrow$ , and therefore we have that  $R\phi\downarrow = R'\phi\downarrow$ .  $\square$

LEMMA 4.5. *Let  $\theta$  be a substitution with  $\text{dom}(\theta) \subseteq \Sigma_{\text{fresh}}$  and whose image contains  $\Sigma_0^-$ -recipes. Let  $R$  be a  $\Sigma_0^+$ -recipe in normal form w.r.t.  $\rightarrow$  such that  $(R\theta)\phi\downarrow$  is a  $\Sigma_0^+$ -message for some  $\Sigma_0^-$ -frame  $\phi$ . We have that  $R'$  is a simple  $\Sigma_0^+$ -recipe for any  $R' \in \text{St}(R)$ .*

PROOF. We prove this result by structural induction on  $R$ .

*Base case:*  $R \in \mathcal{W} \cup \Sigma_0^+$ . In both cases, the result holds since  $R$  is a simple  $\Sigma_0^+$ -recipe.

*Induction case:* We have that  $R = f(R_1, \dots, R_k)$  for some  $f \in \Sigma$ , and we know that  $R_1, \dots, R_k$  are in normal form w.r.t.  $\downarrow$ .

- *Case  $f \in \Sigma_c$ .* We have that  $(R\theta)\phi\downarrow = f((R_1\theta)\phi\downarrow, \dots, (R_k\theta)\phi\downarrow)$  is a  $\Sigma_0^+$ -message for some  $\Sigma_0^-$ -frame  $\phi$ , and thus  $(R_i\theta)\phi\downarrow$  is a  $\Sigma_0^+$ -message for  $i \in \{1, \dots, k\}$ . Applying our induction hypothesis on  $R_i$  ( $1 \leq i \leq k$ ), we easily conclude.
- *Case  $f = \text{des} \in \Sigma_d$ .* Let  $\ell_{\text{des}} \rightarrow r_{\text{des}}$  be the rule in  $\mathcal{R}$  such that  $\text{root}(\ell_{\text{des}}) = \text{des}$ , and  $\ell'_{\text{des}} \rightarrow r_{\text{des}}$  its associated forced rewriting rule. If  $r_{\text{des}} \in \mathcal{T}_0(\Sigma_c, \emptyset)$  then we have that  $R \rightarrow r_{\text{des}}$ , which is impossible as  $R$  is in normal form w.r.t.  $\rightarrow$ . Thus, there is a unique position  $p_0$  of  $\ell_{\text{des}}$  such that  $\ell_{\text{des}}|_{p_0} = r_{\text{des}}$  and  $p_0 = 1.p'_0$ . We know that each  $R_i$  is in normal form w.r.t.  $\rightarrow$ , and we have  $(R_i\theta)\phi\downarrow$  is a  $\Sigma_0^+$ -message ( $1 \leq i \leq k$ ) as  $(R\theta)\phi\downarrow$  is a  $\Sigma_0^+$ -message. Thus, our induction hypothesis applies and we deduce that any subterm of  $R_i$  is a simple  $\Sigma_0^+$ -recipe ( $1 \leq i \leq k$ ). We first assume that  $R_1$  is a subterm  $\Sigma_0^+$ -recipe. Let  $\psi$  be  $\Sigma_0^+$ -frame such that  $R\psi\downarrow$  is a  $\Sigma_0^+$ -message. We have that  $R\psi\downarrow \in \text{St}(R_1\psi\downarrow) \subseteq \text{St}(\psi)$ . Thus,  $R$  is a subterm  $\Sigma_0^+$ -recipe, and thus a simple  $\Sigma_0^+$ -recipe.

Otherwise, we have that  $R_1 = C[R'_1, \dots, R'_{k'}]$  for some context built using symbols from  $\Sigma_c \uplus \Sigma_0^+$ , and each  $R'_j$  ( $1 \leq j \leq k'$ ) is a subterm  $\Sigma_0^+$ -recipe such that  $\text{root}(R'_j) \notin \Sigma_c$ . We have that  $R = \text{des}(C[R'_1, \dots, R'_{k'}], R_2, \dots, R_k)$ , and  $p_0$  does not correspond to a position of the context  $C$  since  $R$  is in normal form w.r.t.  $\rightarrow$ . Let  $p'$  be the longest prefix of  $p'_0$  that corresponds to a position of  $C$ . We have that  $C[R'_1, \dots, R'_{k'}]|_{p'} = R'_j$  for some  $j$ . Let  $\psi$  be  $\Sigma_0^+$ -frame such that

$R\psi\downarrow$  is a  $\Sigma_0^+$ -message. We have that  $R\psi\downarrow \in St(R'\psi\downarrow) \subseteq St(\psi)$  as  $R'_j$  is a subterm  $\Sigma_0^+$ -recipe. Thus,  $R$  is a subterm  $\Sigma_0^+$ -recipe, and thus a simple  $\Sigma_0^+$ -recipe.

This allows us to conclude.  $\square$

## B.2 Our measure

LEMMA B.1. *Let  $\phi_S$  be a  $\Sigma_0^+$ -frame, and  $R$  be a  $\Sigma_0^+$ -recipe. We have that  $\mu_{\phi_S}^2(R) \geq 0$ .*

PROOF. Let  $R = R_0[R_1, \dots, R_n]$  where  $R_0$  is the hat of  $R$ . Since  $R_0$  only contains constructors, we have that  $R\phi_S\downarrow = R_0[R_1\phi_S\downarrow, \dots, R_n\phi_S\downarrow]$ . Hence, we have that  $|R\phi_S\downarrow| \geq |R_0| = \text{hat}(R)$ , which implies  $\mu_{\phi_S}^2(R) \geq 0$ .  $\square$

LEMMA B.2. *Let  $<$  be an ordering on  $\Sigma_{\text{fresh}}$ ,  $\ell_{\text{des}} \rightarrow r_{\text{des}}$  be a rewriting rule from  $\mathcal{R}$  (as defined in Section 2.1), and  $\sigma$  be a substitution such that  $\text{img}(\sigma) \subseteq \mathcal{T}(\Sigma, \Sigma_0^+ \uplus \mathcal{N})$ .*

*We have that  $\text{Multi}(r_{\text{des}}\sigma) < \text{Multi}(\ell_{\text{des}}\sigma)$ . This result also holds when considering the forced rewriting associated to a rewriting rule in  $\mathcal{R}$ .*

PROOF. First, we consider the case where  $r_{\text{des}} \in \mathcal{T}_0(\Sigma_c, \emptyset)$ . In such a case, we have

$$\text{Multi}(r_{\text{des}}\sigma) = \text{Multi}(r_{\text{des}}) < \{\text{des}\} < \text{Multi}(\ell_{\text{des}}\sigma)$$

Now, we consider the case where  $r_{\text{des}} \in St(\ell_{\text{des}})$ . We have that:

$$\text{Multi}(r_{\text{des}}\sigma) < \{\text{des}\} \uplus \text{Multi}(r_{\text{des}}\sigma) \leq \text{Multi}(\ell_{\text{des}}\sigma).$$

Thus, in both cases, we have that  $\text{Multi}(r_{\text{des}}\sigma) < \text{Multi}(\ell_{\text{des}}\sigma)$ . The proof regarding the case of a forced rewriting rule can be done in similar way.  $\square$

LEMMA B.3. *Let  $<$  be an ordering on  $\Sigma_{\text{fresh}}$ ,  $f \in \Sigma$  of arity  $k$ , and  $t_1, \dots, t_k \in \mathcal{T}(\Sigma, D)$  for some set  $D$  of data. We have that  $\text{Multi}(f(t_1, \dots, t_k)\downarrow) \leq \text{Multi}(f(t_1\downarrow, \dots, t_k\downarrow))$ , and similarly for  $\downarrow$ .*

PROOF. First, we consider the case where  $f(t_1, \dots, t_k)\downarrow = f(t_1\downarrow, \dots, t_k\downarrow)$ . In such a situation, the result trivially holds. Thus, we know that  $f = \text{des} \in \Sigma_d$ , and  $\text{des}(t_1, \dots, t_k)\downarrow \neq \text{des}(t_1\downarrow, \dots, t_k\downarrow)$ . It means that there exists a substitution  $\sigma$  such that:

$$\text{des}(t_1\downarrow, \dots, t_k\downarrow) = \ell_{\text{des}}\sigma \text{ and } \text{des}(t_1, \dots, t_k)\downarrow = r_{\text{des}}\sigma.$$

Thanks to Lemma B.2, we know that  $\text{Multi}(\text{des}(t_1, \dots, t_k)\downarrow) < \text{Multi}(\text{des}(t_1\downarrow, \dots, t_k\downarrow))$ . This concludes the proof. A similar reasoning allows us to conclude regarding  $\downarrow$ .  $\square$

LEMMA 4.6. *Let  $<$  be an ordering on  $\Sigma_{\text{fresh}}$ ,  $\phi_S$  be a  $\Sigma_0^+$ -frame,  $R_1, R_2$  be two  $\Sigma_0^+$ -recipes such that  $R_2\phi_S\downarrow$  is not a  $\Sigma_0^+$ -message, and  $\mu_{\phi_S}^1(R_1) < \mu_{\phi_S}^1(R_2)$ . Let  $R_0$  be a  $\Sigma_0^+$ -recipe, and  $p$  a position in  $R_0$ . We have that:*

$$\mu_{\phi_S}^1(R_0[R_1]_p) < \mu_{\phi_S}^1(R_0[R_2]_p).$$

PROOF. We first establish the following claim by induction on the length of  $p$  ( $\square$  is not a message).

$$\text{Multi}(R_0[R_1]_p\phi_S\downarrow) \leq (\text{Multi}(R_0\phi_S[\square]_p\downarrow) \setminus \{\square\}) \uplus \text{Multi}(R_1\phi_S\downarrow).$$

Base case:  $p = \epsilon$ . We have  $\text{Multi}(R_0\phi_S[\square]_p\downarrow) = \{\square\}$ . So

$$\text{Multi}(R_0[R_1]_p\phi_S\downarrow) = \text{Multi}(R_1\phi_S\downarrow) = (\text{Multi}(R_0\phi_S[\square]_p\downarrow) \setminus \{\square\}) \uplus \text{Multi}(R_1\phi_S\downarrow)$$

Inductive case:  $p = j.p'$ , and  $R_0 = f(R'_1, \dots, R'_k)$  for some  $\Sigma_0^+$ -recipes  $R'_1, \dots, R'_k$ . Thanks to Lemma B.3, we obtain  $\text{Multi}(R_0[R_1]_p\phi_S\downarrow) \leq \text{Multi}(f(R'_1\phi_S\downarrow, \dots, R'_j[R_1]_{p'}\phi_S\downarrow, \dots, R'_k\phi_S\downarrow))$ , and thus

$$\text{Multi}(R_0[R_1]_p\phi_S\downarrow) \leq \{f\} \uplus (\uplus_{i \neq j} \text{Multi}(R'_i\phi_S\downarrow)) \uplus \text{Multi}(R'_j[R_1]_{p'}\phi_S\downarrow).$$

By induction hypothesis we have:  $\text{Multi}(R'_j[R_1\phi_S\downarrow]_{p'}) \leq (\text{Multi}(R'_j\phi_S[\square]_{p'}\downarrow) \setminus \{\square\}) \uplus \text{Multi}(R_1\phi_S\downarrow)$ . Therefore, we have that:

$$\text{Multi}(R_0[R_1]_p\phi_S\downarrow) \leq \{f\} \uplus (\uplus_{i \neq j} \text{Multi}(R'_i\phi_S\downarrow)) \uplus (\text{Multi}(R'_j\phi_S[\square]_{p'}\downarrow) \setminus \{\square\}) \uplus \text{Multi}(R_1\phi_S\downarrow)$$

But  $R'_j\phi_S[\square]_{p'}\downarrow$  is not a message, and thus no reduction can occur above  $\square$ . Thus:

$$\text{Multi}(R_0\phi_S[\square]_{p'}\downarrow) = \{f\} \uplus (\uplus_{i \neq j} \text{Multi}(R'_i\phi_S\downarrow)) \uplus \text{Multi}(R'_j[\square]_{p'}\phi_S\downarrow).$$

Hence, we deduce that:

$$\text{Multi}(R_0\phi_S[\square]_{p'}\downarrow) \setminus \{\square\} = \{f\} \uplus (\uplus_{i \neq j} \text{Multi}(R'_i\phi_S\downarrow)) \uplus (\text{Multi}(R'_j[\square]_{p'}\phi_S\downarrow) \setminus \{\square\})$$

We deduce:

$$\text{Multi}(R_0[R_1]_p\phi_S\downarrow) \leq (\text{Multi}(R_0[\square]_p\phi_S\downarrow) \setminus \{\square\}) \uplus \text{Multi}(R_1\phi_S\downarrow)$$

This proves the claim.

Now, as  $R_2\phi_S\downarrow$  is not a message,  $R_0[R_2]_p\phi_S\downarrow = (\text{Multi}(R_0\phi_S[\square]_{p'}\downarrow) \setminus \{\square\}) \uplus \text{Multi}(R_2\phi_S\downarrow)$ . Since  $\mu_{\phi_S}^1(R_1) < \mu_{\phi_S}^1(R_2)$ , relying on our claim, we easily deduce that  $\mu_{\phi_S}^1(R_0[R_1]_p) < \mu_{\phi_S}^1(R_0[R_2]_p)$ .  $\square$

**LEMMA 4.7.** *Let  $<$  be an ordering on  $\Sigma_{\text{fresh}}$ ,  $\phi_S$  be a  $\Sigma_0^+$ -frame, and  $R, R'$  be two  $\Sigma_0^+$ -recipes such that  $R \rightarrow R'$ . We have that  $\mu_{\phi_S}(R') < \mu_{\phi_S}(R)$ .*

**PROOF.** We first consider the case where  $R\phi_S\downarrow = R'\phi_S\downarrow$ . Hence, we have that  $\mu_{\phi_S}^1(R) = \mu_{\phi_S}^1(R')$ , and we have also that  $\mu^3(R) < \mu^3(R')$ . Since  $|R\phi_S\downarrow| = |R'\phi_S\downarrow|$ , in order to conclude, it only remains to establish that  $|\text{hat}(R')| \geq |\text{hat}(R)|$ . We have that  $R = R_0[R_1, \dots, R_n]$  with  $R_0 = \text{hat}(R)$ . Since  $R \rightarrow R'$ , we know that  $R' = R_0[R_1, \dots, R'_i, \dots, R_n]$  with  $R_i \rightarrow R'_i$ , and thus  $|\text{hat}(R')| \geq |R_0|$ .

Now, we consider the case where  $R\phi_S\downarrow \neq R'\phi_S\downarrow$ . Let  $\ell'_{\text{des}} \rightarrow r_{\text{des}}$  be the rule applied to rewrite  $R$  in  $R'$ . We have that  $R = R[\ell'_{\text{des}}\delta]_p$  and  $R' = R[r_{\text{des}}\delta]_p$  for some position  $p$ , and some substitution  $\delta$ . Therefore, we have that  $R\phi_S\downarrow = (R\phi_S)[(\ell'_{\text{des}}\delta)\phi_S\downarrow]_p\downarrow$  and  $R'\phi_S\downarrow = (R\phi_S)[(r_{\text{des}}\delta)\phi_S\downarrow]_p\downarrow$ . By Lemma B.2, and as  $([\ell'_{\text{des}}\delta]\phi_S\downarrow)$  does not reduce (otherwise we would have that  $R\phi_S\downarrow = R'\phi_S\downarrow$ ) we have that  $\text{Multi}([\ell'_{\text{des}}\delta]\phi_S\downarrow) > \text{Multi}([r_{\text{des}}\delta]\phi_S\downarrow)$ . We deduce that  $\mu_{\phi_S}^1(\ell'_{\text{des}}\delta) > \mu_{\phi_S}^1(r_{\text{des}}\delta)$ . Then Lemma 4.6 allows to conclude that  $\mu_{\phi_S}^1(R') < \mu_{\phi_S}^1(R)$ .  $\square$

### B.3 Completeness

**LEMMA B.4.** *Let  $\phi_S$  be a  $\Sigma_0^+$ -frame together with  $<$  a total ordering on  $\text{dom}(\phi_S)$ . Let  $\theta$  be a substitution such that  $\text{dom}(\theta) \subseteq \Sigma_{\text{fresh}}$ , and for any  $c \in \Sigma_{\text{fresh}}$  occurring in  $\phi_S$  we have that  $c \in \text{dom}(\theta)$  and  $c\theta \in \mathcal{T}(\Sigma, \Sigma_0^- \uplus \text{dom}(\phi_S))$ . Moreover, we assume that in case  $c \in \Sigma_{\text{fresh}}$  occurs in  $w\phi_S$ , then  $w' < w$  for any  $w' \in \text{vars}(c\theta)$ .*

*We have that any constant  $c' \in \Sigma_{\text{fresh}}$  that occurs in  $(c\theta)\phi_S\downarrow$  is such that  $\text{rank}(c') < \text{rank}(c)$  where  $\text{rank}(c) = \max_{<} \{w \mid w \in \text{vars}(c\theta)\}$  when  $\{w \in \text{vars}(c\theta)\} \neq \emptyset$ , and  $\perp$  otherwise.*

**PROOF.** Let  $\phi_S$  be a  $\Sigma_0^+$ -frame as defined in the lemma, and  $c \in \text{dom}(\theta)$ . Let  $c' \in \Sigma_{\text{fresh}}$  be a constant that occurs in  $(c\theta)\phi_S\downarrow$ . In case  $\text{rank}(c) = \perp$ , then it means that  $\text{vars}(c\theta) = \emptyset$ , and thus no constant from  $\Sigma_{\text{fresh}}$  occurs in  $c\theta$ . Therefore, we are done. Now, let  $w_i = \text{rank}(c)$ , we have that  $\text{vars}(c\theta) \subseteq \{w \mid w \leq w_i\}$ , and by hypothesis on  $\theta$ , we have that  $\text{rank}(c') < w_i$  for any constant  $c' \in \Sigma_{\text{fresh}}$  occurring in  $(c\theta)\phi_S$ , and thus we have that  $\text{rank}(c') < \text{rank}(c)$ .  $\square$

**LEMMA 4.8.** *Let  $\phi_S$  be a  $\Sigma_0^+$ -frame together with  $<$  a total ordering on  $\text{dom}(\phi_S)$ . Let  $\theta$  be a substitution such that  $\text{dom}(\theta) \subseteq \Sigma_{\text{fresh}}$ , and for any  $c \in \Sigma_{\text{fresh}}$  occurring in  $\phi_S$  we have that  $c \in \text{dom}(\theta)$  and  $c\theta \in \mathcal{T}(\Sigma, \Sigma_0^- \uplus \text{dom}(\phi_S))$ . Moreover, we assume that in case  $c \in \Sigma_{\text{fresh}}$  occurs in  $w\phi_S$ , then  $w' < w$  for any  $w' \in \text{vars}(c\theta)$ . We consider the substitution  $\lambda$  whose domain is  $\text{dom}(\theta)$ , and such that:*

$$c\lambda = (c\theta)(\phi_S\lambda)\downarrow \text{ for any } c \in \text{dom}(\lambda).$$

The substitution  $\lambda$  is well-defined. Moreover, if  $(c\theta)\phi_S\downarrow$  is a  $\Sigma_0^+$ -message for each  $c \in \text{dom}(\theta)$ , and  $(c\theta)\phi_S\downarrow$  is an atomic  $\Sigma_0^+$ -message when  $c \in \Sigma_{\text{fresh}}^{\text{atom}}$ , then  $c\lambda$  is a  $\Sigma_0^-$ -message for each  $c \in \text{dom}(\lambda)$ , and  $c\lambda$  is an atomic  $\Sigma_0^-$ -message when  $c \in \Sigma_{\text{fresh}}^{\text{atom}}$ .

We call  $\lambda$  the first-order substitution associated to  $\theta$  through  $\phi_S$ .

PROOF. Let  $\text{dom}(\phi_S) = \{w_1, \dots, w_n\}$  be such that  $w_1 < w_2 < \dots < w_n$ . We show this result by induction on  $\text{rank}(c)$  relying on the order  $<$ .

*Base case:*  $c \in \text{dom}(\theta)$  such that  $\text{rank}(c) = \perp$ . In such a case, we have that  $\text{vars}(c\theta) = \emptyset$ , and thus  $c\lambda = (c\theta)\downarrow$  is well-defined. Moreover, assuming that  $(c\theta)\phi_S\downarrow = (c\theta)\downarrow$  is  $\Sigma_0^+$ -message, then we know that it is actually a  $\Sigma_0^-$ -message, and thus  $c\lambda$  is a  $\Sigma_0^-$ -message which is atomic in case  $(c\theta)\phi_S\downarrow$  is atomic.

*Inductive step:*  $c \in \text{dom}(\theta)$  such that  $\text{rank}(c) = w_i$ . Let  $\lambda_i$  be the substitution which coincides with  $\lambda$  on its domain  $\text{dom}(\lambda_i) = \{c' \mid c' \in \text{dom}(\lambda) \text{ and } \text{rank}(c') < w_i\}$ . We have that  $\lambda_i$  is well-defined, and actually we have that  $w_j\phi_S\lambda_i = w_j\phi_S\lambda$  for any  $w_j \leq w_i$ . Since  $\text{rank}(c) = w_i$ , we know that  $\text{vars}(c\theta) \subseteq \{w_1, \dots, w_i\}$ , and thus  $c\lambda = (c\theta)(\phi_S\lambda)\downarrow = (c\theta)(\phi_S\lambda_i)\downarrow$  is well-defined. Moreover, assuming that  $(c\theta)\phi_S\downarrow$  is a  $\Sigma_0^+$ -message, then we know that any constant  $c' \in \Sigma_{\text{fresh}}$  occurring in  $(c\theta)\phi_S\downarrow$  is such that  $\text{rank}(c') < w_i$  (thanks to Lemma B.4), and thus  $c'\lambda$  is a  $\Sigma_0^-$ -message, and an atomic one when  $c \in \Sigma_{\text{fresh}}^{\text{atom}}$ . Thus, we have that  $(c\theta)\phi_S\downarrow\lambda$  is a  $\Sigma_0^-$ -message and an atomic one in case  $c \in \Sigma_{\text{atom}}^{\text{fresh}}$ . Actually, we have that  $(c\theta)\phi_S\downarrow\lambda = (c\theta)(\phi_S\lambda)\downarrow$  which allows us to conclude.  $\square$

LEMMA 4.9. Let  $\phi_S$  be a  $\Sigma_0^+$ -frame together with  $<$  a total ordering on  $\text{dom}(\phi_S)$ . Let  $\theta$  be a substitution such that  $\text{dom}(\theta) \subseteq \Sigma_{\text{fresh}}$ , and for any  $c \in \Sigma_{\text{fresh}}$  occurring in  $\phi_S$  we have that  $c \in \text{dom}(\theta)$  and  $c\theta \in \mathcal{T}(\Sigma, \Sigma_0^- \uplus \text{dom}(\phi_S))$ . Moreover, we assume that in case  $c \in \Sigma_{\text{fresh}}$  occurs in  $w\phi_S$ , then  $w' < w$  for any  $w' \in \text{vars}(c\theta)$ . Let  $\lambda$  be the first-order substitution associated to  $\theta$  through  $\phi_S$ .

Assume that for any  $c \in \text{dom}(\lambda)$ , we have that  $c\lambda$  is a  $\Sigma_0^-$ -message. Moreover,  $c\lambda$  is an atomic  $\Sigma_0^-$ -message when  $c \in \Sigma_{\text{fresh}}^{\text{atom}}$ . Let  $R \in \mathcal{T}(\Sigma, \Sigma_0^- \uplus \text{dom}(\theta) \uplus \text{dom}(\phi_S))$  such that  $R\phi_S\downarrow$  is a  $\Sigma_0^+$ -message. We have that  $(R\theta)(\phi_S\lambda)\downarrow = (R\phi_S\downarrow)\lambda$ .

PROOF. We prove this result by structural induction on  $R$ .

*Base case:*  $R \in \Sigma_0^- \uplus \text{dom}(\theta) \uplus \text{dom}(\phi_S)$ . In case  $R = c_0 \in \Sigma_0^-$ , then we have that  $(c\theta)(\phi_S\lambda)\downarrow = c_0 = (c\phi_S\downarrow)\lambda$ . In case  $R = c \in \text{dom}(\theta)$ , then we have that  $(c\theta)(\phi_S\lambda)\downarrow = c\lambda = (c\phi_S\downarrow)\lambda$  thanks to Lemma 4.8. In case  $R = w \in \text{dom}(\phi_S)$ , then we have that  $(c\theta)(\phi_S\lambda)\downarrow = w\phi_S\downarrow = (w\phi_S\downarrow)\lambda$ .

*Inductive step:*  $Rf(R_1, \dots, R_k)$ . In case  $f \in \Sigma_c$ , then we have that:

$$(R\theta)(\phi_S\lambda)\downarrow = f((R_1\theta)(\phi_S\lambda)\downarrow, \dots, (R_k\theta)(\phi_S\lambda)\downarrow) = f(R_1\phi_S\downarrow\lambda, \dots, R_k\phi_S\downarrow\lambda) = R\phi_S\downarrow\lambda.$$

In case  $f \in \Sigma_d$ , then for each  $i \in \{1, \dots, k\}$ , by hypothesis we have that  $R_i\phi_S\downarrow$  is a  $\Sigma_0^+$ -message. Thus, relying on our induction hypothesis, we have that:

$$(R\theta)(\phi_S\lambda)\downarrow = f((R_1\theta)(\phi_S\lambda)\downarrow, \dots, (R_k\theta)(\phi_S\lambda)\downarrow) = f((R_1\phi_S\downarrow)\lambda, \dots, (R_k\phi_S\downarrow)\lambda)\downarrow$$

However, we have that  $R\phi_S\downarrow\lambda = f(R_1\phi_S\downarrow\lambda, \dots, R_k\phi_S\downarrow\lambda)\downarrow = f(R_1\phi_S\downarrow, \dots, R_k\phi_S\downarrow)\lambda\downarrow$  as  $c\lambda$  is a  $\Sigma_0^-$ -message whenever  $c \in \text{dom}(\lambda)$  and  $c\lambda$  is an atomic  $\Sigma_0^-$ -message when  $c \in \Sigma_{\text{fresh}}^{\text{atom}}$  by Lemma 4.8. So  $R\phi_S\downarrow\lambda = f(R_1\phi_S\downarrow\lambda, \dots, R_k\phi_S\downarrow\lambda)\downarrow = (R\theta)(\phi_S\lambda)\downarrow$ .  $\square$

LEMMA 4.10. Let  $\mathcal{K}_0 = (\mathcal{P}_0; \phi_0; \emptyset; 0)$  be an initial  $\Sigma_0$ -configuration and  $\mathcal{K} = (\mathcal{P}; \phi; \sigma; i)$  be a  $\Sigma_0$ -configuration such that  $\mathcal{K}_0 \xrightarrow{\text{tr}} \mathcal{K}$  for some  $\text{tr}$  w.r.t.  $\Sigma_0$ .

(1) We have that  $\text{Est}(\mathcal{K}\sigma) \subseteq \text{Est}(\mathcal{K}_0\sigma)$ .

(2) Moreover, in case  $\sigma$  is an mgu between pairs of terms occurring in  $\text{Est}(\mathcal{K}_0)$ , then we have that  $\text{Est}(\mathcal{K}\sigma) \subseteq \text{Est}(\mathcal{K}_0)\sigma$ .

PROOF. We prove  $Est(\mathcal{K}\sigma') \subseteq Est(\mathcal{K}_0\sigma')$  for any  $\sigma'$  which coincide on  $\sigma$  on  $dom(\sigma)$  by induction on the execution  $\mathcal{K}_0 \xrightarrow{\text{tr}} \mathcal{K}$ .

*Base case:*  $\text{tr}$  is empty. In such a case, the result is obvious.

*Inductive case:*  $\text{tr} = \text{tr}_0 \cdot \alpha$ . We have that  $\mathcal{K}_0 \xrightarrow{\text{tr}_0} \mathcal{K}_1 \xrightarrow{\alpha} \mathcal{K}$  where  $\mathcal{K}_1 = (\mathcal{P}_1; \phi_1; \sigma_1; i_1)$ , and  $Est(\mathcal{K}_1\sigma'_1) \subseteq Est(\mathcal{K}_0\sigma'_1)$  for any  $\sigma'_1$  which coincide with  $\sigma_1$  on  $dom(\sigma_1)$ . We distinguish three cases depending on  $\alpha$ :

- In case  $\alpha$  is either a  $\tau$  action or a phase  $i$  action, then  $\sigma = \sigma_1$  and  $St(\mathcal{K}) = St(\mathcal{K}_1)$ . Therefore, let  $\sigma'$  be a substitution which coincides with  $\sigma = \sigma_1$  on  $dom(\sigma)$ , we have that  $Est(\mathcal{K}\sigma') = Est(\mathcal{K}_1\sigma') \subseteq Est(\mathcal{K}_0\sigma')$ .
- In case  $\alpha$  is an input, then  $\mathcal{P}_1 = \text{in}(c, u).P \uplus \mathcal{P}'_1$  and  $\mathcal{P} = P \uplus \mathcal{P}'_1$  so  $St(\mathcal{P}) \subseteq St(\mathcal{P}_1)$ . Moreover,  $\sigma = \sigma_1 \uplus \tau$  and  $dom(\tau) = \text{vars}(u\sigma_1)$ . Hence, we have that  $Est(\tau) \subseteq Est(u\sigma_1\tau) = Est(u\sigma)$ . We also have  $\phi = \phi_1$ , and thus  $Est(\phi) = Est(\phi_1)$ . Therefore, Let  $\sigma'$  be a substitution which coincides with  $\sigma$  on  $dom(\sigma)$ . We have that  $Est(\mathcal{K}\sigma') \subseteq Est(\mathcal{K}_1\sigma')$ . Note that  $\sigma'$  coincides with  $\sigma_1$  on  $dom(\sigma_1)$ , thus thanks to our induction hypothesis, we know that  $Est(\mathcal{K}_1\sigma') \subseteq Est(\mathcal{K}_0\sigma')$ .
- In case  $\alpha$  is an output, then  $\phi = \phi_1 \uplus \{w \triangleright u\sigma_1\}$  for some  $u \in St(\mathcal{K}_1)$  and  $\sigma = \sigma_1$ . Hence we have that  $Est(\phi) \subseteq Est(\mathcal{K}_1\sigma_1)$ . Let  $\sigma'$  be a substitution which coincides with  $\sigma = \sigma_1$  on  $dom(\sigma)$ , we have that  $Est(\mathcal{K}\sigma') \subseteq Est(\mathcal{K}_1\sigma') \subseteq Est(\mathcal{K}_0\sigma')$ .

This concludes the proof for the first item.

To prove item 2, we consider  $\sigma$  the mgu between pairs of terms occurring in  $Est(\mathcal{K}_0)$ , and we show that  $Est(\mathcal{K}_0\sigma) \subseteq Est(\mathcal{K}_0)\sigma$ . Note that this inclusion together with item 1 allows us to conclude. Let  $t \in Est(\mathcal{K}_0\sigma)$  be such that  $t \notin Est(\mathcal{K}_0)\sigma$ . Therefore, we have that  $t \in Est(\text{img}(\sigma))$ . Let  $\bar{\sigma} = \sigma\delta$  where  $\delta$  replaces any occurrence of  $t$  in  $\text{img}(\sigma)$  by a fresh variable  $x$ . We have that:

- $u\bar{\sigma} = v\bar{\sigma}$  for any  $u = v \in \Gamma$ . Indeed, we know that  $u\sigma = v\sigma$ , and thus  $(u\sigma)\delta = (v\sigma)\delta$ . Since  $t \notin Est(\mathcal{K}_0)\sigma$ , and  $u, v \in Est(\mathcal{K}_0)$ , we deduce that  $(u\sigma)\delta = u(\sigma\delta) = u\bar{\sigma}$  and similarly  $(v\sigma)\delta = v(\sigma\delta) = v\bar{\sigma}$ .
- $\bar{\sigma}$  is strictly more general than  $\sigma$ . Indeed, we have that  $\sigma = \bar{\sigma}\tau$  considering  $\tau = \{x \mapsto t\}$  and  $t$  is an encrypted term, and thus not a variable.

This leads to a contradiction since  $\sigma = \text{mgu}(\Gamma)$  and concludes the proof.  $\square$

PROPOSITION 4.11. *Let  $\mathcal{K}_P = (\mathcal{P}_0; \phi_0; \emptyset; i_0)$  be an initial  $\Sigma_0^-$ -configuration, and  $(\text{tr}, \phi) \in \text{traces}_{\Sigma_0^-}(\mathcal{K}_P)$  with underlying substitution  $\sigma$ . Then, there exists  $(\text{tr}_S, \phi_S) \in \text{traces}_{\Sigma_0^+}(\mathcal{K}_P)$  with underlying substitution  $\sigma_S$  with  $dom(\sigma_S) = dom(\sigma)$  such that  $\sigma_S = \text{mgu}(\Gamma)\rho$ , as well as two substitutions  $\lambda$  and  $\theta$  such that:*

- $\Gamma = \{(u, v) \mid u, v \in Est(\mathcal{K}_P) \text{ such that } u\sigma = v\sigma\}$ .
- $\rho$  is a bijective renaming from variables in  $dom(\sigma) \setminus dom(\text{mgu}(\Gamma))$  to constants in  $\Sigma_{\text{fresh}}$  such that  $x\rho \in \Sigma_{\text{fresh}}^{\text{atom}}$  if, and only if,  $x\sigma$  is an atomic  $\Sigma_0^-$ -message.
- $dom(\theta) \subseteq \Sigma_{\text{fresh}}$ , for any  $c \in \Sigma_{\text{fresh}}$  occurring in  $\text{tr}_S$ , we have that  $c \in dom(\theta)$ ,  $c\theta \in \mathcal{T}(\Sigma, \Sigma_0^- \uplus dom(\phi_S))$ , and  $w' < c$  for any  $w' \in \text{vars}(c\theta)$  (where  $<$  is the ordering induced by  $\text{tr}_S$ ).
- for any  $c \in dom(\theta)$ ,  $(c\theta)\phi_S \downarrow$  is a  $\Sigma_0^+$ -message and it is an atom when  $c \in \Sigma_{\text{fresh}}^{\text{atom}}$ .
- $\lambda$  is the first-order substitution associated to  $\theta$  through  $\phi_S$ .
- $\phi = \phi_S\lambda$ ,  $\sigma = \sigma_S\lambda$ , and  $(\text{tr}_S\theta)\phi \downarrow = \text{tr}\phi \downarrow$ .

PROOF. We know that  $\mathcal{K}_P \xrightarrow{\text{tr}} (\mathcal{P}; \phi; \sigma; i)$ . Let  $\Gamma = \{(u, v) \mid u, v \in Est(\mathcal{K}_P) \text{ such that } u\sigma = v\sigma\}$ , and  $\rho$  be a bijective renaming from variables in  $dom(\sigma) \setminus dom(\text{mgu}(\Gamma))$  to constants in  $\Sigma_{\text{fresh}}$  such that  $x\rho \in \Sigma_{\text{fresh}}^{\text{atom}}$  if, and only if,  $x\sigma$  is an atomic  $\Sigma_0^-$ -message. Let  $\sigma_S$  be such that  $dom(\sigma_S) = dom(\sigma)$

and  $\sigma_S = \text{mgu}(\Gamma)\rho$ . As  $\text{mgu}(\Gamma)$  is more general than  $\sigma$ , we have  $\sigma = \text{mgu}(\Gamma)\lambda_0$  for some  $\lambda_0$ . Let  $\lambda = \rho^{-1}\lambda_0$ . We have that  $\sigma = \sigma_S\lambda$ .

We show by induction on the length of a prefix  $\mathcal{K}_P \xrightarrow{\text{tr}^+} (\mathcal{P}^+; \phi^+; \sigma^+; i^+)$  of this execution trace that there exists  $(\text{tr}_S^+, \phi_S^+) \in \text{trace}_{\Sigma_0^+}(\mathcal{K}_P)$  with underlying substitution  $\sigma_S^+ = \sigma_S|_{\text{dom}(\sigma^+)}$ , as well as two substitutions  $\theta^+$  and  $\lambda^+$  such that:

- $\text{dom}(\theta^+) \subseteq \Sigma_{\text{fresh}}$ , for any  $c \in \Sigma_{\text{fresh}}$  occurring in  $\text{tr}_S^+$ , we have that  $c \in \text{dom}(\theta^+)$ ,  $c\theta^+ \in \mathcal{T}(\Sigma, \Sigma_0^- \uplus \text{dom}(\phi_S^+))$ , and  $w' <^+ c$  for any  $w' \in \text{vars}(c\theta^+)$  (where  $<^+$  is the ordering induced by  $\text{tr}_S^+$ ).
- for any  $c \in \text{dom}(\theta^+)$ ,  $(c\theta^+)\phi_S^+\downarrow$  is a  $\Sigma_0^+$ -message and it is an atom when  $c \in \Sigma_{\text{fresh}}^{\text{atom}}$ .
- $\lambda^+$  is the first-order substitution associated to  $\theta^+$  through  $\phi_S^+$ .
- $\phi^+ = \phi_S^+\lambda^+$ ,  $\sigma^+ = \sigma_S^+\lambda^+$ , and  $(\text{tr}_S^+\theta^+)\phi^+\downarrow = \text{tr}^+\phi^+\downarrow$ .

*Base case:*  $\text{tr}^+$  is empty. In such a case, we have that  $\text{dom}(\sigma^+) = \emptyset$ , and  $\phi^+ = \phi_0$ . Let  $\text{tr}_S^+ = \epsilon$ ,  $\phi_S^+ = \phi_0$ , and  $\sigma_S^+ = \emptyset$ . Choosing  $\theta^+$  and  $\lambda^+$  such that  $\text{dom}(\theta^+) = \text{dom}(\lambda^+) = \emptyset$ , the result trivially holds.

*Inductive case:*  $\text{tr}^+ = \text{tr}^-.\alpha$ . In such a case, we have that:

$$\mathcal{K}_P = (\mathcal{P}_0; \phi_0; \emptyset; i_0) \xrightarrow{\text{tr}^-} (\mathcal{P}^-; \phi^-; \sigma^-; i^-) \xrightarrow{\alpha} (\mathcal{P}^+; \phi^+; \sigma^+; i^+).$$

Thanks to our induction hypothesis applied on  $\text{tr}^-$ , we know that there exists  $(\text{tr}_S^-, \phi_S^-) \in \text{trace}_{\Sigma_0^+}(\mathcal{K}_P)$  with underlying substitution  $\sigma_S^- = \sigma_S|_{\text{dom}(\sigma^-)}$ , as well as two substitutions  $\theta^-$  and  $\lambda^-$  such that:

- $\text{dom}(\theta^-) \subseteq \Sigma_{\text{fresh}}$ , for any  $c \in \Sigma_{\text{fresh}}$  occurring in  $\text{tr}_S^-$  we have that  $c \in \text{dom}(\theta^-)$ ,  $c\theta^- \in \mathcal{T}(\Sigma, \Sigma_0^- \uplus \text{dom}(\phi_S^-))$ , and  $w' <^- c$  for any  $w' \in \text{vars}(c\theta^-)$  (where  $<^-$  is the ordering induced by  $\text{tr}_S^-$ ).
- for any  $c \in \text{dom}(\theta^-)$ ,  $(c\theta^-)\phi_S^-\downarrow$  is a  $\Sigma_0^+$ -message and it is an atom when  $c \in \Sigma_{\text{fresh}}^{\text{atom}}$ .
- $\lambda^-$  is the first-order substitution associated to  $\theta^-$  through  $\phi_S^-$ .
- $\phi^- = \phi_S^-\lambda^-$ ,  $\sigma^- = \sigma_S^-\lambda^-$ , and  $(\text{tr}_S^-\theta^-)\phi^-\downarrow = \text{tr}^-\phi^-\downarrow$ .

Let  $c \in \Sigma_{\text{fresh}}$  and  $w \in \text{dom}(\phi_S^-)$  such that  $c$  occurs in  $w\phi_S^-$ . Then, as  $c$  does not occur in the  $\Sigma_0^-$ -configuration  $\mathcal{K}_P$ ,  $c$  must have been introduced in an input before the output of  $w$ . So  $c <^- w$ . Let  $w' \in \text{vars}(c\theta^-)$ . Then  $w' <^- c$  by definition of  $<^-$ . So  $w' <^- w$  and the order induced by  $<^-$  on  $\text{dom}(\phi_S^-)$  satisfies the condition of Lemma 4.8 and Lemma 4.9. We distinguish three cases depending on  $\alpha$ .

Case where  $\alpha = \text{phase } j \text{ for some integer } j$ . In such a case, we have that  $\mathcal{P}^+ = \mathcal{P}^-$ ,  $\phi^+ = \phi^-$ ,  $\sigma^+ = \sigma^-$ , and  $i^+ = j > i^-$ . Let  $\mathcal{P}_S^+ = \mathcal{P}_S^-$ ,  $\phi_S^+ = \phi_S^-$ ,  $\sigma_S^+ = \sigma_S^-$ , and  $i_S^+ = j$ . Since  $i_S^- = i^- < j$ , we have that:

$$(\mathcal{P}_S^-; \phi_S^-; \sigma_S^-; i_S^-) \xrightarrow{\text{phase } j} (\mathcal{P}_S^+; \phi_S^+; \sigma_S^+; j) = (\mathcal{P}_S^+; \phi_S^+; \sigma_S^+; i_S^+).$$

Considering  $\theta^+ = \theta^-$ ,  $\lambda^+ = \lambda^-$ , and  $<^+ = <^-$ , it is easy to show that all our requirements are satisfied.

Case where  $\alpha = \text{out}(c, w_0)$ . In such a case, we have that  $\mathcal{P}^- = \{\text{out}(c, u).P_c\} \uplus \mathcal{Q}$  for some  $u$ ,  $P_c$ , and  $\mathcal{Q}$ ,  $\mathcal{P}^+ = \{P_c\} \uplus \mathcal{Q}$ ,  $\phi^+ = \phi^- \uplus \{w_0 \triangleright u\sigma^-\}$ ,  $\sigma^+ = \sigma^-$ , and  $i^+ = i^-$ . Let  $\mathcal{P}_S^+ = \{P_c\} \uplus \mathcal{Q}$ ,  $\phi_S^+ = \phi_S^- \uplus \{w_0 \triangleright u\sigma_S^-\}$ ,  $\sigma_S^+ = \sigma_S^-$ , and  $i_S^+ = i_S^-$ . We define  $\theta^+ = \theta^-$  and  $\lambda^+ = \lambda^-$ .

First, we need to show that  $u\sigma_S^-$  is a  $\Sigma_0^+$ -message. Thanks to our induction hypothesis, we know that  $u\sigma^- = u\sigma_S^-\lambda^-$ , and by hypothesis we have that  $u\sigma^-$  is a  $\Sigma_0^-$ -message. Thus, in order to conclude, we only have to show that  $c\lambda^- \in \Sigma_0^-$  implies that  $c \in \Sigma_{\text{fresh}}^{\text{atom}}$  for any  $c \in \Sigma_{\text{fresh}}$  occurring in  $u\sigma_S^-$ . Let  $c \in \Sigma_{\text{fresh}}^{\text{atom}}$  occurring in  $u\sigma_S^-$ . Since  $u\sigma^- = u\sigma_S^-\lambda^-$ , we know that  $c \in \text{dom}(\lambda^-)$ . Assume that  $c\lambda^- \in \Sigma_0^-$  and let  $x \in \text{dom}(\sigma) \setminus \text{dom}(\text{mgu}(\Gamma))$  be the unique variable such that  $\rho(x) = c$ . We have that  $x\text{mgu}(\Gamma) = x$ , thus we deduce that  $c\lambda^- = ((x\text{mgu}(\Gamma))\rho)\lambda^- = x\sigma_S^-\lambda^- = x\sigma^-$ . Hence, we have that  $x\sigma^- \in \Sigma_0^-$ , and thus  $\rho(x) = c \in \Sigma_{\text{fresh}}^{\text{atom}}$  by definition of the renaming  $\rho$ .

Therefore, we have shown that  $u\sigma^-$  is a  $\Sigma_0^+$ -message, and thus we have that:

$$(\mathcal{P}_S^-; \phi_S^-; \sigma_S^-; i_S^-) \xrightarrow{\text{out}(c, w_0)} (\mathcal{P}_S^+; \phi_S^- \uplus \{w \triangleright u\sigma_S^-\}; \sigma_S^-; i_S^-) = (\mathcal{P}_S^+; \phi_S^+; \sigma_S^+; i_S^+).$$

Considering  $\theta^+ = \theta^-$ ,  $\lambda^+ = \lambda^-$ , and  $<^+$  the extension of  $<^-$  with  $u <^+ w_0$  for any  $u \in \mathcal{W} \uplus \Sigma_{\text{fresh}}$  occurring in  $\text{tr}_S^-$  or in  $\text{dom}(\phi_0)$ , it is easy to show that all our requirements are satisfied.

*Case where  $\alpha = \text{in}(c, R)$ .* We have that  $\mathcal{P}^- = \{\text{in}(c, u).P_c\} \cup \mathcal{Q}$  for some  $u \in \mathcal{T}_0(\Sigma_c, \Sigma_0^- \uplus \mathcal{N})$  and  $R\phi^- \downarrow = (u\sigma^-)\tau$  for some  $\tau$  with  $\text{dom}(\tau) = \text{vars}(u\sigma^-)$ . Moreover, we have that  $\sigma^+ = \sigma^- \uplus \tau$ ,  $(u\sigma^-)\tau = u\sigma^+$ ,  $\phi^+ = \phi^-$ , and  $\mathcal{P}^+ = \{P_c\} \cup \mathcal{Q}$ . We consider  $R_S$  minimal w.r.t.  $\mu_{\phi_S^-}$  such that  $(R_S\theta^-)\phi^- \downarrow = (u\sigma^-)\tau = u\sigma^+$ . Note that such a  $R_S$  exists since  $R_S = R$  is actually a candidate (but not necessary a minimal one). We can assume w.l.o.g. that  $R_S$  only use constants from  $\Sigma_{\text{fresh}}$  that have been introduced by  $\text{tr}_S^-$ , and thus that are in  $\text{dom}(\theta^-)$ .

**Step 1:** We prove that  $R_S\phi_S^- \downarrow$  is a  $\Sigma_0^+$ -message. Assume that  $R_S\phi_S^- \downarrow$  is not a  $\Sigma_0^+$ -message. We take the smallest subterm  $R'$  of  $R_S$  such that  $R'\phi_S^- \downarrow$  is not a  $\Sigma_0^+$ -message. Let  $p$  be such that  $R_S|_p = R'$ . As  $R'\phi_S^- \downarrow$  is not a  $\Sigma_0^+$ -message, we know that  $R' \notin \Sigma_0^+ \uplus \text{dom}(\phi_S^-)$ . Thus, we have that  $R' = f(R_1, \dots, R_k)$  for some  $f \in \Sigma$ . Moreover, by minimality of  $R'$ , we know that  $R_i\phi_S^- \downarrow$  is a  $\Sigma_0^+$ -message for  $1 \leq i \leq k$ . We now establish the following claim:

*Claim.* If  $R_i\phi_S^- \downarrow \in \Sigma_{\text{fresh}}$  for some  $i \in \{1, \dots, k\}$ , then  $R_S$  is not minimal.

*Proof.* Assume  $R_i\phi_S^- \downarrow = c \in \Sigma_{\text{fresh}}$  for some  $i \in \{1, \dots, k\}$ . Note that this implies that  $c$  occurs in  $\phi_S^-$ , and thus  $c$  occurs in  $\text{tr}_S$ , and therefore  $c \in \text{dom}(\theta^-)$ . We consider  $R'_i = c\theta^-$ . Thanks to Lemma 4.9, we have that  $(R_i\theta^-)\phi^- \downarrow = R_i\phi_S^- \downarrow \lambda^-$ . We have that  $R_i\phi_S^- \downarrow \lambda^- = c\lambda^- = (c\theta^-)(\phi_S^- \lambda^-) \downarrow$  since  $\lambda^-$  is the first-order substitution associated to  $\theta^-$  through  $\phi_S^-$ . Thus we have that  $(R_i\theta^-)\phi^- \downarrow = (c\theta^-)\phi^- \downarrow = (R'_i\theta^-)\phi^- \downarrow$ . Let  $\overline{R_S} = R_S[f(R_1, \dots, R'_i, \dots, R_k)]_p$ . We have that  $(\overline{R_S}\theta^-)\phi^- \downarrow = (R_S\theta^-)\phi^- \downarrow$ . We have also that  $\mu_{\phi_S^-}^1(R'_i) < \mu_{\phi_S^-}^1(R_i)$  since  $R'_i\phi_S^- \downarrow = (c\theta^-)\phi_S^- \downarrow$  is a  $\Sigma_0^+$ -message and it is an atom when  $c \in \Sigma_{\text{fresh}}^{\text{atom}}$ , and  $R_i\phi_S^- \downarrow = c$ . Thus, thanks to Lemma 4.6, we deduce that  $\mu_{\phi_S^-}^1(\overline{R_S}) < \mu_{\phi_S^-}^1(R_S)$ . Thus  $R_S$  is not minimal, and this proves the claim.

We now distinguish two cases depending on whether  $f \in \Sigma_c$  or  $f \in \Sigma_d$ .

*Case where  $f \in \Sigma_c$ .*  $R'\phi_S^- \downarrow$  is either not well-shaped or not well-sorted as it is not a  $\Sigma_0^+$ -message. If it is not well-sorted, then for one of its subrecipes  $R_i$ ,  $R_i\phi_S^- \downarrow$  is not an atom (it is well-sorted by minimality of  $R'$ ) while it should be. In particular,  $(R_i\theta^-)\phi^- \downarrow = R_i\phi_S^- \downarrow \lambda^-$  is an atom. So  $R_i\phi_S^- \downarrow$  must be in  $\Sigma_{\text{fresh}}$ , which will contradict the minimality of  $R_S$  thanks to our claim. We deduce that  $R'\phi_S^- \downarrow$  is well-sorted.

Now, we assume that  $R'\phi_S^- \downarrow$  is not well-shaped, we consider the shape of  $f$ ,  $sh_f = f(s_1, \dots, s_k)$  for some  $s_1, \dots, s_k$ . As  $R'\phi_S^- \downarrow$  has a bad shape and is a  $f$ -term, there must be a  $j$  such that  $R_j\phi_S^- \downarrow$  is not an instance of  $s_j$ . In particular,  $s_j$  is not a variable and we have that  $s_j = sh_g$  for some function symbol  $g$  (thanks to the compatibility of the shapes). We know that  $R_j\phi_S^- \downarrow$  is a  $\Sigma_0^+$ -message and thus we have that  $(R_j\theta^-)\phi^- \downarrow = (R_j\phi_S^- \downarrow)\lambda^-$  (thanks to Lemma 4.9) is an instance of  $s_j$  as  $(R\theta^-)\phi^- \downarrow$  is a  $\Sigma_0^-$ -message. Relying on our claim, we know that  $R_j\phi_S^- \downarrow \notin \Sigma_{\text{fresh}}$ , thus  $R_j\phi_S^- \downarrow$  is a  $g$ -term, and since we know that  $R_j\phi_S^- \downarrow$  is a  $\Sigma_0^+$ -message, we know that it is an instance of  $s_j$ , yielding to a contradiction.

*Case where  $f = \text{des} \in \Sigma_d$ .* In such a case, we have that  $R' = \text{des}(R_1, \dots, R_k)$ . Let  $\ell_{\text{des}} = \text{des}(t_1, t_2, \dots, t_k)$ . We distinguish two subcases.

First, we assume that there is some  $i \in \{1, \dots, k\}$  such that  $R_i\phi_S^- \downarrow$  does not unify with  $t_i$ . As  $R_i\phi_S^- \downarrow$  is a  $\Sigma_0^+$ -message, it has a good shape. Thus, the only way to not unify with the linear term  $t_i$

whereas  $R_i\phi_S^-\downarrow\lambda^- = (R_i\theta^-)\phi^-\downarrow$  (thanks to Lemma 4.9) does, is when  $R_i\phi_S^-\downarrow = c$  for some  $c \in \Sigma_{\text{fresh}}$ . Relying on our claim, we obtain a contradiction.

Second, we assume that  $R_i\phi_S^-\downarrow$  unifies with  $t_i$  for each  $i \in \{1, \dots, k\}$ . In such a case, we know that  $\ell_{\text{des}} = \text{des}(t_1, t_2, \dots, t_k)$  is a non-linear term and we denote  $x$  the non linear variable occurring in  $\ell_{\text{des}}$ . Let  $I_0 = \{1 \leq i \leq k \mid x \text{ occurs in } t_i\}$ . We know that  $1 \in I_0$ . For any  $i \in I_0$ , we denote  $p_i$  the position in  $t_i$  such that  $t_i|_{p_i} = x$ .

Since  $R'\phi_S^-\downarrow\lambda^-$  is a  $\Sigma_0^-$ -message, we know that  $t = \text{des}(R_1\phi_S^-\downarrow\lambda^-, \dots, R_k\phi_S^-\downarrow\lambda^-)$  unifies with  $\text{des}(t_1, \dots, t_k)$ . Therefore, we know that there exists an atomic  $\Sigma_0^-$ -message  $a$  such that  $t|_{i.p_i} = a$  for any  $i \in I_0$ . We know that  $R'\phi_S^-\downarrow$  is not a  $\Sigma_0^+$ -message whereas  $R_i\phi_S^-\downarrow$  are  $\Sigma_0^+$ -message. Thus, we have that  $t_S = \text{des}(R_1\phi_S^-\downarrow, \dots, R_k\phi_S^-\downarrow)$  does not unify with  $\text{des}(t_1, \dots, t_k)$ . We deduce that for any  $i \in I_0$ , we have that either  $t_S|_{i.p_i} = a$ , or  $t_S|_{i.p_i} = c$  for some  $c \in \Sigma_{\text{fresh}}$  such that  $c\lambda^- = a$ . We distinguish two cases depending on whether  $R_1\phi_S^-\downarrow|_{p_1} = c'$  for some  $c' \in \Sigma_{\text{fresh}}$  or not.

First, we assume that  $R_1\phi_S^-\downarrow|_{p_1} = c'$  for some  $c' \in \Sigma_{\text{fresh}}$ . Let  $\nu_{\text{des}}$  be the substitution such that  $x\nu_{\text{des}} = c'$  and  $y\nu_{\text{des}} = c_{\text{min}}$  for any other variable  $y \in \text{vars}(\ell_{\text{des}})$ . Let  $\overline{R'} = \text{des}(R_1, t_2\nu_{\text{des}}, \dots, t_k\nu_{\text{des}})$ . Actually, we have that  $\overline{R'}\phi_S^-\downarrow$  is a  $\Sigma_0^+$ -message, and thanks to Lemma 4.9, we know that  $(\overline{R'}\theta^-)\phi^-\downarrow = \overline{R'}\phi_S^-\downarrow\lambda^-$ . Since  $\overline{R'}\phi_S^-\downarrow$  is a  $\Sigma_0^+$ -message, we have that  $\mu_{\phi_S^-}^1(\overline{R'}) < \{\text{des}\}$ , and thus  $\mu_{\phi_S^-}^1(\overline{R'}) < \mu_{\phi_S^-}^1(R')$ . We also deduce that  $(\overline{R'}\theta^-)\phi^-\downarrow$  is a  $\Sigma_0^-$ -message, and we have that  $(\overline{R'}\theta^-)\phi^-\downarrow = (R'\theta^-)\phi^-\downarrow$  since the  $\Sigma_0^+$ -recipies  $\overline{R'}$  and  $R'$  coincide on their first argument.

Second, we assume that  $R_1\phi_S^-\downarrow|_{p_1} \notin \Sigma_{\text{fresh}}$ , i.e.  $R_1\phi_S^-\downarrow|_{p_1} = a$ . We know that there exists  $i_0 \in I_0$  such that  $R_{i_0}\phi_S^-\downarrow|_{p_{i_0}} = c'$  for some  $c' \in \Sigma_{\text{fresh}}$  (otherwise  $t_S$  will reduce), and we have that  $c'\lambda^- = a$ . Let  $\nu_{\text{des}}$  be the substitution such that  $x\nu_{\text{des}} = c'\theta^-$  and  $y\nu_{\text{des}} = c_{\text{min}}$  for any other variable  $y \in \text{vars}(\ell_{\text{des}})$ . Let  $\overline{R'} = \text{des}(R_1, t_2\nu_{\text{des}}, \dots, t_k\nu_{\text{des}})$ . As  $\mu_{\phi_S^-}^1(c'\theta^-) < \mu_{\phi_S^-}^1(c')$ , we have that  $\mu_{\phi_S^-}^1(R_1) \uplus \mu_{\phi_S^-}^1(t_2\nu_{\text{des}}) \uplus \dots \uplus \mu_{\phi_S^-}^1(t_k\nu_{\text{des}}) < \mu_{\phi_S^-}^1(R_1) \uplus \dots \uplus \mu_{\phi_S^-}^1(R_k)$ . Therefore, relying on Lemma B.3, we deduce that:

$$\begin{aligned} \mu_{\phi_S^-}^1(\overline{R'}) &= \text{Multi}(\overline{R'}\phi_S^-\downarrow) \\ &\leq \text{Multi}(\text{des}(R_1\phi_S^-\downarrow, t_2\nu_{\text{des}}\phi_S^-\downarrow, \dots, t_k\nu_{\text{des}}\phi_S^-\downarrow)) \\ &= \{\text{des}\} \uplus \mu_{\phi_S^-}^1(R_1) \uplus \mu_{\phi_S^-}^1(t_2\nu_{\text{des}}) \uplus \dots \uplus \mu_{\phi_S^-}^1(t_k\nu_{\text{des}}) \\ &< \{\text{des}\} \uplus \mu_{\phi_S^-}^1(R_1) \uplus \dots \uplus \mu_{\phi_S^-}^1(R_k) \\ &= \mu_{\phi_S^-}^1(R') \end{aligned}$$

Since  $R_1\phi_S^-\downarrow$  is a  $\Sigma_0^+$ -message, we have that  $\text{des}((R_1\theta^-)\phi^-\downarrow, ((t_2\nu_{\text{des}})\theta^-)\phi^-\downarrow, \dots, ((t_k\nu_{\text{des}})\theta^-)\phi^-\downarrow) = \text{des}((R_1\phi_S^-\downarrow)\lambda^-, ((t_2\nu_{\text{des}})\theta^-)\phi^-\downarrow, \dots, ((t_k\nu_{\text{des}})\theta^-)\phi^-\downarrow)$ . Such a term unifies with  $\ell_{\text{des}}$  since we have that  $R_1\phi_S^-\downarrow\lambda^-|_{p_1} = R_1\phi_S^-\downarrow|_{p_1}\lambda^- = a\lambda^- = a$ , and for any  $i \in I_0$ , we have that:

$$((t_i\nu_{\text{des}})\theta^-)\phi^-\downarrow|_{p_i} = (t_i\nu_{\text{des}})\phi^-\downarrow|_{p_i} = ((t_i\nu_{\text{des}})|_{p_i})\phi^-\downarrow = (c'\theta^-)\phi^-\downarrow = c'\lambda^- = a.$$

Thus, we have that  $(\overline{R'}\theta^-)\phi^-\downarrow$  is a  $\Sigma_0^-$ -message, and we have that  $(\overline{R'}\theta^-)\phi^-\downarrow = (R'\theta^-)\phi^-\downarrow$  since the  $\Sigma_0^+$ -recipies  $\overline{R'}$  and  $R'$  coincide on their first argument.

In both cases, we have seen that  $(\overline{R'}\theta^-)\phi^-\downarrow = (R'\theta^-)\phi^-\downarrow$ , and also that  $\mu_{\phi_S^-}^1(\overline{R'}) < \mu_{\phi_S^-}^1(R')$ . Since we know that  $R'\phi_S^-\downarrow$  is not a  $\Sigma_0^+$ -message, Lemma 4.6 applies, we obtain that  $\mu_{\phi_S^-}^1(R_S[\overline{R'}]_p) < \mu_{\phi_S^-}^1(R_S[R']_p) = \mu_{\phi_S^-}^1(R_S)$ , and this contradicts the minimality of  $R_S$ .

**Step 2:** We now prove that  $R_S$  is a simple  $\Sigma_0^+$ -recipe, in normal form w.r.t.  $\downarrow$ , and of the form  $C[R_1, \dots, R_n]$  where for each  $i \in \{1, \dots, n\}$ , we have that  $R_i\phi_S^-\downarrow$  is either an encrypted term, or a name from  $\mathcal{N}$ , or a constant from  $\Sigma_0^+$ .

Assume  $R_S$  is *not* in normal form w.r.t.  $\downarrow$ . By Lemma 4.7, we know that  $\mu_{\phi_S^-}^1(R_S \downarrow) < \mu_{\phi_S^-}^1(R_S)$ . Moreover, as  $R_S \theta^- \twoheadrightarrow^* R_S \downarrow \theta^-$ , Lemma 4.3 applies:  $(R_S \downarrow \theta^-) \phi^- \downarrow = (R_S \theta^-) \phi^- \downarrow$ , and this contradicts the minimality of  $R_S$ . Therefore, we know that  $R_S$  is in normal form w.r.t.  $\downarrow$ , and thus  $R_S$  is a simple  $\Sigma_0^+$ -recipe thanks to Lemma 4.5. Therefore, we have that  $R_S = C[R_1, \dots, R_n]$  where each  $R_i$  is a subterm recipe with  $1 \leq i \leq n$ . If there is  $i_0 \in \{1, \dots, n\}$  such that  $\text{root}(R_{i_0} \phi_S^- \downarrow) = f \in \Sigma_c$  and  $f$  is a transparent function symbol, then  $R_{i_0} \phi_S^- \downarrow = f(C_1^f[R_{i_0}], \dots, C_k^f[R_{i_0}]) \phi_S^- \downarrow$ . We consider the context  $\bar{C}$  such that  $\bar{C}[R_1, \dots, R_n] = C[R_1, \dots, f(C_1^f[R_{i_0}], \dots, C_k^f[R_{i_0}]), \dots, R_n]$ . We have that  $R_S' = \bar{C}[R_1, \dots, R_n]$  is a  $\Sigma_0^+$ -recipe such that  $R_S' \phi_S^- \downarrow = R_S \phi_S^- \downarrow$ , and thus  $\mu_{\phi_S^-}^1(R_S) = \mu_{\phi_S^-}^1(R_S')$ , and  $(R_S' \theta^-) \phi^- \downarrow = R_S' \phi_S^- \downarrow \lambda^-$  by Lemma 4.9, which gives  $(R_S' \theta^-) \phi^- \downarrow = R_S' \phi_S^- \downarrow \lambda^- = R_S \phi_S^- \downarrow \lambda^- = (R_S \theta^-) \phi^- \downarrow$ . We have that  $\mu_{\phi_S^-}^2(R_S') < \mu_{\phi_S^-}^2(R_S)$  so this contradicts the minimality of  $R_S$ . Therefore, we deduce that each  $R_i \phi_S \downarrow$  (with  $1 \leq i \leq n$ ) is either an encrypted term, a constant from  $\Sigma_0^+$ , or a name from  $\mathcal{N}$ .

**Step 3.** Let  $\mathcal{P}_S^+ = \overline{\mathcal{P}}^+$ ,  $\phi_S^+ = \phi_S^-$ ,  $\sigma_S^+ = \sigma_S |_{\text{dom}(\sigma^+)}$ , and  $i_S^+ = i_S^-$ . We are going to show that there exists a  $\Sigma_0^+$ -recipe  $\overline{R}_S$  such that:

$$(\mathcal{P}_S^-; \phi_S^-; \sigma_S^-; i_S^-) \xrightarrow{\text{in}(c, \overline{R}_S)} (\mathcal{P}_S^+; \phi_S^+; \sigma_S^+; i_S^+)$$

as well as two substitutions  $\theta^+$  and  $\lambda^+$  that satisfy all our requirements.

If  $R_S \phi_S^- \downarrow = u \sigma_S^+$ , then let  $\overline{R}_S = R_S$ ,  $\theta^+ = \theta^-$ , and  $\lambda^+ = \lambda^-$ . To conclude, it remains to establish that all our requirements are satisfied. In particular we have to show that (i)  $(\overline{R}_S \theta^+) \phi^+ \downarrow = R \phi^+ \downarrow$ , and (ii)  $\sigma^+ = \sigma_S^+ \lambda^+$ .

(i) We have that  $(\overline{R}_S \theta^+) \phi^+ \downarrow = (R_S \theta^-) \phi^- \downarrow = u \sigma^+ = R \phi^- \downarrow = R \phi^+ \downarrow$ .

(ii) Let  $Z = \text{vars}(u \sigma^-) = \text{dom}(\tau)$ . We have that  $\overline{R}_S \phi_S^- \downarrow = u \sigma_S^+ = u(\sigma_S^- \uplus \sigma_S |_Z)$  is a  $\Sigma_0^+$ -message, and  $(R_S \theta^-) \phi^- \downarrow = R \phi^- \downarrow = u \sigma^+ = u(\sigma^- \uplus \sigma |_Z)$ . By Lemma 4.9, we know that  $\overline{R}_S \phi_S^- \downarrow \lambda^- = (R_S \theta^-) \phi^- \downarrow$ , and thus  $u(\sigma_S^- \lambda^- \uplus \sigma_S |_Z \lambda^-) = u(\sigma^- \uplus \sigma |_Z)$ . This allows us to conclude that  $\sigma_S |_Z \lambda^- = \sigma |_Z$ , and thus we have that:

$$\sigma_S^+ \lambda^+ = (\sigma_S^- \uplus \sigma_S |_Z) \lambda^- = \sigma_S^- \lambda^- \uplus \sigma_S |_Z \lambda^- = \sigma^- \uplus \sigma |_Z = \sigma^- \uplus \tau = \sigma^+.$$

Therefore, from now on, we assume that  $R_S \phi_S^- \downarrow \neq u \sigma_S^+$ . Let  $A$  be the set of fresh constants that occur until this execution step, i.e.  $A = \text{St}(\text{img}(\sigma_S^+)) \cap \Sigma_{\text{fresh}}$ . We define  $\lambda^+ = \lambda |_A$ . As  $\sigma = \sigma_S \lambda$ , we deduce  $\sigma^+ = \sigma_S^+ \lambda^+$ . Since  $R_S \phi_S^- \downarrow$  is a  $\Sigma_0^+$ -message, relying on Lemma 4.9, we deduce that  $R_S \phi_S^- \downarrow \lambda^+ = R_S \phi_S^- \downarrow \lambda^- = (R_S \theta^-) \phi^- \downarrow = R \phi^- \downarrow = u \sigma^+ = (u \sigma_S^+) \lambda^+$ . Let  $t = R_S \phi_S \downarrow$  and  $v = u \sigma_S^+$ . We have that  $t \neq v$  and  $t \lambda^+ = v \lambda^+$ .

Since  $t \neq v$ , we know that there exists a position  $p$  defined in  $t$  and  $v$  such that  $\text{root}(t|_p) \neq \text{root}(v|_p)$ . Let  $p$  be any position defined in  $t$  and  $v$  such that  $\text{root}(t|_p) \neq \text{root}(v|_p)$ . Since  $t \lambda^+ = v \lambda^+$  and  $\text{dom}(\lambda^+) \subseteq \Sigma_{\text{fresh}}$ , we have that  $t|_p \in \Sigma_{\text{fresh}}$  or  $v|_p \in \Sigma_{\text{fresh}}$ .

We first assume that there exists such a position  $p$  that falls outside the context  $C$ . More precisely, we have that  $p = p'.p''$  (with  $p'$  a strict prefix of  $p$ ) and  $C[R_1, \dots, R_n] |_{p'} = R_{i_0}$  for some  $i_0 \in \{1, \dots, n\}$ . Therefore, since  $R_{i_0}$  is a subterm-recipe, we know that  $t|_{p'} = R_{i_0} \phi_S^- \downarrow$  is an encrypted subterm of  $\phi_S^-$ . Relying on Lemma 4.10 and denoting  $\mathcal{K}_S^- = (\mathcal{P}_S^-; \phi_S^-; \sigma_S^-; i_S^-)$ , we have that:

- $t|_{p'} \in \text{ESt}(\phi_S^-) \subseteq \text{ESt}(\mathcal{K}_S^- \sigma_S^-) \subseteq \text{ESt}(\mathcal{K}_P \sigma_S^-) = \text{ESt}(\mathcal{K}_P(\text{mgu}(\Gamma) |_{\text{dom}(\sigma_S^-)})) \subseteq \text{ESt}(\mathcal{K}_P) \sigma_S^-$ .
- $v|_{p'} = u \sigma_S^+ |_{p'} \in \text{ESt}(\mathcal{K}_P \sigma_S^+) \subseteq \text{ESt}(\mathcal{K}_P(\text{mgu}(\Gamma) |_{\text{dom}(\sigma_S^+)})) \subseteq \text{ESt}(\mathcal{K}_P) \sigma_S^+$ .

This allows us to conclude that there exist  $t', v' \in \text{ESt}(\mathcal{K}_0)$  such that  $t' \sigma_S^- = t|_{p'}$ , and  $v' \sigma_S^+ = v|_{p'}$ . Since  $t|_{p'}$  is a  $\Sigma_0^+$ -message, we also know that  $t' \sigma_S^+ = t|_{p'}$ . Since  $t \lambda^+ = v \lambda^+$ , we know that  $t|_{p'} \lambda^+ = v|_{p'} \lambda^+$ , and thus  $(t' \sigma_S^+) \lambda^+ = (v' \sigma_S^+) \lambda^+$ . We have that  $(t' \sigma_S^+) \lambda^+ = t' (\sigma_S^+ \lambda^+)$  and also that  $(v' \sigma_S^+) \lambda^+ = v' (\sigma_S^+ \lambda^+)$ . Since we have that  $\sigma^+ = \sigma_S^+ \lambda^+$ , we deduce that  $t' \sigma^+ = v' \sigma^+$ , and thus

$t'\sigma = v'\sigma$ . By definition of  $\sigma_S$ , we have that  $t'\sigma_S = v'\sigma_S$ . We know that  $t'\sigma_S^- = t|_{p'}$ , and since  $t|_{p'}$  is ground, we deduce that  $t'\sigma_S = t|_{p'}$ . Similarly, we have that  $v'\sigma_S^+ = v|_{p'}$ , and since  $v|_{p'}$  is ground, we deduce that  $v'\sigma_S = v|_{p'}$ . Thus, we have that  $t|_{p'} = v|_{p'}$  leading to a contradiction since we have assumed that  $t$  and  $v$  differ below the position  $p'$ .

Now, we know that for any position  $p$  defined in  $t$  and  $v$  such that  $\text{root}(t|_p) \neq \text{root}(v|_p)$ , we have that  $t|_p$  or  $v|_p$  is in  $\Sigma_{\text{fresh}}$ , and  $p$  is a position of  $C$ . If  $t|_p = c \in \Sigma_{\text{fresh}}$ , let  $R'_S = R_S[c\theta^-]_p$ , we have that  $\mu_{\phi_S^-}^1(R'_S) < \mu_{\phi_S^-}^1(R_S)$  since  $\mu_{\phi_S^-}^1(c\theta^-) < \mu_{\phi_S^-}^1(R_S|_p)$  (note that  $R_S|_p\phi_S^- \downarrow = c$  whereas  $(c\theta^-)\phi_S^- \downarrow$  is a  $\Sigma_0^+$ -message and it is an atom when  $c \in \Sigma_{\text{fresh}}^{\text{atom}}$ ). Moreover, we have that  $(R'_S\theta^-)\phi^- \downarrow = (R_S\theta^-)\phi^- \downarrow$ . This will contradict the minimality of  $R_S$ . Therefore, we have that  $t|_p \notin \Sigma_{\text{fresh}}$ , and thus  $v|_p = c$  for some  $c \in \Sigma_{\text{fresh}}$ .

Let  $p_1, \dots, p_m$  be the positions such that for each  $i \in \{1, \dots, m\}$ , we have that  $p_i$  is defined in both  $t$  and  $v$ , and  $\text{root}(t|_{p_i}) \neq \text{root}(v|_{p_i})$ . For each  $i \in \{1, \dots, m\}$ , we know that  $p_i$  is a position of  $C$  such that  $t|_{p_i} \notin \Sigma_{\text{fresh}}$ , and  $v|_{p_i} \in \Sigma_{\text{fresh}}$ . We denote  $c_{\text{fresh}}^i$  the constant from  $\Sigma_{\text{fresh}}$  such that  $v|_{p_i} = c_{\text{fresh}}^i$ . Note that it may happen that  $c_{\text{fresh}}^i = c_{\text{fresh}}^j$  for some  $i \neq j$ . Let  $\bar{C}$  be the context obtained from  $C$  by putting  $c_{\text{fresh}}^1$  at position  $p_1$ ,  $c_{\text{fresh}}^2$  at position  $p_2$ , ... Let  $\bar{R}_S = \bar{C}[R_1, \dots, R_n]$ . We have that  $\bar{R}_S\phi_S^- \downarrow = u\sigma_S^+$  by construction. Let  $R_{p_i} = (C[R_1, \dots, R_n]|_{p_i})\theta^-$  for each  $i \in \{1, \dots, m\}$ . Thanks to Lemma 4.9, we have that  $R_{p_i}\phi^- \downarrow = R_{p_i}\phi_S^- \downarrow \lambda^-$  for each  $i \in \{1, \dots, m\}$ . As for each  $i \in \{1, \dots, m\}$ , we have that  $R_{p_i}\phi_S^- \downarrow \lambda^- = u\sigma_S^+ \lambda^+|_{p_i}$ , we get that  $R_{p_i}\phi_S^- \downarrow \lambda^- = c_{\text{fresh}}^i \lambda^+$  for each  $i \in \{1, \dots, m\}$ . Note that in case  $c_{\text{fresh}}^i = c_{\text{fresh}}^j$ , we have that  $R_{p_i}\phi^- \downarrow = R_{p_j}\phi^- \downarrow$ . Let  $\theta^+ = \theta^- \uplus \{c_{\text{fresh}}^i \mapsto R_{p_i} \mid c_{\text{fresh}}^i \notin \text{dom}(\theta^-)\}$ . In case we have that  $c_{\text{fresh}}^i = c_{\text{fresh}}^j$  for some  $i \neq j$ , we choose arbitrarily between  $R_{p_i}$  and  $R_{p_j}$ .

Now, it remains to establish that all our requirements are satisfied. In particular, we have to show that:

- (i)  $\sigma_S^+ = \sigma_S^- \uplus \tau_S$  for some  $\tau_S$  such that  $\text{dom}(\tau_S) = \text{vars}(u\sigma_S^-)$  and  $\bar{R}_S\phi_S^- \downarrow = (u\sigma_S^-)\tau_S$ .
- (ii) for any  $c \in \text{dom}(\theta^+) \setminus \text{dom}(\theta^-)$ ,  $(c\theta^+)\phi_S^- \downarrow$  is a  $\Sigma_0^+$ -message, and it is an atom when  $c \in \Sigma_{\text{fresh}}^{\text{atom}}$ .
- (iii) for any  $c \in \text{dom}(\theta^+) \setminus \text{dom}(\theta^-)$ , we have that  $c\lambda^+ = (c\theta^+)\phi_S^- \downarrow \lambda^-$ .
- (iv)  $(\bar{R}_S\theta^+)\phi^+ \downarrow = R\phi^+ \downarrow$ .

We prove each item one by one.

- (i) Let  $\tau_S = \sigma_S|_{\text{dom}(\tau)}$ . We have that  $\text{dom}(\tau_S) = \text{dom}(\tau) = \text{vars}(u\sigma^-) = \text{vars}(u\sigma_S^-)$ . We have shown that  $\bar{R}_S\phi_S^- \downarrow = u\sigma_S^+$ , and thus  $\bar{R}_S\phi_S^- \downarrow = u(\sigma_S^- \uplus \tau_S) = (u\sigma_S^-)\tau_S$ .
- (ii) Let  $c \in \text{dom}(\theta^+) \setminus \text{dom}(\theta^-)$ . We have that  $c = c_{\text{fresh}}^i$  for some  $i \in \{1, \dots, m\}$ , and  $(c_{\text{fresh}}^i \theta^+)\phi_S^- \downarrow = R_{p_i}\phi_S^- \downarrow$  is a  $\Sigma_0^+$ -message. Assume that  $c_{\text{fresh}}^i \in \Sigma_{\text{fresh}}^{\text{atom}}$ . In such a case, there exists  $x_i \in \text{dom}(\rho)$  such that  $x_i\rho = c_{\text{fresh}}^i$ . As  $x_i\rho$  is atomic, we know that  $x_i\sigma$  is atomic (by definition of  $\rho$ ), and we have that  $x_i\sigma = x_i\sigma_S\lambda$ . Since  $\sigma_S = \text{mgu}(\Gamma)\rho$ , we have that  $x_i\sigma = x_i\text{mgu}(\Gamma)\rho\lambda$ . As  $x_i \in \text{dom}(\rho)$ ,  $x_i \notin \text{dom}(\text{mgu}(\Gamma))$  by definition of  $\rho$ . So  $x_i\sigma = x_i\rho\lambda = c_{\text{fresh}}^i\lambda = c_{\text{fresh}}^i\lambda^+$ . Since we have shown that  $x_i\sigma$  is atomic, we deduce that  $c_{\text{fresh}}^i\lambda^+$  is atomic. Thus, since we have shown that  $R_{p_i}\phi_S^- \downarrow \lambda^- = c_{\text{fresh}}^i\lambda^+$ , we know that  $R_{p_i}\phi_S^- \downarrow \lambda^-$  is atomic which implies that  $R_{p_i}\phi_S^- \downarrow$  is either atomic or a  $c \in \Sigma_{\text{fresh}}$  with  $c \in \text{dom}(\lambda^-)$ . So we can assume  $c \in \Sigma_{\text{fresh}}$  with  $c \in \text{dom}(\lambda^-)$ . There is a  $x \in \text{dom}(\rho)$  such that  $x\rho = c$ . We have  $x\sigma = x\sigma_S\lambda = x\text{mgu}(\Gamma)\rho\lambda$ . As  $x \in \text{dom}(\rho)$ ,  $x \notin \text{dom}(\text{mgu}(\Gamma))$  and  $x\sigma = x\rho\lambda = c\lambda = c\lambda^-$ . As  $x\sigma$  is atomic,  $x\rho$  is atomic (by definition of  $\rho$ ), so  $c$  is atomic, and thus  $R_{p_i}\phi_S^- \downarrow$  is atomic.
- (iii) Let  $c \in \text{dom}(\theta^+) \setminus \text{dom}(\theta^-)$ . We have that  $c = c_{\text{fresh}}^i$  for some  $i \in \{1, \dots, m\}$ , and  $c_{\text{fresh}}^i\lambda^+ = R_{p_i}\phi^- \downarrow = R_{p_i}(\phi_S^- \lambda^-) \downarrow = (c_{\text{fresh}}^i \theta^+)(\phi_S^- \lambda^-) \downarrow$ .
- (iv)  $(\bar{R}_S\theta^+)\phi^+ \downarrow = (R_S\theta^-)\phi^- \downarrow = R\phi^- \downarrow = R\phi^+ \downarrow$ .

This concludes the case where  $\alpha$  is an input, and we get the result.  $\square$

We can conclude with the proof of our main theorem on reachability properties.

**THEOREM 3.8.** *Let  $\mathcal{K}_P$  be a  $\Sigma_0^-$ -configuration type-compliant w.r.t.  $(\mathcal{T}_0, \delta_0)$ . If  $\mathcal{K}_P \xrightarrow{\text{tr}} (\mathcal{P}; \phi; \sigma; i)$  w.r.t.  $\Sigma_0^-$  then there exists a well-typed execution  $\mathcal{K}_P \xrightarrow{\text{tr}'} (\mathcal{P}; \phi'; \sigma'; i)$  w.r.t.  $\Sigma_0^+$  such that  $\overline{\text{tr}'} = \overline{\text{tr}}$ .*

*Conversely, if  $\mathcal{K}_P \xrightarrow{\text{tr}'} (\mathcal{P}; \phi'; \sigma'; i)$  is a well-typed execution w.r.t.  $\Sigma_0^+$ , then there exists  $\mathcal{K}_P \xrightarrow{\text{tr}} (\mathcal{P}; \phi; \sigma; i)$  w.r.t.  $\Sigma_0^-$  such that  $\overline{\text{tr}} = \overline{\text{tr}'}$ .*

**PROOF.** The converse part is Lemma 3.9. Thus, we now prove the direct part. Let  $\mathcal{K}_P$  be a  $\Sigma_0^-$ -configuration type-compliant w.r.t.  $(\mathcal{T}_0, \delta_0)$ . Assume  $\mathcal{K}_P \xrightarrow{\text{tr}} (\mathcal{P}; \phi; \sigma; i)$  w.r.t.  $\Sigma_0^-$ . Thanks to Proposition 4.11, we know that there exists  $(\text{tr}_S, \phi_S) \in \text{trace}_{\Sigma_0^+}(\mathcal{K}_P)$  with underlying substitution  $\sigma_S$  with  $\text{dom}(\sigma_S) = \text{dom}(\sigma)$  such that  $\sigma_S = \text{mgu}(\Gamma)\rho$ , as well as two substitutions  $\lambda$  and  $\theta$  such that:

- $\Gamma = \{(u, v) \mid u, v \in \text{Est}(\mathcal{K}_P) \text{ such that } u\sigma = v\sigma\}$ .
- $\rho$  is a bijective renaming from variables in  $\text{dom}(\sigma) \setminus \text{dom}(\text{mgu}(\Gamma))$  to constants in  $\Sigma_{\text{fresh}}$  such that  $x\rho \in \Sigma_{\text{fresh}}^{\text{atom}}$  if, and only if,  $x\sigma$  is an atomic  $\Sigma_0^-$ -message.
- $\text{dom}(\theta) \subseteq \Sigma_{\text{fresh}}$ , for any  $c \in \Sigma_{\text{fresh}}$  occurring in  $\text{tr}_S$ , we have that  $c \in \text{dom}(\theta)$ ,  $c\theta \in \mathcal{T}(\Sigma, \Sigma_0^- \uplus \text{dom}(\phi_S))$ , and  $w' < c$  for any  $w' \in \text{vars}(c\theta)$  (where  $<$  is the ordering induced by  $\text{tr}_S$ ).
- for any  $c \in \text{dom}(\theta)$ ,  $(c\theta)\phi_S \downarrow$  is a  $\Sigma_0^+$ -message and it is an atom when  $c \in \Sigma_{\text{fresh}}^{\text{atom}}$ .
- $\lambda$  is the first-order substitution associated to  $\theta$  through  $\phi_S$ .
- $\phi = \phi_S\lambda$ ,  $\sigma = \sigma_S\lambda$ , and  $(\text{tr}_S\theta)\phi \downarrow = \text{tr}\phi \downarrow$ .

Since  $(\text{tr}_S\theta)\phi \downarrow = \text{tr}\phi \downarrow$ , we have that  $\overline{\text{tr}_S} = \overline{\text{tr}}$ . Since we have enough constants of each type, we may assume w.l.o.g. that  $\rho$  is well-typed. Since  $\mathcal{K}_P$  is type-compliant, we know that encrypted subterms in  $\text{Est}(\mathcal{K}_P)$  which are unifiable have the same type. Then, by definition of a typing system, this allows us to deduce that  $\text{mgu}(\Gamma)$  is well-typed, and thus  $\sigma_S = \text{mgu}(\Gamma)\rho$  is well-typed. This means that  $(\text{tr}_S, \phi_S)$  is well-typed and concludes the proof.  $\square$

## C PROOF OF SECTION 5

**PROPOSITION 5.4.** *Let  $\mathcal{K}_P$  and  $\mathcal{K}_Q$  be two initial  $\Sigma_0^-$ -configurations such that  $\mathcal{K}_Q$  is action-deterministic, and  $\mathcal{K}_P \not\sqsubseteq_t \mathcal{K}_Q$  w.r.t.  $\Sigma_0^-$ . Let  $(\text{tr}, \phi) \in \text{trace}_{\Sigma_0^-}(\mathcal{K}_P)$  with underlying substitution  $\sigma$  be a witness of non-inclusion of minimal length. Then, there exists  $(\text{tr}_S, \phi_S) \in \text{trace}_{\Sigma_0^+}(\mathcal{K}_P)$  a witness of this non-inclusion with underlying substitution  $\sigma_S$  such that  $\sigma_S = \text{mgu}(\Gamma)\rho$ , as well as two substitutions  $\lambda_P$  and  $\theta$  such that:*

- $\Gamma = \{(u, v) \mid u, v \in \text{Est}(\mathcal{K}_P) \text{ such that } u\sigma = v\sigma\}$ .
- $\rho$  is a bijective renaming from variables in  $\text{dom}(\sigma) \setminus \text{dom}(\text{mgu}(\Gamma))$  to constants in  $\Sigma_{\text{fresh}}$  such that  $x\rho \in \Sigma_{\text{fresh}}^{\text{atom}}$  if, and only if,  $x\sigma$  is an atomic  $\Sigma_0^-$ -message.
- $\text{dom}(\theta) \subseteq \Sigma_{\text{fresh}}$ , for any  $c \in \Sigma_{\text{fresh}}$  occurring in  $\text{tr}_S$ , we have that  $c \in \text{dom}(\theta)$ ,  $c\theta \in \mathcal{T}(\Sigma, \Sigma_0^- \uplus \text{dom}(\phi_S))$ , and  $w' < c$  for any  $w' \in \text{vars}(c\theta)$  (where  $<$  is the ordering induced by  $\text{tr}_S$ ).
- for any  $c \in \text{dom}(\theta)$ ,  $(c\theta)\phi_S \downarrow$  is a  $\Sigma_0^+$ -message and it is an atom when  $c \in \Sigma_{\text{fresh}}^{\text{atom}}$ .
- $\lambda_P$  is the first-order substitution associated to  $\theta$  through  $\phi_S$ .
- $\phi = \phi_S\lambda_P$ ,  $\sigma = \sigma_S\lambda_P$ , and  $(\text{tr}_S\theta)\phi \downarrow = \text{tr}\phi \downarrow$ .

**PROOF.** Let  $(\text{tr}, \phi) \in \text{trace}_{\Sigma_0^-}(\mathcal{K}_P)$  be a witness of non-inclusion of minimal length with underlying substitution  $\sigma$ . First, we apply Proposition 4.11. We deduce that there exists  $(\text{tr}_S, \phi_S) \in \text{trace}_{\Sigma_0^+}(\mathcal{K}_P)$  with underlying substitution  $\sigma_S$  with  $\text{dom}(\sigma_S) = \text{dom}(\sigma)$  such that  $\sigma_S = \text{mgu}(\Gamma)\rho$ , as well as two substitutions  $\lambda_P$  and  $\theta$  such that:

- $\Gamma = \{(u, v) \mid u, v \in \text{Est}(\mathcal{K}_P) \text{ such that } u\sigma = v\sigma\}$ .
- $\rho$  is a bijective renaming from variables in  $\text{dom}(\sigma) \setminus \text{dom}(\text{mgu}(\Gamma))$  to constants in  $\Sigma_{\text{fresh}}$  such that  $x\rho \in \Sigma_{\text{fresh}}^{\text{atom}}$  if, and only if,  $x\sigma$  is an atomic  $\Sigma_0^-$ -message.

- $dom(\theta) \subseteq \Sigma_{\text{fresh}}$ , for any  $c \in \Sigma_{\text{fresh}}$  occurring in  $\text{tr}_S$ , we have that  $c \in dom(\theta)$ ,  $c\theta \in \mathcal{T}(\Sigma, \Sigma_0^- \uplus dom(\phi_S))$ , and  $w' < c$  for any  $w' \in vars(c\theta)$  (where  $<$  is the ordering induced by  $\text{tr}_S$ ).
- for any  $c \in dom(\theta)$ ,  $(c\theta)\phi_S \downarrow$  is a  $\Sigma_0^+$ -message and it is an atom when  $c \in \Sigma_{\text{fresh}}^{\text{atom}}$ .
- $\lambda_P$  is the first-order substitution associated to  $\theta$  through  $\phi_S$ .
- $\phi = \phi_S \lambda_P$ ,  $\sigma = \sigma_S \lambda_P$ , and  $(\text{tr}_S \theta)\phi \downarrow = \text{tr} \phi \downarrow$ .

Our goal is to show that  $(\text{tr}_S, \phi_S) \in \text{trace}_{\Sigma_0^+}(\mathcal{K}_P)$  is a witness of  $\mathcal{K}_P \not\sqsubseteq_t \mathcal{K}_Q$  w.r.t  $\Sigma_0^+$ .

Let  $\psi_S$  be such that  $(\text{tr}_S, \psi_S) \in \text{trace}_{\Sigma_0^+}(\mathcal{K}_Q)$ . Note that in case such a  $\psi_S$  does not exist, then the result trivially holds. Moreover, we know that  $\phi_S \sqsubseteq_s \psi_S$  (and thus  $dom(\phi_S) = dom(\psi_S)$ ) since otherwise the result trivially holds.

We have that  $\phi_S$  is a  $\Sigma_0^+$ -frame and  $<$  is an ordering on  $dom(\phi_S)$ . We have  $dom(\theta) \subseteq \Sigma_{\text{fresh}}$  and  $c\theta \in \mathcal{T}(\Sigma, \Sigma_0^- \uplus dom(\phi_S))$  for any  $c \in dom(\theta)$ . Moreover, if  $c \in \Sigma_{\text{fresh}}$  occurs in  $w\phi_S$ , then, as  $c$  does not occur in  $\mathcal{K}_P$ , it must have been introduced in an input before the output of  $w$ . So  $c < w$ . Let  $w' \in vars(c\theta)$ . Then  $w' < c$  by definition of  $<$ . So  $w' < w$  and the order induced by  $<$  on  $dom(\phi_S)$  satisfies the condition of Lemma 4.8 and Lemma 4.9.  $(c\theta)\phi_S \downarrow$  is a  $\Sigma_0^+$ -message for each  $c \in dom(\theta)$  and  $(c\theta)\phi_S \downarrow$  is an atomic  $\Sigma_0^+$ -message when  $c \in \Sigma_{\text{fresh}}^{\text{atom}}$ . So Lemma 4.8 applies and for each  $c \in dom(\lambda_P)$ ,  $c\lambda_P$  is a  $\Sigma_0^-$ -message and  $c\lambda_P$  is atomic if  $c \in \Sigma_{\text{fresh}}^{\text{atom}}$ . So Lemma 4.9 applies, and for any recipe  $R$  such that  $R\phi_S \downarrow$  is a  $\Sigma_0^+$ -message, we have  $(R\theta)(\phi_S \lambda_P) \downarrow = (R\phi_S \downarrow)\lambda_P$ .

$\mathcal{K}_Q$  is a  $\Sigma_0^-$ -configuration, and  $(\text{tr}_S, \psi_S) \in \text{trace}_{\Sigma_0^+}(\mathcal{K}_Q)$ . Moreover,  $dom(\theta) \subseteq \Sigma_{\text{fresh}}$ , and  $c \in dom(\theta)$  for each  $c$  occurring in  $\text{tr}_S$ . We have  $dom(\phi_S) = dom(\psi_S)$  by  $\phi_S \sqsubseteq_s \psi_S$  so for each  $c \in dom(\theta)$ ,  $c\theta \in \mathcal{T}(\Sigma, \Sigma_0^- \uplus dom(\phi_S)) \subseteq \mathcal{T}(\Sigma, \Sigma_0^- \uplus dom(\psi_S))$ . Moreover, if  $c \in \Sigma_{\text{fresh}}$  occurs in  $w\psi_S$ , then, as  $c$  does not occur in the protocol, it must have been introduced in an input before the output of  $w$ . So  $c < w$ . Let  $w' \in vars(c\theta)$ . Then  $w' < c$  by definition of  $<$ . So  $w' < w$  and the order induced by  $<$  on  $dom(\psi_S)$  satisfies the condition of Lemma 4.8 and Lemma 4.9. By  $\phi_S \sqsubseteq_s \psi_S$ ,  $(c\theta)\psi_S \downarrow$  is a  $\Sigma_0^+$ -message for any  $c \in dom(\theta)$  and an atomic one in case  $c \in \Sigma_{\text{fresh}}^{\text{atom}}$ . Hence, we have that both Lemma A.1 and Lemma 4.8 apply. We obtain that  $(\text{tr}_S \theta, \psi_S \lambda_Q) \in \text{trace}_{\Sigma_0^-}(\mathcal{K}_Q)$  where  $\lambda_Q$  is the first-order substitution associated to  $\theta$  through  $\psi_S$ . We also get that  $c\lambda_Q$  is a  $\Sigma_0^-$ -message for each  $c \in dom(\lambda_Q)$  and it is atomic when  $c \in \Sigma_{\text{fresh}}^{\text{atom}}$ . Therefore, Lemma 4.9 applies, and we have that for any  $R \in \mathcal{T}(\Sigma, \Sigma_0^- \uplus dom(\theta) \uplus dom(\psi_S))$  such that  $R\psi_S \downarrow$  is a  $\Sigma_0^+$ -message,  $(R\theta)(\psi_S \lambda_Q) \downarrow = (R\psi_S \downarrow)\lambda_Q$ . Moreover, since  $\lambda_Q$  preserves atomicity,  $(R\psi_S \downarrow)\lambda_Q$  is a  $\Sigma_0^-$ -message whenever  $(R\psi_S \downarrow)$  is a  $\Sigma_0^+$ -message.

In the remaining of this proof, we suppose that  $\phi_S \sqsubseteq_s \psi_S$  (meaning that  $(\text{tr}_S, \phi_S) \in \text{trace}_{\Sigma_0^+}(\mathcal{K}_P)$  is not a witness), and we show that  $\phi \sqsubseteq_s \psi$  leading to a contradiction since by hypothesis, we know that  $(\text{tr}, \phi) \in \text{trace}_{\Sigma_0^-}(\mathcal{K}_P)$  is a witness, and  $\text{tr}$  passes in  $\mathcal{K}_Q$  leading to the frame  $\psi$ .

To establish this result, we rely on Lemma 5.3 and thus we reason with the notion  $\sqsubseteq_s^{\text{atom}}$ . We consider a test  $T$  (built on  $\mathcal{T}(\Sigma, \Sigma_0^+ \cup dom(\phi_S))$ ) such that  $T\theta$  holds in  $\phi$ . We assume that for all  $T'$  such that  $\mu_{\phi_S}(T') < \mu_{\phi_S}(T)$ , we have that:

$T'\theta$  holds in  $\phi$  implies that  $T'\theta$  holds in  $\psi$ .

We have to prove that  $T\theta$  holds in  $\psi$ . We distinguish three cases depending on the form of the test:

- (1) The test  $T$  is a  $\Sigma_0^+$ -recipe  $R$  such that  $(R\theta)\phi \downarrow$  is a  $\Sigma_0^-$ -message. In such a case, we have to establish that  $(R\theta)\psi \downarrow$  is a  $\Sigma_0^-$ -message
- (2) The test  $T$  is a  $\Sigma_0^+$ -recipe such that  $(R\theta)\phi \downarrow$  is an atomic  $\Sigma_0^-$ -message, i.e.  $(R\theta)\phi \downarrow \in \Sigma_0^- \uplus \mathcal{N}$ . In such a case, we have to establish that  $(R\theta)\psi \downarrow$  is an atomic  $\Sigma_0^-$ -message.
- (3) The test  $T$  is made of two  $\Sigma_0^+$ -recipes  $R, R'$  such that both  $(R\theta)\phi \downarrow$  and  $(R'\theta)\phi \downarrow$  are  $\Sigma_0^-$ -messages, and  $(R\theta)\phi \downarrow = (R'\theta)\phi \downarrow$ . In such a case, we have to establish that  $(R\theta)\psi \downarrow = (R'\theta)\psi \downarrow$ .

(1)  $R$  is  $\Sigma_0^+$ -recipe such that  $(R\theta)\phi\downarrow$  is a  $\Sigma_0^-$ -message.

Assume that  $R\phi_S\downarrow$  is not a  $\Sigma_0^+$ -message. We take the smallest subterm  $R'$  of  $R$  such that  $R'\phi_S\downarrow$  is not a  $\Sigma_0^+$ -message. Let  $p$  be such that  $R|_p = R'$ . As  $R'\phi_S\downarrow$  is not a  $\Sigma_0^+$ -message, we know that  $R' \notin \Sigma_0^+ \uplus \text{dom}(\phi_S)$ . Thus, we have that  $R' = f(R_1, \dots, R_k)$  for some  $f \in \Sigma$ . Moreover, by minimality of  $R'$ , we know that  $R_i\phi_S\downarrow$  is a  $\Sigma_0^+$ -message for  $1 \leq i \leq k$ . We now establish the following claim:

**Claim.** If  $R_i\phi_S\downarrow \in \Sigma_{\text{fresh}}$  for some  $i \in \{1, \dots, k\}$ , then  $(R\theta)\psi\downarrow$  is a  $\Sigma_0^-$ -message.

*Proof.* Assume  $R_i\phi_S\downarrow = c \in \Sigma_{\text{fresh}}$  for some  $i \in \{1, \dots, k\}$ , and let  $R'_i = c\theta$ . We have that  $R'_i\theta = c\theta$ , and thus  $(R'_i\theta)\phi\downarrow = (c\theta)\phi\downarrow$ , and  $(R'_i\theta)\psi\downarrow = (c\theta)\psi\downarrow$ . We have that the test  $c = R_i$  holds in  $\phi_S$ , and thus since  $\phi_S \sqsubseteq_s \psi_S$ , it also holds in  $\psi_S$ . Lemma 4.9 applies, and we obtain:  $(R_i\theta)\psi\downarrow = (R_i\psi_S\downarrow)\lambda_Q = c\lambda_Q = (c\theta)\psi\downarrow = (R'_i\theta)\psi\downarrow$ . Let  $\bar{R} = R[R'_i]_{(p,i)}$ . We have that:

- $(\bar{R}\theta = R\theta)$  holds in both  $\phi$  and  $\psi$ ;
- $\mu_{\phi_S}^1(R'_i) < \mu_{\phi_S}^1(R_i)$  thanks to Lemma B.4, and thus  $\mu_{\phi_S}^1(\bar{R}) < \mu_{\phi_S}^1(R)$  thanks to Lemma B.3 and Lemma 4.6.

As  $(\bar{R}\theta)\phi\downarrow = (R\theta)\phi\downarrow$  is a  $\Sigma_0^-$ -message, such a test transfers to  $\psi$  (relying on our induction hypothesis), and  $(\bar{R}\theta)\psi\downarrow$  is a  $\Sigma_0^-$ -message. It proves our claim.

We now distinguish two cases depending on whether  $f \in \Sigma_c$  or  $f \in \Sigma_d$ .

Case where  $f \in \Sigma_c$ . In such a case,  $R'\phi_S\downarrow$  is either not well-shaped or not well-sorted. If it is not well-sorted, then for one of its subrecipes  $R_i$ ,  $R_i\phi_S\downarrow$  is not an atom (it is well-sorted by minimality of  $R'$ ) while it should be. In particular,  $(R_i\theta)\phi\downarrow = R_i\phi_S\downarrow\lambda_P$  is an atom. So  $R_i\phi_S\downarrow$  must be in  $\Sigma_{\text{fresh}}$ , which implies by our claim that  $(R\theta)\psi\downarrow$  is a  $\Sigma_0^-$ -message, and thus we are done. We deduce that  $R'\phi_S\downarrow$  is well-sorted.

Now, we assume that  $R'\phi_S\downarrow$  is not well-shaped, we consider the shape of  $f$ ,  $sh_f = f(s_1, \dots, s_k)$  for some  $s_1, \dots, s_k$ . As  $R'\phi_S\downarrow$  has a bad shape and is a  $f$ -term, there must be a  $j$  such that  $R_j\phi_S\downarrow$  is not an instance of  $s_j$ . In particular,  $s_j$  is not a variable and we have  $s_j = sh_g$  for some function symbol  $g$  (thanks to the compatibility of the shapes). But  $R_j\phi_S\downarrow$  is a  $\Sigma_0^+$ -message and thus we know that  $(R_j\theta)\phi\downarrow = (R_j\phi_S\downarrow)\lambda_P$  (thanks to Lemma 4.9) is an instance of  $s_j$  as  $(R_j\theta)\phi\downarrow$  is a  $\Sigma_0^+$ -message. Relying on our claim, we know that  $R_j\phi_S\downarrow \notin \Sigma_{\text{fresh}}$ , thus  $R_j\phi_S\downarrow$  is a  $g$ -term, and since we know that  $R_j\phi_S\downarrow$  is a  $\Sigma_0^+$ -message, we know that it is an instance of  $s_j$ , yielding to a contradiction.

Case where  $f = \text{des} \in \Sigma_d$ . In such a case,  $R' = \text{des}(R_1, \dots, R_k)$ . Let  $\ell_{\text{des}} = \text{des}(t_1, t_2, \dots, t_k)$ . We distinguish two subcases.

First, we assume that there is some  $i \in \{1, \dots, k\}$  such that  $R_i\phi_S\downarrow$  does not unify with  $t_i$ . As  $R_i\phi_S\downarrow$  is a  $\Sigma_0^+$ -message, it has a good shape. Thus, the only way to not unify with the linear term  $t_i$  whereas  $(R_i\phi_S)\lambda_P = (R_i\theta)\phi\downarrow$  (thanks to Lemma 4.9) does, is when  $R_i\phi_S\downarrow = c$  for some  $c \in \Sigma_{\text{fresh}}$ . Relying on our claim, we obtain a contradiction.

Second, we assume that  $R_i\phi_S\downarrow$  unifies with  $t_i$  for each  $i$ . In such a case, we know that  $\ell_{\text{des}} = \text{des}(t_1, \dots, t_k)$  is a non-linear term and we denote  $x$  the non-linear variable occurring in  $\ell_{\text{des}}$ . Let  $I_0 = \{1 \leq i \leq k \mid x \text{ occurs in } t_i\}$ . We know that  $1 \in I_0$ . For any  $i \in I_0$ , we denote  $p_i$  the position in  $t_i$  such that  $t_i|_{p_i} = x$ . Since  $R'\phi_S\downarrow\lambda_P$  is a  $\Sigma_0^-$ -message, we know that  $t = \text{des}(R_1\phi_S\downarrow\lambda_P, \dots, R_k\phi_S\downarrow\lambda_P)$  unifies with  $\text{des}(t_1, \dots, t_k)$ . Therefore, we know that there exists an atomic  $\Sigma_0^-$ -message  $a$  such that  $t|_{i,p_i} = a$  for any  $i \in I_0$ . We know that  $R'\phi_S\downarrow$  is not a  $\Sigma_0^+$ -message whereas  $R_i\phi_S\downarrow$  are  $\Sigma_0^+$ -messages. Thus, we have that  $t_S = \text{des}(R_1\phi_S\downarrow, \dots, R_k\phi_S\downarrow)$  does not unify with  $\text{des}(t_1, \dots, t_k)$ . We deduce the following fact:

**Fact:** for any  $i \in I_0$ , we have  $t_S|_{i,p_i} = a$ , or  $t_S|_{i,p_i} = c$  for some  $c \in \Sigma_{\text{fresh}}$  such that  $c\lambda_P = (c\theta)\phi\downarrow = a$ .

Let  $c$  be a constant from  $\Sigma_{\text{fresh}}$  such that  $t_S|_{i.p_i} = c$  for some  $i \in I_0$ . Let  $I_1 = \{i \in I_0 \mid R_i \phi_S \downarrow|_{p_i} = c\}$ . We will build two recipes  $\overline{R}'$  and  $\overline{R}''$  derived from  $R'$  and enjoying some nice properties: in particular both  $(\overline{R}'\theta)\psi \downarrow$  and  $(\overline{R}''\theta)\psi \downarrow$  will be  $\Sigma_0^-$ -message, and this will allow us to derive that  $(R\theta)\psi \downarrow$  is a  $\Sigma_0^-$ -message too.

*Construction of  $\overline{R}'$ .* Let  $v'_{\text{des}}$  be the substitution such that  $xv'_{\text{des}} = c\theta$ , and  $yv'_{\text{des}} = c_{\min}$  for any other variable  $y \in \text{vars}(\ell_{\text{des}})$ . For  $i \in \{1, \dots, k\}$ , let  $R'_i = t_i v'_{\text{des}}$  in case  $i \in I_1$ , and  $R'_i = R_i$  otherwise. Let  $\overline{R}' = \text{des}(R'_1, \dots, R'_k)$ . Each  $R'_i \phi_S \downarrow$  is a  $\Sigma_0^+$ -message, and thus by Lemma 4.9, we have that  $(R'_i \theta)\phi \downarrow = R'_i \phi_S \downarrow \lambda_P$  is a  $\Sigma_0^-$ -message. By construction of  $\overline{R}'$  and relying on our fact, we have that  $(\overline{R}'\theta)\phi \downarrow$  is a  $\Sigma_0^-$ -message. Therefore, relying on Lemma B.3, and since  $\mu_{\phi_S}^1(R'_i) < \mu_{\phi_S}^1(R_i)$  for  $i \in I_1 \neq \emptyset$ , and  $\mu_{\phi_S}^1(R'_i) = \mu_{\phi_S}^1(R_i)$  otherwise, we deduce that:

$$\begin{aligned} \mu_{\phi_S}^1(\overline{R}') &= \text{Multi}(\overline{R}'\phi_S \downarrow) \\ &\leq \text{Multi}(\text{des}(R'_1 \phi_S \downarrow, \dots, R'_k \phi_S \downarrow)) \\ &= \{\text{des}\} \uplus \mu_{\phi_S}^1(R'_1) \uplus \dots \uplus \mu_{\phi_S}^1(R'_k) \\ &< \{\text{des}\} \uplus \mu_{\phi_S}^1(R_1) \uplus \dots \uplus \mu_{\phi_S}^1(R_k) \\ &= \mu_{\phi_S}^1(R) \end{aligned}$$

As  $(\overline{R}'\theta)\phi \downarrow$  is a  $\Sigma_0^-$ -message, we deduce that  $(\overline{R}'\theta)\psi \downarrow$  is a  $\Sigma_0^-$ -message. Since  $R'\phi_S \downarrow$  is not a  $\Sigma_0^+$ -message, Lemma 4.6 applies, and we obtain  $\mu_{\phi_S}^1(R[\overline{R}']_p) < \mu_{\phi_S}^1(R[R']_p) = \mu_{\phi_S}^1(R)$ .

*Construction of  $\overline{R}''$ .* Let  $v''_{\text{des}}$  be the substitution such that  $xv''_{\text{des}} = c$ , and  $yv''_{\text{des}} = c_{\min}$  for any other variable  $y \in \text{vars}(\ell_{\text{des}})$ . For  $i \in \{1, \dots, k\}$ , let  $R''_i = R_i$  in case  $i \in I_1$ , and  $R''_i = t_i v''_{\text{des}}$  otherwise. Let  $\overline{R}'' = \text{des}(R''_1, \dots, R''_k)$ . By construction of  $\overline{R}''$ , we have that  $\overline{R}''\phi_S \downarrow$  is a  $\Sigma_0^+$ -message. By hypothesis we have that  $\phi_S \sqsubseteq_s \psi_S$ , and thus we deduce that  $\overline{R}''\psi_S \downarrow$  is a  $\Sigma_0^+$ -message. Then, thanks to Lemma 4.9, we deduce that  $(\overline{R}''\theta)\psi \downarrow = \overline{R}''\psi_S \downarrow \lambda_Q$ . Regarding the measure, we have that  $\{\text{des}\} < \mu_{\phi_S}^1(R')$  since  $\text{des}$  occurs in  $R'\phi_S \downarrow$ . We have that  $\mu_{\phi_S}^1(\overline{R}'') < \{\text{des}\}$  since  $\overline{R}''\phi_S \downarrow$  is a  $\Sigma_0^+$ -message. Therefore, we have that  $\mu_{\phi_S}^1(\overline{R}'') < \mu_{\phi_S}^1(R')$ . Since  $R'\phi_S \downarrow$  is not a  $\Sigma_0^+$ -message, Lemma 4.6 applies, and we obtain  $\mu_{\phi_S}^1(R[\overline{R}'']_p) < \mu_{\phi_S}^1(R[R']_p) = \mu_{\phi_S}^1(R)$ .

At this point, we have that  $\overline{R}' = \text{des}(R'_1, \dots, R'_k)$ ,  $\overline{R}'' = \text{des}(R''_1, \dots, R''_k)$ , and both  $(\overline{R}'\theta)\psi \downarrow$  and  $(\overline{R}''\theta)\psi \downarrow$  are  $\Sigma_0^-$ -message. By construction, for each  $1 \leq i \leq k$ , we have that either  $R_i = R'_i$  or  $R_i = R''_i$ . Therefore, for each  $1 \leq i \leq k$ , we have that  $(R_i \theta)\psi \downarrow$  is a  $\Sigma_0^-$ -message and unifies with  $t_i$ . We put a  $c\theta$  in key positions of  $\ell_{\text{des}}$  in some  $R'_i$ . As  $(\overline{R}'\theta)\psi \downarrow$  is a  $\Sigma_0^-$  message, it means that each of the  $(R'_i \theta)\psi \downarrow$  has  $(c\theta)\psi \downarrow$  in key position of  $\ell_{\text{des}}$ . Similarly, we get that each of the  $(R''_i \theta)\psi \downarrow$  has  $(c\theta)\psi \downarrow$  in key position of  $\ell_{\text{des}}$ . So there is  $(c\theta)\psi \downarrow$  in key position of  $\ell_{\text{des}}$  for each  $(R_i \theta)\psi \downarrow$ . We deduce that  $(R\theta)\psi \downarrow$  is a  $\Sigma_0^-$ -message.

Furthermore, we have  $R_1 = R'_1$  or  $R_1 = R''_1$ . Let  $\overline{R} = \overline{R}'$  in case  $R_1 = R'_1$ , and  $\overline{R} = \overline{R}''$  in case  $R_1 = R''_1$ . We have that:

- $\mu_{\phi_S}^1(R[\overline{R}]_p) < \mu_{\phi_S}^1(R)$ ,
- $(R[\overline{R}]_p \theta)\phi \downarrow = (R[R']_p \theta)\phi \downarrow = (R\theta)\phi \downarrow$ , and
- $(R[\overline{R}]_p \theta)\psi \downarrow = (R\theta)\psi \downarrow$ .

As  $(R[\overline{R}]_p \theta)\phi \downarrow$  is a  $\Sigma_0^-$ -message, by minimality  $(R[\overline{R}]_p \theta)\psi \downarrow$  is a  $\Sigma_0^-$ -message, and so  $(R\theta)\psi \downarrow$  is a  $\Sigma_0^-$ -message which is the result we want to prove.

Thus, we have that  $R\phi_S\downarrow$  is a  $\Sigma_0^+$ -message. By  $\phi_S \sqsubseteq_s \psi_S$ , we know that  $R\psi_S\downarrow$  is a  $\Sigma_0^+$ -message, and Lemma 4.9 allows us to conclude that  $(R\theta)\psi\downarrow = R\psi_S\downarrow\lambda_Q$  is a  $\Sigma_0^-$ -message.

(2)  $R$  is a  $\Sigma_0^+$ -recipe such that  $(R\theta)\phi\downarrow$  is an atomic  $\Sigma_0^-$ -message.

First, we have that  $R\phi_S\downarrow$  is a  $\Sigma_0^+$ -message (see case (1)), and  $(R\theta)\phi\downarrow = R\phi_S\downarrow\lambda_P$  thanks to Lemma 4.9. As a first step, we establish that  $R\psi_S\downarrow$  is atomic. As  $R\phi_S\downarrow\lambda_P$  is an atom, we know that  $R\phi_S\downarrow$  is either an atom from  $\Sigma_0^- \cup \mathcal{N}$ , or a constant from  $\Sigma_{\text{fresh}}$ .

- If  $R\phi_S\downarrow \notin \Sigma_{\text{fresh}}$ , then  $R\phi_S\downarrow = R\phi_S\downarrow\lambda_P$  is atomic, and relying on our hypothesis  $\phi_S \sqsubseteq_s \psi_S$ , we deduce that  $R\psi_S\downarrow$  is atomic.
- If  $R\phi_S\downarrow = c \in \Sigma_{\text{fresh}}$ , then there exists  $x$  such that  $x\rho = c$ . Since  $x \in \text{dom}(\rho)$ , we know that  $x \notin \text{dom}(\text{mgu}(\Gamma))$ , and thus  $x\text{mgu}(\Gamma) = x$ . Therefore, we have that  $x\sigma = x\sigma_S\lambda_P = x(\text{mgu}(\Gamma)\rho)\lambda_P = (x\rho)\lambda_P = c\lambda_P = R\phi_S\downarrow\lambda_P$ . As  $R\phi_S\downarrow\lambda_P$  is an atom, we deduce that  $x\sigma$  is atomic, and by definition of  $\rho$ , we have that  $c = x\rho \in \Sigma_{\text{fresh}}^{\text{atom}}$ , and thus  $R\phi_S\downarrow$  is atomic. Relying on our hypothesis  $\phi_S \sqsubseteq_s \psi_S$ , we deduce that  $R\psi_S\downarrow = c$  is atomic.

Since  $\lambda_Q$  replaces atoms by atoms, we deduce in both cases that  $R\psi_S\downarrow\lambda_Q$  is atomic, and thus  $(R\theta)\psi\downarrow = (R\psi_S\downarrow)\lambda_Q$  (Lemma 4.9) is an atomic  $\Sigma_0^-$ -message.

(3)  $R$  and  $R'$  are  $\Sigma_0^+$ -recipes,  $(R\theta)\phi\downarrow, (R'\theta)\phi\downarrow$  are  $\Sigma_0^-$ -messages, and  $(R\theta)\phi\downarrow = (R'\theta)\phi\downarrow$ .

**Step 1:** We prove that  $R$  and  $R'$  are simple  $\Sigma_0^+$ -recipe, in normal form w.r.t.  $\downarrow$ . Moreover, we show that  $R'$  is a subterm recipe such that  $R'\phi_S\downarrow$  is either an encrypted term, or a name from  $\mathcal{N}$ , or a constant from  $\Sigma_0^+$ . Regarding  $R$ , we show that  $R$  is of the form  $C[R_1, \dots, R_n]$  where for each  $i \in \{1, \dots, n\}$ , we have that  $R_i\phi_S\downarrow$  is either an encrypted term, or a name from  $\mathcal{N}$ , or a constant from  $\Sigma_0^+$ .

We have that  $(R\theta)\phi\downarrow$  and  $(R'\theta)\phi\downarrow$  are  $\Sigma_0^-$ -messages,  $\mu_{\phi_S}(R) < \mu_{\phi_S}(R = R')$  and  $\mu_{\phi_S}(R') < \mu_{\phi_S}(R = R')$ . Hence, we deduce that  $(R\theta)\psi\downarrow$  and  $(R'\theta)\psi\downarrow$  are  $\Sigma_0^-$ -messages.

Assume that either  $R$  or  $R'$  is not in normal form w.r.t.  $\downarrow$ , say  $R$ . Then  $\mu_{\phi_S}^1(R\downarrow) < \mu_{\phi_S}^1(R)$  by Lemma 4.7. Moreover, as  $R\theta \rightarrow^* R\downarrow\theta$ , Lemma 4.3 applies:  $(R\downarrow\theta)\phi\downarrow = (R\theta)\phi\downarrow$  and  $(R\downarrow\theta)\psi\downarrow = (R\theta)\psi\downarrow$  as  $(R\theta)$  gives a  $\Sigma_0^-$ -message in both  $\phi$  and  $\psi$ . So  $(R\downarrow\theta = R'\theta)$  holds in  $\phi$ . By  $\mu_{\phi_S}(R\downarrow = R') < \mu_{\phi_S}(R = R')$ , it transfers to  $\psi$  and we deduce  $(R\theta)\psi\downarrow = (R\downarrow\theta)\psi\downarrow = (R'\theta)\psi\downarrow$  which is the result we want to establish.

Now, we assume that both  $R$  and  $R'$  are in normal form w.r.t.  $\downarrow$ . Thus, both are simple by Lemma 4.5. In case both  $R$  and  $R'$  have a constructor as root symbol, then this is necessarily the same. Therefore, we have that  $R = f(R_1, \dots, R_k)$  and  $R' = f(R'_1, \dots, R'_k)$ . We have that  $(R_i\theta)\phi\downarrow$  and  $(R'_i\theta)\phi\downarrow$  are  $\Sigma_0^-$ -messages ( $1 \leq i \leq k$ ), and  $(R_i\theta)\phi\downarrow = (R'_i\theta)\phi\downarrow$  ( $1 \leq i \leq k$ ). Since  $\mu_{\phi_S}(R_i = R'_i) < \mu_{\phi_S}(R = R')$ , we deduce that  $(R_i\theta)\psi\downarrow = (R'_i\theta)\psi\downarrow$ , and thus  $(R\theta)\psi\downarrow = (R'\theta)\psi\downarrow$  which is the result we want to prove.

Therefore we can assume that say  $R'$  is a subterm-recipe, and  $R$  is simple, so  $R = C[R_1, \dots, R_n]$  where for each  $i$ ,  $R_i$  is a subterm-recipe. Now, assume that there is  $i_0$  such that  $\text{root}(R_{i_0}\phi_S\downarrow) = f \in \Sigma_c$  and  $f$  is transparent, then  $R_{i_0}\phi_S\downarrow = f(C_1^f[R_{i_0}], \dots, C_k^f[R_{i_0}])\phi_S\downarrow$ . We consider the context  $\bar{C}$  such that  $\bar{C}[R_1, \dots, R_n] = C[R_1, \dots, f(C_1^f[R_{i_0}], \dots, C_k^f[R_{i_0}]), \dots, R_n]$ . We have that  $\bar{R} = \bar{C}[R_1, \dots, R_n]$  is a  $\Sigma_0^+$ -recipe such that  $\bar{R}\phi_S\downarrow = R\phi_S\downarrow$ , and thus  $\mu_{\phi_S}^1(R) = \mu_{\phi_S}^1(\bar{R})$ , and  $(\bar{R}\theta)\phi\downarrow = \bar{R}\phi_S\downarrow\lambda_P$  by Lemma 4.9, which gives  $(\bar{R}\theta)\phi\downarrow = \bar{R}\phi_S\downarrow\lambda_P = R\phi_S\downarrow\lambda_P = (R\theta)\phi\downarrow$ . We have that  $\mu_{\phi_S}^2(\bar{R}) < \mu_{\phi_S}^2(R)$ . The equality  $\bar{R}\phi_S\downarrow = R\phi_S\downarrow$  transfers to  $\bar{R}\psi_S\downarrow = R\psi_S\downarrow$  by  $\phi_S \sqsubseteq_s \psi_S$  and we deduce  $(\bar{R}\theta)\psi\downarrow = (R\theta)\psi\downarrow$  by Lemma 4.9. As  $\mu_{\phi_S}(\bar{R} = R') < \mu_{\phi_S}(R = R')$ , the equality  $(\bar{R}\theta)\phi\downarrow = (R'\theta)\phi\downarrow$  transfers to  $(\bar{R}\theta)\psi\downarrow = (R'\theta)\psi\downarrow$  and we deduce that  $(R\theta)\psi\downarrow = (R'\theta)\psi\downarrow$  which is the result we want to prove.

Therefore, we deduce that each  $R_i\phi_S\downarrow$  (with  $1 \leq i \leq n$ ) is either an encrypted term, a constant from  $\Sigma_0^+$ , or a name from  $\mathcal{N}$ . A similar reasoning allows us to establish that  $R'\phi_S\downarrow$  is either an encrypted term, a constant from  $\Sigma_0^+$ , or a name from  $\mathcal{N}$ .

**Step 2:** We now establish that  $(R\theta)\psi\downarrow = (R'\theta)\psi\downarrow$ .

Let  $t = R\phi_S\downarrow$  and  $v = R'\phi_S\downarrow$ . By Lemma 4.9 and  $(R\theta)\phi\downarrow = (R'\theta)\phi\downarrow$ , we know that  $t\lambda_P = v\lambda_P$ . If  $t = v$ , then we have that  $R\phi_S\downarrow = R'\phi_S\downarrow$  since  $\phi_S \sqsubseteq_s \psi_S$ . Then by Lemma 4.9, we deduce that  $(R\theta)\psi\downarrow = (R'\theta)\psi\downarrow$ .

From now on, we assume that  $t \neq v$ . Since  $t \neq v$ , we know that there exists a position  $p$  defined in  $t$  and  $v$  such that  $\text{root}(t|_p) \neq \text{root}(v|_p)$ . Let  $p$  be any position defined in  $t$  and  $v$  such that  $\text{root}(t|_p) \neq \text{root}(v|_p)$ . Since  $t\lambda_P = v\lambda_P$ , and  $\text{dom}(\lambda_P) \subseteq \Sigma_{\text{fresh}}$ , we have that  $t|_p \in \Sigma_{\text{fresh}}$  or  $v|_p \in \Sigma_{\text{fresh}}$ .

We first assume that there exists such a position  $p$  that falls outside the context  $C$ . More precisely, we have that  $p = p'.p''$  (with  $p'$  a strict prefix of  $p$ ) and  $C[R_1, \dots, R_n]|_{p'} = R_{i_0}$  for some  $i_0 \in \{1, \dots, n\}$ . Therefore, since  $R_{i_0}\phi_S\downarrow$  is not a leaf ( $p'' \neq \epsilon$ ), we know that  $t|_{p'} = R_{i_0}\phi_S\downarrow$  is an encrypted subterm of  $\phi_S$ . Relying on Lemma 4.10, we have that:

- $t|_{p'} \in \text{ESt}(\phi_S) \subseteq \text{ESt}(\mathcal{K}_S\sigma_S) \subseteq \text{ESt}(\mathcal{K}_P(\text{mgu}(\Gamma)\rho)) \subseteq \text{ESt}(\mathcal{K}_P)\sigma_S$ .
- $v|_{p'} \in \text{ESt}(\phi_S) \subseteq \text{ESt}(\mathcal{K}_S\sigma_S) \subseteq \text{ESt}(\mathcal{K}_P(\text{mgu}(\Gamma)\rho)) \subseteq \text{ESt}(\mathcal{K}_P)\sigma_S$ .

This allows us to conclude that there exist  $t', v' \in \text{ESt}(\mathcal{K}_P)$  such that  $t'\sigma_S = t|_{p'}$ , and  $v'\sigma_S = v|_{p'}$ . Since  $t\lambda_P = v\lambda_P$ , we know that  $(t\lambda_P)|_{p'} = (v\lambda_P)|_{p'}$ , thus  $t|_{p'}\lambda_P = v|_{p'}\lambda_P$ , and  $(t'\sigma_S)\lambda_P = (v'\sigma_S)\lambda_P$ . We have that  $(t'\sigma_S)\lambda_P = t'(\sigma_S\lambda_P)$  and also that  $(v'\sigma_S)\lambda_P = v'(\sigma_S\lambda_P)$ . Since we have that  $\sigma = \sigma_S\lambda_P$ , we deduce that  $t'\sigma = v'\sigma$ . By definition of  $\sigma_S$ , we have that  $t'\sigma_S = v'\sigma_S$ . Thus, we have that  $t|_{p'} = v|_{p'}$  leading to a contradiction since we have assumed that  $t$  and  $v$  differ below the position  $p'$ .

Thus, we know that for any position  $p$  defined in  $t$  and  $v$  such that  $\text{root}(t|_p) \neq \text{root}(v|_p)$ , we have that  $t|_p$  or  $v|_p$  is in  $\Sigma_{\text{fresh}}$ , and  $p$  is a position of  $C$ .

If  $t|_p = c \in \Sigma_{\text{fresh}}$ , let  $\bar{R} = R[c\theta]_p$ . We have that  $\mu_{\phi_S}^1(\bar{R}) < \mu_{\phi_S}^1(R)$  since  $\mu_{\phi_S}^1(c\theta) < \mu_{\phi_S}^1(R|_p)$  (note that  $R|_p\phi_S\downarrow = c$  whereas  $(c\theta)\phi_S\downarrow$  is a  $\Sigma_0^+$ -message and it is an atom when  $c \in \Sigma_{\text{fresh}}^{\text{atom}}$ ). Moreover, we have that:

- $(\bar{R}\theta)\phi\downarrow = (R\theta)\phi\downarrow = (R'\theta)\phi\downarrow$ , and
- $\mu_{\phi_S}(\bar{R} = R') < \mu_{\phi_S}(R = R')$ .

Thus, by induction hypothesis, we have that  $(\bar{R}\theta)\psi\downarrow = (R'\theta)\psi\downarrow$ . We also have  $R|_p\phi_S\downarrow = c$  so by  $\phi_S \sqsubseteq_s \psi_S$ , we know that  $R|_p\psi_S\downarrow = c$ . By Lemma 4.9,  $(R|_p\theta)\psi\downarrow = (c\theta)\psi\downarrow$ . So  $(\bar{R}\theta)\psi\downarrow = (R\theta)\psi\downarrow$ . We deduce  $(R\theta)\psi\downarrow = (R'\theta)\psi\downarrow$  which is the result we want to prove.

Hence, from now on, we assume that  $t|_p \notin \Sigma_{\text{fresh}}$ , and thus  $v|_p = c$  for some  $c \in \Sigma_{\text{fresh}}$ . Let  $p_1, \dots, p_m$  be the positions such that for each  $i \in \{1, \dots, m\}$ , we have that  $p_i$  is defined in both  $t$  and  $v$ , and  $\text{root}(t|_{p_i}) \neq \text{root}(v|_{p_i})$ . For each  $i \in \{1, \dots, m\}$ , we know that  $p_i$  is a position of  $C$  such that  $t|_{p_i} \notin \Sigma_{\text{fresh}}$ , and  $v|_{p_i} \in \Sigma_{\text{fresh}}$ . We denote  $c_{\text{fresh}}^i$  the constant from  $\Sigma_{\text{fresh}}$  such that  $v|_{p_i} = c_{\text{fresh}}^i$ . We have  $(c_{\text{fresh}}^i\theta)\phi\downarrow = (R|_{p_i}\theta)\phi\downarrow$ .  $\mu_{\phi_S}^1(c_{\text{fresh}}^i) < \mu_{\phi_S}^1(R')$  and  $\mu_{\phi_S}^1(R|_{p_i}) \leq \mu_{\phi_S}^1(R)$  so  $\mu_{\phi_S}(c_{\text{fresh}}^i = R|_{p_i}) < \mu_{\phi_S}(R = R')$ . We deduce  $(c_{\text{fresh}}^i\theta)\psi\downarrow = (R|_{p_i}\theta)\psi\downarrow$ .

Now, let  $\bar{C}$  be the context obtained from  $C$  by putting  $c_{\text{fresh}}^i$  at position  $p_i$  for each  $i$ . Let  $\bar{R} = \bar{C}[R_1, \dots, R_n]$ .  $(\bar{R}\theta)\psi\downarrow = (R\theta)\psi\downarrow$  by  $(c_{\text{fresh}}^i\theta)\psi\downarrow = (R|_{p_i}\theta)\psi\downarrow$ . Furthermore, we have that  $\bar{R}\phi_S\downarrow = R'\phi_S\downarrow$  by construction. By  $\phi_S \sqsubseteq_s \psi_S$ , we get  $\bar{R}\psi_S\downarrow = R'\psi_S\downarrow$ . By Lemma 4.9, we get  $(\bar{R}\theta)\psi\downarrow = (R'\theta)\psi\downarrow$ , and thus  $(R\theta)\psi\downarrow = (R'\theta)\psi\downarrow$  which is the result we want to prove.  $\square$

We can conclude with the proof of our main theorem on equivalence.

**THEOREM 3.10.** *Let  $\mathcal{K}_P$  be a  $\Sigma_0^-$ -configuration type-compliant w.r.t.  $(\mathcal{T}_0, \delta_0)$  and  $\mathcal{K}_Q$  be an action-deterministic  $\Sigma_0^-$ -configuration. We have that  $\mathcal{K}_P \not\sqsubseteq_t \mathcal{K}_Q$  w.r.t.  $\Sigma_0^-$  if, and only if, there exists a witness  $(\text{tr}, \phi) \in \text{trace}_{\Sigma_0^+}(\mathcal{K}_P)$  of this non-inclusion such that its underlying execution  $\mathcal{K}_P \xrightarrow{\text{tr}} (\mathcal{P}; \phi; \sigma; i)$  w.r.t.  $\Sigma_0^+$  is well-typed.*

**PROOF.** The converse part is Lemma 3.11. Thus, we now prove the direct part. Let  $\mathcal{K}_P$  be a  $\Sigma_0^-$ -configuration type-compliant w.r.t.  $(\mathcal{T}_0, \delta_0)$  and  $\mathcal{K}_Q$  be an action-deterministic  $\Sigma_0^-$ -configuration. Assume  $\mathcal{K}_P \not\sqsubseteq_t \mathcal{K}_Q$  w.r.t.  $\Sigma_0^-$ . Let  $(\text{tr}, \phi) \in \text{trace}_{\Sigma_0^-}(\mathcal{K}_P)$  with underlying substitution  $\sigma$  be a witness of non-inclusion of minimal length. Thanks to Proposition 5.4, we know that there exists  $(\text{tr}_S, \phi_S) \in \text{trace}_{\Sigma_0^+}(\mathcal{K}_P)$  a witness of this non-inclusion with underlying substitution  $\sigma_S$  such that  $\sigma_S = \text{mgu}(\Gamma)\rho$ , as well as two substitutions  $\lambda_P$  and  $\theta$  such that:

- $\Gamma = \{(u, v) \mid u, v \in \text{Est}(\mathcal{K}_P) \text{ such that } u\sigma = v\sigma\}$ .
- $\rho$  is a bijective renaming from variables in  $\text{dom}(\sigma) \setminus \text{dom}(\text{mgu}(\Gamma))$  to constants in  $\Sigma_{\text{fresh}}$  such that  $x\rho \in \Sigma_{\text{fresh}}^{\text{atom}}$  if, and only if,  $x\sigma$  is an atomic  $\Sigma_0^-$ -message.
- $\text{dom}(\theta) \subseteq \Sigma_{\text{fresh}}$ , for any  $c \in \Sigma_{\text{fresh}}$  occurring in  $\text{tr}_S$ , we have that  $c \in \text{dom}(\theta)$ ,  $c\theta \in \mathcal{T}(\Sigma, \Sigma_0^- \uplus \text{dom}(\phi_S))$ , and  $w' < c$  for any  $w' \in \text{vars}(c\theta)$  (where  $<$  is the ordering induced by  $\text{tr}_S$ ).
- for any  $c \in \text{dom}(\theta)$ ,  $(c\theta)\phi_S\downarrow$  is a  $\Sigma_0^+$ -message and it is an atom when  $c \in \Sigma_{\text{fresh}}^{\text{atom}}$ .
- $\lambda_P$  is the first-order substitution associated to  $\theta$  through  $\phi_S$ .
- $\phi = \phi_S\lambda_P$ ,  $\sigma = \sigma_S\lambda_P$ , and  $(\text{tr}_S\theta)\phi\downarrow = \text{tr}\phi\downarrow$ .

First, since  $\mathcal{K}_P$  is type-compliant, we know that encrypted subterms in  $\text{Est}(\mathcal{K}_P)$  which are unifiable have the same type. Then, by definition of a typing system, this allows us to deduce that  $\text{mgu}(\Gamma)$  is well-typed. Since we have enough constants of each type, we may assume w.l.o.g. that  $\rho$  is also well-typed. Hence, we have that  $\sigma_S = \text{mgu}(\Gamma)\rho$  is well-typed, which means that  $(\text{tr}_S, \phi_S)$  is a well-typed witness of the non-inclusion  $\mathcal{K}_P \not\sqsubseteq_t \mathcal{K}_Q$  w.r.t.  $\Sigma_0^+$ , and concludes the proof.  $\square$
