Abstract: The analysis and control of DES is often supported by interpreted Petri nets (IPN), allowing describing the input-output behavior of the involved components. One of the main challenges of the analysis and synthesis methods is the size of the model when the system is large and performs complex behavior. In order to alleviate such a hard problem, a model abstraction method for IPN is proposed in which the events and the outputs of the IPN are considered in order to preserve in the reduced model, the controllable observable language of the original IPN. The reductions are considerable in such a manner that reachability set is drastically reduced. The abstraction procedure is polynomial-time on the size of the IPN.

Keywords: Interpreted Petri nets; Model abstraction; Controllable observable language.

1. INTRODUCTION

It is well known that for large Discrete Event Systems (DES) involving complex behaviour, the number of states can be extremely high and consequently, the models are huge despite the power of expression of Petri nets (PN).

PN have been widely used for validation and control of DES in several problems, namely deadlock detection and avoidance, stability analysis and stabilizing control, process identification, supervisory control, and regulation control. One of the challenges in these problems is the efficiency of the methods due to the size of the PN when it is not possible to find structural-based solutions.

In order to alleviate such a hardship, PN reduction methods have been proposed, allowing simplifying the models while preserving key properties for the analysis. The aim was to reduce the size of the PN and thus, reduce the size of the reachability graph. Several approaches can be found in [Berthelot, 1986], [Silva, 1985], [Lee-Kwang, 1985], [Lee-Kwang, 1987][Murata, 1989], [Desel, 1990], [Esparza, 1994], and [Desel, 1995].

In this paper, we present a model abstraction method for Interpreted PN (IPN), which reduces the size of the model by considering the type of input events associated to transitions and outputs associated to places. In contrast to other proposed methods, the events and the outputs of the IPN associated with transitions and places respectively are taken into account to preserve in the reduced model, the controllable output language of the original IPN.

The method performs structural transformations around a designated subset of places labelled with specified outputs that must remain in the reduced IPN. This allows improving the efficiency of the techniques addressing for example the problems of regulation control [Santoyo, 2008] or stability analysis in which the reachability of markings involving a subset of places is handled.

The method is based on a set of local transformation operators, which consider the behaviour of the IPN to preserve the properties regarding the controllability of firing sequences and the reachability of a subset of observable places associated to selected outputs. An efficient procedure manages the application of the operators; it obtains a reduced IPN that has the same controllable output language than the original one. The abstraction technique allows a drastic reduction of IPN size, and consequently, of the number of states.

The rest of the paper is organised as follows. Section 2 presents the basic notions of observable behaviour of IPN. Section 3 describes the abstraction technique, based on a kit of transformation operators for ordinary and safe IPN; an example of application to an IPN is presented to illustrate the model abstraction technique.

2. THE OBSERVABLE LANGUAGES EQUIVALENCE

2.1. Interpretated Petri Nets

Definition 1. An ordinary Petri Net structure G is a bipartite digraph represented by the 4-tuple $N = (P, T, I, O)$ where: $P = \{p_1, p_2, ..., p_{|P|}\} \text{ and } T = \{t_1, t_2, ..., t_{|T|}\}$ are finite sets of vertices named places and transitions respectively; $I : T \times T \rightarrow \{0,1\}$ $O : T \times P \rightarrow \{0,1\}$ is a function representing the arcs going from places to transitions (from transitions to places) [Murata, 1989]. A marking function $M : P \rightarrow \{0,1\}$ represents the number of tokens residing inside each place; it is usually expressed as an $P$-entry vector.

A Petri net (PN) is the pair $(N, M_0)$, where $M_0$ is an initial marking. In a PN, a transition $t_j$ is enabled at marking $M_k$ if $\forall p \in P, M_k(p) \geq I(p, t_j)$; an enabled transition $t_j$ can be fired reaching a new marking $M_{k+1}$; it is computed by the state...
equation: \( M_{k+1} = M_k - l(p_{t_i}, t_i) + o(p_{t_i}) \). The reachability set of a PN is the set of all possible reachable markings from \( M_0 \) firing only enabled transitions; this set is denoted as \( R(G, M_0) \). For any \( t_j \in T \); \( t_j = \{ p \mid l(p, t_j) = 1 \} \), and \( t_j^* = \{ p \mid o(p, t_j) = 1 \} \); similarly, for any \( p_i \in P \); \( \gamma_i = \{ t_j \mid o(t_j, p_i) = 1 \} \), and \( p_i^* = \{ t_j \mid l(p, t_j) = 1 \} \). A PN where \( M_0(p_i) \in \{0, 1\} \) is called safe or 1-bounded.

An Interpreted Petri net (IPN) is an extension of a PN that includes events and outputs of a modelled process.

**Definition 2.** An Interpreted Petri Net (IPN) is a 6-tuple \( Q = (N, M_0, \Sigma, \Phi, \lambda, \varphi) \), also denoted as \( (Q, M_0) \) where:

- \( \Sigma = \{ \alpha_1, \alpha_2, \ldots, \alpha_r \} \) is the finite input symbol alphabet.
- \( \Phi = \{ \phi_1, \phi_2, \ldots, \phi_s \} \) is the finite output symbol alphabet.
- \( \lambda: T \to \Sigma \cup \{ \varepsilon \} \) is the transition labeling function with the following constraints:
  \[ \forall t_j, t_k \in T, j \neq k, \quad \text{if} \quad \lambda(t_j) = \lambda(t_k) \neq \varepsilon, \quad \text{then} \quad \lambda(t_j) \neq \lambda(t_k). \]
- \( \varphi: R(Q, M_0) \to (Z^+)^q \) is the output function, which associates each marking in \( R(Q, M_0) \), with a \( q \)-entry output vector, where \( q = |\Phi| \). \( \varphi \) is represented by a \( q \times |P| \) matrix, such that the output symbol \( \phi_i \) is present every time that \( M(p_i) > 0 \), then \( \varphi(i, j) = 1 \), otherwise \( \varphi(i, j) = 0 \).

The state equation of \( Q \) is completed with the marking projection \( \gamma_k = \varphi M_k \), where \( \gamma_k \in (Z^+)^q \) is output vector of the \( k \)-th state equation with \( M_k \).

**Definition 3.** Let \((Q, M_0) = (N, M_0, \Sigma, \Phi, \lambda, \varphi)\) be an IPN. If \( \lambda(t_j) \neq \varepsilon \), the transition \( t_j \) is called controllable, otherwise it is called uncontrollable. \( T_U \) is the set of uncontrollable transitions and \( T_C \) is the set of controllable transitions in \((Q, M_0) \). \( T_U = T \setminus T_C \) and \( T_U \cap T_C = \emptyset \). When an enabled transition \( t_i \) is controllable, then to fire \( t_i \) it is also needed that the input symbol \( \lambda(t_i) \) is present. When an enabled transition \( t_i \) is uncontrollable, it can be fired. A place \( p_i \in P \) is said to be measurable if the \( i \)-th column vector of \( \varphi \) (denoted as \( \varphi(i, \bullet) \)) is not null, otherwise it is not measurable. \( P = P_p \cup P_o \) and \( P_p \cap P_o = \emptyset \); where \( P_p \) is the set of measurable places and \( P_o \) the set of non-measurable places.

**Example 1.** In Figure 1 it is shown an IPN \((Q, M_0) = (N, M_0, \Sigma, \Phi, \lambda, \varphi) \). \( \Sigma = \{ q, y, e, d, g \} \). \( \Phi = \{ A, B, C \}. \)

\[ \lambda(t_0) = q, \lambda(t_1) = y, \lambda(t_2) = v, \lambda(t_3) = e, \lambda(t_4) = e, \lambda(t_5) = d, \lambda(t_6) = g. \]

The matrix representing the output function \( \varphi \) is

\[
\varphi = \begin{bmatrix}
1 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 1 & 0
\end{bmatrix}
\]

where every row represents one of the outputs \( A, B, C \in \Phi \). \( P_p = \{ p_1, p_4, p_6 \} \), \( P_o = \{ p_2, p_3, p_5 \} \). Pictorially, places in \( P_p \) and transitions in \( T_U \) are dimmed.

![Fig. 1. Interpreted Petri net (Q, M0).](image)

**Definition 4.** Let \((Q, M_0)\) be an IPN. The set of all firing sequences of \((Q, M_0)\), called the firing language of \((Q, M_0)\), is

\[ L(Q, M_0) = \{ o \mid t_1, t_2, \ldots, t_k \in M_0, t_1 \rightarrow t_2 \rightarrow \ldots \rightarrow t_k \}. \]

Note that for a reachable marking \( M_t \in R(Q, M_0) \), the firing language \( L(Q, M_t) \) denotes the set of all firing sequences enabled from \( M_t \) in \((Q, M_0)\).

**Notation:** The Parikh vector \( \sigma: T \to (Z^+)^n \) of \( \sigma \in L(Q, M_0) \) maps every \( t_i \in T \) to the number of occurrences of \( t_i \) in \( \sigma \). The input language of \((Q, M_0)\) is \( L_{in}(Q, M_0) = \{ \lambda(\sigma) \mid \sigma \in L(Q, M_0) \} \). Given \( w \in L \) a word of a language \( L \) the prefix set of \( w \) is \( \bar{w} = \{ w' \mid \exists \psi \text{ such that } \bar{w} = w \} \).

2.2. IPN Observable language equivalence

In this section we define the observable behaviour to describe when two IPN models can be equivalent, with respect to their output languages.

2.2.1. Observable behaviour equivalence

The measurable places in an IPN \((Q, M_0) = (N, M_0, \Sigma, \Phi, \lambda, \varphi) \) generate signals that an external agent can observe; thus, given a reachable marking \( M \in R(Q, M_0) \), the output \( \varphi(M) \) describes the actual observable state of a process.

The observable equivalence between two IPN determines the behaviour equivalence from an external point of view; i.e., when the observable behaviours of two IPN are indistinguishable regardless the evolution of their markings. A necessary condition for observable equivalence of an IPN \((Q, M_0) = (N, M_0, \Sigma, \Phi, \lambda, \varphi) \), with respect to another IPN \((Q', M_0') = (N', M_0', \Sigma', \Phi', \lambda', \varphi') \), is that they share a set of output symbols \( \Phi_k \subseteq \Phi \) and \( \Phi_k \subseteq \Phi' \). In order to consider only those outputs of interest, let \( \tilde{\varphi} \) be a new output function of \((Q, M_0)\) that considers only those measurable places that are related to an output symbol in \((Q', M_0') \); where \( \tilde{\varphi} \) is composed by only those rows in \( \varphi \) such that the \( i \)-th row of \( \tilde{\varphi} \) represents the activation of the same symbol \( \phi_i \); as the \( i \)-th row of \( \varphi \).

The following notion deals with sequences that generate changes in the output.

**Definition 5.** Let \((Q, M_0) = (N, M_0, \Sigma, \Phi, \lambda, \varphi)\) be an IPN. Let \( \sigma = t_1, t_2, \ldots, t_r \in L(Q, M_0) \) a sequence of transitions such that \( M_0 \rightarrow t_1 \rightarrow M_1 \rightarrow t_2 \rightarrow \ldots \rightarrow M_r \). It is said that \( \sigma \) is an Output Switching sequence (OSS) in \((Q, M_0)\) iff there exist \( i, j \) such that:

- \( \varphi(M_0) \neq 0, \varphi(M_0) \neq 0 \)
- \( \forall M_\rho, 0 \leq x \leq i, \varphi(M_\rho) = \varphi(M_0) \)
- \( \text{if } j = i + 1 \text{ then } \varphi(M_0) \neq \varphi(M_r), \text{else } \forall M_\rho, i < y < j, \varphi(M_\rho) = 0 \)
- \( \forall M_\rho, j \leq z \leq r, \varphi(M_\rho) = \varphi(M_r) \)

The firing of OSSs in \((Q, M_0)\) determine observable words.

**Definition 6.** Let \((Q, M_0) = (N, M_0, \Sigma, \Phi, \lambda, \varphi)\) be an IPN. Let \( \sigma = \sigma_1, \sigma_2, \ldots, \sigma_l \in L(Q, M_0) \) such that \( M_0 \overset{\sigma_1}{\rightarrow} M_1 \overset{\sigma_2}{\rightarrow} \ldots \overset{\sigma_l}{\rightarrow} M_l \) and, \( \sigma_i (1 \leq i \leq l) \) is an OSS or \( \sigma \) is empty. The observable
language of \((Q, M_0)\) is \(L_{\text{obs}}(Q, M_0) = \{ w \mid \exists \sigma \in L(Q, M_0) \}\), where \(w = \phi(M_0) \phi(M_1) \ldots \phi(M_t)\) is the observable word generated by \(\sigma\) in \((Q, M_0)\). The function \(f_{\text{obs}}(Q, M_0): L(Q, M_0) \rightarrow L_{\text{obs}}(Q, M_0)\) maps every firing sequence into its observable word.

**Example 2.** Consider the IPN \((Q, M_0) = (N, M_0, \Sigma, \Phi, \lambda, \varphi)\) of Figure 1. When the sequence \(\sigma = t_0 t_1 t_2 t_3 t_4 t_5 t_6\) is fired in \((Q, M_0)\) it generates the observable word:

\[
w = f_{\text{obs}}(Q, M_0)(t_0 t_1 t_2 t_3 t_4 t_5 t_6) = [1\ 0\ 0\ 0\ 0\ 1\ 0\ 0]
\]

Now we can define the equivalence between two IPN with respect to their observable behaviour.

**Definition 7.** Let \((Q, M_0) = (N, M_0, \Sigma, \Phi, \lambda, \varphi)\) and \((Q', M'_0) = (N', M'_0, \Sigma', \Phi', \lambda', \varphi')\) be two IPN models. \((Q, M_0)\) is observable equivalent to \((Q', M'_0)\) iff \(L_{\text{obs}}(Q, M_0) = L_{\text{obs}}(Q', M'_0)\).

Is easy to see that for \((Q, M_0)\) and \((Q', M'_0)\) in Figures 1 and 2.a respectively, \((Q, M_0)\) is observable equivalent to \((Q', M'_0)\).

### 2.2.2. Controllability

Let \((Q, M_0)\) be an IPN and \(K \subseteq L(Q, M_0)\) be the specification language. The language \(K\) is controllable with respect to \(L(Q, M_0)\). iff \(\forall t_i \in T_\varphi\) it holds that \(t_i \cap L(Q, M_0) \subseteq \overline{K}\).

Now it is possible to define all those observable words that can be generated by an IPN by the firing of uncontrollable firing sequences only.

**Definition 8.** Let \((Q, M_0) = (N, M_0, \Sigma, \Phi, \lambda, \varphi)\) be an IPN model. The controllable observable language of \((Q, M_0)\) is \(L'_{\text{obs}}(Q, M_0) = \{ w \in L_{\text{obs}}(Q, M_0)\mid \exists \sigma \text{ controllable in } (Q, M_0) \} \) it is the set of all the controllable observable words in \(L_{\text{obs}}(Q, M_0)\).

Now we can define when two IPN models can be equivalent, with respect to their controllable observable languages.

**Definition 9.** Let \((Q, M_0) = (N, M_0, \Sigma, \Phi, \lambda, \varphi)\) and \((Q', M'_0) = (N', M'_0, \Sigma', \Phi', \lambda', \varphi')\) be two IPN models. \((Q, M_0)\) is controllable observable equivalent to \((Q', M'_0)\) iff \(L'_{\text{obs}}(Q, M_0) = L'_{\text{obs}}(Q', M'_0)\).

Given \((Q, M_0)\) and \((Q', M'_0)\), when the controllable observable languages of \((Q, M_0)\) and \((Q', M'_0)\) are equal, it means that for every controllable firing sequence in \((Q', M'_0)\) that generates an observable word \(w\), there exists a controllable firing sequence in \((Q, M_0)\) that generates \(w\) and vice versa.

It is easy to see that for \((Q, M_0)\) and \((Q', M'_0)\) in Figures 1 and 2.b respectively, \(L'_{\text{obs}}(Q, M_0) = L'_{\text{obs}}(Q', M'_0)\); thus, \((Q, M_0)\) is controllable observable equivalent to \((Q', M'_0)\).

### 3. IPN ABSTRACTION

Several transformation methods have been proposed in [Berthelot, 1986], [Murata, 1989] and [Lee-Kwang, 1987], which are applicable to general PN. The rules from [Berthelot, 1986] preserve the paths in the original net that always fire consecutively the transitions to be merged by the transformation. Whereas the interest in some of the reduction rules from [Murata, 1989] and [Lee-Kwang, 1987] is to remove unnecessary paths and redundant nodes.

The above-mentioned transformations do not consider properties regarding the controllability of events and reachability of observable states. Then, an abstraction technique based on a set of graph rewriting operators \(\sigma\) for safe IPN is proposed in this paper; the aim is to eliminate structural redundancies and unnecessary parallel evolutions while preserving the observable language and controllable observable language with respect to a set of outputs \(\Phi\).

#### 3.1 Transformation operators

A transformation operator \(\mathcal{T}_x\) changes a part of a source IPN \((Q, M_0)\) into another one preserving desired properties while reducing the number of nodes. The resulting IPN after the application of an operator \(\mathcal{T}_x\) is denoted as \((Q, M_0)|_{\mathcal{T}_x}\). Six transformation operators \(\sigma = \{\mathcal{T}_1, \mathcal{T}_2, \mathcal{T}_3, \mathcal{T}_4, \mathcal{T}_5, \mathcal{T}_6\}\) are presented; every \(\mathcal{T}_x\) is illustrated through an example.

#### 3.1.1 Operator \(\mathcal{T}_1\): post-fusion of transitions

This operator eliminates a non-measurable place \(p\) and merges the pre-set \(B\) of \(p\) with its post-set \(F\); that is, the transitions in \(B\) and \(F\) are substituted by a set of transitions that represent the possible firing sequences from a transition in \(B\) to a transition in \(F\). Then, the original paths are recorded as transition sequences in the new transitions of the abstracted net.

**Definition 10.** Operator \(\mathcal{T}_1\). Let \((Q, M_0) = (N, M_0, \Sigma, \Phi, \lambda, \varphi)\) be an ordinary and safe IPN. The operator \(\mathcal{T}_1\) is applicable to \((Q, M_0)\) if there exist a non-measurable place \(p \in P\) and sets \(B = \{p, F = p\} \subseteq T\) such that:

- \(i.\ B \cap F = \emptyset\), \(p \notin B^*\) and \(p \notin F^*\)
- \(ii.\ \{F\} = \{p\}\), The only input of \(F\) is \(p\)
- \(iii.\ F^* = \emptyset\), \(F\) has at least one output place
- \(iv.\ |B| = 1\) or \(|F| = 1\) \(B\) or \(F\) has only one transition
- \(v.\ M_0(p) = 0\) \(p\) is initially unmarked
- \(vi.\ \emptyset \in P_p\), \(p\) is not a measurable place
- \(vii.\ One\ of\ the\ following\ conditions\ holds:\
  \hspace{1cm}vii.1.\ "B \cap P_p = \emptyset, B^* = \emptyset\) and either vii.1.1 or vii.1.2 is fulfilled
  \hspace{1cm}vii.1.1. \((B \cup F) \cap T_\varphi = \emptyset\) and 
  \hspace{2.5cm}vt \in B, vt' \in \{(c(t)) \cap \{t\}\} \cap T_\varphi: \{t\} \subseteq \{t'\}
  \hspace{1cm}vii.1.2. \(F \subseteq T_\varphi\) and \(|F| = 1\)
  \hspace{1cm}vii.2. \(F^* \cap P_p = \emptyset, (B^*(p))^* \cap T_\varphi = \emptyset, B^* \cap F^* = \emptyset\) and \(vii.2.1.\) or \(vii.2.2.\)
  \hspace{1cm}vii.2.1. \((B \cup F \cup F^*)^* \cap T_\varphi = \emptyset\)
  \hspace{1cm}vii.2.2. \(F \subseteq T_\varphi, |F| = 1\)

therefore, \((Q, M_0)\) can be transformed into \((Q, M_0)|_{\mathcal{T}_1}\) after the application of the following steps:
1. \( \forall t_j \in p, \forall t_j \in p \)
   
   1.1. \( T = T \cup \{ t_k \} \)
   
   1.2. \( \forall p_q \in T, \lambda(p_q, t_k) \leftarrow 1 \)
   
   1.3. \( \forall p_r \in (t_i \cup p \cup t_j), \lambda(p_r, t_k) \leftarrow 1 \)
   
   1.4. \( \lambda(t_k) \leftarrow \lambda(t_i) \cdot \lambda(t_j) \)

2. \( T \leftarrow T \setminus \{ p \} \)

3. \( P \leftarrow P \setminus \{ p \} \)

Notice that \( \lambda(t_k) \) created in step 1.4 is the concatenation of the labels of the merged transitions.

The conditions from \( i \) to \( iii \) are sufficient to preserve liveness and safeness; they are equivalent to those in [Berthelot, 1986] when the conditions are restricted to safe Petri nets. The condition \( iv \) is needed to assure that every application of \( T_1 \) always reduces the number of nodes of the original IPN. The application conditions \( v \) and \( vi \) are needed to preserve the initial marking and the measurable places of interest. Conditions in \( vii \) are necessary to preserve the observable and controllable observable languages from the original IPN.

**Example 3.** Fig. 3.a shows an IPN that satisfies \( 'B \cap P_p = \emptyset; B = \{ p_1 \} \), it also satisfies conditions \( vii.1.1 \) and \( vii.1.2 \) respectively. The transformed IPN is shown in figure 3.b. The dashed places and arrows represent structural conditions that are not allowed for applying the operator \( T_1 \).

![Fig. 3. a) IPN (Q, M₀) satisfying vii.1.1. b) (Q, M₀)|T₁.](image)

3.1.2. **Operator \( T_2 \): pre-fusion of transitions**

Alike to \( T_1 \), this operator merges the single transition \( b \) in the pre-set of a non measurable place \( p \), with the set of transitions \( F \) of the post-set of \( p \), when the enabling of any transition in \( F \) cannot occur after the firing of \( b \).

**Definition 11.** Operator \( T_2 \). Let \( (Q, M₀) = (N, M₀, \Sigma, \Phi, \lambda, \varphi) \) be an ordinary and safe IPN. The transformation operator \( T_2 \) is applicable to \( (Q, M₀) \) if there exist a place \( p \in P \), a transition \( b \in T \) and a set \( F \subseteq T \) such that:

1. \( 'p = \{ b \} \). The only input of \( p \) is \( b \)
2. \( b^* = \{ p \} \). The only output of \( b \) is \( p \)
3. \( 'b = \emptyset, b \) has at least an input place
4. \( b \notin F, b \) is not an output of \( p \)
5. \( M₀(p) = 0, p \) is initially unmarked
6. \( 'b = \{ b \}, b \) does not share its input places
7. \( p \notin P_{p_{\emptyset}}, p \) is not a measurable place
8. \( 'p \cap P_{p_{\emptyset}} = \emptyset \) and one of the following conditions:
   
   viii.1. \( (b \cup F) \cap T₀ = \emptyset \)
   
   viii.2. \( F \cap T₀ = \emptyset, b \in T₀ \) and \( 'b \cap T₀ = \emptyset \)

then, \( (Q, M₀) \) is transformed into \( (Q, M₀)|T₂ \) after the application of the following steps:

1. \( \forall t_j \in p^* \)
   
   1.1. \( T = T \cup \{ t_k \} \)
   
   1.2. \( \lambda(t_k) \leftarrow \lambda(b) \lambda(t_j) \)
   
   1.3. \( \forall p_r \in ('t_i \setminus \{ p \}) \cup \{ b \}, \lambda(p_r, t_k) \leftarrow 1 \)
   
   1.4. \( \forall p_q \in t_i \setminus (\emptyset, \lambda(p_q, t_k) \leftarrow 1 \)

2. \( T \leftarrow T \setminus \{ b \} \)

3. \( P \leftarrow P \setminus \{ p \} \)

Similarly to \( T_1 \), the application conditions from \( i \) to \( vi \) are sufficient to preserve liveness and safeness, since they are equivalent to those in [Berthelot, 1986] when the conditions are restricted to ordinary and safe Petri nets. Conditions \( vii \) and \( viii \) are necessary to preserve the observable language and controllable observable language from the original IPN.

**Example 4.** In the IPN shown in Figure 4, the place \( p_1 \) is removed after the application of the operator \( T_2 \), since the conditions \( 'B \cap P_p = \emptyset \) and \( viii.1 \) are satisfied. The dashed places and arrows represent some structures not allowed.

![Fig. 4. a) IPN (Q, M₀) satisfying vii.1.1. b) (Q, M₀)|T₁.](image)

3.1.3. **Operator \( T_3 \): parallel place removal**

This transformation operator removes a non measurable place \( p \) in the Petri net, when there exist another place that has the same pre-set and post-set than \( p \), such that the initial marking assigns the same number of tokens to them.

**Definition 12.** Operator \( T_3 \). Let \( (Q, M₀) = (N, M₀, \Sigma, \Phi, \lambda, \varphi) \) be an ordinary and safe IPN. The transformation operator \( T_3 \) is applicable to \( (Q, M₀) \) if there exist non-measurable places \( p, r \in P \) where \( p \neq r \), such that:

1. \( 'p = r \)
2. \( p^* = r^* \)
3. \( M₀(p) = M₀(r) \)
4. \( p \notin P_{p_{\emptyset}} \) or \( r \notin P_{p_{\emptyset}} \)

then, \( (Q, M₀) \) is transformed into \( (Q, M₀)|T₃ \) after applying the update: if \( p \in P_{p_{\emptyset}} \) then \( P \leftarrow P \setminus \{ r \} \) else \( P \leftarrow P \setminus \{ p \} \).

It is easy to see that this operator preserves liveness and safeness of the PN. Furthermore, this transformation does not alter the firing sequences, since no transition is ever removed and for every reachable marking, both \( r \) and \( p \) have the same number of tokens.

**Example 5.** Figure 5.a shows an IPN \( (Q, M₀) \), where the places \( p_5 \) and \( p_6 \) are parallel to \( p_2 \) and \( p_3 \) respectively. Figure 5.b shows \( (Q, M₀)|T₃ \), the resulting IPN after the application of the operator \( T₂ \), where the non measurable parallel places \( p_5 \) and \( p_6 \) are eliminated.
The identical transition removal operator deletes a controllable transition when there exists another transition with the same pre-set and post-set, because the firing of either one will lead to the same marking. If one transition is not controllable, then the controllable one is eliminated. This transformation operator preserves liveness and safeness of the IPN.

**Definition 13.** Operator $\mathcal{T}_4$. Let $(Q, M_0) = (N, M_0, \Sigma, \Phi, \lambda, \varphi)$ be an ordinary and safe IPN. The transformation operator $\mathcal{T}_4$ is applicable to $(Q, M_0)$ if there exist transitions $t, y \in T$, $t \neq y$ such that:

i. $t = y$,

ii. $t^* = y^*$,

iii. $t \notin T_U$ or $y \notin T_U$.

$(Q, M_0)$ is transformed into $(Q, M_0)|_{\mathcal{T}_4}$ after the application of the following step:

$\text{If } t \notin T_U \text{ then } T \leftarrow T \setminus \{t\} \text{ else } T \leftarrow T \setminus \{y\}$

**Example 6.** Figure 6.a shows an IPN $(Q, M_0)$, where the transition $t_4$ is redundant with respect to $t_1$. Fig. b shows the resulting IPN after the application of the operator $\mathcal{T}_4$, where the identical transition $t_4$ is removed.

The transformation operator $\mathcal{T}_5$ removes an initially marked self-loop place when it is non-measurable.

**Definition 14.** Transformation operator $\mathcal{T}_5$. Let $(Q, M_0) = (N, M_0, \Sigma, \Phi, \lambda, \varphi)$ be an ordinary and safe IPN. The transformation operator $\mathcal{T}_5$ is applicable to $(Q, M_0)$ if there exist a non-measurable place $p \in P$ and transition $t \in T$ such that:

i. $\mathcal{P} = p^*$,

ii. $M_0(p) = 1$,

iii. $p \in P$,

iv. $|\mathcal{P}| > 1$.

$(Q, M_0)$ is transformed into $(Q, M_0)|_{\mathcal{T}_5}$ after the application of the following step: $P \leftarrow P \setminus \{p\}$

It is easy to see that this transformation operator preserves liveness and keeps the PN safe. Since no transition is removed, this transformation does not alter the reachability analysis.

**Example 7.** Figure 7 shows two IPN representing the original IPN (a) and the resulting IPN after the application of the transformation operator $\mathcal{T}_5$ (b); the initially marked non-measurable self-loop place $p_3$ is eliminated.

The self-loop transition removal transformation operator eliminates a self-loop transition when it is controllable.

**Definition 15.** Transformation operator $\mathcal{T}_6$. Let $(Q, M_0) = (N, M_0, \Sigma, \Phi, \lambda, \varphi)$ be an ordinary and safe IPN. The transformation operator $\mathcal{T}_6$ is applicable to $(Q, M_0)$ if there exist a transition $t \in T$, and a non-measurable place $p \in P$ such that:

i. $t = t^* = \{p\}$

ii. $t \notin T_U$.

$(Q, M_0)$ is transformed into $(Q, M_0)|_{\mathcal{T}_6}$ after the application of the following step: $T \leftarrow T \setminus \{t\}$

A self-loop transition can be removed because its firing leads to the same marking; then it is not useful for the reachability analysis. The constraint regarding the controllable transitions is held to preserve the controllability of the IPN firing sequences. This transformation also preserves liveness and safeness of the transformed IPN.

**Example 8.** In Figure 8 it is shown two IPN representing the original IPN (a) and the resulting IPN after the application of the transformation operator $\mathcal{T}_6$ (b), where the controllable self-loop transitions $t_3$ and $t_5$ are removed.

After the application of the operators, the incidence matrix changes. After removing a place $p_i$, the $i$-th column of the matrix $\varphi$ is removed. Similarly, for a transition $t_j$ the $j$-th row is removed.

**3.2. Properties of the model transformed by the operators**

As mentioned in subsection 3.1, all the operators preserve liveness and safeness. Besides safeness, in order to apply a transformation operator to an already transformed IPN it is necessary that the resulting IPN remains ordinary.
Proposition 1. Let \((Q, M_0)\) be an ordinary and safe IPN and let \((Q', M_0')\) be the resulting safe IPN after the application of the transformation operators \(T_x \in \mathcal{O}\) to \((Q, M_0)\). \((Q', M_0')\) is an ordinary Petri net.

Now, we can state that the abstraction obtained by the application of all the transformation operators \(T_x \in \mathcal{O}\) preserves the observable and controllable output languages. This is summarised in the next statement:

Proposition 2. Let \((Q, M_0) = (N, M_0, \Sigma, \Phi, \lambda, \phi)\) be an ordinary and safe IPN and let \((Q', M_0') = (N', M_0', \Sigma', \Phi', \lambda', \phi')\) be the resulting IPN after the application of the transformation operator \(T_x \in \mathcal{O}\) to \((Q, M_0)\), for \(x = 1, 2, \ldots, 6\).

i) \((Q, M_0)\) is observable equivalent to \((Q', M_0')\) (i.e. \(L_{\text{obs}}(Q, M_0) = L_{\text{obs}}(Q', M_0')\)).

ii) \((Q, M_0)\) is controllable observable equivalent to \((Q', M_0')\) (i.e. \(L_{\text{obs}}^c(Q, M_0) = L_{\text{obs}}^c(Q', M_0')\)).

The proofs are omitted for space reasons; they can be found in [Chavarin, 2017]. Indeed, they are twelve proofs regarding the application conditions and the transforming steps for every \(T_x \in \mathcal{O}\) and the languages \(L_{\text{obs}}\) and \(L_{\text{obs}}^c\).

4. AN IPN REDUCTION SCHEME

As described in [Silva, 1985], there are two ways to apply the transformation operators: a predefined strategy or a specific strategy. The predefined strategy consists in defining a priori the order of the application of each transformation operator; this approach allows handling complex structures efficiently. In contrast, the specific strategy consists in selecting stepwise, the application of the next operator; this procedure must be driven by an expert.

4.1 Strategy

Here, we propose as a convenient strategy, to apply first the transformation operators \(T_6\) and \(T_5\), because they may yield structures in which the transformation operators \(T_3\) and \(T_4\) can be applied. After that, the operators \(T_3\) and \(T_4\) can be applied to remove redundant nodes. Finally the operators \(T_1\) and \(T_2\) can be applied since they produce more significant reductions.

This predefined strategy has shown experimentally to obtain faster the abstract IPN [Chavarin, 2017]. It is summarised below as a procedure \(\pi\): \(T_x^*\) denotes the application of \(T_x\) repeatedly until there is no more transformation. \(\pi\): Do \{\(T_6^*; T_5^*; T_3^*; T_2^*; T_1^*\)\} while a \(T_x\) can be applied.

The complexity of the procedure for applying the kit of transformation operators is polynomial-time on the size of the Petri net.

The application of any operator of the kit reduces the net at least by one node. The number of possible transformations is finite. Furthermore, all the transformations operators are local. If one operator in \(\{T_1, T_2, T_3, T_6\}\) is applied, the reachability graph decreases, whereas if \(T_3\) or \(T_2\) are applied, the marking size is reduced but the size of the reachability graph is not decreased; however, they are needed to unlock new possible applications of other operators.

4.2 Properties of the abstract model

Theorem 1. Let \((Q, M_0) = (N, M_0, \Sigma, \Phi, \lambda, \phi)\) be an ordinary and safe IPN and let \((Q', M_0') = (N', M_0', \Sigma', \Phi', \lambda', \phi')\) be the resulting ordinary and safe IPN after the application of the procedure \(\pi\) to \((Q, M_0)\).

a) \((Q, M_0)\) is observable equivalent to \((Q', M_0')\) (i.e. \(L_{\text{obs}}(Q, M_0) = L_{\text{obs}}(Q', M_0')\)).

b) \((Q, M_0)\) is controllable observable equivalent to \((Q', M_0')\) (i.e. \(L_{\text{obs}}^c(Q, M_0) = L_{\text{obs}}^c(Q', M_0')\)).

Proof: By Proposition 2, we have that the application of each transformation operator to a safe IPN will preserve both the observable language and the controllable observable language. Then, applying consecutively any transformation in any order, in particular that stabilised by \(\pi\), the observable languages will be preserved.

Observe that Theorem 1 ensures that for every controllable observable word \(w \in L_{\text{obs}}^c(Q, M_0)\), there exist a controllable firing sequence \(\sigma \in L(Q', M_0')\) that generates \(w\).

Is easy to see that the firing sequences in a resulting IPN model \((Q', M_0')\), after the application of any of the operators \(T_3\) to \(T_6\) to an IPN \((Q, M_0)\), is a firing sequence of \(L(Q, M_0)\). For the case of the operators \(T_1\) or \(T_2\) to \((Q, M_0)\), represents the firing of the transition \(t_p\) followed by \(t_x\), thus every firing sequence in \(L(Q', M_0')\) represents a firing sequence in \(L(Q, M_0)\).

Example 9. Let the IPN \((Q_p, M_0) = (N, M_0, \Sigma, \Phi, \lambda, \phi)\) shown in Figure 9 representing a manufacturing process, \(T_0 = \{t_10, t_11, t_12, t_14, t_{22}\}\), \(T_c = T \setminus T_0\), \(P_p = P\) and \(P_0 = \emptyset\). The measurable places of interest are \(P_0 = \{p_4, p_{11}, p_{12}, p_{13}\}\). The output function \(\phi\) that considers only the output symbols of interest \(\Phi^R \in \Phi\) with respect to the reference model \((Q_0, M_0^R)\) is

\[
\phi = \begin{bmatrix}
0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0
\end{bmatrix}
\]

Fig. 9. IPN process model of Example 9.

Now, by the iterative application of the operator \(T_1\) the places \(p_1, p_{10}, p_{14}, p_{15}, p_{21}, p_{22}, p_{23}, p_3\) and \(p_9\) are removed, the resulting IPN after this transformation is represented by the IPN depicted in Figure 10.

After that, the redundant nodes \(p_6, t_5, t_{20}\) and \(p_{16}\) are removed by the application of the operators \(T_5, T_3\) and \(T_3\) respectively, the resulting IPN is shown in Figure 11.
The removal of the redundant nodes create new application cases; the nodes $p_9$ and $p_{10}$ are removed by the operators $T_2$ and $T_3$ respectively. After that, the self-loop transition $t_2$, $t_3$, $t_4$ and the self-loop place $p_9$ are removed by the operators $T_6$ and $T_7$ respectively. Those were the final possible reductions by $\pi$, the resulting IPN representing the abstract model $(Q_p, M_0)$ of the process $(Q_p, M_0)$ with respect to the output symbols of interest, is shown in Figure 12.

It is easy to verify that both the observable language and the controllable observable language are preserved. Furthermore, the reachability set is highly decreased: the reachability graph of the original IPN has 315 states with 890 arcs, while that of the abstract model has 16 states with 32 arcs.

The abstract IPN of this example (and many others) has been obtained with the help a software developed using the proposed technique. This is reported in [Chavarin, 2017], where the abstract models are used in regulation control scheme.

4. CONCLUSIONS

A model abstraction technique for safe Interpreted Petri Nets (IPN) has been proposed. The technique is oriented to the analysis and control of Discrete Event Systems (DES); it can be used to simplify the controllability analysis and the controller synthesis in a regulation control framework. The abstraction method includes a kit of local transformation operators that simplifies stepwise the structure of an initial IPN by reducing its size progressively. The abstraction is done with respect to a subset of observable places of interest, by preserving the controllability feature of the paths in the transformed structures. Thus, the abstracted IPN preserves the observable language and the controllable observable language with respect to the original IPN.
