Abstract

The first step in the verification of cryptographic protocols is to decide the intruder deduction problem, that is the vulnerability to a so-called passive attacker. We extend the *Dolev-Yao* model in order to model this problem in presence of the equational theory of a commutative encryption operator which distributes over the *exclusive-or* operator. The interaction between the commutative distributive law of the encryption and *exclusive-or* offers more possibilities to decrypt an encrypted message than in the non-commutative case, which imply a more careful analysis of the proof system. We prove decidability of the intruder deduction problem for a commutative encryption which distributes over *exclusive-or* with a DOUBLE-EXP-TIME procedure. And we obtain that this problem is EXPSPACE-hard in the binary case.

1 Introduction

Today, the number of interactive services proposed on the Internet is exploding. Most of them use cryptographic protocols to guarantee some level of security. They can be seen as relatively simple programs which are executed in an unsecure environment. There are different approaches for modeling cryptographic protocols and analyzing their security properties. One of them is the approach of Dolev and Yao [DY83], which models the attacker capabilities by a deduction system. This model is often used to analyze the security of protocols against a *passive* attacker, *i.e* an intruder which obtains information by eavesdropping on the communications between honest participants and deduces some information from these messages. The question whether a passive attacker gets a certain information from observed messages on the network is called the *intruder deduction problem*.

Algebraic Properties: Usually the capabilities of the intruder are based on the so-called *perfect cryptography assumption*, *i.e.* it is impossible to obtain

any information about an encrypted message without knowing the exact key necessary to decrypt this message. Unfortunately, this perfect cryptography assumption is too idealistic: There are protocols which can be proved secure under the perfect cryptography assumption, but which are in reality insecure since an attacker can use properties of the cryptographic primitives in combination with the protocol rules to learn some secret informations (see [CDL06] for a survey). It is necessary to relax this assumption by increasing the deductive power of the intruder. One possibility is to add the capability to take into account some algebraic properties to model an intruder in a more realistic way, which may find new attacks.

Related Work: Solutions to the intruder deduction problem modulo an equational theory are known for the cases of modular exponentiation [CKRT03b, MS03], of *exclusive-or*, of Abelian groups [CLS03, CKRT03a], of a homomorphism symbol alone [CLT03], and of combinations of homomorphism and one of the operators of *exclusive-or* or Abelian groups [LLT05a, Del06]. Another result [CKRT04] proves that the so-called *active intruder* with just a commutative encryption and the classical Dolev-Yao model is decidable. We have already studied in [LLT05b] the intruder deduction problem for a non-commutative encryption which distributes over the *exclusive-or* symbol, denoted $\oplus$. A natural question is to consider now the case of commutative encryption, *i.e.* $\{\{u\}_{k1}\}_{k2} = \{\{u\}_{k2}\}_{k1}$, for instance the encryption RSA. Notice that in this case the equational theories of the $\oplus$ operation and of the commutative encryption operation which distributes over the *exclusive-or* symbol, *i.e.* $\{x \oplus y\}_k = \{x\}_k \oplus \{y\}_k$, are not disjointed because they share the encryption symbol function, hence the combination algorithm proposed in [CR05] can not be applied.

Our contribution: We investigate the intruder deduction problem with the equational theory of a commutative encryption, *i.e.* $\{\{u\}_{k1}\}_{k2} = \{\{u\}_{k2}\}_{k1}$ which distributes over the *exclusive-or i.e.* $\{x \oplus y\}_k = \{x\}_k \oplus \{y\}_k$, where *exclusive-or* has the properties of Associativity, Commutativity, Unity and Nilpotency. The interaction between the commutative distributive law of the encryption and *exclusive-or* offers more possibilities to decrypt an encrypted message than in the non-commutative case. The commutativity of encryption requires to define new notions and to find new proof transformations, since one encrypted message can be partially decrypted by several different keys. In the non-commutative case for solving this problem it is enough to construct some normalization of proofs where applications of the *exclusive-or* rules are applied as early as possible. In the case of the commutative encryption, we have to apply as early as possible the decryption and after as early as possible the *exclusive-or*. This raises some difficulties that we solve by characterizing new proof notions, constructing transformations to pass from one to another, designing a right set of subterms and proving a normalization of proof to get the result. We obtain a decision procedure in DOUBLE-EXP-TIME for the intruder deduction problem with the equational theory of the *exclusive-or* and commutative distributive encryption over this operator. We prove also in the particular case of the binary proofs that the intruder deduction problem is EXPSPACE-hard for this equational theory.

Plan: We recall in Section 2 usual notions required in the rest of the paper. In Section 3 we introduce the extended Dolev-Yao model of intruder capacities. In Section 4 we present the generalization of McAllester's locality algorithm. In the rest we introduce all required notions to show the locality result in Section 9. Finally in Section 10 we present the binary case and conclude in Section 11.

2 Preliminaries

We refer the reader to [DJ90, BN98] for an overview of rewriting.
Let Σ be a signature. $T(\Sigma, X)$ denotes the set of terms over the signature Σ and the set of variables X, that is the smallest set such that: (*i*) $X \subseteq T(\Sigma, X)$, (*ii*) if $t_1, \ldots, t_n \in T(\Sigma, X)$, and $f \in \Sigma$ has arity $n \geq 0$, then $f(t_1, \ldots, t_n) \in T(\Sigma, X)$. We abbreviate $T(\Sigma, \emptyset)$ as $T(\Sigma)$; elements of $T(\Sigma)$ are called Σ-*ground terms*. The set of variables occurring in a term t is denoted by $\mathcal{V}(t)$.

The *set of occurrences* of a term t is defined recursively as $\mathcal{O}(f(t_1, \ldots, t_n)) = \{\epsilon\} \cup \bigcup_{i=1\ldots n} i \cdot \mathcal{O}(t_i)$. For instance, $\mathcal{O}(f(a, g(b, x))) = \{\epsilon, 1, 2, 21, 22\}$. The *size* $|t|$ of a term t is defined as its number of occurrences, that is $|t| = \mathit{cardinality}(\mathcal{O}(t))$. We extend the notion of size to a set of terms T by $|T| = \Sigma_{t \in T}|t|$. If $o \in \mathcal{O}(t)$ then the *subterm of t at position o* is defined recursively by:

- $t \mid_\epsilon = t$
- $f(t_1, \ldots, t_n) \mid_{j \cdot o} = t_j \mid_o$

A term r is a *subterm* of a term t if r is a subterm of t at some position of t.

A Σ-*equation* is a pair $(l, r) \in T(\Sigma, X)$, commonly written as $l = r$. The relation $=_E$ generated by a set of Σ-equations E is the smallest congruence on $T(\Sigma)$ that contains all ground instances of all equations in E.

A Σ-*rewriting system* R is a finite set of so-called *rewriting rules* $l \to r$ where $l \in T(\Sigma, X)$ and $r \in T(\Sigma, \mathcal{V}(l))$. A term t is in *normal form* if there is no term s with $t \to s$. If $t \to^* s$ and s is a normal form then we say that s is a *normal form of* t, and write $s = t\!\downarrow$.

Let T be a set of terms, the mapping $S : T \to T$ is idempotent if for every $X \subseteq T$: $S(S(X)) = S(X)$. The mapping S is monotone if for all $X, Y \subseteq T$: if $X \subseteq Y$ then $S(X) \subseteq S(Y)$. S is transitive if for all $X, Y, Z \subseteq T$, $X \subseteq S(Y)$ and $Y \subseteq S(Z)$ implies $X \subseteq S(Z)$. The following Proposition is straightforward.

Proposition 1 *Let S be a mapping from sets of terms to sets of terms. If S is idempotent and monotone then S is transitive.*

3 A Dolev-Yao Model for Rewriting Modulo *AC*

We consider the classic model of deduction rules introduced by Dolev and Yao [DY83] in order to model the deductive capabilities of a passive intruder. We present an extension of this model with the equational theory XCDE (*eXclusive-or* with a Commutative Distributive Encryption over $\oplus$).

The knowledge of the intruder is represented by terms built over a finite signature $\Sigma = \{\langle\cdot,\cdot\rangle, \{\cdot\}_\cdot, \oplus\} \uplus \Sigma_0$, where Σ_0 is a set of constant symbols. The term $\langle u, v\rangle$ represents the pairing of the two terms u and v. The term $\{u\}_K$ represents the encryption of the term u by a finite multiset of keys K and we consider that $\{u\}_\emptyset = u$. For the sake of simplicity, we consider symmetric commutative encryption, all results can be extended to the asymmetric case.

The equational theory XCDE is represented by the following convergent rewriting system R: $0 \oplus x \to x$; $x \oplus x \to 0$; $\{x \oplus y\}_z \to \{x\}_z \oplus \{y\}_z$;$\{0\}_z \to 0$ (the last rule is required to get the confluence of R). R is terminating and confluent modulo associativity and commutativity of $\oplus$, and such that for all terms $t, s \in T(\Sigma)$ we have that $t =_E s$ if and only if $t\downarrow =_{AC} s\downarrow$. The deduction system of Figure 1 corresponds to the deductive capabilities of an attacker considering the equational theory XCDE.

$$(A)\frac{u \in T}{T \vdash u\downarrow} \qquad (P)\frac{T \vdash u \qquad T \vdash v}{T \vdash \langle u, v\rangle\downarrow}$$

$$(C)\frac{T \vdash u \qquad T \vdash K}{T \vdash \{u\}_K\downarrow} \qquad (D)\frac{T \vdash r \qquad T \vdash K}{T \vdash u\downarrow} \text{ if } r =_E \{u\}_K$$

$$(UL)\frac{T \vdash r}{T \vdash u\downarrow} \text{ if } \langle u, v\rangle = r \qquad (UR)\frac{T \vdash r}{T \vdash v\downarrow} \text{ if } \langle u, v\rangle = r$$

$$(GX)\frac{T \vdash u_1 \qquad \ldots \qquad T \vdash u_n}{T \vdash u_1 \oplus \ldots \oplus u_n\downarrow}$$

Figure 1: A Dolev-Yao proof system working on normal forms by a rewrite system R modulo AC for a commutative encryption, where $K = \{k_1^{\alpha_1}, \ldots, k_n^{\alpha_n}\}$is a multiset of keys, where α_i represents the multiplicity of the keys k_i in K.

This proof system is composed of the following rules: (A) the intruder may use any term which is in his initial knowledge, (P) the intruder can build a pair of two messages, (UL),(UR) he can extract each member of a pair, (C) he can encrypt a message u with a multiset K of keys, (D) if he knows a multiset K of keys then he can decrypt a message encrypted by K. Let $K = \{k_1^{\alpha_1}, \ldots, k_n^{\alpha_n}\}$ be a multiset of keys, the sequent $T \vdash K$ is short for: α_1 times the sequent $T \vdash k_1, \ldots, \alpha_n$ times the sequent $T \vdash k_n$. Sometimes, we shall annotate the rules (C) and (D) by the multiset of keys that they use, yielding rules (C_K) and (D_K). Because of the algebraic properties of the $\oplus$ operator, we add a family of rules (GX) which allows the intruder to build a new term from an arbitrary number of already known terms by using the $\oplus$ operator.

Definition 1 *A proof P of $T \vdash w$ is a finite tree such that:*

- *every leaf of P is labeled by $v \in T$.*
- *every node of P with n children ($n \geq 1$) labeled with $T \vdash v_1, \ldots, T \vdash v_n$, is labeled with $T \vdash v$ such that $\frac{T \vdash v_1 \quad \ldots \quad T \vdash v_n}{T \vdash v}(R)$ is an instance of the rule of Figure 1.*

- *the root of P is labeled with $T \vdash w$.*

A sub-proof *P' of a proof P is a sub-tree of P. The* size *of a proof P is the number of nodes in P, denoted by $|P|$.*

In fact, this proof system is equivalent in deductive power to a variant of the system in which terms are not automatically normalized, but in which arbitrary equational proofs are allowed at any moment of the deduction. The equivalence of the two proof systems has been shown in [CLT03] without *AC* axioms; and in [LLT05a] this has been extended to the case of a rewrite system modulo *AC*. In the following, all terms are normalized and we omit the normalization symbol $\downarrow$.

4 Locality Result and Complexity

Our starting point is the locality technique introduced by McAllester [McA93]. He considers deduction systems which are represented by finite sets of Horn clauses. He shows that there exists a polynomial-time algorithm to decide the deducibility of a term w from a finite set of terms T if the deduction system has the so-called *locality property*. A deduction system has the *locality property* if any proof can be transformed into a *local proof*, that is a proof where all nodes are syntactic subterms of $T \cup \{w\}$. The idea of the proof is to check existence of a local proof by a saturation algorithm which computes all syntactic subterms of $T \cup \{w\}$ that are deducible from T. In [LLT05b] we generalize McAllester's approach, here we just recall the definition of a local proof and the locality Theorem. In the rest of the paper we denote $T \cup \{w\}$ by T, w.

Definition 2 *Let S be a function which maps a set of terms to a set of terms. A proof P of $T \vdash w$ is* S-local *if all nodes are labeled by some $T \vdash v$ with $v \in S(T, w)$. A proof system is* S-local *if whenever there is a proof of $T \vdash w$ then there is also a S-local proof of $T \vdash w$.*

Theorem 1 *Let S be a function mapping a set of terms to a set of terms, and P a proof system. Let T be a set of terms, let w be a term and let n be $|T, w|$. If:*

1. *one-step deducibility of $S \vdash u$ in P is decidable in time $g(|S, u|)$ for any term u and set of terms S,*
2. *the set $S(T, w)$ can be constructed in time $f(n)$,*
3. *P is S-local,*

then provability of $T \vdash w$ in the proof system P is decidable in time $f(n) + f(n) * f(n) * g(f(n))$ (non-deterministic if one of (2), (1) is non-deterministic).

We say that u is one-step deducible from a set of hypotheses H if there exists an instance $\dfrac{T \vdash r_1 \quad \ldots \quad T \vdash r_n}{T \vdash r}(R)$ of some deduction rule such that $r = u$

and $r_i \in H$. The one-step deducibility is decidable in polynomial time for the equational theory XCDE. Observe first that all rules of deduction of Figure 1 are binary except the rule (GX) (rule (C_K) (resp. (D_K)) are shorts for finite number of consecutive applications of rule (C_{k_i}) (resp. (D_{k_i})). For all these binary rules proving the one-step deducibility takes a polynomial time. For the rule (GX) the problem can reduce to solve system of equations in $\mathbb{Z}/2\mathbb{Z}$ as in [LLT05b]. We illustrate the idea of this reduction, with the following example.

Example 1 *Let $T = \{a_1 \oplus a_2 \oplus a_3, a_1 \oplus a_4, a_2 \oplus a_4\}$ and $w = a_1 \oplus a_2$, where every a_i contains no $\oplus$. We introduce one numerical variable x_0, x_1, x_2 for each element of T:*

$$\begin{array}{lll} x_0 & for & a_1 \oplus a_2 \oplus a_3 \\ x_1 & for & a_1 \oplus a_4 \\ x_2 & for & a_2 \oplus a_4 \end{array}$$

For every element of the sum we create an equation, we get the equation system:

$$\begin{array}{lcl} a_1 & : & x_0 \oplus x_1 = 1 \\ a_2 & : & x_0 \oplus x_2 = 1 \\ a_3 & : & x_0 = 0 \\ a_4 & : & x_1 \oplus x_2 = 0 \end{array}$$

The system has a solution over $\mathbb{Z}/2\mathbb{Z}$ if and only if w is deducible in one-step from T by (GX). In this example the system has a solution: $x_0 = 0, x_1 = 1, x_2 = 1$.

In the rest of the paper, to prove the locality of the deduction system, we define a new notion of subterms (Definition 6) and some transformations of proof which enable us to prove that any proof can be transformed into a normal proof. Hence we prove that a normal proof is in fact a local proof in Theorem 2, yielding the decidability of the intruder deduction problem, using Theorem 1.

5 Terms and Subterms

Definition 3 *Let u be a term in normal form, u is* headed with $\oplus$ *if u is of the form $u_1 \oplus \ldots \oplus u_n$ with $n > 1$. Otherwise u is* not headed with $\oplus$. *A term u in normal form is called* headed with $\{.\}_K$ *if u is of the form $u = \{t\}_K$. Otherwise u is* not headed with $\{.\}_K$. *We define the function atoms(u):*

- *If $u = u_1 \oplus \ldots \oplus u_n$, where each of the u_i is not headed with $\oplus$, then atoms$(u) = \{u_1, \ldots, u_n\}$. The u_i's are called the* atoms *of u.*
- *If u is not headed with $\oplus$ then atoms$(u) = \{u\}$.*

Example 2 *$t_1 = u \oplus \langle v, w\rangle$ is headed with $\oplus$, but $t_2 = \langle u, v \oplus w\rangle$ is not, hence atoms$(t_1) = \{u, \langle v, w\rangle\}$ and atoms$(t_2) = \{t_2\}$.*

The definition of atoms is generalized to sets of terms T in normal form by setting atoms$(T) := \bigcup_{t\in T}$ atoms(t). According to the definition, the function atoms is monotone and idempotent. We denote by $\mathcal{P}[K]$ the set of all the partitions of the set K.

Definition 4 *The set of* syntactic subterms *of a term t is the smallest set $S(t)$ such that:*

1. $t \in S(t)$.
2. *if* $\langle u, v\rangle \in S(t)$ *then* $u, v \in S(t)$.
3. *if* $\{u\}_K \in S(t)$ *and* $K = \{k_1^{\alpha_1}, \ldots, k_p^{\alpha_p}\}$ *then* $u \in S(t)$ *and* $k_i \in S(t)$ *for all* $i, 1 \leq i \leq p$.
4. *if* $u = u_1 \oplus \ldots \oplus u_n \in S(t)$ *then* $atoms(u) \subseteq S(t)$.

Example 3 *If* $u = \{a\}_{k_1,k_2,k_3}$ *i.e. the term a is encrypted by the keys k_1, k_2 and k_3 then* $S(u) = \{u, a, k_1, k_2, k_3, \{a\}_{k_1}, \{a\}_{k_2}, \{a\}_{k_3}, \{a\}_{k_1,k_2}, \{a\}_{k_2,k_3}, \{a\}_{k_1,k_3}\}$, *for instance the term* $\{a\}_{k_1}$ *comes from the point (iii) of the previous definition with* $K = \{k_2, k_3\}$.

The definition of S is extended to a set T of terms in normal form by setting $S(T) := \bigcup_{t\in T} S(t)$. Since the encryption is commutative, the number of subterms of $S(T)$ is exponential in the size of the set of keys of T (consider all the possible combinations of keys for an encrypted term). In the definition of $S(t)$ we do not take care of the distributivity of encryption. Because we work only on normal forms the notion of a syntactic subterm ignores the fact that the term $\{a\}_K \oplus \{b\}_K \oplus \{c\}_K$ is equal to $\{a \oplus b \oplus c\}_K$, and that $a \oplus b \oplus c$ should be considered to be a subterm of $\{a\}_K \oplus \{b\}_K \oplus \{c\}_K$ and also all sums encrypted with the set $\mathcal{P}[K]$.

Definition 5 *For any term t, $S_T(t)$ is the smallest set such that:*

- $S(t) \subseteq S_T(t)$.
- *If* $n > 1$, $K = \{k_1^{\alpha_1}, \ldots, k_p^{\alpha_p}\}$ *and* $\{u_1\}_K \oplus \ldots \oplus \{u_n\}_K \in S_T(t)$ *then* $u_1 \oplus \ldots \oplus u_n \in S_T(t)$.

By definition $S(t) \subseteq S_T(t)$. The definition is extended to a set T of terms in normal form by setting $S_T(T) := \bigcup_{t\in T} S_T(t)$. As in Definition 4, Definition 5 considers also all the possible combinations of keys for an encrypted sum of terms.

Proposition 2 *For any set of terms $M \subseteq T_\Sigma$, we have:*

- $atoms(M) \subseteq S(M)$.
- $atoms(S_T(M)) \subseteq S_T(M)$.
- $S(S(M)) = S(M)$ *and* $S_T(S_T(M)) = S_T(M)$.

Proof: Obvious from the definitions of S, atoms and S_T. □

Definition 6 *Define $S_\oplus$ as all combinations of terms of $S_T(T)$ by $\oplus$:*

$$S_\oplus(T) := \left\{ (\bigoplus_{s\in M} s)\downarrow \mid M \subseteq S_T(T) \right\}$$

Note that the size of $S_\oplus$ is double-exponential in the size of T and $S_T(T) \subseteq S_\oplus(T)$: one exponential for the computation of $S(T) \subseteq S_T(T)$ and the second exponential for all the partial sums.

Proposition 3 *Let A and B be two sets of terms in normal form, the mappings S, S_T and $S_\oplus$ are monotone and have the property:*

- $S(A \cup B) = S(A) \cup S(B)$.
- $S_T(A \cup B) = S_T(A) \cup S_T(B)$.
- $S_\oplus(A) \cup S_\oplus(B) \subseteq S_\oplus(A \cup B)$.

Proof: It is an immediate consequence of the definitions of $S(T)$, $S_T(T)$ and $S_\oplus(T)$. □
Remark: Let $A = \{a\}$ and $B = \{b\}$, $S_\oplus(A) = \{0, a\}$ and $S_\oplus(B) = \{0, b\}$ then $S_\oplus(A) \cup S_\oplus(B) = \{0, a, b\} \subseteq S_\oplus(A \cup B) = \{0, a \oplus b, a, b\}$ but $S_\oplus(A) \cup S_\oplus(B) \neq S_\oplus(A \cup B)$.

Lemma 1 *Let T be a set of terms then $S_T(S_\oplus(T)) = S_\oplus(T)$.*

Proof: By definition 5, $S_\oplus(T) \subseteq S_T(S_\oplus(T))$. We prove the converse inclusion by induction on the number of applications of the rule for $\oplus$ in the construction of $S_T(S_\oplus(T))$ (step (ii) in Definition 5). Let $u \in S_T(S_\oplus(T))$, and let n be the number of applications of the rule for $\oplus$. By induction hypothesis, we assume that each term $u' \in S_T(S_\oplus(T))$ obtained with less than n applications of the rule for $\oplus$ is in $S_\oplus(T)$.

Base case $n = 0$: $u \in S_T(v)$ for some $v \in S_\oplus(T)$, where $v = v_1 \oplus \ldots \oplus v_p$ and all $v_i \in S_T(T)$. If $u = v$ then $u \in S_\oplus(T)$. Otherwise $u \neq v$. In this case $u \in S(v_i) \subseteq S_T(v_i)$ for some i (since $v_i \in S_T(T)$ and $S(S_T(T)) = S_T(T)$). Since $v \in S_\oplus(T)$ there exists a $t_i \in T$ such that $v_i \in S_T(t_i)$. Therefore $v_i \in S_T(t_i) \subseteq S_T(T)$ with $t_i \in T$, hence $u \in S_T(S_T(T)) = S_T(T) \subseteq S_\oplus(T)$ by idempotence of S_T.

Induction step: let $u = u_1 \oplus \ldots \oplus u_n$ be obtained from $\{u_1\}_K \oplus \ldots \oplus \{u_n\}_K \in S_T(S_\oplus(T))$. By induction hypothesis $\{u_1\}_K \oplus \ldots \oplus \{u_n\}_K \in S_\oplus(T)$. Hence there exists a partition $I_1 \cup \ldots \cup I_q = \{1, \ldots, n\}$ such that for every j, $1 \leq j \leq q$, $w_j = \oplus_{i \in I_j} \{u_i\}_K \in S_T(t_j)$. Hence, $\oplus_{i \in I_j} u_i \in S_T(t_j)$ by definition of S_T. As a consequence, $u \in S_\oplus(T)$. □

Proposition 4 *Let M be a set of terms then $S_\oplus(S_\oplus(M)) = S_\oplus(M)$. The mappings S, S_T and $S_\oplus$ are transitive.*

Proof: The first point is a consequence of Lemma 1 and Proposition 2. The second is a consequence of the first point and Propositions 1, 2 and 3. □

All these results will be used implicitly in the rest of the paper.

6 Different Kinds of Proofs

After a description of the different notions of subterms, we now introduce the different proof's characterizations which is a crucial ingredient in the demonstration of the locality result.

Definition 7 *Let P be a proof of $T \vdash w$. P is* **flat** *if there is no (GX) (respectively (C) and (D)) rule immediately above another (GX) (respectively (C) and (D)) rule. P is* **simple** *if* (1) *each node $T \vdash v$ occurs at most once on each branch,* (2) *each node $T \vdash v$ occurs at most once as hypothesis of a rule (GX),* (3) *there is no consecutive application of (C_K) and $(D_{K'})$ (in either order) if $K \cap K' \neq \emptyset$.*

Any proof can be transformed into a simple proof since we can always cut some branch or piece of branch of the proof. In any proof we can always merge two consecutive applications of a rule (C_K) (respectively (D_K) and (GX)) and get a flat proof. Hence a flat proof can always be transformed into a flat and simple proof.

Proposition 5 *Let K and K' be two sets of keys such that $K \cap K' = \emptyset$. Applying the rule (D_K) to a term u and then the rule $(C_{K'})$ yields the same result as applying the rule $(C_{K'})$ to u and then the rule (D_K).*

Proof: The fact that $K \cap K' = \emptyset$ is the key of this result. □

Intuitively, in a *D-eager* proof the (D) rule is applied as early as possible and in a *$\oplus$-eager* proof the (GX) rule is applied as early as possible.

Definition 8 *Let P be a proof of $T \vdash w$. P is a* ***D-eager*** *proof if:* (1) *there is no hypothesis of a rule (GX) which is headed with $\{.\}_K$ and a rule $(D_{K'})$ just after a (GX) such that $K \cap K' \neq \emptyset$,* (2) *there is no (C) just above rule (D). P is a* ***$\oplus$-eager*** *proof if all the rules (C_{K_i}) immediately above a (GX) in P have $K_i \cap K_j = \emptyset$ for all i, j such that $i \neq j$.*

We refine the notion of S-local proof by $S(T)$-local, where T is the set of terms on which S is applied. A **normal** proof consists of initial subproofs which are $S_\oplus(T)$-local, followed by a proof tree consisting of the rules (GX), (C), (P) only.

Definition 9 *Let P be a proof of $T \vdash u$. P is a* normal proof *if :*

- *either $u \in S_\oplus(T)$ and P is an $S_\oplus(T)$-local proof,*
- *or $P = C[P_1, \ldots, P_n]$ where every proof P_i is a normal proof of some $T \vdash v_i$ with $v_i \in S_\oplus(T)$ and the context C is built using the inference rules (P), (C), (GX) only.*

7 Transformations of Proofs

We modify by successive transformations a proof into a simple flat proof, then into a simple flat *D-eager* proof, next into a simple flat *D-eager* $\oplus$*-eager* proof and finally into a normal proof. With all these transformations we first apply the rule of decryption, then we make the sum with the (GX) rule to simplify or construct terms to get a normal proof.

Lemma 2 *Let P be a simple and flat proof of $T \vdash w$. Then there exists a proof P' of $T \vdash w$ such that P' is a simple, flat and D-eager proof.*

Proof: Let P be a simple and flat proof of $T \vdash w$. We transform this proof into a simple, flat and *D-eager* proof of $T \vdash w$ by induction on the number of nodes of P. We consider the last rule of the proof, if it is:

- (A): the result holds.
- (GX), (P), (UR), (UL), (C): we apply the induction hypothesis on all direct sub-proofs.
- (D_{K_2}): we always apply the induction hypothesis on the key part of the rule (D_{K_2}), for the encrypted part we consider the rule above (D_{K_2}) is :
  - (A), (P), (UR), (UL) we apply the induction hypothesis on all direct sub-proofs.
  - (C): we can switch the two rules using Proposition 5 and simplicity (to get a *D-eager* proof). Hence we apply the induction hypothesis on the sub-proofs.
  - (GX) if all encrypted hypotheses of the (GX) are encrypted by sets of keys K_i such that $K_i \cap K_2 = \emptyset$ then we apply the induction hypothesis on the sub-proofs. Otherwise we consider that the hypotheses of the rule (GX) can be split into smaller sums which all give an encrypted term and we apply the transformation described in Figure 2. In certain cases some additional transformations are required to preserve simplicity: we cut the same hypotheses of the rule (GX) or branch of the proof for the new nodes introduced. Moreover if a rule (GX) has just one hypothesis, this rule can be deleted. Since $K_2 \cap K_1 \neq \emptyset$ and $n \geq 2$, the size of the initial proof is $\Sigma_{i=1}^{i=n}|\pi_{B_i}| + |\pi_{K_2}| + 2$ is greater or equal than $\Sigma_{i=1}^{i=n_1}|\pi_{B_i}| + |\pi_{K_2 \cap K_1}| + 2$ the size of this sub-proof, hence we apply the induction hypothesis on the sub-proof ended by the rule $(D_{K_2 \cap K_1})$.

□

Proposition 6 *The transformations of proofs given in Figures 3 and 4 decrease the number of nodes of the initial proof.*

Figure 2: Transformation *D-eager* $K_2 \cap K_1 \neq \emptyset$ and $n \geq 2$

$$(GX)\dfrac{(GX)\dfrac{T \vdash x_1 \quad \ldots \quad T \vdash x_n}{T \vdash x_1 \oplus \ldots \oplus x_n} \qquad T \vdash y_1 \quad \ldots \quad T \vdash y_m}{T \vdash x_1 \oplus \ldots \oplus x_n \oplus y_1 \oplus \ldots \oplus y_m}$$

$$\Downarrow$$

$$(GX)\dfrac{T \vdash x_1 \quad \ldots \quad T \vdash x_n \quad T \vdash y_1 \quad \ldots \quad T \vdash y_m}{T \vdash x_1 \oplus \ldots \oplus x_n \oplus y_1 \oplus \ldots \oplus y_m}$$

Figure 3: Transformation of (GX)-(GX) into (GX)

Proof: We denote by π_x the subproof of P with root $T \vdash x$. These transformations transform a proof with some hypotheses and a conclusion into a proof of the same hypotheses and the same conclusion. Figure 3: It is obvious.
Figure 4: The number of nodes of the initial proof is:
$\alpha_I = \Sigma_{i=1}^{i=m}|\pi_{z_i}| + |\pi_{x_1}| + |\pi_{x_2}| + |\pi_{K_1}| + |\pi_{K_2}| + 3$
The number of nodes of the transformed proof is:
$\alpha_T = \Sigma_{i=1}^{i=m}|\pi_{z_i}| + |\pi_{x_1}| + |\pi_{x_2}| + |\pi_{K_1 \setminus K_2}| + |\pi_{K_2 \setminus K_1}| + |\pi_{K_1 \cap K_2}| + 5$
Observe that $|\pi_{K_1}| = |\pi_{K_1 \cap K_2}| + |\pi_{K_1 \setminus K_2}|$ and $|\pi_{K_2}| = |\pi_{K_1 \cap K_2}| + |\pi_{K_2 \setminus K_1}|$.

$$\begin{aligned}
\alpha_I - \alpha_T &= |\pi_{K_1}| + |\pi_{K_2}| - |\pi_{K_1 \setminus K_2}| - |\pi_{K_2 \setminus K_1}| - |\pi_{K_1 \cap K_2}| - 2 \\
&= |\pi_{K_1 \cap K_2}| + |\pi_{K_1 \setminus K_2}| + |\pi_{K_2}| - |\pi_{K_1 \setminus K_2}| - |\pi_{K_2 \setminus K_1}| - |\pi_{K_1 \cap K_2}| - 2 \\
&= |\pi_{K_1 \cap K_2}| + |\pi_{K_2 \setminus K_1}| - |\pi_{K_2 \setminus K_1}| - 2 \\
&= |\pi_{K_1 \cap K_2}| - 2
\end{aligned}$$

Since $K_1 \cap K_2 \neq \emptyset$, hence $|\pi_{K_1 \cap K_2}| \geq 2$ and the number of nodes is decreasing. □

Lemma 3 *If there is a simple, flat and D-eager proof of $T \vdash w$ then there is also a simple, flat, D-eager and $\oplus$-eager of $T \vdash w$.*

Proof: Let P be a simple, flat and *D-eager* proof of $T \vdash w$, we apply many times the proof transformation rules given in Figures 3 and 4. The application of these transformations terminates because Proposition 6 shows that they decrease the number of nodes of a proof and the transformation of a proof into a simple and flat proof decreases obviously the number of nodes. Moreover these transformations do not make appear any rule (D) just after a rule (GX) and any rule (D) just after a rule (C), hence the proof is again *D-eager*. □

8 Properties of Proofs

Thanks to previous transformations we consider a simple, flat *D-eager* $\oplus$*-eager* proof P of $T \vdash w$. Lemma 5 shows, using Lemma 4, that all nodes stemmed

$$
(GX)\dfrac{(C_{K_1})\dfrac{T \vdash x_1}{T \vdash \{x_1\}_{K_1}} \quad T \vdash K_1 \quad (C_{K_2})\dfrac{T \vdash x_2}{T \vdash \{x_2\}_{K_2}} \quad T \vdash K_2 \quad (R_1)\dfrac{\vdots}{T \vdash z_1}\ldots(R_m)\dfrac{\vdots}{T \vdash z_m}}{T \vdash \{x_1\}_{K_1} \oplus \{x_2\}_{K_2} \oplus z_1 \oplus \ldots \oplus z_m}
$$

$$
\Downarrow
$$

$$
(C_{K_1 \cap K_2})\dfrac{(GX)\dfrac{(C_{K_1 \setminus K_2})\dfrac{T \vdash x_1}{T \vdash \{x_1\}_{K_1 \setminus K_2}} \quad T \vdash K_1 \setminus K_2 \quad (C_{K_2 \setminus K_1})\dfrac{T \vdash x_2}{T \vdash \{x_2\}_{K_2 \setminus K_1}} \quad T \vdash K_2 \setminus K_1}{T \vdash \{x_1\}_{K_1 \setminus K_2} \oplus \{x_2\}_{K_2 \setminus K_1}} \quad T \vdash K_1 \cap K_2 \quad (R_1)\dfrac{\vdots}{T \vdash z_1}\ldots(R_m)\dfrac{\vdots}{T \vdash z_m}}{T \vdash \{x_1\}_{K_1} \oplus \{x_2\}_{K_2} \oplus z_1 \oplus \ldots \oplus z_m}
$$

Figure 4: Transformation *D-eager* $K_2 \cap K_1 \neq \emptyset$ and $n \geq 2$

from a rule (UR)(UL) are in $S(T)$ for simple proof. Lemma 6 proves that all nodes stemmed from a rule (D) have the encrypted hypothesis in $S_{\oplus}(T)$ for a simple, flat, *D-eager* and $\oplus$-*eager* proof. In Lemma 7 we prove that such a proof can be transformed in a normal proof using Lemma 5 and Lemma 6.

Lemma 4 *Let P be a simple proof of the form:*

$$P = \left\{ \quad \frac{P_1 \dots P_n}{T \vdash w} \right.$$

If $T \vdash u$ does not occur in any of $P_1, \dots, P_n$ and $\langle u, v\rangle \in S(w)$ then there is at least one P_i and there exists w' such that $\langle u, v\rangle \in S(w')$ and either the root of P_i is $T \vdash w'$ or $w' \in T$.

Proof: We consider all possible rules for the root of P:

- The last rule is (A): obvious since all elements of T are normalized.
- The last rule is (UL) or (UR): $\langle u, v\rangle \in S(w)$ by hypothesis, we denote $w' = \langle u_1, u_2\rangle$ and by construction $w \in S(\langle u_1, u_2\rangle)$. We deduce by transitivity of the subterm relation that $\langle u, v\rangle \in S(w')$ and conclude with the induction hypothesis.
- The last rule is (D): $\langle u, v\rangle \in S(w)$ by hypothesis, we denote $w' = \{u_1\}_{u_2}$ and by construction $w \in S(\{u_1\}_{u_2})$. We deduce by transitivity of the subterm relation that $\langle u, v\rangle \in S(w')$ and conclude with the induction hypothesis.
- The last rule is (GX): $\langle u, v\rangle \in S(w)$ by hypothesis and $w = (u_1 \oplus \dots \oplus u_n)\downarrow$. Hence by definition of the subterm relation $\langle u, v\rangle \in \cup_i S(u_i)$, more precisely there exists i such that $\langle u, v\rangle \in S(u_i)$, because $\langle u, v\rangle$ is not headed with $\oplus$ and conclude with the induction hypothesis.
- The last rule is (P): since $T \vdash u$ can not occur in P we have that $w = \langle w_1, w_2\rangle \neq \langle u, v\rangle$. But $\langle u, v\rangle \in S(w)$ by hypothesis so $\langle u, v\rangle \in S(\langle w_1, w_2\rangle)$. It is a subterm of w_1 or of w_2 and we conclude with the induction hypothesis.
- The last rule is (C): We have that $w = \{w_1\}_{w_2} \neq \langle u, v\rangle$. But $\langle u, v\rangle \in S(w)$ by hypothesis so $\langle u, v\rangle \in S(\{w_1\}_{w_2})$. It is a subterm of w_1 or of w_2 and we conclude with the induction hypothesis.

□

Lemma 5 *Let P be a simple proof of $T \vdash u$ or $T \vdash v$. If P is one of*

$$(UL)\frac{\begin{array}{c}\vdots\\ T \vdash \langle u, v\rangle\end{array}}{T \vdash u} \qquad (UR)\frac{\begin{array}{c}\vdots\\ T \vdash \langle u, v\rangle\end{array}}{T \vdash v}$$

then $\langle u, v\rangle \in S(T)$.

Proof: Let us assume that the last rule is (UL), the case (UR) is similar.

$$P = \begin{cases} \dfrac{P_1 \ldots P_n}{T \vdash \langle u, v \rangle} \\ \\ T \vdash u \end{cases}$$

P is simple so $T \vdash u$ does not occur in any of $P_1, \ldots, P_n$. Hence, we can apply Lemma 4 to $\dfrac{P_1 \ldots P_n}{T \vdash \langle u, v \rangle}$. Either $\langle u, v \rangle \in T$, or there is some P_i with root $T \vdash w$ such that $\langle u, v \rangle \in S(w)$ and $T \vdash u$ does not occur in P_i. Lemma 4 can be applied again and the iteration of this reasoning finally leads to $\langle u, v \rangle \in T$. □

Lemma 6 *Let P be a simple, flat, D-eager and $\oplus$-eager proof of $T \vdash u$. If P is*

$$(D_K)\dfrac{(R)\dfrac{\vdots}{T \vdash \{u\}_K\downarrow = r} \quad \dfrac{\vdots}{T \vdash K\downarrow}}{T \vdash u}$$

then $\{u\}_K \in S_\oplus(T)$.

Proof: The proof is by structural induction on P.

Base case: obvious.

Induction step: we perform a case analysis on the last rule (R) used in the subproof of P with root $\{u\}_v\downarrow$

- (R) is (A), (UL), (UR): the result is true by definition (rule (A)) or Lemma 5 (rule (UL), (UR)).
- (R) is some rule (P): this cannot happen because $\{u\}_K\downarrow$ is not a pair.
- (R) is some rule $(C_{K'})$: P is *D-eager* by consequence it is impossible.
- (R) is some rule $(D_{K'})$ impossible since P is flat.
- (R) is (GX). The last deductions in the proof P are described in Figure 5 and we discuss the different cases according to the rules (R_i) and the structure of $\{u\}_K\downarrow$.

  We show that every atom of $\{u\}_K\downarrow$ is in fact an element of $S_T(T)$. Let $a \in \text{atoms}(\{u\}_K\downarrow)$. Note that a is necessarily of the form $\{a'\}_K$, and that there is an i such that $a \in \text{atoms}(B'_i)$. We consider different possible cases for the rule (R_i):

  - (R_i) is (A), (UL) or (UR). By definition or Lemma 5, $B'_i \in S_\oplus(T)$.

$$\dfrac{\dfrac{\dfrac{T \vdash B_1}{T \vdash B'_1}(R_1) \quad \ldots \quad \dfrac{T \vdash B_n}{T \vdash B'_n}(R_n)}{T \vdash \{u\}_K\downarrow}(GX) \qquad \dfrac{\vdots}{T \vdash K\downarrow}}{T \vdash u\downarrow}(D_K)$$

Figure 5: Illustration of the case (D_K) in Lemma 6.

- (R_i) is $(D_{K'})$ s.t. $(D_{K'})\ \dfrac{T \vdash \{w_1\}_{K'}\ T \vdash K'}{T \vdash w_1 = B'_i}$. By induction hypothesis $\{w_1\}_{K'} \in S_\oplus(T)$, therefore $w_1 = B'_i \in S_\oplus(T)$.
- (R_i) is (P): $B'_i = \langle w_1, w_2\rangle$, B'_i cannot occur in $\{u\}_K\downarrow$ by consequence B'_i is canceled by another hypotheses B'_j of (GX) such that $B'_i \in S_T(B'_j)$. B'_j can not be the result of a rule (P) by simplicity, neither a rule (C) since it is a pair, neither (GX) since the proof is flat. In the other cases B'_j stems from a rule (A), (UL), (UR) or (D) by consequence $B'_j \in S_\oplus(T)$. We deduce that $B'_i \in S_\oplus(T)$.
- (R_i) is (C), since P is *D-eager* we get that B'_i is headed with $\{.\}_{K'}$ such that $K \cap K' = \emptyset$. By consequence B'_i is canceled by another hypotheses B'_j of (GX) such that $B'_j \in S_T(B'_i)$. B'_j can not be the result of a rule (P) since it is an encrypted term, neither another rule (C) since P is $\oplus$*-eager*, neither (GX) since the proof is flat. In the other cases the copy B'_j stems from a rule (A), (UL), (UR) or (D) by consequence $B'_j \in S_\oplus(T)$. We deduce that $B'_i \in S_\oplus(T)$.

Therefore in all cases $\{u\}_K\downarrow = \bigoplus_{i=1,\ldots,n} B'_i\downarrow = \bigoplus\{t_i\}_K$ where $\{t_i\}_K \in S_\oplus(T) \cap (\cup_{i=1,\ldots,n}\text{atoms}(B_i))$ because all atoms of B'_i are in $S_\oplus(T)$ or canceled.

□

Lemma 7 *Let P be a flat, simple, $\oplus$-eager and D-eager proof of $T \vdash u$. There is a normal proof of $T \vdash u$.*

Proof: Consider first the case where $u \in S_\oplus(T)$. We proceed by structural induction on the proof P and case distinction of the last rule (R) of P:

- (R) is (A): P is obviously a normal proof.
- (R) is some rule (UL) or (UR) s.t. $\dfrac{T \vdash \langle u_1, u_2\rangle}{T \vdash u}$. The induction hypothesis gives that there exists a normal proof of $\langle u_1, u_2\rangle$. P is simple, we apply Lemma 5 and get $\langle u_1, u_2\rangle \in S(T) \subseteq S_\oplus(T)$ then the normal proof of $\langle u_1, u_2\rangle$ is $S_\oplus(T)$-local so P is normal since $u \in S_\oplus(T)$.

- (R) is some rule (D) s.t. $\dfrac{T \vdash \{u\}_K \;\; T \vdash K}{T \vdash u}$. The induction hypothesis gives that there exists a normal proof of $\{u\}_K$. P is flat, simple, *D-eager* and $\oplus$-*eager* with Lemma 6 we get $\{u\}_K \in S(T) \subseteq S_\oplus(T)$ and then the normal proof of $\{u\}_K$ is $S_\oplus(T)$-local so we deduce that P is normal because $u \in S_\oplus(T)$.

- (R) is some rule (P), (C) are similar. We only give the proof for $u = \{u_1\}_{u_2}$. (R) is some (C) s.t. $\dfrac{T \vdash u_1 \;\; T \vdash u_2}{T \vdash \{u_1\}_{u_2}}$ Since $\{u_1\}_{u_2} = u \in S_\oplus(T)$ we deduce that $u_1 \in S_\oplus(T)$ and $u_2 \in S_\oplus(T)$. Hence applying the induction hypothesis there are normal proofs of u_1 and u_2 that are $S_\oplus$-local, hence P is normal.

- (R) is some rule (GX) s.t. $(GX)\dfrac{(R_1)\dfrac{T \vdash B_1}{T \vdash B'_1} \qquad ...(R_n)\dfrac{T \vdash B_n}{T \vdash B'_n}}{T \vdash u}$. We will show that for every (R_i) we have that $B'_i \in S_\oplus(T)$. We discuss the different cases for the rules (R_i)'s:

  - (R_i) is not (GX) because P is flat.
  - (R_i) is (A), (UL), (UR) or (D) with the definition or Lemma 5 or Lemma 6 then $B'_i \in S_\oplus(T)$. Applying the induction hypothesis there is a normal proof of B'_i which is $S_\oplus(T)$-local.
  - (R_i) is (P), there are two possibilities: B'_i is in $S_T(u)$ or not.
    * $B'_i \in S_T(u) \subseteq S_\oplus(T)$ we can apply the induction hypothesis and get a normal proof of B'_i which is $S_\oplus(T)$-local.
    * $B'_i \notin S_T(u)$ hence B'_i is canceled by some other elements B'_j. B'_j can not come from a rule (P) because P is simple, from a rule (C) because a pair is not headed with $\{.\}_.$. So B'_j come from a rule (A), (UL), (UR) or (D) with the definition or Lemma 5 or Lemma 6 then $B'_j \in S_\oplus(T)$. More precisely $\bigoplus B'_j \in S_\oplus(T)$, since $B'_i \in S_\oplus(\bigoplus B'_j)$, we deduce that $B'_i \in S_\oplus(T)$. We apply the induction hypothesis and get a normal proof of B'_i which is $S_\oplus(T)$-local.
  - (R_i) is (C_K), this case is similar to the previous case. There are two possibilities: B'_i is in $S_T(u)$ or not:
    * $B'_i \in S_T(u) \subseteq S_\oplus(T)$, we apply the induction hypothesis and get a normal proof of B'_i which is $S_\oplus(T)$-local.
    * $B'_i \notin S_T(u)$ hence B'_i is canceled by some other elements B'_j. B'_j can not stem from a rule (P) since a pair is not headed with $\{.\}_.$, from a rule $(C_{K'})$ with $K' \neq K$ since B'_i not headed with $\{.\}_K$ and not from another rule $(C_{K'})$ where $K' \cap K \neq \emptyset$ since P is $\oplus$-*eager*. So B'_j come from a rule (A), (UL), (UR) or (D) with the definition or Lemma 5 or Lemma 6 then $B'_j \in S_\oplus(T)$. More

precisely $\bigoplus B'_j \in S_\oplus(T)$, since $B'_i \in S_\oplus(\bigoplus B'_j)$ we deduce that $B'_i \in S_\oplus(T)$. we can apply the induction hypothesis and get a normal proof of B'_i which is $S_\oplus(T)$-local.

Since all the subproofs of $T \vdash B'_i$ are normal we can conclude that P is normal.

In the second case, we assume that $u \notin S_\oplus(T)$ and the proof is of the form $C[P_1, \ldots, P_n]$ where $P_1, \ldots, P_n$ are maximal $S_\oplus$-local subproofs. We prove the result by structural induction on P:

- If C is empty, then $u \in S_\oplus(T)$
- If the last rule is (UL), (UR) or (D) we use the definition and Lemma 5 and Lemma 6 to get $u \in S_\oplus(T)$.
- In the others cases we apply the induction hypothesis.

□

9 Our Main Result

In this section, we prove Theorem 2 which says that a normal proof is equivalent to a $S_\oplus(T, w)$-proof. Thanks to Theorem 1 we conclude that there is a DOUBLE-EXP-TIME procedure to decide the intruder deduction problem in equational theory XCDE(complexity due to the computation of the set $S_\oplus(T, w)$).

Theorem 2 *Let P be a flat, simple, D-eager and $\oplus$-eager proof of $T \vdash w$ then P is normal $\Leftrightarrow$ P is $S_\oplus(T, w)$-local.*

Proof: $\Leftarrow$ Let us assume that P is $S_\oplus(T, w)$-local and prove that P is normal:

- If $w \in S_\oplus(T)$ then P is $S_\oplus(T)$-local *i.e.* P is normal.
- If $w \notin S_\oplus(T)$ then we proceed by structural induction on P. The base case (A) is trivial, consider the last rule:
  - (UR), (UL), (D) impossible since Lemma 5 and Lemma 6 show that $w \in S_\oplus(T)$ which contradicts the hypothesis.
  - (P), (C), (GX) by induction hypothesis, the hypotheses w_i of the rule stem from normal proofs. Because the last rule is (P), (C), (GX) then P is normal.

$\Rightarrow$ Let us assume that P is normal and prove that P is $S_\oplus(T, w)$-local:

- If $w \in S_\oplus(T)$: P is $S_\oplus(T)$-local, hence P is $S_\oplus(T, w)$-local.
- If $w \notin S_\oplus(T)$ we proceed by structural induction on P. The base case is trivial, consider the last rule:

– (UR), (UL), (D): impossible by definition of normal proof.

– (P), (C) are similar, we just give the proof for (C). P is s.t. $\dfrac{T \vdash w_1 \;\; T \vdash w_2}{T \vdash \{w_1\}_{w_2}}$. By definition for $i = 1, 2$ $w_i \in S_\oplus(T, w_i)$, $w_i \in S_T(\{w_1\}_{w_2}) = S_T(w) \subseteq S_\oplus(w)$, and induction hypothesis which guarantees that all nodes of the sub-proof are in $S_\oplus(T, w_i)$, we conclude that P is $S_\oplus(T, w)$-local.

– (GX) P is s.t. $(GX)\dfrac{(R_1)\dfrac{T \vdash B_1}{T \vdash B'_1} \quad \ldots \quad (R_n)\dfrac{T \vdash B_n}{T \vdash B'_n}}{T \vdash w}$. We will prove that all B'_i are in $S_\oplus(T, w)$, consider the different cases for the (R_i):

  * (A): by definition $B'_i \in S_\oplus(T)$,
  * (UR), (UL), (D): by Lemma 5 and Lemma 6 we get $B'_i \in S_\oplus(T)$.
  * (GX): impossible because P is flat.
  * (P): if $B'_i \in S_\oplus(T)$ the claim holds, otherwise $B'_i \notin S_\oplus(T)$. Either B'_i is not canceled in a sum, then $B'_i \in S_T(w) \subseteq S_\oplus(w)$, or otherwise B'_i is canceled by another element of the sum B'_j. Since B'_i is a pair B'_j can not be deduced from a rule (C) neither a rule (P) since P is simple. Hence it stems from one of the rules (A), (UL), (UR) or (D) and $B'_i \in S_T(B'_j)$. According to Lemma 5 and Lemma 6 $B'_j \in S_\oplus(T)$, hence we get the result by transitivity of $S_\oplus$.
  * (C_K): if $B'_i \in S_\oplus(T)$ the claim holds, otherwise $B'_i \notin S_\oplus(T)$. Note that B'_i can be partially canceled in a sum. There are two possibilities for the atoms of B'_i: to be present in w, in which case $\text{atoms}(B'_i) \in \text{atoms}(S_T(w)) \subseteq \text{atoms}(S_\oplus(w))$, or to be canceled by other elements B'_j of the sum, in which case $\text{atoms}(B'_i) \in \text{atoms}(S_\oplus(B'_j)) \subseteq \text{atoms}(S_\oplus(T))$. In the latter case, since B'_i is encrypted by the set of keys K, B'_j can not be the result of a rule $(C_{K'})$ with $K' \neq K$, nor the result of the rule (C'_K) with $K' \cap K \neq \emptyset$ since P is $\oplus$-*eager*, nor (P), hence it stems from one of the rules (A), (UL), (UR) or (D). Thanks to Lemma 5 and Lemma 6 $B'_j \in S_\oplus(T)$, we conclude with the transitivity of $S_\oplus$. In summary, for all i we get that $\text{atoms}(B'_i) \in \text{atoms}(S_\oplus(T, w))$, that is $B'_i \in S_\oplus(T, w)$). Hence P is $S_\oplus(T, w)$-local.

□

10 The Binary Case

We call the binary case the situation where the set of assumptions T and the goal u of the proof P of $T \vdash u$ do not contain terms with more than two consecutive applications of the symbol $\oplus$.

In the case of a commuting encryption operation, we show an EXPSPACE lower bound by reduction of the *uniform word problem in commutative semigroups* (abbreviated *CSG*) which is EXPSPACE-hard [MM82]. An instance of CSG is:

$$\alpha_1 = \beta_1, \ldots, \alpha_n = \beta_n \models \alpha = \beta$$

where α, β, α_i and β_i are words over some alphabet. It is essential for the complexity of the problem that the alphabet is infinite (of course, any instance $\mathscr{C}$ of *CSG* uses only a finite portion $\Sigma(\mathscr{C})$ of that alphabet). Such an instance of *CSG* has a solution if and only if $\alpha = \beta$ in every *commutative* semigroup satisfying the axioms $\alpha_i = \beta_i$. Denoting by $x =_c y$ the equality of two words x and y modulo commutativity, this is equivalent to the following assertion:

> Either $\alpha =_c \beta$, or there exists a sequence of pairs $(\gamma_1, \delta_1), \ldots, (\gamma_l, \delta_l)$ such that each pair (γ_j, δ_j) is either some $\alpha_i = \beta_i$ or some $\beta_i = \alpha_i$ and a sequence of words $c_1, \ldots, c_l$ with $c_j \in \Sigma(\mathscr{C})^*$ such that
>
> $$\alpha =_c \gamma_1 c_1 \quad , \quad \delta_1 c_1 =_c \gamma_2 c_2, \ldots, \delta_{l-1} c_{l-1} =_c \gamma_l c_l \quad , \quad \delta_l c_l =_c \beta$$

We consider asymmetric encryption to prove the hardness result in the binary case, *i.e* a term $\{u\}_k$ can be decrypted if and only if we know the inverse of the key k, denoted $Inv(k)$. We just need to add the Inv symbol in the signature and modify the decryption rule:

$$(D_K)\frac{T \vdash \{u\}_K \qquad T \vdash Inv(K)}{T \vdash u\downarrow}$$

where K is the non-empty multi-set $\{k_1^{\alpha_1}, \ldots, k_n^{\alpha_n}\}$, $Inv(K)$ is a notation for the multi-set $\{Inv(k_1)^{\alpha_1}, \ldots, Inv(k_n)^{\alpha_n}\}$, and as previously $T \vdash Inv(K)$ denotes many times the sequent of each inverse keys. Notice if you do not know an inverse of a key, there is no way to generate it. In this case we have also the locality result.

Theorem 3 *In case of the equational theory XCDE the binary intruder deduction problem is EXPSPACE-hard.*

Proof: We show that this is even true for binary T, u not containing any decryption key as a subterm (*i.e.* there is no symbol Inv) and any term headed with the pair function.

Given an instance $\mathscr{C} = (\alpha_1 = \beta_1, \ldots, \alpha_n = \beta_n \models \alpha = \beta)$ of *CSG*, let

$$\begin{aligned} T &= \{\{\boxtimes\}_{\alpha_i} \oplus \{\boxtimes\}_{\beta_i} \mid 1 \leq i \leq n\} \cup \Sigma(\mathscr{C}) \\ u &= \{\boxtimes\}_{\alpha} \oplus \{\boxtimes\}_{\beta} \end{aligned}$$

where $\boxtimes$ is some constant, and all the symbols of $\Sigma(\mathscr{C})$ are considered as constants.

By locality Theorem 2 we know that all nodes of the proofs of $T \vdash u$ are in the set of subterms of $T \cup \{u\}$. Hence these proofs are not using the (D) rule

$$
\dfrac{\dfrac{\dfrac{T \vdash x_1 \quad \ldots \quad T \vdash x_n}{T \vdash x_1 \oplus \ldots \oplus x_n}(GX) \qquad T \vdash K}{T \vdash \{x_1\}_K \oplus \ldots \oplus \{x_n\}_K}(C_K)}{\Downarrow}
$$

$$
\dfrac{\dfrac{T \vdash x_1 \quad T \vdash K}{T \vdash \{x_1\}_K}(C_K) \quad \ldots \quad \dfrac{T \vdash x_n \quad T \vdash K}{T \vdash \{x_n\}_K}(C_K)}{T \vdash \{x_1\}_K \oplus \ldots \oplus \{x_n\}_K}(GX)
$$

Figure 6: Permutation of the rules (*GX*)-(*C*) into (*C*)-(*GX*).

(since no decryption key is a subterm of T or u) and not the rules (*UR*), (*UL*) and (*P*) because there is no term headed with the pair function in $T \cup \{u\}$. By consequence theses proofs contains only the rules (*A*), (*C*) and (*GX*).

Applying the transformations of the Figure 3 (merge of two (*GX*) rules) and Figure 6 (switch rules (*GX*) and (*C*)), existence of such a proof is equivalent to existence of a proof of the following form:

$$
\dfrac{\dfrac{\dfrac{\dfrac{\{\boxtimes\}_{\gamma_1} \oplus \{\boxtimes\}_{\delta_1} \in T}{T \vdash \{\boxtimes\}_{\gamma_1} \oplus \{\boxtimes\}_{\delta_1}}(A)}{\vdots}(C)}{T \vdash \{\boxtimes\}_{\gamma_1 c_1} \oplus \{\boxtimes\}_{\delta_1 c_1}}(C) \quad \ldots \quad \dfrac{\dfrac{\dfrac{\{\boxtimes\}_{\gamma_l} \oplus \{\boxtimes\}_{\delta_l} \in T}{T \vdash \{\boxtimes\}_{\gamma_l} \oplus \{\boxtimes\}_{\delta_l}}(A)}{\vdots}(C)}{T \vdash \{\boxtimes\}_{\gamma_l c_l} \oplus \{\boxtimes\}_{\delta_l c_l}}(C)}{T \vdash \{\boxtimes\}_\alpha \oplus \{\boxtimes\}_\beta}(GX)
$$

where we may assume without loss of generality that no non-empty subset of the premises of the (*GX*) rule sums up to 0. There exists such a proof if either $\{\boxtimes\}_\alpha = \{\boxtimes\}_\beta$, or if there exists a sequence of terms $\{\boxtimes\}_{\gamma_1} \oplus \{\boxtimes\}_{\delta_1}, \ldots, \{\boxtimes\}_{\gamma_l} \oplus \{\boxtimes\}_{\delta_l}$ such that each of them is either some $\{\boxtimes\}_{\alpha_i} \oplus \{\boxtimes\}_{\beta_i}$ or some $\{\boxtimes\}_{\beta_i} \oplus \{\boxtimes\}_{\alpha_i}$, and a sequence $c_1, \ldots, c_l$ such that:

$$
\{\boxtimes\}_\alpha = \{\boxtimes\}_{\gamma_1 c_1}, \{\boxtimes\}_{\delta_1 c_1} = \{\boxtimes\}_{\gamma_2 c_2}, \ldots, \{\boxtimes\}_{\delta_{l-1} c_{l-1}} = \{\boxtimes\}_{\gamma_l c_l}, \{\boxtimes\}_{\delta_l c_l} = \{\boxtimes\}_\beta
$$

in the term algebra, which is equivalent to the existence of a solution to $\mathscr{C}$. The claim follows from the EXPSPACE-hardness of *CSG* [MM82]. □

11 Conclusion

We propose a DOUBLE-EXP-TIME decision procedure for solving the intruder deduction problem in presence of the equational theory XCDE (*eXclusive-or* with a Commutative and Distributive Encryption). The commutativity of the encryption requires to consider all combinations of keys in the subterms, to

be more attentive and to develop a new normalization of proof. We also prove in the binary case that this problem is EXPSPACE-hard. The next stage will be to find the exact complexity of this problem. The intruder deduction problem is the first step in the verification of cryptographic protocols as for instance in [RT01] without any equational theory, or later in [CLS03, CKRT03a] to consider the equational theory of *exclusive-or*. The second step is verifying the case of an active intruder. The active case without equational theory, but with a commutative encryption, was shown to be decidable by [CKRT04]. We prove that the problem is decidable for an active intruder with a homomorphic operation which is not the encryption [DLLT06]. In the case of the equational theory of the *exclusive-or* and non-commutative distributive encryption over this operator, it seems impossible to solve the equations systems in the usual way. But after having studied the first step by demonstrating the intruder deduction problem in the XCDE case, we could apply some mathematical results for solving these equations systems.
