HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire HAL, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

# History-Preserving Bisimulations on Reversible Calculus of Communicating Systems 

Clément Aubert ${ }^{1}$ and Ioana Cristescu ${ }^{2}$<br>${ }^{1}$ Augusta University, Augusta, GA 30912, USA<br>${ }^{2}$ Inria Rennes, France

#### Abstract

History- and hereditary history-preserving bisimulation (HPB and HHPB) are equivalences relations for denotational models of concurrency. Finding their counterpart in process algebras is an open problem, with some partial successes: there exists in calculus of communicating systems (CCS) an equivalence based on causal trees that corresponds to HPB. In Reversible CSS (RCCS), there is a bisimulation that corresponds to HHPB, but it considers only processes without auto-concurrency. We propose equivalences on CCS with auto-concurrency that correspond to HPB and HHPB, and their so-called "weak" variants. The equivalences exploit not only reversibility but also the memory mechanism of RCCS.

Keywords: Formal semantics • Process algebras and calculi • Reversible CCS • Hereditary history-preserving bisimulation.

## 1 Introduction

Reversing Concurrent Computation Implementing reversibility in a programming language often requires to record the history of the execution. Ideally, this history should be complete, so that every forward step can be unrolled, and minimal, so that only the relevant information is saved. Concurrent programming languages have a third requirement: the history should be distributed, to avoid centralization of information. To fulfill those requirements, Reversible CCS [6,7] uses memories attached to the threads of a process.

Equivalences for Reversible Processes A theory of reversible concurrent computation relies not only on a syntax, but also on "meaningful" behavioral equivalences. In this paper we study behavioral equivalences defined on configuration structures [14], which are denotational models for concurrency. In configuration structures, an event represents an execution step, and a configuration-a set of events that occurred - represents a state. A forward transition is then represented as moving from a configuration to one of its superset, and backward transitions have a "built-in" representation: it suffices to move from a configuration to one of its subset. Many behavioral equivalences have been defined for configuration structures ; some of them, like history- and hereditary history-preserving bisimulations (HPB and HHPB), use that "built-in" notion of reversibility.

Fig. 1: The encoding of $O_{R}$, of the future and of the past of a reversible $R$.

Encoding Reversible Processes in Configuration Structures An ongoing research effort $[1,10]$ is to transfer equivalences defined in denotational models, which are by construction adapted for reversibility, back into the reversible process algebra. Of course, showing that an equivalence on configuration structures corresponds to one on RCCS processes depends on the encoding of RCCS terms into configuration structures. One of them uses the fact that we are typically interested only in reachable reversible processes-processes $R$ which can backtrack to a process $O_{R}$ with an empty memory - called its origin. Then, a natural choice is to consider $\llbracket O_{R} \rrbracket$ - the encoding of the origin of $R$, using the common mapping for CCS processes [14]-, and to identify in it the configuration corresponding to the current state of the reversible process. In this set-up, the encoding of $R$ is one configuration, $\llbracket R \rrbracket$, in the configuration structure $\llbracket O_{R} \rrbracket$ : every configuration "below" is the "past" of $R$, every configuration "above", its "future" (Fig. 1).

Contribution This paper improves on previous results by defining relations on CCS processes that correspond to HPB, HHPB, and their "weak function" variants. The result does not require to consider a restricted class of processes. We introduce an encoding of memories independent of the rest of the process and show that, as expected, the "past" of a process corresponds to the encoding of its memory. The memories attached to a process are no longer only a syntactic layer to implement reversibility, but become essential for defining equivalences. This result gives an insight on the expressiveness of reversibility, as the back-and-forth moves of a process are not enough to capture HHPB.

Related work The correspondence between HHPB and back-and-forth bisimulations for processes without auto-concurrency $[1,10]$ motivated some of the work presented here. Our approach shares similarity with causal trees-in the sense that we encode only part of the execution in a denotational representationwhere some bisimulations corresponds to HPB [8].

Outline We start by recalling the definitions of configuration structures (Sect. 2.1), of the encoding of CCS in configuration structures (Sect. 2.2), of (hereditary) history-preserving bisimulations (Sect. 2.3), of RCCS (Sect. 2.4) and of related notions. We also recall previous result on HHPB (Theorem 1). We consider the
reader familiar with CCS, in particular with its congruence relations and reduction rules.

Sect. 3 starts by defining a structure slightly richer than configuration structures, that we call "identified configuration structures" (Sect. 3.1), and defines basic operations on them. Sect. 3.2 defines and illustrates with numerous examples how identified configuration structures can encode memories. Finally, Sect. 3.3 uses this encoding to define relations on RCCS and CSS processes that are then stated to correspond to HPB and HHPB on configuration structures.

Sect. 4 concludes, and Sect. A gathers the proofs and establishes the robustness of the tools introduced.

## 2 Preliminary Definitions

We recall the definitions of configuration structures, auto-concurrency (Sect. 2.1), how to encode CCS processes into configuration structures (Sect. 2.2) and the history-preserving bisimulations (Sect. 2.3).

We write $\subseteq$ the set inclusion, $\mathcal{P}$ the power set, $\backslash$ the set difference, Card the cardinal, o the composition of functions, $A \rightarrow B$ the set of functions between $A$ and $B, A \rightharpoonup B$ the partial functions and $f \upharpoonright_{C}$ the restriction of $f: A \rightarrow B$ to $C \subseteq A$.

Let $\mathrm{N}=\{a, b, c, \ldots\}$ be a set of names and $\overline{\mathrm{N}}=\{\bar{a}, \bar{b}, \bar{c}, \ldots\}$ its co-names. The complement of a (co-)name is given by a bijection $\overline{[\cdot]}: \mathrm{N} \rightarrow \overline{\mathrm{N}}$, whose inverse is also denoted by $\overline{[\cdot]}$. We write $\vec{a}$ for a list of names $a_{1}, \cdots, a_{n}$. We define the sets of labels $\mathrm{L}=\mathrm{N} \cup \overline{\mathrm{N}} \cup\{\tau\}$, let $\mathcal{L}=\mathcal{P}(\mathrm{L})$, and use $\alpha$ (resp. $\lambda, \nu$ ) to range over $\mathrm{L}($ resp. $\mathrm{L} \backslash\{\tau\})$.

### 2.1 Configuration Structures

Definition 1 (Configuration structures). A configuration structure $\mathcal{C}$ is a tuple $(E, C, L, \ell)$ where $E$ is a set of events, $L \subseteq \mathcal{L}$ is a set of labels, $\ell: E \rightarrow L$ is a labeling function and $C \subseteq \mathcal{P}(E)$ is a set of subsets satisfying:

$$
\begin{align*}
& \forall x \in C, \forall e \in x, \exists z \in C \text { finite, } e \in z, z \subseteq x  \tag{Finiteness}\\
& \forall x \in C, \forall e, e^{\prime} \in x, e \neq e^{\prime} \Rightarrow \exists z \in C, z \subseteq x, e \in z \Longleftrightarrow e^{\prime} \notin z
\end{align*}
$$

(Coincidence Freeness)
$\forall X \subseteq C, \exists y \in C$ finite $, \forall x \in X, x \subseteq y \Rightarrow \bigcup X \in C \quad$ (Finite Completness)
$\forall x, y \in C, x \cup y \in C \Rightarrow x \cap y \in C$
We denote $\mathbf{0}$ the configuration structure with $E=\emptyset$, and write $x \xrightarrow{e} y$ and $y \stackrel{e}{\leadsto} x$ for $x, y \in C$ such that $x=y \cup\{e\}$.

For the rest of this paper, we often omit $L$, let $x, y, z$ range over configurations, and assume that we are always given $\mathcal{C}=(E, C, \ell)$ and $\mathcal{C}_{i}=\left(E_{i}, C_{i}, \ell_{i}\right)$, for $i=1,2$.

Definition 2 (Causality, Concurrency, and Maximality). For $x \in C$ and $d, e \in x$, the causality relation on $x$ is given by $d<_{x} e$ iff $d \leqslant_{x} e$ and $d \neq e$, where $d \leqslant_{x} e$ iff for all $y \in C$ with $y \subseteq x$, we have $e \in y \Rightarrow d \in y$. The concurrency relation on $x$ [9, Definition 5.6] is given by $d \mathrm{co}_{x} e$ iff $\neg\left(d<_{x} e \vee e<_{x} d\right)$. Finally, $x$ is maximal if $\forall y \in \mathcal{C}, x=y$ or $x \nsubseteq y$.

Fig. 2: Examples of configuration structures

Example 1. Consider the configuration structures of Fig. 2, where the set of events and of configurations can be read from the diagram, and where we make the abuse of notation of writing the events as their labels (with a subscript if multiple events have the same label). Note that two events with complement names can happen at the same time (Fig. 2c), in which case they are labeled with $\tau$ and called silent transition, as it is usual in CCS (Sect. 2.2).
Definition 3 (Category of configuration structures). We define $\mathbb{C}$ the category of configuration structure, where objects are configuration structures, and a morphism $f$ from $\mathcal{C}_{1}$ to $\mathcal{C}_{2}$ is a triple $\left(f_{E}, f_{L}, f_{C}\right)$ such that
$-f_{E}: E_{1} \rightarrow E_{2}$ preserves labels: $\ell_{2}\left(f_{E}(e)\right)=f_{L}\left(\ell_{1}(e)\right)$, for $f_{L}: L_{1} \rightarrow L_{2}$;
$-f_{C}: C_{1} \rightarrow C_{2}$ is defined as $f_{C}(x)=\left\{f_{E}(e): e \in x\right\}$.
If there exists an isomorphism $f: \mathcal{C}_{1} \rightarrow \mathcal{C}_{2}$, then we write $\mathcal{C}_{1} \cong \mathcal{C}_{2}$.
We omit the $f_{L}$ part of the morphisms when it is the identity morphism.
We now recall how process algebra constructors are defined on configuration structures [13]. The definition below may seem technical, but Definition 6 should make it clear that they capture the right notion.

This definition uses the product $\left(\times_{\star}, p_{1}, p_{2}\right)$ of the category of sets and partial functions [13, Appendix A]: letting $\star$ denote undefined for a partial function, $C^{\star}=C \cup\{\star\}$ for a set $C$, we define, for two sets $A$ and $B$,

$$
A \times_{\star} B=\{(a, \star) \mid a \in A\} \cup\{(\star, b) \mid b \in B\} \cup\{(a, b) \mid a \in A, b \in B\}
$$

with $p_{1}: A \times_{\star} B \rightarrow A^{\star}$ and $p_{2}: A \times_{\star} B \rightarrow B^{\star}$.

## Definition 4 (Operations on configuration structures [1,12]).

The product of $\mathcal{C}_{1}$ and $\mathcal{C}_{2}$ is $\mathcal{C}_{1} \times \mathcal{C}_{2}=\left(E_{1} \times_{\star} E_{2}, C, \ell\right)$. Define the projections $\pi_{i}: \mathcal{C} \rightarrow \mathcal{C}_{i}$ and the configurations $x \in C$ such that:

$$
\begin{aligned}
& \forall e \in E, \pi_{i}(e)=p_{i}(e), \pi_{i}\left(\ell_{i}(e)\right)=\ell_{i}\left(\pi_{i}(e)\right) \\
& \pi_{i}(x) \in C_{i} \\
& \forall e, e^{\prime} \in x, \pi_{1}(e)=\pi_{1}\left(e^{\prime}\right) \neq \star \text { or } \pi_{2}(e)=\pi_{2}\left(e^{\prime}\right) \neq \star \Rightarrow e=e^{\prime} \\
& \forall e \in x, \exists z \subseteq x \text { finite }, \pi_{1}(x) \in C_{1}, \pi_{2}(x) \in C_{2}, e \in z \\
& \forall e, e^{\prime} \in x, e \neq e^{\prime} \Rightarrow \exists z \subseteq x, \pi_{i}(z) \in C_{i}, e \in z \Longleftrightarrow e^{\prime} \notin z
\end{aligned}
$$

The labeling function $\ell: E_{1} \times_{\star} E_{2} \rightarrow L_{1} \cup L_{2} \cup\left(L_{1} \times L_{2}\right)$ is

$$
\ell(e)= \begin{cases}\ell_{1}\left(e_{1}\right) & \text { if } \pi_{1}(e)=e_{1} \neq \star \text { and } \pi_{2}(e)=\star \\ \ell_{2}\left(e_{2}\right) & \text { if } \pi_{1}(e)=\star \text { and } \pi_{2}(e)=e_{2} \neq \star \\ \left(\ell_{1}\left(e_{1}\right), \ell_{2}\left(e_{2}\right)\right) & \text { otherwise }\end{cases}
$$

The relabeling of $\mathcal{C}_{1}$ along $r: E_{1} \rightarrow L$ is $r \circ \mathcal{C}_{1}=\left(E_{1}, C_{1}, r\right)$.
The restriction of $\mathcal{C}_{1}$ to $E \subseteq E_{1}$ is $\mathcal{C}_{1} \upharpoonright_{E}=\left(E, C, \ell \upharpoonright_{E}\right)$, where $x \in C \Longleftrightarrow x \in$ $C_{1}$ and $x \subseteq E$. The restriction of $\mathcal{C}_{1}$ to a name a is $\mathcal{C}_{1} \upharpoonright_{a}:=\mathcal{C}_{1} \upharpoonright_{E_{1}^{a}}$ where $E_{1}^{a}=\left\{e \in E_{1} \mid \ell(e) \notin\{a, \bar{a}\}\right\}$. For $\vec{a}=a_{1}, \ldots, a_{n}$ a list of names, we define similarly $\mathcal{C}_{1} \upharpoonright_{\vec{a}}=\mathcal{C}_{1} \upharpoonright_{E_{1}^{\vec{a}}}$ for $E_{1}^{\vec{a}}=\left\{e \in E_{1} \mid \ell(e) \notin\left\{a_{1}, \overline{a_{1}}, \ldots, a_{n}, \overline{a_{n}}\right\}\right\}$.
The parallel composition of $\mathcal{C}_{1}$ and $\mathcal{C}_{2}$ is $\mathcal{C}_{1} \mid \mathcal{C}_{2}=\left(r \circ\left(\mathcal{C}_{1} \times \mathcal{C}_{2}\right)\right) \upharpoonright_{F}$, with $-\mathcal{C}_{1} \times \mathcal{C}_{2}=\mathcal{C}_{3}=\left(E_{3}, C_{3}, \ell_{3}\right)$ is the product; $-r \circ \mathcal{C}_{3}$ with $r: E_{3} \rightarrow L_{1} \cup L_{2} \cup\{\perp\}$ defined as follows:

$$
r(e)= \begin{cases}\ell_{3}(e) & \text { if } \ell_{3}(e) \in\{a, \bar{a}\} \\ \tau & \text { if } \ell_{3}(e) \in\{(a, \bar{a}),(\bar{a}, a), \tau\} \\ \perp & \text { otherwise }\end{cases}
$$

$$
-\left(r \circ \mathcal{C}_{3}\right) \upharpoonright_{F}, \text { where } F=\left\{e \in E_{3} \mid r(e) \neq \perp\right\}
$$

The coproduct of $\mathcal{C}_{1}$ and $\mathcal{C}_{2}$ is $\mathcal{C}_{1}+\mathcal{C}_{2}=\mathcal{C}$, where $E=\left(\{1\} \times E_{1}\right) \cup\left(\{2\} \times E_{2}\right)$ and $C=\left\{\{1\} \times x \mid x \in C_{1}\right\} \cup\left\{\{2\} \times x \mid x \in C_{2}\right\}$. The labeling function $\ell$ is defined as $\ell(e)=\ell_{i}\left(\pi_{2}(e)\right)$ when $\pi_{1}(e)=i$.
The prefixing of $\mathcal{C}_{1}$ by the name $\lambda$ is $\lambda . \mathcal{C}_{1}=\left(e \cup E_{1}, C, \ell\right)$, for $e \notin E_{1}$ where $x \in C \Longleftrightarrow x=\emptyset \vee \exists x^{\prime} \in C_{1}, x=x^{\prime} \cup e ; \ell(e)=\lambda$ and $\forall e^{\prime} \neq e$, $\ell\left(e^{\prime}\right)=\ell_{1}\left(e^{\prime}\right)$.

Definition 5 (Auto-concurrency [9, Definition 9.5]). If $\forall x \in C, \forall e_{1}, e_{2} \in$ $x, e_{1} \mathrm{co}_{x} e_{2}$ and $\ell\left(e_{1}\right)=\ell\left(e_{2}\right)$ implies $e_{1}=e_{2}$, then $\mathcal{C}$ is without auto-concurrency.

Any configuration structure where configurations have at most one event (like Fig. 2a) are without auto-concurrency. Fig. 2b, on the other hand, is a configuration structure with auto-concurrency: for $x=\left\{a_{1}, a_{2}\right\}$ we have that $a_{1} \operatorname{co}_{x} a_{2}, \ell\left(a_{1}\right)=\ell\left(a_{2}\right)$, and yet $a_{1} \neq a_{2}$.

### 2.2 CCS and its Encoding in Configuration Structures

The set of CCS processes P is inductively defined:

$$
P, Q:=\lambda . P\|P \mid Q\| \lambda . P+\nu . Q\|P \backslash a\| 0 \quad \text { (CCS Processes) }
$$

In the category of configuration structures $\mathbb{C}$ (Definition 3) one can "match" the process constructors of CCS with the categorical operations of Definition 4.

Definition 6 (Encoding a CCS process [15, p. 57]). Given a CCS process $P$, its encoding $\llbracket P \rrbracket$ as a configuration structure is built inductively:

$$
\begin{aligned}
\llbracket \lambda \cdot P \rrbracket & =\lambda \cdot \llbracket P \rrbracket & \llbracket P \mid Q \rrbracket & =\llbracket P \rrbracket \mid \llbracket Q \rrbracket \\
\llbracket P \backslash a \rrbracket & =\llbracket P \rrbracket \upharpoonright_{a} & \llbracket 0 \rrbracket & =\mathbf{0}
\end{aligned}
$$

For now on we assume that all structures use the same set of labels L.
Definition 7 (Auto-concurrency in CCS). A process $P$ is without autoconcurrency if $\llbracket P \rrbracket$ is.

## 2.3 (Hereditary) History-Preserving Bisimulations

HPB [11,10], [2, Theorem 4] and HHPB [3, Definition 1.4], [2, Theorem 1] are equivalences on configuration structures that use label- and order-preserving bijections between the events of the two configuration structures.

Definition 8 (Label- and order-preserving functions). A function $f$ : $x_{1} \rightarrow x_{2}$, for $x_{i} \in C_{i}, i \in\{1,2\}$ is label-preserving if $\ell_{1}(e)=\ell_{2}(f(e))$ for all $e \in x_{1}$. It is order-preserving if $e_{1} \leqslant x_{1} e_{2} \Rightarrow f\left(e_{1}\right) \leqslant x_{2} f\left(e_{2}\right)$, for all $e_{1}, e_{2} \in x_{1}$.

Definition 9 (HPB and HHPB). A relation $\mathcal{R} \subseteq C_{1} \times C_{2} \times\left(E_{1} \rightharpoonup E_{2}\right)$ such that $(\emptyset, \emptyset, \emptyset) \in \mathcal{R}$, and if $\left(x_{1}, x_{2}, f\right) \in \mathcal{R}$, then $f$ is a label- and order-preserving bijection between $x_{1}$ and $x_{2}$ and (1) and (2) (resp. (1-4)) hold is called a history(resp. hereditary history-) preserving bisimulation between $\mathcal{C}_{1}$ and $\mathcal{C}_{2}$.

$$
\begin{align*}
& \forall y_{1}, x_{1} \xrightarrow{e_{1}} y_{1} \Rightarrow \exists y_{2}, g, x_{2} \xrightarrow{e_{2}} y_{2}, g \upharpoonright_{x_{1}}=f,\left(y_{1}, y_{2}, g\right) \in \mathcal{R}  \tag{1}\\
& \forall y_{2}, x_{2} \xrightarrow{e_{2}} y_{2} \Rightarrow \exists y_{1}, g, x_{1} \xrightarrow{e_{1}} y_{1}^{\prime}, g \upharpoonright_{x_{1}}=f,\left(y_{1}, y_{2}, g\right) \in \mathcal{R}  \tag{2}\\
& \forall y_{1}, x_{1} \stackrel{e_{1}}{\sim} y_{1} \Rightarrow \exists y_{2}, g, x_{2} \stackrel{e_{2}}{\sim} y_{2}, g=f \upharpoonright_{x_{1}},\left(y_{1}, y_{2}, g\right) \in \mathcal{R}  \tag{3}\\
& \forall y_{2}, x_{2} \xrightarrow{e_{2}} y_{2} \Rightarrow \exists y_{1}, g, x_{1} \xrightarrow{e_{1}} y_{1}, g=f \upharpoonright_{x_{1}},\left(y_{1}, y_{2}, g\right) \in \mathcal{R} \tag{4}
\end{align*}
$$

Note that the bijection on events is preserved from one step to the next. This condition can be weakened, and we call the corresponding relations the weakfunction HPB and weak-function HHPB [3, Definition1.4], [10, Definition3.11].3
${ }^{3}$ The names weak-HPB and weak-HHPB are more common [3,10], but can be confused with the weak equivalences of process algebra, which refers to ignoring $\tau$-transitions.

Definition 10 ( $w f \mathrm{HPB}$ ). $A$ weak-function history-preserving bisimulation between $\mathcal{C}_{1}$ and $\mathcal{C}_{2}$ is a relation $\mathcal{R} \subseteq C_{1} \times C_{2} \times\left(E_{1} \rightharpoonup E_{2}\right)$ such that $(\emptyset, \emptyset, \emptyset) \in \mathcal{R}$ and if $\left(x_{1}, x_{2}, f\right) \in \mathcal{R}$, then $f$ is a label- and order-preserving bijection between $x_{1}$ and $x_{2}$ and

$$
\begin{aligned}
& \forall y_{1}, x_{1} \xrightarrow{e_{1}} y_{1} \Rightarrow \exists y_{2}, g, x_{2} \xrightarrow{e_{2}} y_{2},\left(y_{1}, y_{2}, g\right) \in \mathcal{R} \\
& \forall y_{2}, x_{2} \xrightarrow{e_{2}} y_{2} \Rightarrow \exists y_{1}, g, x_{1} \xrightarrow{e_{1}} y_{1},\left(y_{1}, y_{2}, g\right) \in \mathcal{R}
\end{aligned}
$$

Similarly one defines $w f$ HHPB. If there is a HPB between $\mathcal{C}_{1}$ and $\mathcal{C}_{2}$, we just write that $\mathcal{C}_{1}$ and $\mathcal{C}_{2}$ are HPB, and similarly for HHPB, $w f \mathrm{HPB}$ and $w f$ HHPB.

Fig. 3: There is no HHPB relation between $\llbracket a . a \mid b \rrbracket$ and $\llbracket a|a| b \rrbracket$.

Example 2. Observe that $\llbracket a . a \mid b \rrbracket$ and $\llbracket a|a| b \rrbracket$, presented in Fig. 3, are HPB, but not HHPB. Any HHPB relation would have to associate the maximal configurations $\left\{a_{1}, a_{2}, b\right\}$ of the two structures and to construct a bijection: taking $\left(a_{1} \mapsto a_{1}, a_{2} \mapsto a_{2}, b \mapsto b\right)$ wouldn't work, since $\llbracket a|a| b \rrbracket$ can backtrack on $a_{2}$ and $\llbracket a . a \mid b \rrbracket$ cannot. Taking the other bijection, $\left(a_{1} \mapsto a_{2}, a_{2} \mapsto a_{1}, b \mapsto b\right)$, fails too, since $\llbracket a|a| b \rrbracket$ can backtrack on $a_{1}$ and $\llbracket a . a \mid b \rrbracket$ cannot.
Example 3 ([9]). The processes $a|(b+c)+a| b+(a+c) \mid b$ and $a|(b+c)+(a+c)|$ $b$ is another example of processes whose encodings are HPB but not HHPB.

Example 4. Finally, observe that $a .(b+b)$ and $a . b+a . b$ are not structuraly congruent in CCS, but the encoding of the two processes are HHPB.

### 2.4 Reversible CCS and Coherent Memories

Let I be a set of identifiers, and $i, j, k$ range over elements of I. The set of RCCS processes R is built on top of the set of CCS processes P (Sect. 2.1):

$$
\begin{align*}
e & :=\langle i, \lambda, P\rangle  \tag{MemoryEvents}\\
m & :=\emptyset\|\quad \gamma . m\| e . m \\
T, U & :=m \triangleright P \\
R, S & :=T\|T \mid U\| R \backslash a
\end{align*}
$$

(Memory Stacks)
(Reversible Thread)
(RCCS Processes)

We denote $\mathrm{I}(m)$ (resp. $\mathrm{I}(R), \mathrm{I}(e))$ the set of identifiers occurring in $m$ (resp. $R, e)$, and always take $\mathrm{I}=\mathbb{N}$. A structural congruence $\equiv$ can be defined on RCCS terms [1, Definition 5], the only rule we will use here is distribution of memory: $m \triangleright(P \mid Q) \equiv(\curlyvee . m \triangleright P) \mid(\curlyvee . m \triangleright Q)$. We also note that $R \equiv\left(\prod_{i} m_{i} \triangleright P_{i}\right) \backslash \vec{a}$, for any reversible process $R$ and for some names $\vec{a}$, memories $m_{i}$ and CCS processes $P_{i}$, writing $\prod_{i}$ the $i$-ary parallel composition.

$$
\begin{aligned}
& i \notin \mathrm{I}(m) \xrightarrow[{(m \triangleright \lambda . P+Q) \xrightarrow{i: \lambda}\langle i, \lambda, Q\rangle . m \triangleright} P]{ } \text { act. } \quad \frac{R \xrightarrow{i: \lambda} R^{\prime} S \xrightarrow{i: \bar{\lambda}} S^{\prime}}{R\left|S \xrightarrow{i: \tau} R^{\prime}\right| S^{\prime}} \text { syn. }
\end{aligned}
$$

$$
\begin{aligned}
& i \notin \mathrm{I}(S) \frac{R \xrightarrow[\longrightarrow]{i: \alpha} R^{\prime}}{R\left|S \xrightarrow[\longrightarrow]{i: \alpha} R^{\prime}\right| S} \text { par. } \quad \frac{R \xrightarrow[\longrightarrow]{i: \alpha} R^{\prime} \quad a \notin \alpha}{R \backslash a \xrightarrow{i: \alpha} R^{\prime} \backslash a} \text { res. } \quad \frac{R_{1} \equiv R \xrightarrow{i: \alpha} R^{\prime} \equiv R_{1}^{\prime}}{R_{1} \xrightarrow{i: \alpha} R_{1}^{\prime}} \equiv
\end{aligned}
$$

Fig. 4: Rules of the labeled transition system

The labeled transition system for RCCS is given by the rules of Fig. 4. We use $\xrightarrow{i: \alpha}$ as a wildcard for $\xrightarrow{i: \alpha}$ (forward) or $\stackrel{i: \alpha}{\longrightarrow}$ (backward transition), and if there are indices $i_{1}, \ldots, i_{n}$ and labels $\alpha_{1}, \ldots, \alpha_{n}$ such that $R_{1} \xrightarrow{i_{1}: \alpha_{1}} \cdots \xrightarrow{i_{n}: \alpha_{n}} R_{n}$, then we write $R_{1} \xrightarrow{\star} R_{n}$. If there is a CCS term $P$ such that $\emptyset \triangleright P \xrightarrow{\star} R$, we say that $R$ is reachable, that $P$ is the origin of $R[1$, Lemma 1$]$ and write $P=O_{R}$. Similarly to what we did in Definition 7, we will write that $R$ is without auto-concurrency if $\llbracket O_{R} \rrbracket$ is. An example of the execution of a reversible process is given at the beginning of Example 7.

Note that we cannot work up to $\alpha$-renaming of the identifiers: concurrent, distributed computation is about splitting threads between independent units of computation. If one of unit were to re-tag a memory event $\langle 89, \lambda, \underline{P}\rangle$ as $\langle 1, \lambda, P\rangle$, and another were to try to backtrack on the memory event $\langle 89, \bar{\lambda}, P\rangle$, then the trace of the synchronization would be lost, and backtracking made impossible. Since we don't want to keep a "global index" which would go against the benefits of distributed computation, the only option is to forbid $\alpha$-renaming of identifiers.

Memory coherence [6, Definition 1] was defined for RCCS processes with less structured memory events (i.e., without identifiers), but can be adapted.

Definition 11 (Coherence relation). Coherence, written $\frown$, is the smallest symmetric relation on memory stacks such that rules of Fig. 5 hold.

Note that $\sim$ is not reflexive, and hence not an equivalence, nor anti-reflexive. For the rest of this paper, we will just write "memory" for "memory stack".

$$
\begin{gathered}

\end{gathered}
$$

Fig. 5: Rules for the coherence relation

Definition 12 (Coherent processes, [6, Definition 2]). A RCCS process is coherent if all of its memories are pairwise coherent, or if its only memory is coherent with $\emptyset$.

We require the memory to be coherent with $\emptyset$ to make it impossible to have $\langle 1, \lambda, P\rangle \cdot\langle 1, \nu, Q\rangle . \emptyset$ as a memory in a coherent process.
Lemma 1 ([7, Lemma 5]). If $R \xrightarrow{\star} S$ and $R$ is coherent then so is $S$.
Corollary 1. For every reachable $m \triangleright P$ and $i \in I(m)$, $i$ occurs once in $m$.
Note that the property above holds for reversible threads, and not for RCCS processes in general: indeed, we actually want memory events to have the same identifiers if they result from a synchronization or a fork.

Definition 13 (Back-and-forth bisimulation). A back-and-forth bisimulation in $R C C S$ is a relation $\mathcal{R} \subseteq \mathrm{R} \times \mathrm{R}$ such that if $\left(R_{1}, R_{2}\right) \in \mathcal{R}$

$$
\begin{aligned}
& \forall S_{1}, R_{1} \xrightarrow{i: \alpha} S_{1} \Rightarrow \exists S_{2}, R_{2} \xrightarrow{j: \alpha} S_{2},\left(S_{1}, S_{2}\right) \in \mathcal{R} \\
& \forall S_{2}, R_{2} \xrightarrow{i: \alpha} S_{2} \Rightarrow \exists S_{1}, R_{1} \xrightarrow{j: \alpha} S_{1},\left(S_{1}, S_{2}\right) \in \mathcal{R} \\
& \forall S_{1}, R_{1} \stackrel{i: \alpha}{\sim} S_{1} \Rightarrow \exists S_{2}, R_{2} \xrightarrow{j: \alpha} S_{2},\left(S_{1}, S_{2}\right) \in \mathcal{R} \\
& \forall S_{2}, R_{2} \xrightarrow{i: \alpha} S_{2} \Rightarrow \exists S_{1}, R_{1} \xrightarrow{j: \alpha} S_{1},\left(S_{1}, S_{2}\right) \in \mathcal{R}
\end{aligned}
$$

Example 5. The processes $\emptyset \triangleright(a . a \mid b)$ and $\emptyset \triangleright(a|a| b)$ are in a back-and-forth bisimulation.

Theorem 1 ([1, Theorem 2],[10]). Back-and-forth bisimulation on RCCS processes without auto-concurrency corresponds to HHPB on their encoding.

Note that this result does not hold for the processes in Example 5 (see also Example 2). This does not contradict the theorem, as the processes in Example 5 are with auto-concurrency.

## 3 Lifting the Restrictions

To define a bisimulation on RCCS (with auto-concurrency) that corresponds to HHPB we first have to encode the memories of a reversible process into a structure similar to the configuration structures, called identified configuration structures (Sect. 3.1). We can then define the encoding (Sect. 3.2), and the equivalences in RCCS that use this encoding of memories (Sect. 3.3).

### 3.1 Identified Configuration Structures

Definition 14 (Identified configuration structure). An identified configuration structure, or $\mathcal{D}$-structure, $\mathcal{D}=(E, C, \ell, I, m)$ is a configuration structure $\mathcal{C}=(E, C, \ell)$ endowed with a set of identifiers I and a function $m: E \rightarrow I$ such that,

$$
\forall x \in C, \forall e_{1}, e_{2} \in x, m\left(e_{1}\right) \neq m\left(e_{2}\right) \quad \text { (Collision Freeness) }
$$

We call $\mathcal{C}$ the underlying configuration structure of $\mathcal{D}$ and write $\mathcal{D}=\mathcal{C}+m$. We write $\mathbf{0}$ for the identified configuration structure with $E=\emptyset$.

For the rest of this paper, we omit I, and assume that we are always given $\mathcal{D}=(E, C, \ell, m)$ and $\mathcal{D}_{i}=\left(E_{i}, C_{i}, \ell_{i}, m_{i}\right)$, for $i=1,2$.

Example 6. Fig. 2c, with $m(a)=1, m(\bar{a})=2, m(b)=3$ and $m(\tau)=4$, is a $\mathcal{D}$-structure. Note that it is possible to have fewer identifiers than events: take $\mathrm{I}=\{1,2,3\}$ and $m(a)=m(\tau)=1, m(\bar{a})=2$ and $m(b)=3$.

For the following remark, we need to suppose that every configuration structure is endowed with a total ordering on its events.

Remark 1. Every configuration structure can be mapped to a $\mathcal{D}$-structure.
The mapping is trivial: take I to be $\{1, \ldots, \operatorname{Card} E\}$, and define $m: E \rightarrow \mathrm{I}$ to follow the ordering on $E$. Note that, in this case, $m$ is a bijection.

Definition 15 (Category of $\mathcal{D}$-structures). We define $\mathbb{D}$ the category of identified configuration structure, where objects are $\mathcal{D}$-structures, and a morphism $f$ from $\mathcal{D}_{1}$ to $\mathcal{D}_{2}$ is a triple $\left(f_{E}, f_{C}, f_{m}\right)$ such that
$-\left(f_{E}, f_{C}\right)$ is a morphism in $\mathbb{C}$ from $\left(E_{1}, C_{1}, \ell_{1}\right)$ to $\left(E_{2}, C_{2}, \ell_{2}\right)$;
$-f_{m}: I_{1} \rightarrow I_{2}$ preserves identifiers: $f_{m}\left(m_{1}(e)\right)=m_{2}\left(f_{E}(e)\right)$.
We denote $\mathcal{F}: \mathbb{D} \rightarrow \mathbb{C}$ the forgetful functor.

## Definition 16 (Operations on $\mathcal{D}$-structures).

The product of $\mathcal{D}_{1}$ and $\mathcal{D}_{2}$ is $\mathcal{D}_{1} \times \mathcal{D}_{2}=(E, C, \ell, m)$ :
$-\left(E_{1}, C_{1}, \ell_{1}\right) \times\left(E_{2}, C_{2}, \ell_{2}\right)=(E, C, \ell)$ is the product in the category of configuration structures with projections $\pi_{i}:(E, C, \ell) \rightarrow\left(E_{i}, C_{i}, \ell_{i}\right)$;
$-m: E_{1} \times_{\star} E_{2} \rightarrow\left(I_{1} \cup\left\{m_{\star}\right\}\right) \times\left(I_{2} \cup\left\{m_{\star}\right\}\right)$, for $m_{\star} \notin I_{1} \cup I_{2}$, is defined as

$$
m(e)= \begin{cases}\left(m_{1}\left(\pi_{1}(e)\right), m_{\star}\right) & \text { if } \pi_{2}(e)=\star \\ \left(m_{\star}, m_{2}\left(\pi_{2}(e)\right)\right) & \text { if } \pi_{1}(e)=\star \\ \left(m_{1}\left(\pi_{1}(e)\right), m_{2}\left(\pi_{2}(e)\right)\right) & \text { otherwise }\end{cases}
$$

with the projections $p_{i}: m \rightarrow m_{i} \cup\left\{m_{\star}\right\}$.
Define the projections $\gamma_{i}: \mathcal{D}_{1} \times \mathcal{D}_{2} \rightarrow \mathcal{D}_{i}$ as the pair $\left(\pi_{i}, p_{i}\right)$.
The relabeling of $\mathcal{D}_{1}$ along $r: E_{1} \rightarrow L$ is $r \circ \mathcal{D}_{1}=\left(E_{1}, C_{1}, r, m_{1}\right)$.
The restriction of $\mathcal{D}_{1}$ to $E \subseteq E_{1}$ is $\mathcal{D}_{1} \upharpoonright_{E}=\left(\left(E_{1}, C_{1}, \ell_{1}\right) \upharpoonright_{E}+m_{1} \upharpoonright_{E}\right)$.

The parallel composition of $\mathcal{D}_{1}$ and $\mathcal{D}_{2}$ is $\mathcal{D}_{1} \mid \mathcal{D}_{2}=\left(r \circ\left(\mathcal{D}_{1} \times \mathcal{D}_{2}\right)\right) \upharpoonright_{F}$, with $-\mathcal{D}_{1} \times \mathcal{D}_{2}=\mathcal{D}_{3}=\left(E_{3}, C_{3}, \ell_{3}, m_{3}\right)$ is the product of $\mathcal{D}$-structures.
$-r \circ \mathcal{D}_{3}$, with $r: E_{3} \rightarrow L \cup\{\perp\}$ defined as follows,

$$
r(e)=\left\{\begin{array}{ll}
\perp & \text { if } \pi_{1}(e)=e_{1} \neq \star \wedge \pi_{2}(e)=e_{2} \neq \star \wedge m_{1}\left(e_{1}\right) \neq m_{2}\left(e_{2}\right) \\
& \text { or if } \pi_{1}(e)=e_{1} \neq \star \wedge \pi_{2}(e)=\star \\
\wedge\left(\exists e_{2} \in E_{2}, \text { s.t. } m_{1}\left(e_{1}\right)=m_{2}\left(e_{2}\right)\right) \\
& \text { or if } \pi_{2}(e)=e_{2} \neq \star \wedge \pi_{1}(e)=\star \\
\wedge\left(\exists e_{1} \in E_{1}, \text { s.t. } m_{1}\left(e_{1}\right)=m_{2}\left(e_{2}\right)\right) \\
\tau \quad & \text { if } \pi_{1}(e)=e_{1} \neq \star \wedge \pi_{2}(e)=e_{2} \neq \star \wedge m_{1}\left(e_{1}\right)=m_{2}\left(e_{2}\right) \\
\text { and } \ell_{3}(e)=(\alpha, \bar{\alpha}) \quad(\operatorname{Valid} \operatorname{Synchronisations)} \\
\alpha \quad & \text { if } \pi_{1}(e)=e_{1} \neq \star \wedge \pi_{2}(e)=e_{2} \neq \star \wedge m_{1}\left(e_{1}\right)=m_{2}\left(e_{2}\right) \\
\text { and } \ell_{3}(e)=(\alpha, \alpha) \\
\ell_{3}(e) & \text { otherwise }
\end{array} \quad \text { (Valid Forks) }\right)
$$

$-\left(r \circ \mathcal{D}_{3}\right) \upharpoonright_{F}$, where $F=\left\{e \in E_{3} \mid r(e) \neq \perp\right\}$.
In the definition of parallel composition, $r$ detects the wrong synchronization (or fork) pairs: if two events occur at the same time, then they must have the same identifier. And if an event occurs alone, then no other event can occur with the same identifier.

### 3.2 Encoding the Memory of Reversible Processes

Definition 17 (Encoding a RCCS memory). The encoding of the memory of a RCCS process in a $\mathcal{D}$-structure is defined ${ }^{4}$ by induction on the process:

$$
\text { For }\lfloor\langle i, \alpha, P\rangle . m\rfloor \text {, letting }\lfloor m\rfloor=\left(E_{m}, C_{m}, \ell_{m}, m_{m}\right) \text { and } e \notin E_{m} \text {, we let }(E, C, \ell, m)
$$ be $E=E_{m} \cup e, C=C_{m} \cup\left\{x \cup\{e\} \mid x \in C_{m}\right.$ is maximal $\}, \ell=\ell_{m} \cup\{e \mapsto \alpha\}$ and $m\left(e^{\prime}\right)=m_{m}\left(e^{\prime}\right)$ if $e^{\prime} \neq e$, and $m(e)=i$ otherwise.

The memories of any RCCS process could be encoded into $\mathcal{D}$-structures, but we will encode only reachable (and thus coherent) processes (Definition 12).
Example 7. Consider the following transitions:

$$
\begin{aligned}
\emptyset \triangleright(a . b \mid c . \bar{a}) & \equiv(\curlyvee . \emptyset \triangleright a . b) \mid(\curlyvee . \emptyset \triangleright c . \bar{a}) \\
& \xrightarrow{1: c}(\curlyvee . \emptyset \triangleright a . b) \mid(\langle 1, c, 0\rangle . \curlyvee . \emptyset \triangleright \bar{a}) \\
& \xrightarrow{2: \tau}(\langle 2, a, 0\rangle . \curlyvee . \emptyset \triangleright b) \mid(\langle 2, \bar{a}, 0\rangle .\langle 1, c, 0\rangle . \curlyvee . \emptyset \triangleright 0) \\
& \xrightarrow{3: b}(\langle 3, b, 0\rangle .\langle 2, a, 0\rangle . \curlyvee . \emptyset \triangleright 0) \mid(\langle 2, \bar{a}, 0\rangle .\langle 1, c, 0\rangle . \curlyvee . \emptyset \triangleright 0)
\end{aligned}
$$

[^0]\[

$$
\begin{aligned}
& \lfloor m \triangleright P\rfloor=\lfloor m\rfloor \\
& \lfloor\langle i, \alpha, P\rangle . m\rfloor=(E, C, m) \\
& \left\lfloor R_{1} \mid R_{2}\right\rfloor=\left\lfloor R_{1}\right\rfloor \mid\left\lfloor R_{2}\right\rfloor \\
& \lfloor R \backslash a\rfloor=\lfloor R\rfloor
\end{aligned}
$$
\]

Fig. 6: (Identified) Configurations Structures of Examples 7 and 8

Fig. 7: Configurations Structure of Example 7 (Continued)

Now, observe that:

$$
\begin{aligned}
& \lfloor(\langle 3, b, 0\rangle \cdot\langle 2, a, 0\rangle \cdot \curlyvee . \emptyset \triangleright 0) \mid(\langle 2, \bar{a}, 0\rangle \cdot\langle 1, c, 0\rangle \cdot \curlyvee . \emptyset \triangleright 0)\rfloor \\
= & \lfloor\langle 3, b, 0\rangle \cdot\langle 2, a, 0\rangle \cdot \curlyvee . \emptyset \triangleright 0\rfloor \mid\lfloor\langle 2, \bar{a}, 0\rangle \cdot\langle 1, c, 0\rangle \cdot \curlyvee . \emptyset \triangleright 0\rfloor \\
= & \lfloor\langle 3, b, 0\rangle \cdot\langle 2, a, 0\rangle . \curlyvee . \emptyset\rfloor \mid\lfloor\langle 2, \bar{a}, 0\rangle \cdot\langle 1, c, 0\rangle . \curlyvee . \emptyset\rfloor
\end{aligned}
$$

If we let (with the obvious labeling functions $\ell(x)=x$ for $x \in\{a, \bar{a}, b, c\}$ ):

$$
\begin{aligned}
& \lfloor\langle 3, b, 0\rangle \cdot\langle 2, a, 0\rangle \cdot \curlyvee . \emptyset\rfloor=(\{a, b\},\{\emptyset,\{a\},\{b, a\}\},\{a \mapsto 2, b \mapsto 3\} \\
& \lfloor\langle 2, \bar{a}, 0\rangle \cdot\langle 1, c, 0\rangle \cdot \curlyvee . \emptyset\rfloor=(\{c, \bar{a}\},\{\emptyset,\{c\},\{c, \bar{a}\}\},\{c \mapsto 1, \bar{a} \mapsto 2\})
\end{aligned}
$$

Then we respectively get the structures of Figures 6a and 6b.
The product of those two configurations results in the following set of events (where we keep naming the events after their label):

| $(a, \star)$ | $($ ev. 1) | $(\star, c)$ | $($ ev. 3) | $(a, c)$ | $($ ev. 5) | $(b, c)$ | $($ ev. 7) |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| $(b, \star)$ | $($ ev. 2) | $(\star, \bar{a})$ | $($ ev. 4) | $(a, \bar{a})$ | $($ ev. 6) | $(b, \bar{a})$ | $($ ev. 8) |

When doing the parallel composition, the relabeling labels with $\perp$ events ev. 5 , ev. 7 and ev. 8, since their event identifier do not match, as well as ev. 1 and ev. 4 , since they have the same identifiers but occur unsynchronized. Hence, we obtain the $\mathcal{D}$-structure of Fig. 6c, with $m(\star, c)=1, m(a, \bar{a})=2$ and $m(b, \star)=3$.

Observe the encoding of the origin of this process, a.b|c. $\bar{a}$, in Fig. 7: the underlying configuration of the encoding of the memory previously exposed is just a particular path in that configuration structure. This remark is made formal in Lemma 2.

Example 8. Similarly, we can encode the execution

$$
\emptyset \triangleright(a . b \mid c) \xrightarrow{1: c} \xrightarrow{2: a} \rightarrow(\langle 3, b, 0\rangle .\langle 2, a, 0\rangle . \curlyvee . \emptyset \triangleright 0) \mid(\langle 1, c, 0\rangle . \curlyvee . \emptyset \triangleright 0)
$$

and obtain the structure of Fig. 7, with $m(c)=1, m(a)=2$ and $m(b)=3$.
For the rest of this subsection, we assume given a coherent reversible process $R$ whose origin is written $O_{R}$. As expected the underlying configuration of $\lfloor R\rfloor$ is included in $\llbracket O_{R} \rrbracket$ (this will be a direct consequence of Lemma 4):

Lemma 2. $\mathcal{F}(\lfloor R\rfloor) \subseteq \llbracket O_{R} \rrbracket .{ }^{5}$
The following lemma states that all memory events in $R$ are either causally linked or concurrent. Therefore their encoding results in partially ordered set (poset) with one maximal element (Definition 2), linked by the subset relation. This is illustrated by Examples 7 and 8, and proved by induction on the RCCS process.

Lemma 3. $\lfloor R\rfloor$ is a poset with one maximal configuration.

[^1]Another way to encode a reachable memory in a configuration structure [1] is to encode $R$ as a configuration, called the address of $R$, inside $\llbracket O_{R} \rrbracket^{6}$ :

$$
\llbracket R \rrbracket=\left(\llbracket O_{R} \rrbracket, x\right) \text { where } x \text { is a configuration in } \llbracket O_{R} \rrbracket .
$$

Definition 18 (Generation). Given $(E, C, \ell)$ and $x \in C$, the configuration structure generated by $x$ is $x \downarrow=\left(x, C_{x},\left.\ell\right|_{x}\right)$, where $C_{x}=\{y \mid y \in C, y \subseteq x\} .{ }^{7}$

The encoding of the memory of $R,\lfloor R\rfloor$, is the configuration structure generated by the configuration $x$. In other words, the memory of $R$ is "everything under" the address of $R$ in $\llbracket O_{R} \rrbracket$. We state this formally in the following lemma:

Lemma 4. For $\llbracket R \rrbracket=\left(\llbracket O_{R} \rrbracket, x\right), \mathcal{F}(\lfloor R\rfloor) \cong x \downarrow$.
We can now make the intuitions of Fig. 1 formal, letting $R \equiv\left(\prod_{i} m_{i} \triangleright P_{i}\right) \backslash \vec{a}$ and $O_{R}$ be its origin. Informally speaking, the memories of $R$, i.e. the $m_{i}$, is the "past" of $R$, and the process $\left(\prod_{i} P_{i}\right) \backslash \vec{a}$ is its "future": in the configuration structure $\llbracket O_{R} \rrbracket$, they are respectively represented by $\mathcal{F}(\lfloor R\rfloor)$ and $\llbracket\left(\prod_{i} P_{i}\right) \backslash \vec{a} \rrbracket$. Consider Example 7: the past of the process is the structure shown in Fig. 6c, which corresponds to the gray part in Fig. 6d. The future of this process is empty, as all actions have been consumed.

However, we cannot recover the origin process from the encoding of the past and future of a reversible process. There is a loss of information that occurs for the synchronisation events when encoding memories into identified configuration structures: we label $\tau$ such events, whereas in the memories of a RCCS process the synchronised events keep their input (or output) label.

## 3.3 (Hereditary) History-Preserving Bisimulations on CCS

We adapt the (hereditary) history-preserving bisimulations of Sect. 2.3 to CCS, making the bijections becomes isomorphisms between memory encodings.

Below, we let $P_{1}$ and $P_{2}$ be two CCS processes (possibly with auto-concurrency, Definition 7), and $\llbracket P_{i} \rrbracket=\left(E_{i}, C_{i}, \ell_{i}\right)$, for $i=1,2$.

Definition 19 (HPB and HHPB on CCS). A relation $\mathcal{R} \subseteq \mathrm{R} \times \mathrm{R} \times\left(E_{1} \rightharpoonup E_{2}\right)$ such that $\left(\emptyset \triangleright P_{1}, \emptyset \triangleright P_{2}, \emptyset\right) \in \mathcal{R}$ and if $\left(R_{1}, R_{2}, f\right) \in \mathcal{R}$ then $f$ is an isomorphism between $\mathcal{F}\left(\left\lfloor R_{1}\right\rfloor\right)$ and $\mathcal{F}\left(\left\lfloor R_{2}\right\rfloor\right)$ and (6) and (7) (resp. (6-9)) hold is called a

[^2]history-(resp. hereditary history-) preserving bisimulation between $P_{1}$ and $P_{2}$.
\[

$$
\begin{align*}
& \forall S_{1}, R_{1} \xrightarrow{i: \alpha} S_{1} \Rightarrow \exists S_{2}, g, R_{2} \xrightarrow{j: \alpha} S_{2}, g \upharpoonright_{\mathcal{F}\left(\left\lfloor S_{1}\right\rfloor\right)}=f,\left(S_{1}, S_{2}, g\right) \in \mathcal{R}  \tag{6}\\
& \forall S_{2}, R_{2} \xrightarrow{i: \alpha} S_{2} \Rightarrow \exists S_{1}, g, R_{1} \xrightarrow{j: \alpha} S_{1}, g \upharpoonright_{\mathcal{F}\left(\left\lfloor S_{1}\right\rfloor\right)}=f,\left(S_{1}, S_{2}, g\right) \in \mathcal{R}  \tag{7}\\
& \forall S_{1}, R_{1} \stackrel{i: \alpha}{\sim} S_{1} \Rightarrow \exists S_{2}, f, R_{2} \xrightarrow[\sim]{j: \alpha} S_{2}, g=f \upharpoonright_{\mathcal{F}\left(\left\lfloor S_{1}\right\rfloor\right)},\left(S_{1}, S_{2}, g\right) \in \mathcal{R}  \tag{8}\\
& \forall S_{2}, R_{2} \xrightarrow{i: \alpha} S_{2} \Rightarrow \exists S_{1}, g, R_{1} \xrightarrow[\sim]{j: \alpha} S_{1}, g=f \upharpoonright_{\mathcal{F}\left(\left\lfloor S_{1}\right\rfloor\right)},\left(S_{1}, S_{2}, g\right) \in \mathcal{R} \tag{9}
\end{align*}
$$
\]

Definition 20 ( $w f \mathrm{HPB}$ on CCS). $A$ weak-function history-preserving bisimulation between $P_{1}$ and $P_{2}$ is a relation $\mathcal{R} \subseteq \mathrm{R} \times \mathrm{R} \times\left(E_{1} \rightharpoonup E_{2}\right)$ such that $\left(\emptyset \triangleright P_{1}, \emptyset \triangleright P_{2}, \emptyset\right) \in \mathcal{R}$ and if $\left(R_{1}, R_{2}, f\right) \in \mathcal{R}$, then $f$ is a isomorphism between $\mathcal{F}\left(\left\lfloor R_{1}\right\rfloor\right)$ and $\mathcal{F}\left(\left\lfloor R_{2}\right\rfloor\right)$ and

$$
\begin{aligned}
& \forall S_{1}, R_{1} \xrightarrow{i: \alpha} S_{1} \Rightarrow \exists S_{2}, g, R_{2} \xrightarrow{j: \alpha} S_{2},\left(S_{1}, S_{2}, g\right) \in \mathcal{R} \\
& \forall S_{2}, R_{2} \xrightarrow{i: \alpha} S_{2} \Rightarrow \exists S_{1}, g, R_{1} \xrightarrow{j: \alpha} S_{1},\left(S_{1}, S_{2}, g\right) \in \mathcal{R}
\end{aligned}
$$

Of course, wfHHPB on CCS is defined similarly.
Note that the definitions above reflect definitions 9 and 10: the condition $\left(\emptyset \triangleright P_{1}, \emptyset \triangleright P_{2}, \emptyset\right) \in \mathcal{R}$ is intuitively the counterpart to the condition that $(\emptyset, \emptyset, \emptyset)$ have to be included in the relation on configuration structures. Also, $f$ shares similarity with the label- and order-preserving bijection. Finally, note that, to keep the definitions concise, we wrote R , but one needs only to consider the reachable processes from $\emptyset \triangleright P_{1}$ and $\emptyset \triangleright P_{2}$.

Theorem 2 (Main result). $P_{1}$ and $P_{2}$ are HHPB (resp. wfHHPB, HPB, $w f \mathrm{HPB})$ iff $\llbracket P_{1} \rrbracket$ and $\llbracket P_{2} \rrbracket$ are.

## 4 Conclusion

In this paper, we recalled how the previous attempt to characterize syntactically HHPB gave partial result (Theorem 1). Then, we defined a series of bisimulations on CCS processes that corresponds to HPB, HHPB, and their "weak function" variants, on configuration structures. We managed therefore to define an equivalence on CCS which distinguishes for instance $a . a \mid b$ from $a|a| b$, whose encodings are not HHPB. We would like to conclude with three observations.

Fist, we should stress that our relations are defined in terms of CCS processes: on the surface, this paper offers a new result on non-reversible CCS, using tools stemming from the study of reversible computation. We believe this is an interesting contribution, that witnesses the relevance of studying concurrent reversible computation.

Our paper also introduces a natural technical tool, identified configuration structure, to encode information on memory events. It should be noted that a memory event is made of three elements, $\langle i, \alpha, Q\rangle$, and that configuration structures encode names $\alpha$, and $\mathcal{D}$-structures furthermore encode identifiers $i$. We
could take a step further and also enclose information about the residual process $Q$ in a sum. Representing the "whole memory" in denotational model could lead to interesting new bisimulation on processes, but we leave this for a future possible extension.

Other CCS bisimulations such as the pomset bisimulations [5] or the localities bisimulations [4] are known to be different from the history-preserving ones. However, these bisimulations add some information on auto-concurrent events, that can be used to distinguish them. A possible direction of future work is then to adapt these bisimulations to the reversible setting to maybe capture HHPB.

## A Appendix

The appendix is divided in three subsections.
Sect. A. 1 gathers results about identified configuration structures, introduced in Sect. 3.1. They are not required to understand the rest of the technical development, but illustrates why we believe this notion is "solid", and gives some insights on how to manipulate it.

The main purpose of Sect. A. 2 is to prove Lemma 4, stated in Sect. 3.2. This apparently intuitive result actually requires a heavy machinery to be proven: not only do we prove Lemma 3, but we also state and prove some intermediate lemmas.

The immediate advantage of Lemma 4 is that it makes the proof of Theorem 2, in Sect. A.3, almost straightforward.

Before doing so, we need to prove the only new result of Sect. 2:
Proof (Corollary 1, page 9). Since $m \triangleright P$ is reachable, $m \triangleright P$ is coherent by Lemma 1, and hence $m \frown \emptyset$ by Definition 12. Looking at Definition 11, the only way to derive $m \frown \emptyset$ is to start with em., and then to apply ev. to "stack" the memory events. If an identifier were to appear in two memory event in $m$, we would not be able to use ev. to add the second memory event, since the sidecondition would forbid it.

## A. 1 On the Robustness of Identified Configuration Structures

This subsection gathers elementary results on the structures introduced in Sect. 3.1. These results, e.g., that the category of $\mathcal{D}$-structures of Definition 15 is indeed a category (Lemma 5) or that the operations on $\mathcal{D}$-structures of Definition 16 are well-defined (Lemma 7), were not stated in the body of the document, but are implicitely used.

Lemma 5. Identified configuration structure and their morphisms (Definition 15, page 10) form a category .

Proof. Identity For every $\mathcal{D}$-structure $\mathcal{D}=(E, C, \ell, \mathrm{I}, m), \mathrm{id}_{\mathcal{D}}: \mathcal{D} \rightarrow \mathcal{D}$ is defined to be the identity on the underlying configuration structure id : $(E, C, \ell) \rightarrow(E, C, \ell)$ from $\mathbb{C}$, that trivially preserves identifiers. For any mor$\operatorname{phism} f: \mathcal{D}_{1} \rightarrow \mathcal{D}_{2}, f \circ \mathrm{id}_{\mathcal{D}_{1}}=f=\mathrm{id}_{\mathcal{D}_{2}} \circ f$ is trivial.
Associativity for $f: \mathcal{D}_{1} \rightarrow \mathcal{D}_{2}, g: \mathcal{D}_{2} \rightarrow \mathcal{D}_{3}$ and $h: \mathcal{D}_{3} \rightarrow \mathcal{D}_{4}, h \circ(g \circ f)=$ $(h \circ g) \circ f$ is inherited from the associativity in $\mathbb{C}$, and since $f, g$ and $h$ all preserves identifiers.
Hence $\mathbb{D}$ is a category.
Lemma 6. The product of $\mathcal{D}$-structures of Definition 16, page 10, is the product in $\mathbb{D}$.

Proof. First note that $\mathcal{D}_{1} \times \mathcal{D}_{2}$ is a $\mathcal{D}$-structures as it is a configuration structure and from the definition of $m$ every event in a configuration has a unique label. Secondly, it is easy to show that the projections are morphisms. Lastly to show that the structure $\mathcal{D}_{1} \times \mathcal{D}_{2}$ has the universal property, we proceed in two steps:

- the underlying configuration structure is the product of the underlying configuration structures, by definition:

$$
\mathcal{F}\left(\mathcal{D}_{1} \times \mathcal{D}_{2}\right)=\mathcal{F}\left(\mathcal{D}_{1}\right) \times \mathcal{F}\left(\mathcal{D}_{2}\right)
$$

- for any $\mathcal{D}^{\prime}$ which projects into $\mathcal{D}_{1}$ and $\mathcal{D}_{2}$, then $\mathcal{F}\left(\mathcal{D}^{\prime}\right)$ projects into $\mathcal{F}\left(\mathcal{D}_{1}\right)$ and $\mathcal{F}\left(\mathcal{D}_{2}\right)$ and therefore there exists a unique morphism $h: \mathcal{F}\left(\mathcal{D}^{\prime}\right) \rightarrow$ $\mathcal{F}\left(\mathcal{D}_{1} \times \mathcal{D}_{2}\right)$. It is easy to show that since the projections preserve identifiers, then so does $h$ which concludes our proof.

This lemma also follows from [15, Proposition 85].
Lemma 7. The operations of Definition 16 (product, relabeling, restriction and parallel composition), page 10 , preserve $\mathcal{D}$-structures.

Proof. Let us note that (i) the product, relabeling, restriction, and parallel composition on configuration structures from Definition 4 preserve configuration structures and that (ii) any configuration structure endowed with a valid identifier function (i.e., such that no two events in the same configuration have the same identifier, cf. Collision Freeness) is a valid $\mathcal{D}$-structure.

For the product, it follows trivially from Lemma 6.
Relabeling does not change anything but the labels, so we have nothing to prove.

The restriction only removes events in configurations and keeps the identifier function intact. Hence if the initial structure has a valid identifier function, then the identifier function of the new structure is a valid one by assumption.

Let us now consider the parallel composition of two $\mathcal{D}$-structures, denoted $\mathcal{D}_{1} \mid \mathcal{D}_{2}=(E, C, \ell, m)$. Proving that the identifier function is valid follows from a case analysis. Given a configuration $x \in C$ and two events $e, e^{\prime} \in x$, these are the possible cases:
$-\pi_{2}(e)=\star$ and $\pi_{2}\left(e^{\prime}\right)=\star$. In this case, looking at the definition of the product in $\mathcal{D}$-structures, $m(e)=\left(m_{1}\left(\pi_{1}(e)\right), m_{\star}\right)$ and $m\left(e^{\prime}\right)=\left(m_{1}\left(\pi_{1}\left(e^{\prime}\right)\right), m_{\star}\right)$. If $m(e)=m\left(e^{\prime}\right)$, then $m_{1}\left(\pi_{1}(e)\right)=m_{1}\left(\pi_{1}\left(e^{\prime}\right)\right)$ in the configuration $\pi_{1}(x)$ in $\mathcal{D}_{1}$. But that's a contradiction, since $\pi_{1}(e)$ and $\pi_{1}\left(e^{\prime}\right)$ are in the same configuration and the identifier function of $\mathcal{D}_{1}$ is valid.
$-\pi_{1}(e)=\star$ and $\pi_{1}\left(e^{\prime}\right)=\star$. This case is similar as the previous one, except that it uses that the identifier function of $\mathcal{D}_{2}$ is valid.
$-\pi_{1}(e) \neq \star$ and $\pi_{2}\left(e^{\prime}\right) \neq \star$ (with either $\pi_{1}\left(e^{\prime}\right)=\star$ or $\pi_{1}\left(e^{\prime}\right) \neq \star$ ). If $m(e)=$ $m\left(e^{\prime}\right)$, then $m_{i}\left(\pi_{i}(e)\right)=m_{i}\left(\pi_{i}\left(e^{\prime}\right)\right)$ for $i=1,2$. Then in this case,

- either one of them, say, $e$, is a synchronisation or a fork: in this case, $m_{1}\left(\pi_{1}(e)\right)=m_{2}\left(\pi_{2}(e)\right)=m_{2}\left(\pi_{2}\left(e^{\prime}\right)\right)$, and $e^{\prime}$ was relabeled $\perp$ at the relabeling stage of the parallel composition, and then removed during the restriction. Hence a contradiction: $e$ and $e^{\prime}$ can't be two events in the same configuration.
- or none of them is a synchronisation, in which case both events were removed by the restriction. Hence, again, a contradiction: $e$ and $e^{\prime}$ can't be two events in the same configuration.

The symmetric case (where $\pi_{2}(e) \neq \star$ and $\pi_{1}\left(e^{\prime}\right) \neq \star$ ) is similar.

The following lemma makes more formal the intuition of Remark 1, page 10. Remember that we assumed that for every configuration structure ( $E, C, \ell$ ), $E$ was endowed with a total order, that we write $\preceq$.

Lemma 8. $\mathcal{F}: \mathbb{D} \rightarrow \mathbb{C}$, defined by
$-\mathcal{F}(E, C, \ell, I, m)=(E, C, \ell)$
$-\mathcal{F}\left(f_{E}, f_{C}, f_{m}\right)=\left(f_{E}, f_{C}\right)$
and $\mathcal{S}: \mathbb{C} \rightarrow \mathbb{D}$, defined by
$-\mathcal{S}(E, C, \ell)=(E, C, \ell, I, m)$, where $I=\{1, \ldots, \operatorname{Card} E\}$ and $m(e)= \begin{cases}1 & \text { if } \forall e^{\prime}, e \preceq e^{\prime} \\ i+1 & \text { if } \exists e^{\prime}, e^{\prime} \preceq e, m\left(e^{\prime}\right)=i \text { and there is no } e^{\prime \prime} \text { s.t. } e^{\prime} \preceq e^{\prime \prime} \preceq e\end{cases}$
$-\operatorname{For}\left(f_{E}, f_{C}\right):\left(E_{1}, C_{1}, \ell_{1}\right) \rightarrow\left(E_{2}, C_{2}, \ell_{2}\right), \mathcal{S}\left(f_{E}, f_{C}\right)=\left(f_{E}, f_{C}, f_{m}\right)$, where $f_{m}\left(m_{1}(e)\right)=m_{2}\left(f_{E}\left(e_{2}\right)\right)$.
are functors.
Proof. Proving that $\mathcal{F}$ is a functor is immediate.
Proving that $\mathcal{S}(\mathcal{C})$ is a $\mathcal{D}$-structure is immediate, since our construction of $m$ trivially insures Collision Freeness. For $\left(f_{E}, f_{C}\right): \mathcal{C}_{1} \rightarrow \mathcal{C}_{2}$, proving that $\mathcal{S}\left(f_{E}, f_{C}\right)$ is a morphism between $\mathcal{S}\left(\mathcal{C}_{1}\right)$ and $\mathcal{S}\left(\mathcal{C}_{2}\right)$ is also immediate. For the preservation of the identity, we compute:

$$
\begin{aligned}
\mathcal{S}\left(\mathrm{id}_{\mathcal{C}}\right) & =\mathcal{S}\left(\mathrm{id}_{E}, \mathrm{id}_{C}\right) \\
& =\left(\operatorname{id}_{E}, \mathrm{id}_{C}, f_{m}\right)
\end{aligned}
$$

where $f_{m}(m(e))=m\left(\operatorname{id}_{E}(e)\right)=m(e)$, hence $f_{m}=\operatorname{id}_{\mathrm{I}}: \mathrm{I} \rightarrow \mathrm{I}$,

$$
\begin{aligned}
& =\left(\mathrm{id}_{E}, \mathrm{id}_{C}, \mathrm{id}_{\mathrm{I}}\right) \\
& =\operatorname{id}_{\mathcal{S}(\mathcal{C})}
\end{aligned}
$$

For the composition of morphisms, given $f=\left(f_{C}, f_{E}\right): \mathcal{C}_{1} \rightarrow \mathcal{C}_{2}$ and $g=$ $\left(g_{C}, g_{E}\right): \mathcal{C}_{2} \rightarrow \mathcal{C}_{3}$, we write $\mathcal{S}\left(\mathcal{C}_{i}\right)=\left(E_{i}, C_{i}, \ell_{i}, \mathrm{I}_{i}, m_{i}\right)$ and we compute:

$$
\begin{aligned}
\mathcal{S}(g) \circ \mathcal{S}(f) & =\left(g_{C}, g_{E}, g_{m}\right) \circ\left(f_{C}, f_{E}, f_{m}\right) \\
& =\left(g_{C} \circ f_{C}, g_{E} \circ f_{E}, g_{m} \circ f_{m}\right)
\end{aligned}
$$

where, for all $e \in E_{1}$, we compute:

$$
\begin{aligned}
\left(g_{m} \circ f_{m}\right)\left(m_{1}(e)\right) & =g_{m}\left(f_{m}\left(m_{1}(e)\right)\right. \\
& =g_{m}\left(m_{2}\left(f_{E}(e)\right)\right) \\
& =m_{3}\left(g_{E}\left(f_{E}(e)\right)\right)
\end{aligned}
$$

And hence we can conclude:

$$
\mathcal{S}(g) \circ \mathcal{S}(f)=\mathcal{S}(g \circ f)
$$

## A. 2 Proofs for Sect. 3.2

In the following, we start by observing that Lemma 2 follows from Lemma 4. Lemma 4, on its side, requires a bit of work: on top of proving Lemma 3, we state and prove some intermediate lemmas (Lemma 9, 10 and 11) needed to obtain it.

Proof (Lemma 2, page 13). Follows from Lemma 4.
Lemma 9. For all RCCS process $R$, letting $\lfloor R\rfloor=(E, C, m)$, for all $e_{1}, e_{2} \in E$, $m\left(e_{1}\right)=m\left(e_{2}\right)$ implies $e_{1}=e_{2}$.

Proof. We proceed by structural induction on $R$. From Corollary 1 the only interesting case is the parallel composition, i.e. $R=R_{1} \mid R_{2}$. From the definition of parallel composition in $\mathcal{D}$-structures (Definition 16), it follows that $m\left(e_{1}\right)=$ $m\left(e_{2}\right)$ implies $e_{1}=e_{2}$.

Proof (Lemma 3, page 13). We proceed by induction on $R$.
If $R$ is $m \triangleright P$, we prove that $\lfloor m\rfloor$ is a poset with one maximal element by induction on $m$. The base case, if $m$ is $\emptyset$, is trivial, since $\lfloor\emptyset\rfloor=\mathbf{0}$ is a poset with one maximal element. If $m$ is $\curlyvee . m^{\prime}$, then it follows by induction hypothesis, since $\left\lfloor\curlyvee . m^{\prime}\right\rfloor=\left\lfloor m^{\prime}\right\rfloor$. If $m$ is $\langle i, \alpha, P\rangle . m^{\prime}$, then by induction hypothesis, $\left\lfloor m^{\prime}\right\rfloor$ is a poset with one maximal element, and the construction of $\left\lfloor\langle i, \alpha, P\rangle . m^{\prime}\right\rfloor$ detailed in Definition 17 preserves that property.

If $R$ is $R^{\prime} \backslash a$, then it trivially follows by induction hypothesis.
Finally, if $R$ is $R_{1} \mid R_{2}$, then by induction hypothesis we get that $\left\lfloor R_{1}\right\rfloor$ and $\left\lfloor R_{2}\right\rfloor$ are both posets with a maximal configuration. We also know by Lemma 9 that they have disjoint identifiers. Looking at the definition of parallel composition for $\mathcal{D}$-structures (Definition 16), we may observe that $\lfloor R\rfloor=\left\lfloor R_{1} \mid R_{2}\right\rfloor=$ $\left\lfloor R_{1}\right\rfloor\left\lfloor R_{2}\right\rfloor=\left(r \circ\left(\left\lfloor R_{1}\right\rfloor \times\left\lfloor R_{2}\right\rfloor\right)\right) \upharpoonright_{F}$.

We show that there exists more than one maximal configurations in $\left\lfloor R_{1}\right\rfloor \times$ $\left\lfloor R_{2}\right\rfloor$ and that all but one are removed by the restriction.

We show this by first showing that there exists more than one maximal configurations in $\mathcal{F}\left(\left\lfloor R_{1}\right\rfloor\right) \times \mathcal{F}\left(\left\lfloor R_{2}\right\rfloor\right)$, denoted here with $\mathcal{C}$. From the definition of product (Definition 4), we have that there exists $y_{1}, \cdots y_{n}$ maximal configurations in $\mathcal{C}$ such that $\pi_{1}\left(y_{i}\right)$ and $\pi_{2}\left(y_{i}\right)$ are maximal in $\mathcal{C}_{1}$ and $\mathcal{C}_{2}$, respectively. As $\left\lfloor R_{1}\right\rfloor \times\left\lfloor R_{2}\right\rfloor=\left(\mathcal{F}\left(\left\lfloor R_{1}\right\rfloor\right) \times \mathcal{F}\left(\left\lfloor R_{2}\right\rfloor\right)\right)+m$ it follows that the maximal configurations of $\mathcal{C}$ are preserved in $\left\lfloor R_{1}\right\rfloor \times\left\lfloor R_{2}\right\rfloor$.

A second step is then to show that the restriction keeps only one maximal configuration. Let $y_{i}, y_{j}$ be two maximal configurations. As they are maximal it implies that $y_{i} \cup y_{j} \notin \mathcal{C}$, for $i \neq j \leqslant n$. In turn, this implies that there exists $e_{i} \in y_{i}$ and $e_{j} \in y_{j}$ such that $\pi_{1}\left(e_{i}\right)=\pi_{1}\left(e_{j}\right)$ and $e_{i} \neq e_{j}$, as otherwise $y_{i} \cup y_{j}$ would be defined. Here we assume that $\pi_{1}\left(e_{i}\right)=\pi_{1}\left(e_{j}\right)$ but we could also take $\pi_{2}\left(e_{i}\right)=\pi_{2}\left(e_{j}\right)$ and the argument still holds.

Let us now take $d$ an event in $\mathcal{C}_{1}$ and take $e_{1}, \ldots, e_{m}$ the subset of events in $E$ where $\pi_{1}\left(e_{i}\right)=d$. The restriction in the parallel composition of $\left\lfloor R_{1}\right\rfloor \mid\left\lfloor R_{2}\right\rfloor$ keeps only one such event $e_{i}$ and removes the rest. Therefore, from all maximal configurations $y_{1}, \ldots, y_{m}$ such that $e_{i} \in y_{i}, i \leq m$, only one remains.

By applying the argument above to all events in $\left\lfloor R_{1}\right\rfloor$ (and $\left\lfloor R_{2}\right\rfloor$ ), we have that the restriction removes all but one $y_{i}$, which is then the maximal configuration in $\left\lfloor R_{1}\right\rfloor \mid\left\lfloor R_{2}\right\rfloor$.

Let us write $x_{\mathrm{MAX}}$ the maximal configuration from Lemma 3 .
For the following proof, we need to introduce the causality relation on memory events and on transitions from [7]. We write $i_{1}<_{R} i_{2}$ for $R$ a proces and $i_{1}, i_{2} \in \mathrm{I}$ if there exist a memory stack $m .\left\langle i_{1}, \alpha_{1}, P_{1}\right\rangle . m^{\prime} .\left\langle i_{2}, \alpha_{2}, P_{2}\right\rangle . m^{\prime \prime}$ in $R$. We write $i_{1} \leq_{R} i_{2}$ for the transitive closure of $<$ over all memories of $R$.

Lemma 10. Let $R$ be a reversible process and $\lfloor R\rfloor=(E, C, \ell, m)$ be the encoding of its memory, with $x_{\operatorname{MAX}}$ the maximal configuration in C. Let $\left\langle i_{1}, \alpha_{1}, P_{1}\right\rangle$ and $\left\langle i_{2}, \alpha_{2}, P_{2}\right\rangle, i_{1} \neq i_{2}$ be two memory events in $R$ and let $e_{1}, e_{2} \in E$ be the two corresponding events, i.e. $m\left(e_{j}\right)=i_{j}, j \in\{1,2\}$. Then $i_{1} \leq_{R} i_{2} \Longleftrightarrow e_{1} \leq_{x_{\operatorname{Max}}}$ $e_{2}$.

Proof. Follows by a structural induction on $R$.
We also import from [7, Definition 1] the definition of causality on transitions $t_{1}$ and $t_{2}$, of a trace $\theta$, that we denote here with $t_{1} \leq_{\theta} t_{2}$. We do not give the definition formally, as it is lengthy, but intuitively, it is the causality relation on memory events lifted to transitions.

Let $R$ be an RCCS process and $\theta: O_{R} \xrightarrow{\star} R$ a trace. Also, let $\llbracket O_{R} \rrbracket=$ $(E, C, \ell)$ and let $x$ be a configuration such that $\llbracket R \rrbracket=\left(\llbracket O_{R} \rrbracket, x\right)$. We define a bijection from transitions in $\theta$ to events in $x$, that we write TE. We define the bijection by induction on the trace $\theta$ using the fact for each transition $t$ : $R^{\prime} \xrightarrow{i, \alpha} R^{\prime \prime}$ in $\theta$, there exists $x^{\prime}$ a configuration and $e^{\prime}$ an event in $\llbracket O_{R} \rrbracket$ such that $\llbracket R^{\prime} \rrbracket=\left(\llbracket O_{R} \rrbracket, x^{\prime}\right)$ and $\llbracket R^{\prime \prime} \rrbracket=\left(\llbracket O_{R} \rrbracket, x^{\prime} \cup\left\{e^{\prime}\right\}\right)$. Then $\mathrm{TE}(t)=e^{\prime}$.

Lemma 11. Let $t_{1}$ and $t_{2}$ be two transitions of a trace $\theta: O_{R} \xrightarrow{\star} R$ and let $\llbracket R \rrbracket=\left(\llbracket O_{R} \rrbracket, x\right)$. Then $t_{1} \leq_{\theta} t_{2} \Longleftrightarrow \mathrm{TE}\left(t_{1}\right) \leq_{x} \mathrm{TE}\left(t_{2}\right)$.

Proof. Follows by induction on the trace $\theta$.
Proof (Lemma 4, page 14). We reformulate the hypothesis and show a stronger (in the sense that it is more specific) result from which Lemma 4 follows.

As $R$ is reachable there exists a forward-only trace $O_{R} \xrightarrow{i_{1}, \alpha_{1}} \cdots \xrightarrow{i_{n}, \alpha_{n}} R[1$, Lemma 1], denoted by $\theta$. We write $\left\lfloor R_{j}\right\rfloor=\left(E_{j}, C_{j}, \ell_{j}, m_{j}\right)$ for $R_{j}$ a process in the trace above and $\theta_{j}: O_{R} \xrightarrow{i_{1}, \alpha_{1}} \cdots \xrightarrow{i_{j}, \alpha_{j}} R_{j}$ a subtrace of $\theta$.

Let $\llbracket O_{R} \rrbracket=(E, C, \ell)$. From [1] we have that $\llbracket R_{j} \rrbracket=\left(\llbracket O_{R} \rrbracket, x_{j}\right)$ for $x_{j} \in C$. We show that there exists three bijections:
$-\mathrm{TE}_{j}$ between transitions in the trace $\theta_{j}$ and events in $\llbracket O_{R} \rrbracket$, i.e. $\mathrm{TE}_{j}: \theta_{j} \rightarrow E$;
$-\mathrm{MT}_{j}$ between events in $\left\lfloor R_{j}\right\rfloor$ and transitions, i.e. $\mathrm{MT}_{j}: E_{j} \rightarrow \theta_{j}$;
$-\mathrm{ME}_{j}$ between events in $\left\lfloor R_{j}\right\rfloor$ and events in $\llbracket O_{R} \rrbracket$, i.e. $\mathrm{ME}_{j}: E_{j} \rightarrow E$, such that $\mathrm{ME}_{j}=\mathrm{TE}_{j} \circ \mathrm{MT}_{j}$.

Moreover, all three bijections preserve the labels and the causality relations. In particular, ME is label and order preserving for all events in $x_{\mathrm{MAX}}$, the maximal configuration in $\left\lfloor R_{j}\right\rfloor$ :

$$
\begin{array}{r}
\operatorname{ME}_{j}\left(x_{\mathrm{MAX}}\right)=x_{j} \\
e_{1} \leq x_{x_{\mathrm{MAX}}} e_{2} \Longleftrightarrow \operatorname{ME}_{j}\left(e_{1}\right) \leq_{x_{j}} \operatorname{ME}_{j}\left(e_{2}\right) . \tag{11}
\end{array}
$$

From Definition 18, $x \downarrow=\left(x, C_{x}, \ell \upharpoonright_{x}\right)$, for $C_{x}=\{y \mid y \in C, y \subseteq x\}$. We can write $\left\lfloor R_{j}\right\rfloor=x_{\text {MAX }} \downarrow$, and therefore have $\mathcal{F}\left(\left\lfloor R_{j}\right\rfloor\right) \cong\left(\operatorname{ME}_{j}\left(x_{\text {MAX }}\right)\right) \downarrow$.

We proceed by induction on the trace $\theta$, and at each step we extend the three bijections above.

For a transition $R_{j} \xrightarrow{i, \alpha} R_{j+1}$ and a trace $\theta_{j}$ we have by induction that
$-\mathcal{F}\left(\left\lfloor R_{j}\right\rfloor\right) \cong x_{j} \downarrow$, for $\llbracket R_{j} \rrbracket=\left(\llbracket O_{R} \rrbracket, x_{j}\right)$;

- there exists TE ${ }_{j}: \theta_{j} \rightarrow E, \mathrm{MT}_{j}: E_{j} \rightarrow \theta_{j}$ and $\mathrm{ME}_{j}: E_{j} \rightarrow E$
as defined above.
There is an operational correspondence between $R_{j}$ and its encoding [1, Lemma 6], and therefore there exists $e$ an event in $\llbracket O_{R} \rrbracket$ such that

$$
\begin{equation*}
\left(\llbracket O_{R} \rrbracket, x_{j}\right) \xrightarrow{e}\left(\llbracket O_{R} \rrbracket, x_{j} \cup\{e\}\right) \tag{12}
\end{equation*}
$$

with $\ell(e)=\alpha$ and where we write $x_{j+1}=x_{j} \cup\{e\}$.
We have to show that $\mathcal{F}\left(\left\lfloor R_{j+1}\right\rfloor\right) \cong x_{j+1} \downarrow$. More specifically we show that $E_{j+1} \backslash E_{j}=\left\{e_{j+1}\right\}$ and that we can extend the bijections such that

$$
\begin{array}{r}
\mathrm{TE}_{j+1}=\mathrm{TE}_{j} \cup\left\{\left(R_{j} \xrightarrow{i, \alpha} R_{j+1}\right) \mapsto e\right\} \\
\mathrm{MT}_{j+1}=\mathrm{MT}_{j} \cup\left\{e_{j+1} \mapsto\left(R_{j} \xrightarrow{i, \alpha} R_{j+1}\right)\right\} \\
\mathrm{ME}_{j+1}=\mathrm{ME}_{j} \cup\left\{e_{j+1} \mapsto e\right\} \tag{15}
\end{array}
$$

As $\mathrm{ME}_{j+1}$ is a label and order preserving bijection on $x_{\mathrm{MAX}}$, the maximal configuration in $\left\lfloor R_{j+1}\right\rfloor$, it follows that $\operatorname{ME}_{j+1}\left(x_{\mathrm{MAX}}\right)=x_{j+1}$. As $\left\lfloor R_{j+1}\right\rfloor \cong x_{\mathrm{MAX}} \downarrow$ it follows $\mathcal{F}\left(\left\lfloor R_{j+1}\right\rfloor\right) \cong x_{j+1} \downarrow$.

We now proceed by cases on the transition $R_{j} \xrightarrow{i: \alpha} R_{j+1}$. We distinguish two cases: $\alpha$ is an unsynchronized input or output, and $\alpha=\tau$.

- Let us suppose w.l.o.g. that $\alpha=a$. Then we can rewrite the transition as follow:

$$
R_{j}=(\vec{b})(S \mid m \triangleright a . P+Q) \xrightarrow{i, \alpha} R_{j+1}=(\vec{b})(S \mid\langle i, \alpha, Q\rangle . m \triangleright P)
$$

Let us also define the following projection on events: $\pi_{S}(e)=e_{s}$ if there exists $e_{s} \in\lfloor S\rfloor$ such that $e, e_{s}$ have the same identifiers and undefined otherwise. Similarly define $\pi_{m}$ for the projections of events from $\left\lfloor R_{i}\right\rfloor$ to $\lfloor m\rfloor$.
Note that we can extend $\mathrm{TE}_{j+1}$ as in Equation 13. We show that there exists an event in $\left\lfloor R_{j+1}\right\rfloor$ which corresponds to the transition $R_{j} \xrightarrow{i, \alpha} R_{j+1}$. Let
us unfold the encoding of the two processes above:

$$
\begin{array}{r}
\left\lfloor R_{j}\right\rfloor=\lfloor(\vec{b})(S \mid m \triangleright a \cdot P+Q)\rfloor=(r \circ(\lfloor S\rfloor \times\lfloor m\rfloor)) \upharpoonright_{\perp} \upharpoonright_{\vec{b}} \\
\left\lfloor R_{j+1}\right\rfloor=\lfloor(\vec{b})(S \mid\langle i, \alpha, Q\rangle \cdot m \triangleright a)\rfloor=(r \circ(\lfloor S\rfloor \times\lfloor\langle i, \alpha, Q\rangle \cdot m\rfloor)) \upharpoonright_{\perp} \upharpoonright_{\vec{b}}
\end{array}
$$

Let us write $\lfloor m\rfloor=\left(E_{m}, C_{m}, \ell_{m}, m_{m}\right)$. From Lemma 3 we have that there exists a single maximal configuration in $C_{m}$, denoted with $x_{\text {MAX }}^{m}$. Using Definition 17 we can unfold $\lfloor\langle i, \alpha, Q\rangle . m\rfloor$ and write

$$
\begin{aligned}
\left\lfloor R_{j}\right\rfloor=(r \circ & \left.\left(\lfloor S\rfloor \times\left(E_{m}, C_{m}, \ell_{m}, m_{m}\right)\right)\right) \upharpoonright_{\perp} \upharpoonright_{\vec{b}} \\
\left\lfloor R_{j+1}\right\rfloor=(r \circ & (\lfloor S\rfloor \times \\
& \left(E_{m} \cup\left\{e_{m}\right\}, C_{m} \cup\left(x_{\mathrm{MAX}}^{m} \cup\left\{e_{m}\right\}\right),\right. \\
& \left.\left.\left.\ell_{m} \cup\left\{e_{m} \rightarrow \alpha\right\}, m_{m}+\left\{e_{m} \rightarrow i\right\}\right)\right)\right) \upharpoonright_{\perp} \upharpoonright_{\vec{b}}
\end{aligned}
$$

for some event $e_{m} \notin E_{m}$. From rules act. and par. of Fig. $4, i$ is not in the domain of $m_{m}$. Therefore all synchronisations in $\lfloor S\rfloor \times\lfloor\langle i, \alpha, Q\rangle$. $m\rfloor$ of the form $\left(e_{s}, e_{m}\right)$, with $e_{s} \in\lfloor S\rfloor$, are relabeled $\perp$ and removed by the first restriction. The event $\left(\star, e_{m}\right)$ is preserved by the first restriction. It is not removed by the second restriction as $a \notin \vec{b}$. Remember that from Lemma 3 we have that there exists a single maximal configuration in $\left\lfloor R_{j+1}\right\rfloor$ and from the definition of the parallel composition there is only one event in $x \max$ with the first projection equal to $e_{m}$, denoted $e_{j+1}: e_{j+1} \in x_{\mathrm{MAX}}$ with $\pi_{m}\left(e_{j+1}\right)=e_{m}$. It follows that $E_{j+1}=E_{j} \cup\left\{e_{j+1}\right\}$. We extend then the bijections as in Equations 14 and 15. Moreover, $\ell\left(e_{j+1}\right)=\ell_{m}\left(e_{m}\right)$, and from Equation 12 it follows that $\mathrm{ME}_{j+1}$ is label preserving.
The last part is to show Equation 11. We only have to show that

$$
\begin{equation*}
e^{\prime} \leq_{x_{\operatorname{MAX}}} e_{j+1} \Longleftrightarrow \operatorname{ME}_{j+1}\left(e^{\prime}\right) \leq_{x_{j+1}} \operatorname{ME}_{j+1}\left(e_{j+1}\right) \tag{16}
\end{equation*}
$$

as the rest follows by induction on $\mathrm{ME}_{j}$ and from Equation 15. To show Equation 16, consider $e^{\prime} \leq_{x_{\text {Max }}} e_{j+1}$. From Definition 17 there exists a memory event $d=\left\langle i^{\prime}, \alpha^{\prime}, P^{\prime}\right\rangle$ in $\left\lfloor R_{j+1}\right\rfloor$ such that $m_{j}\left(e^{\prime}\right)=i^{\prime}$. From Lemma 10 we have then that $i^{\prime} \leq_{R} i$ and using the definition of causality on transitions ([7, Definition 1]), $\operatorname{MT}_{j+1}\left(e^{\prime}\right) \leq_{\theta} \mathrm{MT}_{j+1}\left(e_{j+1}\right)$.
We conclude using Lemma 11 which shows that $\operatorname{TE}_{j+1}\left(\operatorname{MT}_{j+1}\left(e^{\prime}\right)\right) \leq_{x_{j+1}}$ $\mathrm{TE}_{j+1}\left(\mathrm{MT}_{j+1}\left(e_{j+1}\right)\right)$.
Similarly, we reason for $e^{\prime}$ concurrent with $e_{j+1}$. Lastly, note that there are no events in conflict with $e_{j+1}$ (or with $e$ in $x_{j+1} \downarrow$ ), as there is a single maximal configuration in both $\left\lfloor R_{j+1}\right\rfloor$ and in $x_{j+1} \downarrow$.

- Suppose that $\alpha=\tau$ and let us write the transitions as follows:

$$
\begin{aligned}
& R_{j}=(\vec{b})\left(S\left|m_{1} \triangleright a \cdot P_{1}+Q_{1}\right| m_{2} \triangleright \bar{a} \cdot P_{2}+Q_{2}\right) \\
& \quad \xrightarrow{i, \tau} R_{j+1}=(\vec{b})\left(S\left|\left\langle i, a, Q_{1}\right\rangle \cdot m_{1} \triangleright P_{1}\right|\left\langle i, \bar{a}, Q_{2}\right\rangle \cdot m_{2} \triangleright P_{2}\right)
\end{aligned}
$$

We are assuming here, for simplification, that both thread involved in the synchronisation are under the same set of restricted names. The more general case, does not change the reasoning here, just adds in technicality.

We show that the transition adds a single event $e_{j+1}$ in $\left\lfloor R_{j+1}\right\rfloor$ and that the bijection ME defined on $\left\lfloor R_{j}\right\rfloor$ extends to $e_{j+1}$ such that it remains a label and order preserving bijection between the maximal configuration in $\left\lfloor R_{j+1}\right\rfloor$ and $x_{j+1}$. The proof follows the reasoning above.

## A. 3 Proof of Theorem 2

Before proving the main theorem, let us make the following observation. Let $f:\left(E_{1}, C_{1}, \ell_{1}\right) \rightarrow\left(E_{2}, C_{2}, \ell_{2}\right)$ be a morphism, which is defined as function on events: $f=\left(f_{E}, f_{C}\right)$. As $f_{C}$ is defined by $f_{E}$, we can w.l.o.g. write $f=f_{E}$. Saying that $f$ is an isomorphism is equivalent then to saying that $f: E_{1} \rightharpoonup E_{2}$ is a label- and order-preseving bijection. Therefore the functions $f$ of Definition 9 and Definition 20 are of "the same nature".

Proof (Theorem 2, page 15). Let us prove the HHPB case, the other three cases being similar, and actually simpler.
$\Rightarrow$ Let $\mathcal{R}_{\mathrm{RCCS}}$ be a HHPB between $\emptyset \triangleright P_{1}$ and $\emptyset \triangleright P_{2}$. We show that the following relation

$$
\begin{array}{r}
\mathcal{R}=\left\{\left(x_{1}, x_{2}, f\right) \mid x_{1} \in \llbracket P_{1} \rrbracket, x_{2} \in \llbracket P_{2} \rrbracket, \exists R_{1}, R_{2} \text { s.t. } O_{R_{1}}=P_{1},\right. \\
O_{R_{2}}=P_{2},\left(R_{1}, R_{2}, f\right) \in \mathcal{R}_{\mathrm{RCCS}} \text { and } \\
\left.\qquad R_{1} \rrbracket=\left(\llbracket P_{1} \rrbracket, x_{1}\right), \llbracket R_{2} \rrbracket=\left(\llbracket P_{2} \rrbracket, x_{2}\right)\right\}
\end{array}
$$

is a HHPB between $\llbracket P_{1} \rrbracket$ and $\llbracket P_{2} \rrbracket$.
First note that $(\emptyset, \emptyset, \emptyset) \in \mathcal{R}$ : indeed $\left(\emptyset \triangleright P_{1}, \emptyset \triangleright P_{2}, \emptyset\right) \in \mathcal{R}_{\mathrm{RCCS}}$ and $\llbracket \emptyset \triangleright P_{i} \rrbracket=$ $\left(\llbracket P_{i} \rrbracket, \emptyset\right)$, for $i \in\{1,2\}$.
Let us suppose that $\left(x_{1}, x_{2}, f\right) \in \mathcal{R}$ for $\llbracket R_{i} \rrbracket=\left(\llbracket P_{i} \rrbracket, x_{i}\right)$, for $i \in\{1,2\}$ and $f: x_{1} \rightarrow x_{2}$ an isomorphism. Moreover, note that $\mathcal{F}\left(\left\lfloor R_{i}\right\rfloor\right) \cong x_{i} \downarrow$, from Lemma 4 , and that $\left\lfloor R_{i}\right\rfloor \cong x_{i} \downarrow+m$, for some function $m$, from Definition 14 . To show that $\mathcal{R}$ is a HHPB we have to show that if $x_{1} \xrightarrow{e_{1}} y_{1}$ (or $x_{1} \xrightarrow{e_{1}} y_{1}$ ) then there exists $y_{2}$ such that $x_{2} \xrightarrow{e_{1}} y_{2}$ (or $x_{2} \xrightarrow{e_{2}} y_{2}$ respectively) and such that $\left(y_{1}, y_{2}, f^{\prime}\right) \in \mathcal{R}$ for some $f^{\prime}$.
Let $x_{1} \xrightarrow{e_{1}} y_{1}$, hence by definition, $y_{1}=x_{1} \cup\left\{e_{1}\right\}$. From the correspondence between RCCS and their encodings (from [1, Lemma 6]), it follows that $R_{1} \xrightarrow{i: \alpha} S_{1}$ such that $\llbracket S_{1} \rrbracket=\left(\llbracket P_{1} \rrbracket, y_{1}\right)$. We therefore deduce that $\left\lfloor S_{1}\right\rfloor \cong$ $y_{1} \downarrow+\left(m \cup\left\{e_{1} \mapsto i\right\}\right)$.
As $\left(R_{1}, R_{2}, f\right) \in \mathcal{R}_{\mathrm{RCCS}}$ and as $R_{1} \xrightarrow{i: \alpha} S_{1}$, it follows that there exists a transition $R_{2} \xrightarrow{j: \alpha} S_{2}$ with $f=f^{\prime} \upharpoonright_{\mathcal{F}\left(\left\lfloor R_{1}\right\rfloor\right)}$ and $\left(S_{1}, S_{2}, f^{\prime}\right) \in \mathcal{R}_{\mathrm{RCCS}}$.
Again from the correspondence between $R_{2}$ and $\llbracket R_{2} \rrbracket$ we have that $x_{2} \xrightarrow{e_{2}}$ $y_{2}$ such that $y_{2}=x_{2} \cup\left\{e_{2}\right\}$ and $\llbracket S_{2} \rrbracket=\left(\llbracket P_{2} \rrbracket, y_{2}\right)$. Then we have that $\left(y_{1}, y_{2}, f^{\prime}\right) \in \mathcal{R}$.
We treat similarly the cases where $x_{2}$ does a transition, or when the transitions are backwards.
$\Leftarrow$ Let $\mathcal{R}_{\mathrm{CONF}}$ be a HHPB between $\llbracket P_{1} \rrbracket$ and $\llbracket P_{2} \rrbracket$. We show that the following relation

$$
\begin{aligned}
\mathcal{R}=\left\{\left(R_{1}, R_{2}, f\right) \mid\right. & O_{R_{1}}=P_{1}, O_{R_{2}}=P_{2} \text { and } \llbracket R_{1} \rrbracket=\left(\llbracket P_{1} \rrbracket, x_{1}\right), \\
& \left.\llbracket R_{2} \rrbracket=\left(\llbracket P_{2} \rrbracket, x_{2}\right), \text { with }\left(x_{1}, x_{2}, f\right) \in \mathcal{R}_{\mathrm{CONF}}\right\}
\end{aligned}
$$

is a HHPB between $\emptyset \triangleright P_{1}$ and $\emptyset \triangleright P_{2}$.
We have that $\left(\emptyset \triangleright P_{1}, \emptyset \triangleright P_{2}, \emptyset\right) \in \mathcal{R}$ as $(\emptyset, \emptyset, \emptyset) \in \mathcal{R}_{\mathrm{CONF}}$ and $\llbracket \emptyset \triangleright P_{i} \rrbracket=$ $\left(\llbracket P_{i} \rrbracket, \emptyset\right)$, for $i \in\{1,2\}$.
We suppose now that $\left(R_{1}, R_{2}, f\right) \in \mathcal{R}$, with $f: \mathcal{F}\left(\left\lfloor R_{1}\right\rfloor \rightarrow \mathcal{F}\left(\left\lfloor R_{2}\right\rfloor\right)\right)$. It implies that $\llbracket R_{i} \rrbracket=\left(\llbracket P_{i} \rrbracket, x_{i}\right), i \in\{1,2\}$, we have that $\left(x_{1}, x_{2}, f\right) \in \mathcal{R}_{\text {CONF }}$. As $\mathcal{F}\left(\left\lfloor R_{i}\right\rfloor\right) \cong x_{i} \downarrow$, from Lemma $4, f$ is also defined from $x_{1}$ to $x_{2}$.
To show that $\mathcal{R}$ is a HHPB we have to show that if $R_{1} \xrightarrow{i: \alpha} S_{1}$ (or $R_{1} \stackrel{i: \alpha}{\sim}$ $S_{1}$ ) then there exists $S_{2}$ such that $R_{2} \xrightarrow{j: \alpha} S_{2}$ (or $R_{2} \xrightarrow{j: \alpha} S_{2}$ respectively) and such that $\left(S_{1}, S_{2}, f^{\prime}\right) \in \mathcal{R}$ for some $f^{\prime}$.
Let $R_{1} \xrightarrow{i: \alpha} S_{1}$. We use again the correspondence between RCCS and their encodings (from [1, Lemma 6]) from which we have that there exists $e_{1}$ and $y_{1}=x_{1} \cup\left\{e_{1}\right\}$ such that $x_{1} \xrightarrow{e_{1}} y_{1}$ and $\llbracket S_{1} \rrbracket=\left(\llbracket P_{1} \rrbracket, y_{1}\right)$. As $\left(x_{1}, x_{2}, f\right) \in$ $\mathcal{R}_{\text {CONF }}$ it implies that there exists $e_{2}, y_{2}$ and $f^{\prime}$ such that $x_{2} \xrightarrow{e_{2}} y_{2}$ and $\left(y_{1}, y_{2}, f^{\prime}\right) \in \mathcal{R}_{\text {CONF }}$. Again, from the correspondence between RCCS and configuration structures we have that from $x_{2} \xrightarrow{e_{2}} y_{2}$, there exists $S_{2}$ and some $j$ such that $R_{2} \xrightarrow{j: \alpha} S_{2}$ with $\llbracket S_{2} \rrbracket=\left(\llbracket P_{2} \rrbracket, y_{2}\right)$. Hence $\mathcal{F}\left(\left\lfloor S_{2}\right\rfloor\right)=y_{2} \downarrow$. We conclude therefore that $\left(S_{1}, S_{2}, f^{\prime}\right) \in \mathcal{R}$.
Similarly we show the cases where $R_{1}$ does a backward transition, or if $R_{2}$ does a forward or backward transition.

[^0]:    ${ }^{4}$ We make the abuse of notation of writing $\lfloor\cdot\rfloor$ for the encoding of both a reversible process and a memory, into a $\mathcal{D}$-structure.

[^1]:    ${ }^{5}$ Formally, $\mathcal{C}_{1}=\left(E_{1}, C_{1}, \ell_{1}\right) \subseteq \mathcal{C}_{2}=\left(E_{2}, C_{2}, \ell_{2}\right)$ iff $E_{1} \subseteq E_{2}, C_{1} \subseteq C_{2}$ and $\ell_{1} \subseteq \ell_{2}$.

[^2]:    ${ }^{6}$ By abuse of notation, $\llbracket \rrbracket \rrbracket$ denotes two different encodings, on CCS and RCCS processes.
    ${ }^{7}$ For the reader familiar with event structures, a configuration $x$ defines an event structure $\left(x, \leqslant_{x}, \ell\right)$ for $\leqslant_{x}$ the causality in $x$. The construction here mirrors the transformation from an event structures to a configuration structure [15].
