## 1 Notation used to describe the epitaxy of Pd(-Au) NPs on r-TiO<sub>2</sub>

The epitaxial relationship between a Pd(-Au) NP and the r-TiO<sub>2</sub> is written as follows: Pd(-Au)(hkl)<uvw> || r-TiO<sub>2</sub>(h'k'l')[u'v'w'] where (hkl) and (h'k'l') are respectively the Miller indices of the planes of the NP and of the support in contact. [uvw] and [u'v'w'] are two crystallographic directions of the particle and r-TiO<sub>2</sub> respectively that are parallel to each other and are parallel to the NP-support interface.

## 2 Dewetting of bimetallic Pd(-Au) NPs on rutile titania

Fig. 1S Dewetting of Pd<sub>43</sub>Au<sub>57</sub> NPs in epitaxial relationship Pd<sub>43</sub>Au<sub>57</sub>(111)<101> || r-TiO<sub>2</sub>(110)[1-1-1] as a function of particle size.

Fig. 2S Dewetting of Pd<sub>62</sub>Au<sub>38</sub> NPs in epitaxial relationship Pd<sub>62</sub>Au<sub>38</sub>(100)<101> || r-TiO<sub>2</sub>(110)[1-10] as a function of particle size.

## 3 Derivation of an extended Wulff-Kaishev rule

A first extension of the Wulff-Kaishev model that takes into account the effect of epitaxial stress on thermodynamic equilibrium shape (ES) of a crystal deposited on a support with lattice mismatch was given by P. Müller and R. Kern<sup>1</sup>. In particular, they showed that the expression of the elastic energy stored in a partially relaxed particle of volume  $V$  is expressed as  $\lambda E \varepsilon^2 V$  where  $E \varepsilon^2 V$  is the elastic energy stored in the particle before relaxation.  $\lambda$  is a stress relaxation factor which depends, in complex ways, on the shape of the particle, its orientation with respect to the support and the rigidity of the particle and the support<sup>2</sup>. It varies between 0 and 1. It is 0 for a completely relaxed particle and is 1 in the absence of elastic relaxation.  $E$  is a combination of elastic coefficients of the particle and its support and  $\varepsilon$  is the lattice parameter mismatch between the two systems. According to the theory of nucleation,  $\Delta G$ , the work

necessary to form a polyhedral particle of volume  $V$  from its gaseous phase on a planar support with lattice mismatch is the difference between the free energy of the system in its final and initial states plus energy terms related to epitaxial strain and particle surfaces, particle edges and particle-support interface among others<sup>3,4</sup> :

$$\Delta G = -n\Delta\mu + \sum_{j \neq i} \gamma_m^j A_j + (\gamma_i - \gamma_s)A_i + \lambda E \varepsilon^2 V + \sum_k \rho_k l_k + \sum_i \tau_i l_i \quad (S1)$$

where  $\Delta\mu$  is the supersaturation per atom. It is the difference in chemical potential between a free atom in gaseous phase ( $\mu_0$ ) and an atom in the particle ( $\mu_p$ ), i.e.,  $\Delta\mu = \mu_0 - \mu_p$ .  $n$  is the number of atoms in the particle.  $\gamma_m^j$  is the surface energy of free facet  $j$  of surface area  $A_j$ ,  $\gamma_s$  is the surface energy of the support and  $\gamma_i$  is excess energy associated with the formation of the metal-support interface of surface area  $A_i$  and of perimeter  $L_i$ .  $\tau_i$  is the excess energy due the particle edge  $i$  of length  $l_i$  at the particle-support-vacuum triple phase line (or, as in the main text, simply called the triple line) with  $\sum_i l_i = L_i$ . In comparison,  $\rho_k$  is the excess energy due to free edge  $k$  of length  $l_k$ .

If  $v$  is the atomic volume,  $V = n.v$ . By setting  $k = \lambda.v$ , equation (S1) can be rewritten as follows:

$$\begin{aligned} \Delta G &= -\frac{V}{v}\Delta\mu + \sum_{j \neq i} \gamma_m^j A_j + (\gamma_i - \gamma_s)A_i + \lambda E \varepsilon^2 V + \sum_k \rho_k l_k + \sum_i \tau_i l_i \\ &= \left( \lambda E \varepsilon^2 - \frac{\Delta\mu}{v} \right) \cdot V + \sum_{j \neq i} \gamma_m^j A_j + (\gamma_i - \gamma_s)A_i + \sum_k \rho_k l_k + \sum_i \tau_i l_i \\ &= \left( \frac{kE\varepsilon^2 - \Delta\mu}{v} \right) \cdot V + \sum_{j \neq i} \gamma_m^j A_j + (\gamma_i - \gamma_s)A_i + \sum_k \rho_k l_k + \sum_i \tau_i l_i \end{aligned}$$

In the main text, we have shown that Pd(-Au) NPs studied here were inhomogeneously strained with no clear dependence between lattice strain and size for any given composition. In the following, the relaxation factor  $\lambda$  will thus be considered as size-independent. We will also neglect the contribution of the particle free edge energies. Indeed, as also discussed in the main text, the free edges in Pd(-Au) NPs marginally influence their ES. Finally, the excess energy along the triple line will be considered isotropic with an average value of  $\tau$ . Neglecting the anisotropy of the triple line energy leads to  $\sum_i \tau_i dl_i = \sum_i \tau dl_i = \tau L_i$ . Under these assumptions and neglecting the size dependence of surface and interface energies, the elementary work associated with the nucleation of the particle,  $d\Delta G(n)$  is given by:

$$d\Delta G = \left( \frac{kE\varepsilon^2 - \Delta\mu}{v} \right) \cdot dV + \sum_{j \neq i} \gamma_m^j dA_j + (\gamma_i - \gamma_s)dA_i + \sum_k \rho_k dl_k + \tau L_i \quad (S2)$$

For a supported particle with polyhedral morphology, its volume  $V$  can be divided into congruent pyramids of height  $h_p$  and polygonal base area  $A_p$  such that :

$$V = \frac{1}{3} \sum_p h_p A_p = \frac{1}{3} \left( \sum_{j \neq i} h_j A_j + (h - \Delta h) A_i \right) \quad (S3)$$

where  $(h - \Delta h)$  is the distance from the centre of the particle to the facet of the particle in contact with the support ( $\Delta h$  being the particle truncation due to the support).  $h_j$  is the distance of free facet  $j$  (of surface area  $A_j$ ) from the particle centre. The derivative of  $V$  is :

$$dV = \frac{1}{2} \left( \sum_{j \neq i} h_j dA_j + (h - \Delta h) dA_i \right) \quad (S4)$$

Replacing  $dV$  in equation (S2) by its expression in equation (S4), we obtain :

$$d\Delta G = \left( \frac{kE\varepsilon^2 - \Delta\mu}{v} \right) \cdot \left( \frac{1}{2} \left( \sum_{j \neq i} h_j dA_j + (h - \Delta h) dA_i \right) \right) + \sum_{j \neq i} \gamma_m^j dA_j + (\gamma_i - \gamma_s) dA_i + \sum_k \rho_k dl_k + \tau L_i \quad (S5)$$

When the particle reaches its thermodynamic equilibrium shape, all partial derivatives of  $\Delta G$  cancel out simultaneously. Thus, at equilibrium, any free facet  $j$  verifies the following equation:

$$\left( \frac{\partial \Delta G}{\partial A_j} \right)_{\Delta\mu, A_i} = 0 \quad (S6)$$

while at the interface with the support, we have :

$$\left( \frac{\partial \Delta G}{\partial A_i} \right)_{\Delta\mu, A_j} = 0 \quad (S7)$$

From equations (S6) and (S7), we get:

$$\frac{\gamma_i - \gamma_s + \tau \frac{dL_i}{dA_i}}{h - \Delta h} = \frac{\Delta\mu - kE\varepsilon^2}{3v} \quad (\text{S8})$$

and

$$\frac{\gamma_m}{h} = \frac{\Delta\mu - kE\varepsilon^2}{3v} \quad (\text{S9})$$

respectively.

By combining equations (S8) and (S9), we obtain the extended Wulff-Kaishev rule incorporating the effect of the triple line energy on the thermodynamic ES of the particle:

$$\frac{\Delta h - h}{h} = \frac{\gamma_s - \gamma_i}{\gamma_m} - \frac{\tau}{\gamma_m} \frac{dL_i}{dA_i} \quad (\text{S10})$$

$\frac{dL_i}{dA_i}$  is a geometric factor which varies from one particle to another depending on the geometry of the particle-support interface. The latter is defined by the morphology of the particle and its orientation relatively to the support. In this work, this factor is expressed simply in terms of measurable distances on high resolution transmission electron microscopy (HRTEM) images of single NPs acquired parallel to the particle-support interface as shown in the following and in the main text. In the following sections, we will establish  $\frac{dL_i}{dA_i}$  for a supported face-centered cubic (FCC) particles with octahedral truncated ES in two distinct orientations with respect to the support.

## 4 Expression of the geometric factor $\frac{dL_i}{dA_i}$

### 4.1 Truncated octahedral FCC particle supported on its (010) facet

Fig. 3S (a) Atomic model of a free FCC particle with truncated octahedral morphology along the [101] zone axis. Visible facets and their indices are indicated; (b) Outline of the projection of the particle in [101] zone axis. Square (100) facets of sides length  $a$  can be distinguished.  $O$  is the centre of the projection and  $W$  is the width of the particle in zone axis.

Fig. 3Sa shows an atomic model of a free truncated octahedral particle with closed-packed FCC structure in [101] zone axis. The particle is limited by (100) and (111) facets. The (100) facets have a square shape of side length  $a$ . Let  $W$  denotes the width of the particle in this projection, i.e. its lateral extension along the [10-1] direction (Fig. 3Sb).

From the outline of the particle projection along the [101] direction, we show that :

- $GJ$  being the diagonal of a (100) facet,  $GJ = HI = a\sqrt{2}$ .
- Isolating parallelogram  $ABCLA$ ,  $AL = BC = a$ . By symmetry,  $MD = a$ . Thus,  $JI = W - a$  and  $LM = W - 2a$ .

- $\widehat{ABC} = \widehat{ADE} = \widehat{DAB} = \widehat{DAF} = \theta$  with  $\theta$  being the angle between the (100) and (111) planes. We can thus write  $\cos\theta = \frac{(111) \cdot (100)}{|111||100|} = \frac{1}{\sqrt{3}}$  and deduce that  $\tan\theta = \sqrt{2}$ .

When the particle is deposited on a support, the particle will present an extra truncation at the particle-support interface. Fig. 4Sa shows the outline of the projection of a supported truncated octahedral particle with one of its (100) facet in contact with the support. The particle is truncated at its base by a length  $\Delta h$ . Let's first consider the length of segment  $PQ$ . From Fig. 4Sa, the length of segment  $PQ$  is expressed as :

- $PQ = OP - OQ = OP - KJ = h_{100} - \frac{a}{\sqrt{2}}$ .

Two types of truncation are possible depending on the difference between the length of segment  $PQ$  and particle truncation  $\Delta h$ . If  $\Delta h > PQ$ , the interface will have an octagonal shape (Fig. 4Sb). Otherwise, the interface will be a square (Fig. 5Sb). We will now determine the expression of  $\frac{dL_i}{dA_i}$  in each case.

#### 4.1.1 $\Delta h > PQ$

Fig. 4S(a) Outline of the projection of a supported truncated octahedral FCC particle in [101] zone axis deposited on a (100) facet (black lines). Construction lines are shown in light blue. Point  $R$  is at the intersection of the half-lines  $AF$  and  $DE$ .  $P$  and  $Q$  are the intersections between the segment  $RO$  and segment  $JI$  and  $FE$ , respectively. We set  $z = PR$  and  $h_{100} = OP$ . (b) Outline of the particle-support interface for  $\Delta h > PQ$ . The interface is here of octagonal shape defined by segments  $S'T'$  and  $T'U'$ .

By geometrical construction on Fig. 4Sa:

$$\begin{aligned}
SV &= \frac{RX}{RO}.AD \\
&= \frac{z+\Delta h}{z+h_{100}}.AD \\
&= \left(1 + \frac{\Delta h - h_{100}}{z+h_{100}}\right).AD
\end{aligned}$$

Since,

$$\bullet \quad OR = AO.\tan\theta = \frac{W}{2}\sqrt{2}$$

and  $OR = z + h_{100}$ , we deduce :

$$z + h_{100} = \frac{W}{\sqrt{2}} \quad (S11)$$

Consequently,  $SV$  can be simplified as follows :

$$\begin{aligned}
SV &= \left(1 + \frac{\Delta h - h_{100}}{\frac{W}{\sqrt{2}}}\right).W \\
&= W + (\Delta h - h_{100})\sqrt{2}
\end{aligned}$$

Moreover,

$$\begin{aligned}
ST &= UV \\
&= \frac{QX}{QO}.AL \\
&= \frac{\Delta h - PQ}{QX + XO}.AL \\
&= \frac{\Delta h - h_{100} + \frac{a}{\sqrt{2}}}{\frac{a}{\sqrt{2}}}.a \\
&= a + (\Delta h - h_{100})\sqrt{2}
\end{aligned}$$

From these two distances, we can express the length of segments  $S'T'$  and  $T'U'$  which define the octagonal interface (Fig. 4Sb) as follows:

$$\begin{aligned}
S'T' &= S''T'' = U'V' = U''V'' \\
&= ST\sqrt{2} \\
&= a\sqrt{2} + 2(\Delta h - h_{100})
\end{aligned}$$

and

$$\begin{aligned}
T'U' &= SV - ST - UV \\
&= W + (\Delta h - h_{100})\sqrt{2} - 2(a + (\Delta h - h_{100})\sqrt{2}) \\
&= W - 2a - (\Delta h - h_{100})\sqrt{2}
\end{aligned}$$

Using Fig. 4Sb and by setting  $T'U' = a_i$ , the expressions for the perimeter  $L_i$  and the surface area  $A_i$  of the octagonal particle-support interface are as follows:

$$\begin{aligned}
L_i &= 4(S'T' + T'U') \\
&= 4(a\sqrt{2} + 2(\Delta h - h_{100}) + a_i) \\
&= 4\left(a\sqrt{2} + 2\frac{W - 2a - a_i}{\sqrt{2}} + a_i\right) \\
&= 4(1 - \sqrt{2})a_i + 4\sqrt{2}(W - a) \\
A_i &= SV^2 - S'T'^2 \\
&= (W + (\Delta h - h_{100})\sqrt{2})^2 - (a\sqrt{2} + 2(\Delta h - h_{100}))^2 \\
&= \left(W + \frac{W - 2a - a_i}{\sqrt{2}}\sqrt{2}\right)^2 - \left(a\sqrt{2} + 2\frac{W - 2a - a_i}{\sqrt{2}}\right)^2 \\
&= (2W - 2a - a_i)^2 - ((W - a)\sqrt{2} - a_i\sqrt{2})^2 \\
&= 2(W - a)^2 - a_i^2
\end{aligned}$$

Deriving the expressions of  $L_i$  and  $A_i$  with respect to  $a_i$  (and considering the variations of  $L_i$  and  $A_i$  with  $a$  to be marginal), we get

$$\hat{\Delta} L_i = 4(1 - \sqrt{2})da_i$$

$$\hat{\Delta} A_i = -2a_ida_i$$

from which we deduced the expression of the geometric factor  $\frac{dL_i}{dA_i}$  for  $\Delta h > PQ$  :

$$\frac{dL_i}{dA_i} = \frac{2(\sqrt{2}-1)}{a_i} = \frac{2(\sqrt{2}-1)}{W - 2a - (\Delta h - h_{100})\sqrt{2}} \quad (S12)$$

The geometric factor can be easily calculated with  $W$ ,  $a$ ,  $h_{100}$  and  $\Delta h$  known. All these dimensions are directly measurable on a HRTEM image of the particle in  $[101]$  zone axis.

#### 4.1.2 $\Delta h \leq PQ$

Fig. 5S (a) Outline of the projection of a supported truncated octahedral FCC particle in  $[101]$  zone axis deposited on a  $(100)$  facet when  $\Delta h \leq PQ$  (b) Outline of the square particle-support interface defined by segment  $T'U'$ . Particle-support when  $\Delta h < PQ$  for a truncated octahedral particle with one of its  $(100)$  facets in contact with the support. The interface has here a square shape.

When the shape of the particle-support interface is a square of side length  $b_i$  (Fig. 5Sb),

$$\begin{aligned} T'U' &= b_i \\ &= \frac{RX}{RO} \cdot AD \\ &= \frac{z + \Delta h}{z + h_{100}} \cdot W \\ &= \frac{z + h_{100} + \Delta h - h_{100}}{z + h_{100}} \cdot W \\ &= \left(1 + \frac{\Delta h - h_{100}}{z + h_{100}}\right) \cdot W \end{aligned}$$

Moreover, as according to equation (S11),  $z + h_{100} = \frac{W}{\sqrt{2}}$ ,  $b_i$  simplifies to:

$$b_i = W + (\Delta h - h_{100})\sqrt{2}$$

Since the interface is a square,  $L_i = 4b_i$  and  $A_i = b_i^2$ . By calculating the derivatives  $dL_i$  and  $dA_i$  with respect to  $b_i$ , we obtain :

$$\frac{dL_i}{dA_i} = \frac{2}{b_i} = \frac{2}{W + (\Delta h - h_{100})\sqrt{2}} \quad (\text{S13})$$

In this configuration, the determination of  $\frac{dL_i}{dA_i}$  only requires the knowledge of the  $W$ ,  $\Delta h$  and  $h_{100}$ .

In our study of  $\text{Pd}_{62}\text{Au}_{38}$  NPs in epitaxial relationship  $\text{Pd}_{62}\text{Au}_{38}(100)\langle 101 \rangle \parallel \text{r-TiO}_2(110)[1-10]$ , all NPs displayed ES satisfying  $\Delta h > PQ$ . Hence, the expression of  $\frac{dL_i}{dA_i}$  given by equation (S12) was used in the main text to describe the morphology of these NPs.

## 4.2 Truncated octahedral FCC particle supported on its (111) facet

Fig. 6S (a) Atomic model of a free FCC particle with truncated octahedral shape viewed along the  $[-121]$  zone axis. Visible facets and their indices are indicated. (b) Outline of the projection of the particle in the same zone axis.  $W$  is the width of the particle in this projection.  $\varphi$  is the angle between the  $(-113)$  and  $(11-1)$  planes.

Fig. 6Sa shows an atomic model of a free FCC particle with truncated octahedral morphology viewed along  $[-121]$  zone axis. If the particle is supported on one of its its  $(111)$  facet, the expression of  $\frac{dL_i}{dA_i}$  is, according to<sup>5</sup>, given by :

$$\frac{dL_i}{dA_i} = \frac{2\sqrt{3}}{W + \frac{2\Delta h}{\tan \varphi}} \quad (\text{S14})$$

where  $W$  is the width of the particle along the  $[10-1]$  direction with  $W = h_{111}\sqrt{6}$ ,  $\Delta h$  the truncation of the particle at its base and  $\varphi$  the angle between the  $(-11-3)$  and  $(11-1)$  planes of the FCC lattice leading to  $\tan \varphi = 2\sqrt{\frac{2}{3}} = 1.633$  (Fig. 6Sb). In this work, all monometallic Pd and bimetallic  $\text{Pd}_{43}\text{Au}_{57}$  nanodecahedra in epitaxial relationship  $\text{Pd}(-\text{Au})(111)\langle 101 \rangle \parallel \text{r-TiO}_2(110)[1-1-1]$  were imaged in  $[101]$  zone axis. The latter is rotated from  $[-121]$  direction by  $90^\circ$  around the  $[11-1]$  direction. Although the expression of  $\frac{dL_i}{dA_i}$  is independent of zone axis along which a NP is viewed, neither  $W$  nor  $\Delta h$  can be straightforwardly determined in  $[101]$  zone axis.

To express  $\frac{dL_i}{dA_i}$  in terms of measurable distances in  $[101]$  zone axis, let's consider Fig. 7S. Fig. 7Sa shows an atomic model of a particle in  $[101]$  zone axis. The outline of the projection is shown in Fig. 7Sb.

Since, the expression of  $\frac{dL_i}{dA_i}$  in  $[101]$  zone axis is the same as in equation (S14), we can write :

$$\begin{aligned} \frac{dL_i}{dA_i} &= \frac{2\sqrt{3}}{W + \frac{2\Delta h}{\tan \varphi}} \\ &= \frac{2\sqrt{3}}{h_{111}\sqrt{6} + \frac{2\Delta h}{2\sqrt{\frac{2}{3}}}} \end{aligned}$$

which simplifies to :

Fig. 7S (a) Atomic model of a free FCC particle with truncated octahedral shape viewed along the [101] zone axis. Visible facets and their indices are indicated. (b) Outline of the projection of the particle according to the same zone axis.

$$\frac{dL_i}{dA_i} = \frac{2\sqrt{2}}{\Delta h + 2h_{111}} \quad (\text{S15})$$

The geometric factor  $\frac{dL_i}{dA_i}$  is here expressed as a function of  $\Delta h$  and  $h_{111}$ . Both distances can be determined from a projected image of a supported FCC truncated octahedron in [101] zone axis as explained in the rest of this section. Fig. 8Sa (top) shows the hexagonal shape of the (111) facet in contact with the support. The point  $O'$  corresponds to the perpendicular projection of the particle center  $O$  of the NP on this facet. Due to the symmetry of the particle,  $O'$  is at the center of the hexagon. However,  $O'$  does not lie in the middle of segment  $L'N'$  ( $L'$  and  $N'$  are in the middle of the segments  $B'B''$  and  $D'D''$  respectively) as the hexagon  $B'B''C''D''C'B'$  is not regular. It results that the position of particle centre  $O$  is also not known. Thus, the value of the truncation  $\Delta h$  and  $h_{111}$  are not directly measurable on the two-dimensional projection  $ABDFRQPA$  of the particle along [101] zone axis.

To determine  $\Delta h$  and  $h_{111}$ , we proceed as follows. The extensions of segments  $BD$  and  $PA$  meet at point  $K$  (Fig. 8Sa). Similarly, the extensions of segments  $B'C'$ ,  $B''C''$  and  $D'D''$  delimiting the (111) facet form a triangle  $K'P'Q'$  (Fig. 8Sb). Note that  $K'P'Q'$  is an equilateral triangle of center  $O'$ . Hence, for an equilateral triangle, we have  $K'O' = \frac{2}{3}K'N'$ .

Since  $K'N' = KD$ , we have  $K'O' = \frac{2}{3}KD$ .  $KD$  can be determined from the projection of the particle in [101] zone axis. Let us now express  $K'O'$  in terms of  $h_{111}$ . Let's consider  $OKO''$  which is a right-angled triangle with  $\widehat{KOO''}$  the angle between the (111) and (100) planes. As  $K'O' = KO''$  and  $OO'' = h_{111}$ , we get  $KO'' = OO'' \cdot \tan \theta = h_{111} \cdot \sqrt{2}$ . Hence,

$$h_{111} = \frac{\sqrt{2}}{3} \cdot KD \quad (\text{S16})$$

Once  $h_{111}$  is known,  $\Delta h$  that can be deduced from the measurement of the particle height which is equal to  $2h_{111} - \Delta h$  (Fig. 8Sa).
