Abstract

Type theories with equality reflection, such as extensional type theory (ETT), are convenient theories in which to formalise mathematics, as they make it possible to consider provably equal terms as convertible. Although type-checking is undecidable in this context, variants of ETT have been implemented, for example in NuPRL and more recently in Andromeda. The actual objects that can be checked are not proof-terms, but derivations of proof-terms. This suggests that any derivation of ETT can be translated into a typecheckable proof term of intensional type theory (ITT). However, this result, investigated categorically by Hofmann in 1995, and 10 years later more syntactically by Oury, has never given rise to an effective translation. In this paper, we provide the first effective syntactical translation from ETT to ITT with uniqueness of identity proofs and functional extensionality. This translation has been defined and proven correct in Coq and yields an executable plugin that translates a derivation in ETT into an actual Coq typing judgment. Additionally, we show how this result is extended in the context of homotopy type theory to a two-level type theory.

Keywords dependent types, translation, formalisation

1 Introduction

Type theories with equality reflection, such as extensional type theory (ETT), are convenient theories in which to formalise mathematics, as they make it possible to consider provably equal terms as convertible, as expressed in the following typing rule:

$$\frac{\Gamma \vdash_{\mathsf{x}} e : u =_{A} v}{\Gamma \vdash_{\mathsf{x}} u \equiv v : A}$$
(1)

Here, the type $u =_A v$ is Martin-Löf's identity type with only one constructor refl $u : u =_A u$ which represents proofs

45

of equality inside type theory, whereas $u \equiv v : A$ means that u and v are convertible in the theory–and can thus be silently replaced by one another in any term. Several variants of ETT have been considered and implemented, for example in NuPRL [Allen et al. 2000] and more recently in Andromeda [Bauer et al. 2016]. The prototypical example of the use of equality reflection is the definition of a coercion function between two types A and B that are equal (but not convertible) by taking a term of type A and simply returning it as a term of type *B*:

 $\lambda A B (e : A = B) (x : A). x : \Pi A B. A = B \rightarrow A \rightarrow B.$

In intensional type theory (ITT), this term does not typecheck because x of type A can not be given the type B by conversion. In ETT, however, equality reflection can be used to turn the witness of equality into a proof of conversion and thus the type system validates the fact that x can be given the type *B*. This means that one needs to guess equality proofs during type-checking, because the witness of equality has been lost at the application of the reflection rule. Guessing it was not so hard in this example but is in general undecidable, as one can for instance encode the halting problem of any Turing machine as an equality in ETT. That is, the actual objects that can be checked in ETT are not terms, but instead derivations of terms. It thus seems natural to wonder whether any derivation of ETT can be translated into a typecheckable term of ITT. And indeed, it is well know that one can find a corresponding term of the same type in ITT by *explicitly* transporting the term x of type A using the elimination of internal equality on the witness of equality e_1 , noted e_* :

$$\lambda A B (e : A = B) (x : A). e_* x : \Pi A B. A = B \rightarrow A \rightarrow B.$$

This can be seen as a way to make explicit the silent use of reflection. Furthermore, by making the use of transport as economic as possible, the corresponding ITT term can be seen as a compact witness of the derivation tree of the original ETT term.

This result has first been investigated categorically in the pioneering work of Hofmann [1995, 1997], by showing that the term model of ITT can be turned into a model of ETT by quotienting this model with propositional equality. However, it is not clear how to extend this categorical construction to an explicit and constructive translation from a derivation in ETT to a term of ITT. In 2005, this result has been investigated more syntactically by Oury [2005]. However, his

111presentation does not give rise to an effective translation. 112 By an effective translation we mean that it is entirely con-113 structive and can be used to deterministically *compute* the 114 translation of a given ETT typing derivation. Two issues 115 prevent deriving an effective translation from Oury's presentation, and it is the process of actual formalisation of the 116 117 result in a proof assistant that led us to these discoveries. First, his handling of related contexts is not explicit enough, 118 119 which we fix by framing the translation using ideas coming 120 from the parametricity translation (section 1.2). Addition-121 ally, Oury's proof requires an additional axiom in ITT on top of functional extensionality and uniqueness of identity 122 123 proofs, that has no clear motivation and can be avoided by considering an annotated syntax (section 2.1). 124

Contributions. In this paper, we present the first effective 126 syntactical translation from ETT to ITT (assuming unique-127 ness of identity proofs (UIP) and functional extensionality in 128 ITT). By syntactical translation, we mean an explicit transla-129 tion from a derivation $\Gamma \vdash_{x} t : T$ of ETT (the x index testifies 130 that it is a derivation in ETT) to a context Γ' , term t' and 131 type *T*' of ITT such that $\Gamma' \vdash t' : T'$ in ITT. This translation 132 enjoys the additional property that if *T* can be typed in ITT, 133 *i.e.*, $\Gamma \vdash T$, then $T' \equiv T$. This means in particular that a theo-134 rem proven in ETT but whose statement is also valid in ITT 135 can be automatically transferred to a theorem of ITT. For 136 instance, one could use a *local* extension of the Coq proof 137 assistant with a reflection rule, without being forced to rely 138 on the reflection in the entire development. 139

This translation can be seen as a way to build a syntac-140 tical model of ETT from a model of ITT as described more 141 generally in Boulier et al. [2017] and has been entirely pro-142 grammed and formalised in Coq [Coq development team 143 2017]. For this, we rely on TemplateCoq¹ [Anand et al. 2018], 144 which provides a reifier for Coq terms as represented in 145 Coq's kernel as well as a formalisation of the type system of 146 Coq. Thus, our formalisation of ETT is just given by adding 147 the reflection rule to a subset of the original type system 148 of Coq. This allows us to extract concrete Coq terms and 149 types from a closed derivation of ETT, using a little trick to 150 incorporate Inductive types and induction. We do not treat 151 cumulativity of universes which is an orthogonal feature of 152 Coq's type theory. 153

154 Outline of the Paper. Before going into the technical devel-155 opment of the translation, we explain its main ingredients 156 and differences with previous works. Then, in Section 2, 157 we define the extensional and intensional type theories we 158 consider. In Section 3, we define the main ingredient of the 159 translation, which is a relation between terms of ETT and 160 terms in ITT. Then, the translation is given in Section 4. Sec-161 tion 5 describes the Coq formalisation and Sections 6 and 7 162

165

163

125

discuss limitations and related work. The main proofs are given in detail in Appendices B and C.

The Coq formalisation can be found in https://github.com/ TheoWinterhalter/ett-to-itt.

1.1 On the Need for UIP and Functional Extensionality.

Our translation targets ITT plus UIP and functional extensionality, which correspond to the two following axioms (where \Box_i denotes the universe of types at level *i*):

$$\begin{split} \mathsf{UIP} &: \Pi(A : \Box_i) \; (x \; y : A) \; (e \; e' : x = y). \; e = e' \\ \mathsf{FunExt} &: \Pi(A : \Box_i) \; (B : A \to \Box_i) \; (f \; g : \Pi(x : A). \; B \; x). \\ &\quad (\Pi(x : A). \; f \; x = g \; x) \to f = g \end{split}$$

The first axiom says that any two proofs of the same equality are equal, and the other one says that two (dependent) functions are equal whenever they are pointwise equal². These two axioms are perfectly valid statements of ITT and they can be proven in ETT. Indeed, UIP can be shown to be equivalent to the Streicher's axiom K

K : $\Pi(A:\Box_i)$. $\Pi(x:A)$. $\Pi(e:x=x)$. $e = \operatorname{refl}_x$

using the elimination on the identity type. But K is provable in ETT by considering the type

 $\Pi(A:\Box_i)$. $\Pi(x y:A)$. $\Pi(e:x=y)$. $e = \operatorname{refl}_x$

which is well typed (using the reflection rule to show that e has type x = x) and which can be inhabited by elimination of the identity type. In the same way, functional extensionality is provable in ETT because

	$\Pi(x:A). f x = g x$	
\rightarrow	$x: A \vdash f \ x \equiv g \ x$	by reflection
\rightarrow	$(\lambda(x:A).f x) \equiv (\lambda(x:A).g x)$	by congruence of \equiv
\rightarrow	$f \equiv g$	by η-law
\rightarrow	f = g	

Therefore, applying our translation to the proofs of those theorems in ETT gives corresponding proofs of the same theorems in ITT. However, UIP is independent from ITT, as first shown by Hofmann and Streicher using the groupoid model [Hofmann and Streicher 1998], which has recently been extended in the setting of univalent type theory using the simplicial or cubical models [Bezem et al. 2013; Kapulkin and Lumsdaine 2012]. Similarly, Boulier *et al.* have shown that functional extensionality is independent from ITT using a simple syntactical translation [Boulier *et al.* 2017].

Therefore, our translation provides proofs of axioms independent from ITT, which means that the target of the translation already needs to have both UIP and functional extensionality. Part of our work is to show formally that they are the only axioms required.

219

¹⁶⁴ ¹https://template-coq.github.io/template-coq/

²In Homotopy Type Theory (HoTT) [Univalent Foundations Program 2013], the functional extensionality axiom is stated in a more complete way, using the notion of adjoint equivalences, but this more complete way collapses to our simpler statement in presence of UIP.

1.2 Heterogeneous Equality and the Parametricity Translation.

223 The basic idea behind the translation from ETT to ITT is to interpret conversion using the internal notion of equal-225 ity, i.e., the identity type. But this means that two terms of 226 two convertible types that were comparable in ETT become 227 comparable in ITT only up-to the equality between the two 228 types. One possible solution to this problem is to consider a 229 native heterogeneous equality, such as John Major equality 230 introduced by McBride [2000]. However, to avoid adding additional axioms to ITT as done by Oury [2005], we prefer 232 to encode this heterogeneous equality using the following 233 dependent sums: 234

$$t T \cong_U u := \Sigma(p:T=U). p_* t = u$$

237 During the translation, the same term occurring twice can 238 be translated in two different manners, if the corresponding 239 typing derivations are different. Even the types of the two 240 different translations may be different. However, we have 241 the strong property that any two translations of the same 242 term only differ in places where transports of proof of equal-243 ity have been injected. To keep track of this property, we 244 introduce the relation $t \sim t'$ between two terms of ITT, of 245 possibly different types. The crux of the proof of the transla-246 tion is to guarantee that for every two terms t_1 and t_2 such 247 that $\Gamma \vdash t_1 : T_1, \Gamma \vdash t_2 : T_2$ and $t_1 \sim t_2$, there exists *p* such that 248 $\Gamma \vdash p : t_1 \mid_{T_1} \cong_{T_2} t_2$. However, during the proof, variables of 249 different but (propositionally) equal types are introduced and 250 the context cannot be maintained to be the same for both t_1 251 and t_2 . Therefore, the translation needs to keep track of this 252 duplication of variables, plus a proof that they are heteroge-253 neously equal. This mechanism is similar to what happens 254 in the (relational) internal parametricity translation in ITT 255 introduced by Bernardy et al. [2012] and recently rephrased 256 in the setting of TemplateCoq [Anand et al. 2018]. Namely, a 257 context is not translated as a telescope of variables, but as a 258 telescope of triples consisting of two variables plus a witness 259 that they are in the parametric relation. In our setting, this 260 amounts to consider telescope of triples consisting of two 261 variables plus a witness that they are heterogeneously equal. 262 We can express this by considering the following dependent 263 sums: 264

Pack
$$A_1 A_2 := \Sigma(x : A_1) \cdot \Sigma(y : A_2) \cdot x_{A_1} \cong_{A_2} y$$
.

This presentation inspired by the parametricity translation 268 is crucial in order to get an effective translation, because 269 it is necessary to keep track of the evolution of contexts 270 when doing the translation on open terms. This ingredient 271 is missing in Oury's work [Oury 2005], which prevents him 272 from deducing an effective (*i.e.*, constructive and computable) 273 translation from his theorem. 274

2 Definitions of Extensional and **Intensional Type Theories**

This section presents the common syntax, typing and main properties of ETT and ITT. Our type theories feature a universe hierarchy, dependent products and sums as well as Martin Löf's identity types.

2.1 Syntax of ETT and ITT

The common syntax of ETT and ITT is given in Figure 1. It features: dependent products $\Pi(x : A)$. *B*, with (annotated) λ -abstractions and (annotated) applications, negative dependent sums $\Sigma(x : A)$. B with (annotated) projections, sorts \Box_i , identity types $u =_A v$ with reflection and elimination as well as terms realising UIP and functional extensionality. Annotating terms with otherwise computationally irrelevant typing information is a common practice when studying the syntax of type theory precisely (see [Streicher 1993] for a similar example). We will write $A \rightarrow B$ for $\Pi(:A)$. B the non-dependent product / function type.

We consider a fixed universe hierarchy without cumulativity, which ensures in particular uniqueness of typing (2.2) which is important for the translation.

About Annotations. Although it may look like a technical detail, the use of annotation is more fundamental in ETT than it is in ITT (where it is irrelevant and doesn't affect the theory). And this is actually one of the main differences between our work (and that of Martin Hofmann [1995] who has a similar presentation) and the work of Oury [2005].

Indeed, by using the standard model where types are interpreted as cardinals rather than sets, it is possible to see that the equality $nat \rightarrow nat = nat \rightarrow bool$ is independent from the theory, it is thus possible to assume it (as an axiom, or for those that would still not be convinced, simply under a λ that would introduce this equality). In that context, the identity map $\lambda(x : \text{nat})$. x can be given the type nat \rightarrow bool and we thus type $(\lambda(x : nat), x) = 0$ bool. Moreover, the β -reduction of the non-annotated system used by Oury concludes that this expression reduces to 0, but cannot be given the type bool (as we said, the equality nat \rightarrow nat = nat \rightarrow bool is independent from the theory, so the context is consistent). This means we lack subject reduction in this case (or uniqueness of types, depending on how we see the issue). Our presentation has a blocked β -reduction limited to matching annotations: $(\lambda(x : A).B.t) @_{x:A.B}u = t[x \leftarrow u]$, from which subject reduction and uniqueness of types follow.

Although subtle, this difference is responsible for Oury's need for an extra axiom. Indeed, to treat the case of equality of applications in his proof, he needs to assume the congruence rule for heterogeneous equality of applications, which is not provable when formulated with John Major equality (Fig. 2). Thanks to annotations and our notion of heterogeneous equality, we can prove this congruence rule for applications.

352

353

360

361

As usual in dependent type theory, we consider contexts which are telescopes whose declarations may depend on any variable already introduced. We note $\Gamma \vdash t : A$ to say that thas type *A* in context Γ . $\Gamma \vdash A$ shall stand for $\Gamma \vdash A : s$ for some sort *s* and similarly $\Gamma \vdash A \equiv B$ stands for $\Gamma \vdash A \equiv B : s$.

354 We use two relations $(s, s') \in Ax$ (written (s, s') for short) 355 and $(s, s', s'') \in \mathbb{R}$ (written (s, s', s'')) to constrain the sorts 356 in the typing rules for universes, dependent products and 357 dependent sums, as is done in any Pure Type System (PTS). 358 In our case, because we do not have cumulativity, the rules 359 are as follows:

> $(\Box_i, \Box_{i+1}) \in Ax$ $(\Box_i, \Box_i, \Box_{\max(i, i)}) \in \mathbb{R}$

362 We give the typing rules of ITT in Figure 3. The rules are standard and we do not explain them. Let us just point out the 363 conversion rule, which says that u : A can be given the type 364 u : B when $A \equiv B$, *i.e.*, when A and B are convertible. As the 365 notion of conversion is central in our work-the conversion 366 367 of ETT being translated to an equality in ITT-we provide an exhaustive definition of it, with computational conversion 368 rules (including β -conversion or reduction of the elimination 369 principle of equality over reflexivity, see Figure 4), however 370 371 congruence conversion rules can be found in Appendix A (Figure 6). Note that we use Christine Paulin-Möhring's vari-372 373 ant of the J rule rather than Martin-Löf's original formulation. 374 Although pretty straightforward, being precise here is very important, as for instance the congruence rule for λ -terms 375 is the reason why functional extensionality is derivable in 376 ETT. Congruence of equality terms is a standard extension of 377 congruence to the new principles we add (UIP and functional 378 379 extensionality).

ETT is thus simply an extension of ITT (we write \vdash_x for 380 381 the associated typing judgment) with the reflection rule on equality, which axiomatises that propositionally equal terms 382 383 are convertible (see Equation 1). Note that, as already mentioned, in the presence of reflection and J, UIP is derivable 384 385

so we could remove it from ETT, but keeping it allows us to share a common syntax which makes the statements of theorems simpler and does not affect the development.

2.3 General Properties of ITT and ETT

We now state the main properties of both ITT and ETT. We do not detail their proof as they are standard and can be found in the Coq formalisation.

First, although not explicit in the typing system, weakening is admissible in ETT and ITT.

Lemma 2.1 (Weakening). *If* $\Gamma \vdash \mathcal{J}$ *and* Δ *extends* Γ (*possibly*) interleaving variables) then $\Delta \vdash \mathcal{J}$.

Then, as mentioned above, the use of a non-cumulative hierarchy allows us to prove that a term t can be given at most one type in a context Γ , up-to conversion.

Lemma 2.2 (Uniqueness of typing). *If* $\Gamma \vdash u : T_1$ *and* $\Gamma \vdash u :$ T_2 then $\Gamma \vdash T_1 \equiv T_2$.

Finally, an important property of the typing system (seen as a mutual inductive definition) is the possibility to deduce hypotheses from their conclusion, thanks to inversion of typing. Note that it is important here that our syntax is annotated for applications and projections as it provides a richer inversion principle.

Lemma 2.3 (Inversion of typing).

- 1. If $\Gamma \vdash x : T$ then $(x : A) \in \Gamma$ and $\Gamma \vdash A \equiv T$.
- 2. If $\Gamma \vdash \Box_i : T$ then $\Gamma \vdash \Box_{i+1} \equiv T$.
- 3. If $\Gamma \vdash \Pi(x : A)$. B : T then $\Gamma \vdash A : s$ and $\Gamma, x : A \vdash B : s'$ and $\Gamma \vdash s'' \equiv T$ for some (s, s', s'').
- 4. If $\Gamma \vdash \lambda(x : A)$. B.t : T then $\Gamma \vdash A : s$ and $\Gamma, x : A \vdash B : s'$ and Γ , $x : A \vdash t : B$ and $\Gamma \vdash \Pi(x : A)$. $B \equiv T$.
- 5. If $\Gamma \vdash u \otimes_{x:A,B} v : T$ then $\Gamma \vdash A : s$ and $\Gamma, x : A \vdash$ $B : s' \text{ and } \Gamma \vdash u : \Pi(x : A). B \text{ and } \Gamma \vdash v : A \text{ and }$ $\Gamma \vdash B[x \leftarrow u] \equiv T.$
- 6. ... Analogous for the remaining term and type constructors.

Proof. Each case is proven by induction on the derivation (which corresponds to any number of applications of the conversion rule following one introduction rule).

Relating Translated Expressions 3

We want to define a relation on terms that equates two terms that are the same up to transport. This begs the question of

what notion of transport is going to be used. Transport can be defined from elimination of equality as follows:

Definition 3.1 (Transport). Given $\Gamma \vdash p : T_1 =_s T_2$ and $\Gamma \vdash t : T_1$ we define the transport of *t* along *p*, written $p_* t$, as $J(s, T_1, X.e. T_1 \rightarrow X, \lambda(x : T_1).T_1.x, T_2, p) @_{T_1.T_2} t$ such that $\Gamma \vdash p_* t : T_2.$

However, in order not to confuse the transports added by the translation with the transports that were already present in the source, we consider p_* as part of the syntax in the reasoning. It will be unfolded to its definition only after the complete translation is performed. This idea is not novel as Hofmann already had a Subst operator that was part of his ITT (noted TT_I in his paper [Hofmann 1995]).

We first define the (purely syntactic) relation \Box between ETT terms and ITT terms in Figure 5 stating that the ITT term is simply a decoration of the first term by transports. Its purpose is to state how close to the original term its translation is. Then, we extend this relation to a similarity relation \sim on ETT terms by taking its symmetric and transitive closure:

$$\sim := (\sqsubset \cup \sqsubset^{-1})^+$$

Lemma 3.2 (~ is an equivalence relation). ~ is reflexive, symmetric and transitive.

Proof. For reflexivity we proceed by induction on the term.

The goal is to prove that two terms in this relation, that are well-typed in the target type theory, are heterogeneously equal. As for this notion, we recall the definition we previously gave: $t_T \cong_U u := \Sigma(p : T = U)$. $p_* t = u$. This definition of heterogeneous equality can be shown to be reflexive, symmetric and transitive. Because of UIP, heterogeneous equality collapses to equality when taken on the same type.

Lemma 3.3. If $\Gamma \vdash e : u_A \cong_A v$ then there exists p such that $\Gamma \vdash p : u =_A v.$

Proof. This holds thanks to UIP on equality, which implies K, and so the proof of A = A can be taken to be reflexivity. \Box

Note. In particular, \cong on types corresponds to equality. This is not as trivial as it sounds, one might be concerned about what happens if we have $\Gamma \vdash e : A_s \cong_{s'} B$ with two distinct sorts s and s'. We would thus have s = s', however, for this to be well-typed, we need to give a common type to s and s', which can only be achieved if s and s' are actually the same sort.

Before we can prove the fundamental lemma stating that two terms in relation are heterogeneously equal, we need to consider another construction. As explained in the introduction, when proving the property by induction on terms, we introduce variables in the context that are equal only up-to heterogeneous equality. This phenomenon is similar to what happens in the parametricity translation [Bernardy et al. 2012]. Our fundamental lemma on the decoration relation ~ assumes two related terms of potentially different

types T1 and T2 to produce an heterogeneous equality between them. For induction to go through under binders (e.g. 574 for dependent products and abstractions), we hence need to 575 consider the two terms under different, but heterogeneously equal contexts. Therefore, the context we produce will not only be a telescope of variables, but rather a telescope of triples consisting of two variables of possibly different types, and a witness that they are heterogeneously equal. To make this precise, we define the following macro:

Pack
$$A_1 A_2 := \Sigma(x : A_1) \cdot \Sigma(y : A_2) \cdot x \cong y$$

together with its projections

605

 $\operatorname{Proj}_{2} p := \pi_{1}^{*} \pi_{2}^{*} p$ $\operatorname{Proj}_{e} p := \pi_{2}^{*} \pi_{2}^{*} p.$ $\operatorname{Proj}_1 p := \pi_1 p$

We can then extend this notion canonically to contexts of the same length that are well formed using the same sorts:

Pack
$$(\Gamma_1, x : A_1) (\Gamma_2, x : A_2) :=$$

(Pack $\Gamma_1 \Gamma_2$), $x :$ Pack $(A_1[\gamma_1]) (A_2[\gamma_2])$
Pack • • := •.

When we pack contexts, we also need to apply the correct projections for the types in that context to still make sense. Assuming two contexts Γ_1 and Γ_2 of the same length, we can define left and right substitutions:

598
599

$$\gamma_1 := [x \leftarrow \operatorname{Proj}_1 x \mid (x : _) \in \Gamma_1]$$

 $\gamma_2 := [x \leftarrow \operatorname{Proj}_2 x \mid (x : _) \in \Gamma_2].$

These substitutions implement lifting of terms to packed 600 601 contexts: Γ , Pack $\Gamma_1 \Gamma_2 \vdash t[\gamma_1] : A[\gamma_1]$ whenever $\Gamma, \Gamma_1 \vdash t : A$ 602 (resp. Γ , Pack $\Gamma_1 \Gamma_2 \vdash t[\gamma_2] : A[\gamma_2]$ whenever $\Gamma, \Gamma_2 \vdash t : A$).

603 For readability, when Γ_1 and Γ_2 are understood we will write Γ_p for Pack $\Gamma_1 \Gamma_2$. 604

Implicitly, whenever we use the notation Pack Γ_1 Γ_2 it means that the two contexts are of the same length and well-formed with the same sorts. We can now state the fundamental lemma.

Lemma 3.4 (Fundamental lemma). Let t_1 and t_2 be two terms. If Γ , $\Gamma_1 \vdash t_1 : T_1$ and Γ , $\Gamma_2 \vdash t_2 : T_2$ and $t_1 \sim t_2$ then there exists p such that Γ , Pack $\Gamma_1 \Gamma_2 \vdash p : t_1[\gamma_1] \xrightarrow{T_1[\gamma_1]} \cong_{T_2[\gamma_2]} t_2[\gamma_2]$.

Proof. The proof is by induction on the derivation of $t_1 \sim t_2$. We show the three most interesting cases:

• VAR

$$x \sim x$$

If *x* belongs to Γ , we apply reflexivity—together with uniqueness of typing (2.2)-to conclude. Otherwise, $\operatorname{Proj}_{e} x$ has the expected type (since $x[\gamma_{1}] \equiv \operatorname{Proj}_{1} x$ and $x[\gamma_2] \equiv \operatorname{Proj}_2 x$).

Application

 t_1

6

$$\frac{\sim t_2}{t_1 \otimes_{x:A_1,B_1} u_1 \sim t_2 \otimes_{x:A_2,B_2} u_2} = \frac{\sim t_1 \otimes_{x:A_1,B_1} u_1 \sim t_2 \otimes_{x:A_2,B_2} u_2}{t_1 \otimes_{x:A_1,B_1} u_1 \sim t_2 \otimes_{x:A_2,B_2} u_2}$$

We have Γ , $\Gamma_1 \vdash t_1 @_{x:A_1.B_1} u_1 : T_1$ and Γ , $\Gamma_2 \vdash t_2 @_{x:A_2.B_2}$ $u_2: T_2$ which means by inversion (2.3) that the subterms are well-typed. We apply the induction hypothesis and then conclude.

TRANSPORTLEFT

$$t_1 \sim t_2$$

$$p_* t_1 \sim t_2$$

We have Γ , $\Gamma_1 \vdash p_* t_1 : T_1$ and Γ , $\Gamma_2 \vdash t_2 : T_2$. By inversion (2.3) we have $\Gamma, \Gamma_1 \vdash p : T'_1 = T_1$ and $\Gamma, \Gamma_1 \vdash t_1 : T'_1$. By induction hypothesis we have *e* such that Γ , $\Gamma_p \vdash e$:

		$A_1 \sqsubset A_2$		

 $t_1[\gamma_1] \cong t_2[\gamma_2]$. From transitivity and symmetry we only need to provide a proof of $t_1[\gamma_1] \cong p[\gamma_1]_* t_1[\gamma_1]$ which is inhabited by $\langle p[\gamma_1]; \text{refl } (p[\gamma_1]_* t_1[\gamma_1]) \rangle_{..}$. The complete proof can be found in Appendix B.

We can also prove that \sim preserves substitution.

Lemma 3.5. If $t_1 \sim t_2$ and $u_1 \sim u_2$ then $t_1[x \leftarrow u_1] \sim$ $t_2[x \leftarrow u_2].$

Proof. We proceed by induction on the derivation of $t_1 \sim$ t_2 .

Translating ETT to ITT

The Translation 4.1

We now define the translations (let us stress the plural here) of an extensional judgment. We extend \Box canonically to contexts ($\Gamma \sqsubset \overline{\Gamma}$ when they bind the same variables and the types are in relation for \Box).

Before defining the translation, we define a set $[\Gamma \vdash_{x} t : A]$ of typing judgments in ITT associated to a typing judgment $\Gamma \vdash_{\mathbf{x}} t : A$ in ETT. The idea is that this set describes all the possible translations that lead to the expected property. When $\overline{\Gamma} \vdash \overline{t} : \overline{A} \in [\Gamma \vdash_x t : A]$, we say that $\overline{\Gamma} \vdash \overline{t} : \overline{A}$ realises $\Gamma \vdash_{\mathsf{x}} t : A$. The translation will be given by showing that this set is inhabited by induction on the derivation.

Definition 4.1 (Characterisation of possible translations).

- For any $\vdash_{x} \Gamma$ we define $\llbracket \vdash_{x} \Gamma \rrbracket$ as a set of valid judgments (in ITT) such that $\vdash \overline{\Gamma} \in \llbracket \vdash_{x} \Gamma \rrbracket$ if and only if $\Gamma \sqsubset \overline{\Gamma}$.
- Similarly, $\overline{\Gamma} \vdash \overline{t} : \overline{A} \in \llbracket \Gamma \vdash_{\mathsf{X}} t : A \rrbracket$ iff $\vdash \overline{\Gamma} \in \llbracket \vdash_{\mathsf{X}} \Gamma \rrbracket$ and $A \sqsubset \overline{A}$ and $t \sqsubset \overline{t}$.

In order to better master the shape of the produced realiser, we state the following lemma which shows that it has the same head type constructor as the type it realises. This is important for instance for the case of an application, where we do not know a priori if the translated function has a dependent product type, which is required to be able to use the typing rule for application.

Lemma 4.2. We can always choose types \overline{T} that have the same head constructor as T.

Proof. Assume we have $\overline{\Gamma} \vdash \overline{t} : \overline{T} \in [\Gamma \vdash_{x} t : T]$. By definition of \sqsubset , $T \sqsubset \overline{T}$ means that \overline{T} is shaped $p_* q_* \dots r_* \overline{T}'$ with \overline{T}' having the same head constructor as T. By inversion (2.3), the subterms are typable, including \overline{T}' . Actually, from inversion, we even get that the type of \overline{T}' is a universe. Then, using lemma 3.4 and lemma 3.3, we get $\overline{\Gamma} \vdash e : \overline{T} = \overline{T}'$. We conclude with $\overline{\Gamma} \vdash e_* \overline{t} : \overline{T}' \in \llbracket \Gamma \vdash_{\mathsf{x}} t : T \rrbracket$.

Finally, in order for the induction to go through, we need to know that when we have a realiser of a derivation $\Gamma \vdash_{x} t : T$, we can pick an arbitrary other type realising $\Gamma \vdash_{x} T$ and still get a new derivation realising $\Gamma \vdash_{x} t : T$ with that type. This is important for instance for the case of an application, where the type of the domain of the translated function may differ from the type of the translated argument. So we need to be able to change it *a posteriori*.

Lemma 4.3. When we have $\overline{\Gamma} \vdash \overline{t} : \overline{T} \in \llbracket \Gamma \vdash_{x} t : T \rrbracket$ and $\overline{\Gamma} \vdash \overline{T}' \in \llbracket \Gamma \vdash_{\mathsf{x}} T \rrbracket$ then we also have $\overline{\Gamma} \vdash \overline{t}' : \overline{T}' \in \llbracket \Gamma \vdash_{\mathsf{x}} t : T \rrbracket$ for some \overline{t}' .

771Proof. By definition we have $T \sqsubset \overline{T}$ and $T \sqsubset \overline{T}'$ and thus772 $T \sim \overline{T}$ and $T \sim \overline{T}'$, implying $\overline{T} \sim \overline{T}'$ by transitivity (3.2). By773lemma 3.4 (in the case $\Gamma_1 \equiv \Gamma_2 \equiv \bullet$) we get $\overline{\Gamma} \vdash p : \overline{T} \cong \overline{T}'$ for774some p. By lemma 3.3 (and lemma 4.2 to give universes as775types to \overline{T} and \overline{T}') we can assume $\overline{\Gamma} \vdash p : \overline{T} \equiv \overline{T}'$. Then $\overline{\Gamma} \vdash$ 776 $p_* \ \overline{t} : \overline{T}'$ is still a translation since \sqsubset ignores transports.

We can now define the translation. This is done by mutual induction on context well-formedness, typing and conversion derivations. Indeed, in order to be able to produce a realiser by induction, we need to show that every conversion in ETT is translated as an heterogeneous equality in ITT.

Theorem 4.4 (Translation).

- If $\vdash_{\mathsf{x}} \Gamma$ then there exists $\vdash \overline{\Gamma} \in \llbracket \vdash_{\mathsf{x}} \Gamma \rrbracket$,
- If $\Gamma \vdash_{\mathsf{x}} t : T$ then for any $\vdash \overline{\Gamma} \in \llbracket \vdash_{\mathsf{x}} \Gamma \rrbracket$ there exist \overline{t} and \overline{T} such that $\overline{\Gamma} \vdash \overline{t} : \overline{T} \in \llbracket \Gamma \vdash_{\mathsf{x}} t : T \rrbracket$,
- If $\Gamma \vdash_{\mathbf{x}} u \equiv v : A$ then for $any \vdash \overline{\Gamma} \in \llbracket \vdash_{\mathbf{x}} \Gamma \rrbracket$ there exist $A \sqsubset \overline{A}, A \sqsubset \overline{A}', u \sqsubset \overline{u}, v \sqsubset \overline{v}$ and \overline{e} such that $\overline{\Gamma} \vdash \overline{e} : \overline{u}_{\overline{A}} \cong_{\overline{A}'} \overline{v}$.

Proof. We prove the theorem by induction on the derivation in the extensional type theory. We only show the two most interesting cases of application and conversion. The complete proof is given in Appendix C.

Application

$$\frac{ \begin{array}{cccc} \Gamma \vdash_{\mathbf{x}} A:s & \Gamma, x: A \vdash_{\mathbf{x}} B:s' \\ \Gamma \vdash_{\mathbf{x}} t: \Pi(x:A). & B & \Gamma \vdash_{\mathbf{x}} u:A \\ \hline \Gamma \vdash_{\mathbf{x}} t @_{x:A.B} u: B[x \leftarrow u] \end{array} }$$

Using IH together with lemmata 4.2 and 4.3 we get $\overline{\Gamma} \vdash \overline{A} : s$ and $\overline{\Gamma}, x : \overline{A} \vdash \overline{B} : s'$ and $\overline{\Gamma} \vdash \overline{t} : \Pi(x : \overline{A}). \overline{B}$ and $\overline{\Gamma} \vdash \overline{u} : \overline{A}$ meaning we can conclude $\overline{\Gamma} \vdash \overline{t} @_{x:\overline{A}.\overline{B}}\overline{u} :$ $\overline{B}[x \leftarrow \overline{u}] \in [\Gamma \vdash_x t @_{x:A.B} u : B[x \leftarrow u]].$

Conversion

$$\frac{\Gamma \vdash_{\mathsf{x}} u : A \qquad \Gamma \vdash_{\mathsf{x}} A \equiv B}{\Gamma \vdash_{\mathsf{x}} u : B}$$

By IH and lemma 3.3 we have $\overline{\Gamma} \vdash \overline{e} : \overline{A} = \overline{B}$ which implies $\overline{\Gamma} \vdash \overline{A} \in [\![\Gamma \vdash_x A]\!]$ by inversion (2.3), thus, from lemma 4.3 and IH we get $\overline{\Gamma} \vdash \overline{u} : \overline{A}$, yielding $\overline{\Gamma} \vdash \overline{e}_* \overline{u} : \overline{B} \in [\![\Gamma \vdash_x u : B]\!]$.

4.2 Meta-theoretical Consequences

We can check that all ETT theorems whose type are typable in ITT have proofs in ITT as well:

Corollary 4.5 (Preservation of ITT). *If* $\vdash_{x} t : T$ and $\vdash T$ then there exist \overline{t} such that $\vdash \overline{t} : T \in [\![\vdash_{x} t : T]\!]$.

Proof. Since $\vdash \bullet \in \llbracket \vdash_{\mathsf{x}} \bullet \rrbracket$, by Theorem (4.4), there exists \overline{t} and \overline{T} such that $\vdash \overline{t} : \overline{T} \in \llbracket \vdash_{\mathsf{x}} t : T \rrbracket$ But as $\vdash T$, we have

Théo Winterhalter, Matthieu Sozeau, and Nicolas Tabareau

 $\vdash T \in \llbracket \vdash_{\mathsf{x}} T \rrbracket$, and, using Lemma 4.3, we obtain $\vdash \overline{t} : T \in \llbracket \vdash_{\mathsf{x}} t : T \rrbracket$.

Corollary 4.6 (Relative consistency). Assuming ITT is consistent, there is no term t such that $\vdash_x t : \Pi(A : \Box_0)$. A.

Proof. Assume such a *t* exists. By the Corollary 4.5, because $\vdash \Pi(A : \Box_0)$. *A*, there exists \overline{t} such that $\vdash \overline{t} : \Pi(A : \Box_0)$. *A* which contradicts the assumed consistency of ITT. \Box

4.3 Optimisations

Up until now, we remained silent about one thing: the size of the translated terms. Indeed, the translated term is a decoration of the initial one by transports which appear in many locations. For example, at each application we use a transport by lemma 4.2 to ensure that the term in function position is given a function type. In most cases—in particular when translating ITT terms—this produces unnecessary transports (often by reflexivity) that we wish to avoid.

In order to limit the size explosion, in the above we use a different version of transport, namely transport' such that

The idea is that we avoid *trivially* unnecessary transports (we do not deal with β -conversion for instance). We extend this technique to the different constructors of equality (symmetry, transitivity, ...) so that they reduce to reflexivity whenever possible. Take transitivity for instance:

transitivity'(refl
$$u, q$$
) = q
transitivity'(p , refl u) = p
transitivity'(p, q) = transitivity(p, q).

We show these *defined terms* enjoy the same typing rules as their counterparts and use them instead. In practice it is enough to recover the exact same term when it is typed in ITT.

5 Formalisation with Template-Coq

We have formalised the translation in the setting of TemplateCoq [Anand et al. 2018] in order to have a more precise proof, but also to evidence the fact that the translation is indeed constructive and can be used to perform computations.

TemplateCoq is a Coq library that has a representation of Coq terms as they are in Coq's kernel (in particular using de Bruijn indices for variables) and a (partial) implementation of the type checking algorithm (not checking guardedness of fixpoints or positivity of inductive types). It comes with a Coq plugin that permits to quote Coq terms into their representations, and to produce Coq terms from their representation (if they indeed denote well-typed terms). We have integrated our formalisation within that framework in order to ensure our presentations of ETT and ITT are close to Coq, but also to take advantage of the quoting mechanism

to produce terms using the interactive mode (in particular
we get to use tactics). Note that we also rely on Mangin
and Sozeau's Equations [Sozeau 2010] plugin to derive nice
dependent induction principles.

885 Our formalisation takes full advantage of its easy interfacing with TemplateCoq: we define two theories, namely ETT 886 887 and ITT, but ITT enjoys a lot of syntactic sugar by having 888 things such as transport, heterogeneous equality and pack-889 ing as part of the syntax. The operations regarding these constructors-in particular the tedious ones-are written in 890 891 Coq and then quoted to finally be *realised* in the translation from ITT to TemplateCoq. 892

893 *Interoperability with TemplateCog.* The translation we 894 define from ITT to TemplateCoq is not proven correct, but 895 it is not really important as it can just be seen as a feature to 896 observe the produced terms in a nicer setting. In any case, 897 TemplateCoq does not yet provide a complete formalisa-898 tion of CIC rules, as guard checking of recursive definitions 899 and strict positivity of inductive type declarations are not 900 formalised yet. 901

We also provide a translation from TemplateCoq to ETT that we will describe more extensively with the examples (5.4).

5.1 Quick Overview of the Formalisation

The file SAst.v contains the definition of the (common) abstract syntax of ETT and ITT in the form of an inductive definition with de Bruijn indices for variables (like in TemplateCoq). Sorts are defined separately in Sorts.v and we will address them later in Section 5.3.

```
911 Inductive sterm : Type :=

| sRel (n : nat)

912 | sSort (s : sort)

913 | sProd (nx : name) (A B : sterm)

| sLambda (nx : name) (A B t : sterm)

914 | sApp (u : sterm) (nx : name) (A B v : sterm)

915 | sEq (A u v : sterm)

916 | (* ... *).
```

902

903

904

905

917

918

919

920

921

The files ITyping.v and XTyping.v define respectively the typing judgments for ITT and ETT, using mutual inductive types. Then, most of the files are focused on the meta-theory of ITT and can be ignored by readers who don't need to see yet another proof of subject reduction.

The most interesting files are obviously those where the fundamental lemma and the translation are formalised: FundamentalLemma.v and Translation.v. For instance, here is the main theorem, as stated in our formalisation:

Herein type_glob Σ refers to the fact that some global context is well-typed, its purpose is detailed in Section 5.2. The fact that the theorem holds in Coq ensures we can actually compute a translated term and type out of a derivation in ETT.

5.2 Inductive Types and Recursion

In the proof of Section 4, we didn't mention anything about inductive types, pattern-matching or recursion as it is a bit technical on paper. In the formalisation, we offer a way to still be able to use them, and we will even show how it works in practice with the examples (5.4).

The main guiding principle is that inductive types and induction are orthogonal to the translation, they should more or less be translated to themselves. To realise that easily, we just treat an inductive definition as a way to introduce new constants in the theory, one for the type, one for each constructor, one for its elimination principle, and one equality per computation rule. For instance, the natural numbers can be represented by having the following constants in the context:

nat	$:\square_0$
0	: nat
S	$: nat \rightarrow nat$
natrec	$: \forall P, P \ 0 \rightarrow (\forall m, P \ m \rightarrow P \ (S \ m)) \rightarrow \forall n, P \ n$
$natrec_0$: $\forall P P_z P_s$, natrec $P P_z P_s 0 = P_z$
natrecs	$: \forall P P_z P_s n,$
	natrec $P P_z P_s$ (S n) = $P_s n$ (natrec $P P_z P_s n$)

Here we rely on the reflection rule to obtain the computational behavior of the eliminator natrec.

This means for instance that we do not consider inductive types that would only make sense in ETT, but we deem this not to be a restriction and to the best of our knowledge isn't something that is usually considered in the literature. With that in mind, our translation features a global context of typed constants with the restriction that the types of those constants should be well-formed in ITT. Those constants are thus used as black boxes inside ETT.

With this we are able to recover what we were missing from Coq, without having to deal with the trouble of proving that the translation doesn't break the guard condition of fixed points, and we are instead relying on a more type-based approach.

5.3 About Universes and Homotopy

The experienced reader might have noticed that our treatment of universes (except perhaps for the absence of cumulativity) was really superficial and the notion of sorts used is rather orthogonal to our main development. This is even more apparent in the formalisation. Indeed, we didn't fix a specific universe hierarchy, but instead specify what properties it should have, in what is reminiscent to a (functional³) PTS formulation.

³Meaning the sort of a sort, and the sort of a product are functions, necessary to the uniqueness of types (2.2).

Conference'17, July 2017, Washington, DC, USA

```
991
       Class Sorts.notion := {
         sort : Type ;
992
          succ : sort -> sort ;
993
         prod sort : sort -> sort -> sort :
          sum_sort : sort -> sort -> sort ;
994
          eq_sort : sort -> sort ;
995
          eq_dec : forall s z : sort, {s = z} + {s \diamond z} ;
         succ_inj : forall s z, succ s = succ z -> s = z

1045

From the notion of sorts, we require functions to get the sort of a sort, the sort of a product from the sorts of its arguments, and (crucially) the sort of an identity type. We also require some measure of decidable equality and injectivity on those.

This allows us to instantiate this by a lot of different no-1002 tions including the one presented earlier in the paper or 1003 even its extension with a universe Prop of propositions (like 1004 1005 CIC [Bertot and Castéran 2004]). We present here two instances that have their own interest. 1006

Type *in* Type. One of the instances we provide is one with 1008 only one universe Type, with the inconsistent typing rule 1009 Type : Type. Although inconsistent, this allows us to inter-1010 face with TemplateCoq, without the-for the time being-1011 very time-consuming universe constraint checking. 1012

Homotopy Type System and Two-Level Type Theory. An-1014 other interesting application (or rather instance) of our for-1015 malisation is a translation from Homotopy Type System 1016 (HTS) [Voevodsky 2013] to Two-Level Type Theory (2TT) [Al-1017 tenkirch et al. 2016; Annenkov et al. 2017]. 1018

HTS and 2TT arise from the incompatibility between UIP-1019 recall it is provable in ETT-and univalence. The idea is 1020 to have two distinct notions of equality in the theory, a 1021 strict one satisfying UIP, and a *fibrant* one corresponding 1022 to the homotopy type theory equality, possibly satisfying 1023 univalence. This actually induces a separation in the types 1024 of the theory: some of them are called *fibrant* and the fibrant 1025 or homotopic equality can only be eliminated on those. HTS 1026 can be seen as an extension of 2TT with reflection on the 1027 strict equality just like ETT is an extension of ITT. 1028

We can recover HTS and 2TT in our setting by taking F_i and U_i as respectively the fibrant and strict universes of those theories (for $i \in \mathbb{N}$), along with the following PTS rules:

 (F_{i}, F_{i+1}) (U_{i}, U_{i+1}) ∈Ax $\in Ax$ $(\mathsf{F}_i, \mathsf{U}_i, \mathsf{U}_{\max(i,i)}) \in \mathsf{R}$ $(\mathsf{F}_i, \mathsf{F}_j, \mathsf{F}_{\max(i,j)}) \in \mathsf{R}$ $(U_i, F_j, U_{\max(i,j)}) \in \mathbb{R}$ $(U_i, U_j, U_{\max(i, j)}) \in \mathbb{R}$

and the fact that the sort of the (strict) identity type on A : s1038 is the *strictified* version of *s*, *i.e.*, U_i for $s = U_i$ or $s = F_i$. In 1039 order to have the fibrant equality, one simply needs to do as 1040 in Section 5.2. 1041

In short, the translation from HTS to 2TT is basically the 1042 same as the one from ETT to ITT we presented in this paper, 1043 and this fact is factorised through our formalisation. 1044

Théo Winterhalter, Matthieu Sozeau, and Nicolas Tabareau

5.4 ETT-flavoured Cog: Examples

In this section we demonstrate how our translation can bring extensionality to the world of Coq in action. The examples can be found in plugin demo.v.

First, a pedestrian approach. We would like to begin by showing how one can write an example step by step before we show how it can be used in practice. For this we use a selfcontained example without any inductive types or recursion, illustrating a very simple case of reflection. The term we want to translate is the following:

$$\lambda A B e x. x : \Pi A B. A = B \rightarrow A \rightarrow B$$

This is, in some sense the identity, relying on the equality e: A = B to convert x: A to x: B. Of course, this definition isn't accepted in Coq because the conversion doesn't hold in ITT

Fail Definition pseudoid (A B : Type) (e : A = B) (x : A) : B := x.

However, we still want to be able to write it in some way, in order to avoid manipulating de Bruijn indices directly. For this, we use a little trick by first defining a Coq axiom to represent an ill-typed term:

Axiom candidate : forall A B (t : A), B.

candidate A B t is a candidate t of type A to inhabit type B. We complete this by adding a notation that is reminiscent to Agda's [Norell 2007] hole mechanism. Notation "'{!' t '!}'" := (candidate _ _ t).

```
We can now write the ETT function within Coq.
```

Definition pseudoid (A B : **Type**) (e : A = B) (x : A) : B := $\{! x !\}$.

We can then quote the term and its type to TemplateCoq thanks to the Quote **Definition** command provided by the plugin.

```
Quote Definition pseudoid_term :=
 ltac:(let t := eval compute in pseudoid in exact t).
Quote Definition pseudoid_type :
 ltac:(let T := type of pseudoid in exact T).
```

The terms that we get are now TemplateCoq terms, representing Coq syntax. We need to put them in ETT, meaning adding the annotations, and also removing the candidate axiom. This is the purpose of the fullquote function that we provide in our formalisation.

Definition pretm_pseudoid :=
Eval lazy in fullquote (2^18) Σ [] pseudoid_term empty empty nomap.
Definition tm_pseudoid :=
Eval lazy in match pretm_pseudoid with
Success t => t
Error _ => sRel 0
end.
<pre>Definition prety_pseudoid := Eval lazy in fullquote (2^18) ∑ [] pseudoid_type empty empty nomap. Definition ty_pseudoid := Eval lazy in match prety_pseudoid with</pre>

tm_pseudoid and ty_pseudoid correspond respectively to the ETT representation of pseudoid and its type. We then produce, using our home-brewed Ltac type-checking tactic, 1101 the corresponding ETT typing derivation (notice the use of 1102 reflection to typecheck). 1103 Lemma type_pseudoid : Σi ;;; [] |-x tm_pseudoid : ty_pseudoid. Proof 1104 unfold tm_pseudoid, ty_pseudoid. 1105 ettcheck. cbn. eapply reflection with (e := sRel 1). 1106 ettcheck. 1107 Defined 1108 We can then translate this derivation, obtain the translated 1109 term and then convert it to TemplateCoq. 1110 **Definition** itt_pseudoid : sterm := 1111 Eval lazy in **let** '(_ ; t ;) ·= 1112 type_translation type_pseudoid istrans_nil in t 1113 1114 **Definition** tc pseudoid : tsl result term := 1115 Eval lazy in tsl_rec (2 ^ 18) Σ [] itt_pseudoid empty.

Once we have it, we *unquote* the term to obtain a Coq term (notice that the only use of reflection has been replaced by a transport).

1120

1121

1138

1140

Making a Plugin with TemplateCoq. All of this work
is pretty systematic. Fortunately for us, TemplateCoq also
features a monad to reify Coq commands which we can use
to program the translation steps. As such we have written a
complete procedure, relying on Coq type checkers we wrote
for ITT and ETT, which can generate equality obligations.

Thanks to this, the user doesn't have to know about the
details of implementation of the translation, and stay within
the Coq ecosystem.

1131 For instance, our previous example now becomes:

```
1132Definition pseudoid (A B : Type) (e : A = B) (x : A) : B := {! x !}.1133Run TemplateProgram (Translate \varepsilon "pseudoid").
```

This produces a Coq term pseudoid' corresponding to the
translation. Notice how the user doesn't even have to provide any proof of equality or derivations of any sort. The
derivation part is handled by our own typechecker while the

obligation part is solved automatically by the Coq obligation
 mechanism.

About inductive types. As we promised, our translation is
able to handle inductive types. For this consider the inductive
type of vectors (or length-indexed lists) below, together with
a simple definition (we will remain in ITT for simplicity).
Inductive vec A : nat -> Type :=
vnil : vec A 0
vcons : A -> forall n, vec A n -> vec A (S n).

```
1147
Arguments vnil {_}.
1148
Arguments vcons {_} _ _ _ .
```

1149
Definition vv := vcons 1 _ vnil.

This time, in order to apply the translation we need to extend the translation context with **nat** and vec. Run TemplateProgram ($\Theta < -$ TranslateConstant ε "nat";;

```
1154 \Theta \leftarrow \text{TranslateConstant } \Theta \text{ "vec"};;
1155
```

Translate Θ "vv"

).

Here, ε is the empty translation context and the command TranslateConstant enriches it with the types the inductives and of their constructors. The translation context then also contains associative tables between our own representation of constants and those of Coq. Unsurprisingly, the translated Coq term is the same as the original term.

Reversal of vectors. Next, we tackle a motivating example: reversal on vectors. Indeed, if you want to implement this operation, the same way you would do it on lists, you end up having a conversion problem:

Fail Definition vrev {A n m} (v : vec A n) (acc : vec A m)	
: vec A (n + m) :=	
<pre>vec_rect A (fun n _ => forall m, vec A m -> vec A (n + m))</pre>	
$(fun m acc \Rightarrow acc)$	
(fun a n _ rv m acc => rv _ (vcons a m acc))	
n v m acc.	

The recursive call returns a vector of length n + S m where the context expects one of length S n + m. In ITT these types are not convertible. This example is thus a perfect fit for ETT where we can use the fact that these two expressions always compute to the same thing when instantiated with concrete numbers.

This generates four obligations that are all solved automatically. One of them contains a proof of S n + m = n + S mwhile the remaining three correspond to the computation rules of addition (as mentionned before, add is simply a constant and does not compute in our representation, hence the need for equalities). The returned term is the following, with only one transport remaining (remember our interpretation map removes unnecessary transports).

5.5 Towards an Interfacing between Andromeda and Coq

Andromeda [Bauer et al. 2016] is a proof assistant implementing ETT in a sense that is really close to our formalisation. Aside from a concise nucleus with a basic type theory, most things happen with the declaration of constants with given 1156

1157

Théo Winterhalter, Matthieu Sozeau, and Nicolas Tabareau

1211 types, including equalities to define the computational behaviour of eliminators for instance. This is essentially what 1212 1213 we do in our formalisation. Furthermore, their theory relies on Type : Type, meaning, our modular handling of universes 1214 1215 can accommodate for this as well.

All in all, it should be possible in the near future to use our 1216 translation to produce Cog terms out of Andromeda devel-1217 1218 opments. Note that this would not suffer from the difficulties 1219 in generating typing derivations since Andromeda does it 1220 for you.

1222 **Composition with other Translations** 5.6

1221

1235

1236

1237

1238

1239

1240

1265

1223 This translation also enables the formalisation of translations 1224 that target ETT rather than ITT and still get mechanised 1225 proofs of (relative) consistency by composition with this ETT 1226 to ITT translation. This could also be used to implement plu-1227 gins based on the composition of translations. In particular, 1228 supposing we have a theory which forms a subset of ETT 1229 and whose conversion is decidable. Using this translation, 1230 we could formalise it as an embedded domain-specific type 1231 theory and provide an automatic translation of well-typed 1232 terms into witnesses in Coq. This would make it possible to 1233 extend conversion with the theory of lists for example. 1234

This would provide a simple way to justify the consistency of CoqMT [Jouannaud and Strub 2017] for example, seeing it as an extensional type theory where reflection is restricted to equalities on a specific domain whose theory is decidable.

Limitations and Axioms 6

Currently, the representation of terms and derivations and 1241 the computational content of the proof only allow us to deal 1242 with the translation of relatively small terms but we hope 1243 to improve that in the future. As we have seen, the actual 1244 translation involves the computational content of lemmata of 1245 inversion, substitution, weakening and equational reasoning 1246 and thus cannot be presented as a simple recursive definition 1247 on derivations. 1248

As we already mentioned, the axioms K and functional 1249 extensionality are both necessary in ITT if we want the trans-1250 lation to be conservative as they are provable in ETT [Hof-1251 mann 1995]. However, one might still be concerned about 1252 having axioms as they can for instance hinder canonicity of 1253 the system. In that respect, K isn't really a restriction since 1254 it preserves canonicity. The best proof of that is probably 1255 Agda itself which natively features K-in fact, one needs 1256 to explicitly deactivate it with a flag if they wish to work 1257 without. 1258

The case of functional extensionality is trickier. It is still 1259 possible to realise the axiom by composing our translation 1260 with a setoid interpretation [Altenkirch 1999] which vali-1261 dates it, or by going into a system featuring it, for instance 1262 by implementing Observational Type Theory [Altenkirch 1263 et al. 2007] like EPIGRAM [McBride 2004]. 1264

Related Works and Conclusion

The seminal works on the precise connection between ETT and ITT go back to Streicher [1993] and Hofmann [1995, 1997]. In particular, the work of Hofmann provides a categorical answer to the question of consistency and conservativity of ETT over ITT with UIP and functional extensionality. Ten years later, Oury [2005, 2006] provided a translation from ETT to ITT with UIP and functional extensionality and other axioms (mainly due to technical difficulties). Although a first step towards a move from categorical semantics to a syntactic translation, his work does not stress any constructive aspect of the proof and shows that there merely exist translations in ITT to a typed term in ETT.

van Doorn et al. [2013] have later proposed and formalised a similar translation between a PTS with and without explicit conversion. This does not entail anything about ETT to ITT but we can find similarities in that there is a witness of conversion between any term and itself under an explicit conversion, which internalises irrelevance of explicit conversions. This morally corresponds to a Uniqueness of Conversions principle.

The Program [Sozeau 2007] extension of Coq performs a related coercion insertion algorithm, between objects in subsets on the same carrier or in different instances of the same inductive family, assuming a proof-irrelevance axiom. Inserting coercions locally is not as general as the present translation from ETT to ITT which can insert transports in any context.

In this paper we provide the first effective translation from ETT to ITT with UIP and functional extensionality. The translation has been formalised in Coq using TemplateCoq, a meta-programming plugin of Coq. This translation is also effective in the sense that we can produce in the end a Coq term using the TemplateCoq denotation machinery. With ongoing work to extend the translation to the inductive fragment of Coq, we are paving the way to an extensional version of the Coq proof assistant which could be translated back to its intensional version, allowing the user to navigate between the two modes, and in the end produce a proof term checkable in the intensional fragment.

B Proof of the fundamental lemma

such that Γ , Pack $\Gamma_1 \Gamma_2 \vdash p : t_1[\gamma_1] \xrightarrow{T_1[\gamma_1]} \cong_{T_2[\gamma_2]} t_2[\gamma_2]$.

Proof. We prove it by induction on the derivation of $t_1 \sim t_2$.

expected type (since $x[\gamma_1] \equiv \operatorname{Proj}_1 x$ and $x[\gamma_2] \equiv \operatorname{Proj}_2 x$).

a proof of $t_1 \mid \cong p \mid_* t_1 \mid$ which is inhabited by $\langle p \mid$; refl $(p \mid_* t_1 \mid) \rangle$.

If x belongs to Γ , we apply reflexivity-together with uniqueness of typing (2.2)-to conclude. Otherwise, $\operatorname{Proj}_{e} x$ has the We have $\Gamma, \Gamma_1 \vdash p_* t_1 : T_1$ and $\Gamma, \Gamma_2 \vdash t_2 : T_2$. By inversion (2.3) we have $\Gamma, \Gamma_1 \vdash p : T'_1 = T_1$ and $\Gamma, \Gamma_1 \vdash t_1 : T'_1$. Then by induction hypothesis we have *e* such that $\Gamma, \Gamma_p \vdash e : t_1 \uparrow \cong t_2 \upharpoonright$. From transitivity and symmetry we only need to provide We have $\Gamma, \Gamma_1 \vdash \Pi(x : A_1)$. $B_1 : T_1$ and $\Gamma, \Gamma_2 \vdash \Pi(x : A_2)$. $B_2 : T_2$ so by inversion (2.3) we have $\Gamma, \Gamma_1 \vdash A_1 : s_1$ and $\Gamma, \Gamma_1, x : A_1 \vdash B_1 : s_1' \text{ and } \Gamma, \Gamma_1 \vdash s_1'' \equiv T_1 \text{ for } (s_1, s_1', s_1'') \in \mathbb{R}$ (and similarly with 2s). By induction hypothesis we have $\Gamma, \Gamma_{p} \vdash p_{A} : A_{1} \upharpoonright \cong A_{2} \upharpoonright \text{ and } \Gamma, \Gamma_{p}, x : \text{Pack } A_{1} \land A_{2} \vdash p_{B} : B_{1} \upharpoonright \cong B_{2} \upharpoonright \text{ hence the result (using UIP and functional functi$ extensionality, refer to the formalisation and especially to the file Quotes.v for more details on how to realise this

This one holds by reflexivity and uniqueness of typing (2.2) (indeed, $s \mid \equiv s$ and $s \mid \equiv s$). • LAMBDA

$$\underline{A_1 \sim A_2} \qquad \underline{B_1 \sim B_2} \qquad \underline{t_1 \sim t_2}$$

2s). By induction hypothesis we thus have Γ , $\Gamma_p \vdash p_A : A_1 \cong A_2$

$$\lambda(x:A_1).B_1.t_1 \sim \lambda(x:A_2).B_2.t_2$$

We have Γ , $\Gamma_1 \vdash \lambda(x : A_1) \cdot B_1 \cdot t_1 : T_1$ and Γ , $\Gamma_2 \vdash \lambda(x : A_2) \cdot B_2 \cdot t_2 : T_2$, thus, by inversion 2.3 the subterms are well-typed and we can apply induction hypothesis. The conclusion follows similarly to the Π case.

Application

 $\frac{t_1 \sim t_2 \quad A_1 \sim A_2 \quad B_1 \sim B_2 \quad u_1 \sim u_2}{t_1 @_{x:A_1.B_1} u_1 \sim t_2 @_{x:A_2.B_2} u_2}$

We have Γ , $\Gamma_1 \vdash t_1 \otimes_{x:A_1,B_1} u_1 : T_1$ and Γ , $\Gamma_2 \vdash t_2 \otimes_{x:A_2,B_2} u_2 : T_2$ which means by inversion (2.3) that the subterms are well-typed. We apply the induction hypothesis and then conclude.

 $s \sim s$

Lemma B.1 (Fundamental lemma). Let t_1 and t_2 be two terms. If Γ , $\Gamma_1 \vdash t_1 : T_1$ and Γ , $\Gamma_2 \vdash t_2 : T_2$ and $t_1 \sim t_2$ then there exists p

 $x \sim x$

 $\frac{t_1 \sim t_2}{p_* t_1 \sim t_2}$

 $\frac{t_1 \sim t_2}{t_1 \sim p_* t_2}$

 $\frac{A_1 \sim A_2 \qquad B_1 \sim B_2}{\Pi(x:A_1). \ B_1 \sim \Pi(x:A_2). \ B_2}$

For readability we will abbreviate the left and right substitutions $[\gamma_1]$ and $[\gamma_2]$ by \uparrow and \restriction respectively.

 $A_1 \sim A_2$ $u_1 \sim u_2$

$$\overline{\operatorname{refl}_{A_1} u_1 \sim \operatorname{refl}_{A_2} u_2}$$
1708

We have $\Gamma, \Gamma_1 \vdash \operatorname{refl}_{A_1} u_1 : T_1 \text{ and } \Gamma, \Gamma_2 \vdash \operatorname{refl}_{A_2} u_2 : T_2 \text{ so by inversion (2.3) we have } \Gamma, \Gamma_1 \vdash A_1 : s_1 \text{ and } \Gamma, \Gamma_1 \vdash u_1 : S_1 \to T_1 : s_1 \text{ and } \Gamma, \Gamma_1 \vdash u_1 : S_1 \to T_1 : s_1 \text{ and } \Gamma, \Gamma_1 \vdash u_1 : S_1 \to T_1 : s_1 \text{ and } \Gamma, \Gamma_1 \vdash u_1 : S_1 \to T_1 : s_1 \text{ and } \Gamma, \Gamma_1 \vdash u_1 : S_1 \to T_1 :$ (same with 2s). By IH we have $A_1 \upharpoonright \cong A_2 \upharpoonright$ and $u_1 \upharpoonright_{A_1 \upharpoonright} \cong_{A_2 \upharpoonright} u_2 \upharpoonright$. The proof follows easily. • FUNEXT

$$\frac{A_1 \sim A_2 \qquad B_1 \sim B_2 \qquad f_1 \sim f_2 \qquad g_1 \sim g_2 \qquad e_1 \sim e_2}{\mathsf{funext}(x:A_1, B_1, f_1, g_1, e_1) \sim \mathsf{funext}(x:A_2, B_2, f_2, g_2, e_2)}$$

Similar.

• J

$$\frac{A_1 \sim A_2 \qquad u_1 \sim u_2 \qquad P_1 \sim P_2 \qquad w_1 \sim w_2 \qquad v_1 \sim v_2 \qquad p_1 \sim p_2}{\mathsf{J}(A_1, u_1, x.e.P_1, w_1, v_1, p_1) \sim \mathsf{J}(A_2, u_2, x.e.P_2, w_2, v_2, p_2)}$$

Similar.

Correctness of the translation С

Theorem C.1 (Translation).

- If $\vdash_{\mathbf{x}} \Gamma$ then there exists $\vdash \overline{\Gamma} \in \llbracket \vdash_{\mathbf{x}} \Gamma \rrbracket$,
- If $\Gamma \vdash_{\mathsf{x}} t : T$ then for any $\vdash \overline{\Gamma} \in \llbracket \vdash_{\mathsf{x}} \Gamma \rrbracket$ there exist \overline{t} and \overline{T} such that $\overline{\Gamma} \vdash \overline{t} : \overline{T} \in \llbracket \Gamma \vdash_{\mathsf{x}} t : T \rrbracket$,
- If $\Gamma \vdash_{\mathsf{x}} u \equiv v : A$ then for $any \vdash \overline{\Gamma} \in \llbracket \vdash_{\mathsf{x}} \Gamma \rrbracket$ there exist $A \sqsubset \overline{A}, A \sqsubset \overline{A}', u \sqsubset \overline{u}, v \sqsubset \overline{v}$ and \overline{e} such that $\overline{\Gamma} \vdash \overline{e} : \overline{u} = \overline{u} = \overline{u} = \overline{u} = \overline{u} = \overline{u}$.

Proof. We prove the theorem by induction on the derivation in the extensional type theory. In most cases we need to assume some $\overline{\Gamma}$, translation of the context, we will implicitly refer to $\overline{\Gamma}$ in such cases as the one given as hypothesis.

Емрту

We	have	F	•	\in	[[⊦ _x	•]].
-						

• Extend

$$\frac{\vdash_{\mathsf{x}} \Gamma}{\vdash_{\mathsf{x}} \Gamma, x : A} (x \notin \Gamma)$$

By IH we have $\vdash \overline{\Gamma} \in \llbracket \vdash_x \Gamma \rrbracket$ and, using $\overline{\Gamma}$ as well as lemma 4.2, $\overline{\Gamma} \vdash \overline{A} : s \in \llbracket \Gamma \vdash_x A : s \rrbracket$. Thus $\vdash \overline{\Gamma}, x : \overline{A} \in \llbracket \vdash_x \Gamma, x : A \rrbracket$. • Sort

$$\frac{\vdash_{\mathsf{x}} \Gamma}{\Gamma \vdash_{\mathsf{x}} s: s'}(s, s')$$

We have $\overline{\Gamma} \vdash s : s' \in \llbracket \Gamma \vdash_x s : s' \rrbracket$.

• Product

$$\frac{\Gamma \vdash_{\mathsf{x}} A: s \qquad \Gamma, x: A \vdash_{\mathsf{x}} B: s'}{\Gamma \vdash_{\mathsf{x}} \Pi(x:A). \ B: s''}(s, s', s'')$$

By IH and lemma 4.2 we have $\overline{\Gamma} \vdash \overline{A}$: *s*, meaning $\vdash \overline{\Gamma}, x : \overline{A} \in [\![\vdash_x \Gamma, x : A]\!]$, and then $\overline{\Gamma}, x : \overline{A} \vdash \overline{B} : s'$. We thus conclude $\overline{\Gamma} \vdash \Pi(x:\overline{A}). \ \overline{B}: s'' \in \llbracket \Gamma \vdash_{\mathsf{x}} \Pi(x:A). \ B: s'' \rrbracket.$

• SIGMA

$$\frac{\Gamma \vdash_{\mathbf{x}} A: s \qquad \Gamma, x: A \vdash_{\mathbf{x}} B: s'}{\Gamma \vdash_{\mathbf{x}} \Sigma(x:A). B: s''}(s, s', s'')$$

Similar.

• EOUALITY

 $\frac{\Gamma \vdash_{\mathsf{X}} A: s \qquad \Gamma \vdash_{\mathsf{X}} u: A \qquad \Gamma \vdash_{\mathsf{X}} \upsilon: A}{\Gamma \vdash_{\mathsf{X}} u =_{A} \upsilon: s}$ By IH and lemma 4.2 we have $\overline{\Gamma} \vdash \overline{A}$: s, and—using lemma 4.3—we also have $\overline{\Gamma} \vdash \overline{u}$: \overline{A} and $\overline{\Gamma} \vdash \overline{v}$: \overline{A} . Then $\overline{\Gamma} \vdash \overline{u} =_{\overline{A}} \overline{\upsilon} : s \in \llbracket \Gamma \vdash_{\mathsf{x}} u =_{A} \upsilon : s \rrbracket.$ • VARIABLE $\frac{\vdash_{\mathsf{x}} \Gamma \quad (x:A) \in \Gamma}{\Gamma \vdash_{\mathsf{x}} x:A}$ We have $\vdash \overline{\Gamma} \in \llbracket \vdash_{X} \Gamma \rrbracket$ (as we assumed, this is not an instance of the induction hypothesis) and $(x : A) \in \Gamma$. By definition of $\Gamma \sqsubset \overline{\Gamma}$ we also have some $(x : \overline{A}) \in \overline{\Gamma}$ with $A \sqsubset \overline{A}$, thus $\overline{\Gamma} \vdash x : \overline{A} \in [\![\Gamma \vdash_x x : A]\!]$. CONVERSION $\frac{\Gamma \vdash_{\mathsf{x}} u : A \qquad \Gamma \vdash_{\mathsf{x}} A \equiv B}{\Gamma \vdash_{\mathsf{x}} u : B}$ By IH and lemma 3.3 we have $\overline{\Gamma} \vdash \overline{e} : \overline{A} = \overline{B}$ which implies $\overline{\Gamma} \vdash \overline{A} \in [\Gamma \vdash_x A]$ by inversion (2.3), thus, from lemma 4.3 and IH we get $\overline{\Gamma} \vdash \overline{u} : \overline{A}$, yielding $\overline{\Gamma} \vdash \overline{e}_* \overline{u} : \overline{B} \in [\![\Gamma \vdash_x u : B]\!]$. • LAMBDA $\Gamma \vdash_{\mathsf{x}} A$: By IH and lemma 4.2 we have the second hypothesis to get $\llbracket \Gamma, x : A \vdash_{\mathsf{x}} t : B \rrbracket$. All of this y • Application $\Gamma \vdash_{\mathsf{x}}$ Using IH together with lemmata 4.2 and 4.3 we get $\overline{\Gamma} \vdash \overline{A} : s$ and $\overline{\Gamma}, x : \overline{A} \vdash \overline{B} : s'$ and $\overline{\Gamma} \vdash \overline{t} : \Pi(x : \overline{A})$. \overline{B} and $\overline{\Gamma} \vdash \overline{u} : \overline{A}$ meaning we can conclude $\overline{\Gamma} \vdash \overline{t} @_{x:\overline{A}.\overline{B}} \overline{u} : \overline{B}[x \leftarrow \overline{u}] \in [\![\Gamma \vdash_{\mathsf{x}} t @_{x:A.B} u : B[x \leftarrow u]]\!].$ PAIR Г $-_{\mathbf{x}} \langle u; v \rangle_{x:A.B} : \Sigma(x:A).$ $\langle u; v \rangle_{x:A,B} : \Sigma(x:A).B$. • $PROJ_1$ Similar. • Proj₂ $\overline{\Gamma \vdash_{\mathsf{x}} \pi_2^{x:A.B} p: B[x \leftarrow \pi_1^{x:A.B} p]}$ Similar. • Reflexivity $\frac{\Gamma \vdash_{\mathsf{x}} A: s \qquad \Gamma \vdash_{\mathsf{x}} u: A}{\Gamma \vdash_{\mathsf{x}} \mathsf{refl}_A u: u =_A u}$ By IH we have $\overline{\Gamma} \vdash \overline{u} : \overline{A}$ and thus $\overline{\Gamma} \vdash \operatorname{refl}_{\overline{A}} \overline{u} : \overline{u} =_{\overline{A}} \overline{u} \in [\![\Gamma \vdash_{\mathsf{x}} \operatorname{refl}_{A} u : u =_{A} u]\!]$. • J $\Gamma, x : A, e : u =_A x \vdash_x P : s' \qquad \Gamma \vdash_x p : u =_A v \qquad \Gamma \vdash_x w : P[x \leftarrow u, e \leftarrow \operatorname{refl}_A u]$ $\Gamma \vdash_{\mathsf{x}} A : s \qquad \Gamma \vdash_{\mathsf{x}} u, \upsilon : A$ $\Gamma \vdash_{\mathsf{x}} J(A, u, x.e.P, w, v, p) : P[x \leftarrow v, e \leftarrow p]$ By IH and lemma 4.2 we have $\overline{\Gamma} \vdash \overline{A}$: s. From this and IH and lemma 4.3 we have $\overline{\Gamma} \vdash \overline{u}, \overline{v} : \overline{A}$. We can thus deduce $\vdash \overline{\Gamma}, x : \overline{A}, e : \overline{u} =_{\overline{A}} x \in [\![\Gamma, x : A, e : u =_A x]\!]$ which in turn gives us $\overline{\Gamma}, x : \overline{A}, e : \overline{u} =_{\overline{A}} x \vdash \overline{P} : s'$. Similarly we

By III we have
$$\overline{\Gamma} \vdash \overline{\alpha} \vdash \overline{A}$$
 and thus $\overline{\Gamma} \vdash ref \vdash \overline{\alpha}$.

$$\vdash_{\mathbf{x}} u : A \qquad \Gamma \vdash_{\mathbf{x}} A : s \qquad \Gamma, x : A \vdash_{\mathbf{x}} B : s' \qquad \Gamma \vdash_{\mathbf{x}} v : B[x \leftarrow u]$$
$$\Gamma \vdash_{\mathbf{x}} \langle u; v \rangle_{x \in A} B : \Sigma(x : A). B$$

Using IH with lemmata 4.2 and 4.3 we translate all the hypotheses to conclude $\overline{\Gamma} \vdash \langle \overline{u}; \overline{v} \rangle_{x:\overline{A}|\overline{B}|} : \Sigma(x:\overline{A}), \overline{B} \in [\Gamma \vdash_x \overline{A}]$

$$\Gamma \vdash_{\mathsf{x}} p : \Sigma(x : A). B$$

$$\Gamma \vdash_{\mathbf{x}} p : \Sigma(x : A). B$$

$$\Gamma \vdash_{\mathbf{x}} p : \Sigma(x:A).B$$

$$\Gamma \vdash_{\mathsf{x}} p : \Sigma(x : A). B$$

$$\frac{\Gamma \vdash_{\mathsf{x}} p : \Sigma(x:A).B}{\Gamma \vdash_{\mathsf{x}} \pi_1^{x:A.B} p:A}$$

[]

Conv-Trans	111 and symmetry 01 = .
CONV-1 KANS	$\Gamma \vdash_{x} u \equiv v : A \qquad \Gamma \vdash_{x} v \equiv w : A$
	$\frac{\Gamma \vdash_{x} u \equiv \upsilon : A \qquad \Gamma \vdash_{x} \upsilon \equiv w : A}{\Gamma \vdash_{x} u \equiv w : A}$
We conclude from	n IH and transitivity of \cong .
Conv-Conv	1111 and transitivity 01 =.
	$\Gamma \vdash_{x} t_1 \equiv t_2 : T_1 \qquad \Gamma \vdash_{x} T_1 \equiv T_2$
	$\frac{\Gamma \vdash_{x} t_1 \equiv t_2 : T_1 \qquad \Gamma \vdash_{x} T_1 \equiv T_2}{\Gamma \vdash_{x} t_1 \equiv t_2 : T_2}$
By IH (and lemma	a 3.3) we have $\overline{\Gamma} \vdash \overline{e} : \overline{t}_1 \ \overline{T_1} \cong_{\overline{T}'_1} \overline{t}_2$ and $\overline{\Gamma} \vdash p : \overline{T}''_1 = \overline{T}_2$. Also from lemmata 3.4 and 3.3 we have $\overline{T}'_1 = \overline{T}_2$
and $\overline{T}_1 = \overline{T}_1^{\prime\prime}$, mea	aning we get $\overline{T}'_1 = \overline{T}_2$ and $\overline{T}_1 = \overline{T}_2$. This allows us to conclude by transporting along the aforemention
equalities.	
Conv-Prod	
	$\frac{\Gamma \vdash_{x} A_1 \equiv A_2 : s \qquad \Gamma, x : A_1 \vdash_{x} B_1 \equiv B_2 : s'}{\Gamma \vdash_{x} \Pi(x : A_1). \ B_1 \equiv \Pi(x : A_2). \ B_2 : s''}(s, s', s'')$
	$\overline{\Gamma} \vdash_{\mathbf{x}} \Pi(x:A_1). \ B_1 \equiv \Pi(x:A_2). \ B_2: s'' $
We conclude exa	ctly like we did in the proof of lemma 3.4.
	hold like in proof of lemma 3.4.

1981	• Conv-Eq	2036
1982	$\Gamma \vdash_{x} e : u =_A v$	2037
1983	$\frac{\Gamma \vdash_{x} e : u =_A v}{\Gamma \vdash_{x} u \equiv v : A}$	2038
1984		2039
1985	By IH and lemma 4.2 we have $\overline{\Gamma} \vdash \overline{e} : \overline{u} =_{\overline{A}} \overline{v} \in \llbracket \Gamma \vdash_{x} e : u =_{A} v \rrbracket$ which yields the conclusion we wanted.	2040
