HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

BACKGROUND

- The *Colletotrichum acutatum* species complex (CAsc) includes about 31 species that infect a wide diversity of crop plants worldwide.
- *Colletotrichum lupini* is a species within the CAsc, specific to his host. It is a major threat on Lupin (*Lupinus spp.*). On the contrary, *C. fioriniae*, which is also in the CAsc and can infect a wide host range.
- In addition to its economic impact, *C. lupini* is a useful model to study host speciation process.
- The aim of the project is to gain an understanding in the molecular factors involved in pathogenicity and the genomic signature associated with host specificity in plant pathogenic fungi.

HOST SPECIFICITY

Germinated seeds inoculation by soaking (Unwounded)

Stem inoculation by injection (Wounded)

Inoculum preparation (1x10⁷ spores/mL)

SYNTENY AND SPECIES SPECIFIC REGIONS

- Comparing full genome alignments of the *C. lupini* genomes and other *Colletotrichum* spp. we were able to identify ***C. lupini* specific regions (SSR)**
- One single region (SSR1) of 0.4 Mb **does not show any similarity** with any other genomes analyzed and is present in all *C. lupini* genomes analyzed
- SSR1 harbors **28 putative genes** of which: 9 do not have any similarity with known proteins in public databases and 10 have been predicted to form a PKS/NRPS Hybrid Gene Cluster
- Those genes will be used to investigate their role in ***C. lupini* pathogenicity**

ONGOING ANALYSIS

RESULTS AND CONCLUSION

Pathogenicity tests were developed, focusing on the inoculum concentration, inoculation methods and symptom scoring to study the interaction.

Preliminary tests of infection reveal that *C. lupini* produces symptoms in both infection methods (i.e. with and without wound). On the contrary, *C. fioriniae* did not produce symptoms on unwounded plants.

We could suppose that *C. lupini* host specificity relies on the early stage of infection during the entry of the fungi through plant epidermis.

The genome sequences enabled to identify specific regions of *C. lupini* that might be involved in the ability of this species to infect Lupin plants.

The coming methodological approach will contribute to identify pathogenicity factors and host specificity mechanisms.
