# Performance Enhancement of Extended AFDX via Bandwidth Reservation for TSN/BLS Shapers

A. FINZI, A. MIFDAOUI, F. FRANCES and E. LOCHIN  
University of Toulouse-ISAE, France

**Abstract**—To support mixed-criticality applications, the AFDX may integrate multiple traffic classes: Safety-Critical Traffic (SCT) with hard real-time constraints, Rate-Constrained (RC) traffic requiring bounded latencies and Best Effort (BE) traffic with no delivery constraints. These traffic classes are managed based on a Non-Preemptive Strict Priority (NP-SP) Scheduler, where the highest priority traffic (SCT) is shaped with a Burst Limiting Shaper (BLS). The latter has been defined by the Time Sensitive Networking (TSN) task group to limit the impact of high priority flows on lower priority ones. This paper proposes two bandwidth reservation methods for BLS shapers in AFDX networks. The proposed methods are evaluated on a realistic AFDX configuration. Results show their efficiency to noticeably enhance the RC delay bounds and the SCT schedulability, in comparison to an intuitive method.

**Index Terms**—TSN, BLS, bandwidth reservation, optimization, AFDX, mixed-criticality, avionics.

## I. INTRODUCTION

With the maturity and reliability progress of the AFDX after a decade of successful use, a homogeneous avionic communication architecture based on such a technology to interconnect different avionics domains may bring significant advantages, such as easier installation and maintenance and reduced weight and costs. This homogeneous communication architecture, based on the AFDX technology, needs to support mixed-criticality applications, where safety-critical and best effort traffic co-exist. Hence, in addition to the current AFDX traffic profile, called Rate Constrained (RC) traffic, at least two extra profiles have to be handled. The first, denoted by Safety-Critical Traffic (SCT), is specified to support flows with hard real-time constraints and the highest criticality, e.g., flight control data; whereas the second is for Best-Effort (BE) flows with no delivery constraint and the lowest criticality, e.g., In-Flight Entertainment traffic.

To cope with this emerging issue, in [3], we have assessed the most relevant existing solutions enabling mixed-criticality on the AFDX vs avionics requirements. The Burst-Limiting Shaper (BLS) [5] (defined in the Time Sensitive Networking (TSN) task group [6]) on top of Non-Preemptive Strict-Priority (NP-SP) scheduler has been selected as the most promising solution favoring the main avionics requirements. Preliminary performance evaluation of such a solution, denoted extended AFDX, has been provided based on simulations. The first results were encouraging to pursue this line through providing formal timing analysis to prove certification requirements, a key point in avionics. Afterwards, in [4], we have introduced a Network Calculus-based approach to compute the delay

bounds of SCT and RC classes in such an extended AFDX network, taking into account the impact of the TSN/BLS. The performance evaluation of our proposal on a realistic AFDX configuration has highlighted its efficiency, in comparison with the current AFDX (implementing only NP-SP scheduler).

In this paper, our aim is to provide optimized bandwidth reservation methods with different complexity levels for the TSN/BLS shapers, to enhance as much as possible the schedulability and the delay bounds of the different traffic classes. These methods are based on an extension of the timing analysis introduced in [4] to cover multi-hop communication. We perform a set of experiments to assess the efficiency of our introduced methods, with reference to an intuitive bandwidth reservation method. Similar works have been conducted to define bandwidth reservation methods for Credit Based Shaper (CBS) of AVB networks [2], [1]. However, to the best of our knowledge, this issue has not been handled yet in the literature for TSN/BLS shapers in avionics domain.

The rest of the paper is organized as follows. Section II introduces the system model. Section III details two optimized bandwidth reservation methods with different complexity levels for TSN/ BLS shapers. Section IV evaluates the proposed methods on a realistic avionic configuration to assess their efficiency. Finally, Section VI concludes the paper.

## II. SYSTEM MODEL AND ASSUMPTIONS

In this section, we first describe the extended AFDX switch model. Then, we detail the BLS behavior and its main parameters. Finally, we present the considered schedulability condition and traffic model.

### A. The extended AFDX Switch

The aim of extending the AFDX switch architecture with the TSN/BLS is to handle mixed criticality data, and more specifically three AFDX traffic profiles, as illustrated in Fig. 1: (i) the SCT with its priority set by the BLS and the tightest temporal deadline, e.g., Flight-control flows; (ii) the RC with the medium priority and a deadline constraint to guarantee, e.g., current AFDX flows; (iii) the BE with the lowest priority and no time constraint, e.g., In-Flight Entertainment.

In Fig. 1, we illustrate the architecture of the extended AFDX switch. It consists of: (i) store and forward input ports to verify each frame correctness before sending it to the corresponding output port; (ii) a static configuration table to forward the received frames to the correct output port(s) based on their VL identifier; (iii) the output ports with three

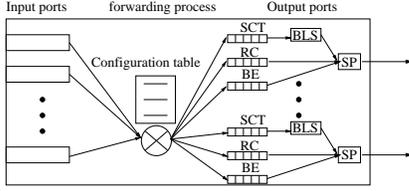

Fig. 1: An extended AFDX switch architecture

priority queues multiplexed with a NP-SP scheduler, and the highest one is shaped with the BLS.

### B. BLS Shaper

The BLS belongs to the credit-based shapers class and it is generally used on top of Non-Preemptive Static Priority (NP-SP) scheduler. It has been defined in [5] by an upper threshold  $L_M$ , a lower threshold  $L_R$ , such as  $0 \leq L_R < L_M$ , and a reserved bandwidth  $BW$ . Additionally, the BLS is characterized by: (i) a decreasing rate  $I_{idle} = BW \cdot C$ , where  $C$  is the link speed and  $BW$  is the percentage of bandwidth reserved for BLS frames; (ii) an increasing rate  $I_{send} = C - I_{idle}$ . Finally, priority of a queue  $q$  shaped by BLS, denoted  $p(q)$ , can vary between a high and a low value (with 0 the highest), denoted  $p_H$  and  $p_L$ .

The behavior of the BLS is illustrated in Fig. 2 for two arrival scenarios. As shown, the credit is always between 0 and  $L_M$  and varies as follows:

- (i) initially, the credit counter starts at 0 and the priority of the shaped queue is high;
- (ii) the main feature of the BLS is the change of priority  $p(k)$  of the shaped queue, which occurs in two contexts: 1) if  $p(k)$  is high and credit reaches  $L_M$ ; 2) if  $p(k)$  is low and credit reaches  $L_R$ ;
- (iii) when a frame is transmitted, the credit increases (is consumed) with a rate of  $I_{send}$ , else the credit decreases (is gained) with a rate of  $I_{idle}$ ;
- (iv) when the credit reaches  $L_M$ , it stays at this level until the end of the transmission of the current frame (if any);
- (v) when the credit reaches 0 it stays at this level until the end of the transmission of the current frame (if any). The credit remains at 0 until a new BLS frame is transmitted.

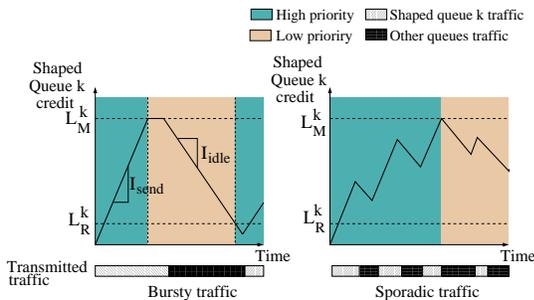

Fig. 2: BLS credit evolution

### C. Schedulability Condition and Traffic Model

First, we define a sufficient schedulability condition for SCT and RC classes, which consists in verifying that the end-to-end delay bound of each traffic flow is lower than its deadline.

The end-to-end delay expression of a flow  $f$  in the class  $j \in \{SCT, RC\}$ ,  $EED_{j,f}$ , along its path  $path_f$  is as follows:

$$EED_{j,f} = d_j^{es} + d_{prop} + \sum_{i \in path_f} d_{j,f}^{sw,i} \quad (1)$$

With  $d_j^{es}$  the delay within the end-system ( $es$ ) to transmit the aggregate traffic of class  $j$  and  $d_{prop}$  the propagation delay along the path, which is generally negligible in an avionics network. The last delay  $d_{j,f}^{sw,i}$  represents the delay within the  $i^{th}$  switch ( $sw$ ) along the flow path and it consists of several parts: (i) the store and forward delay at the input port, equal to the transmission time of a maximum-sized frame; (ii) the technological latency due to the switching process, upper-bounded by  $1\mu s$ ; (iii) the delay of the output port multiplexer ( $mux$ ) due to the BLS ( $bls$ ) and NP-SP ( $sp$ ) scheduler. To enable the computation of upper bounds on these delays, the different parts of the network, and more particularly the BLS have been modeled in terms of service curves [4], where  $\beta_j^n$  is the service guaranteed for traffic class  $j$  in node  $n \in \{es, sw\}$  or a component  $n \in \{bls, sp\}$ .

Secondly, each traffic flow  $f$  of class  $j \in \{SCT, RC, BE\}$ , generated by an end-system, is characterized by  $(BAG_f, MFS_f, Dl_f, J_f)$  for respectively the minimum inter-arrival time, the maximum frame size integrating the protocol overhead, the deadline if any (generally equal to  $BAG_f$  unless explicitly specified and infinite for BE) and the jitter.

The arrival curve of each flow  $f$  in class  $j$  at the input of the  $i^{th}$  node  $n \in \{es, sw\}$  or a component  $n \in \{bls, sp\}$  along its path is modeled as a leaky-bucket curve with a burst  $b_{j,f}^{n,i}$  and a rate  $r_f$ :

$$\alpha_{j,f}^{n,i}(t) = b_{j,f}^{n,i} + r_f \cdot t$$

For instance, the input arrival curve of flow  $f$  in class  $j$  at the end-system is:  $\alpha_{j,f}^{es}(t) = MFS_f + \frac{MFS_f}{BAG_f} \cdot (t + J_f)$ .

Therefore, the arrival curve of the aggregate traffic in class  $j$  at the input of the  $i^{th}$  node  $n \in \{es, sw\}$  or a component  $n \in \{bls, sp\}$  is:  $\alpha_j^{n,i}(t) = \sum_{f \in j} \alpha_{j,f}^{n,i}(t)$ . For instance,

$$\alpha_j^{es}(t) = b_j + r_j t \quad \text{with} \quad \begin{cases} b_j = \sum_{f \in j} MFS_f + \frac{MFS_f}{BAG_f} J_f \\ r_j = \sum_{f \in j} \frac{MFS_f}{BAG_f} \end{cases}$$

## III. BANDWIDTH RESERVATION METHODS

In this section, we first describe the optimization problem associated to the bandwidth reservation problem of the BLS shapers. Afterwards, we detail the two proposed methods to solve such a problem: Heuristic Deadline and Dichotomous Deadline methods.

### A. Problem formulation

The aim is to find reserved BLS bandwidth within each multiplexer  $mux$  along the path of each flow  $f \in RC$ , minimizing the end-to-end delay bound of RC flow  $f$ , while fulfilling the following constraints:

- 1) the **class rate constraint**, stating that in each output port  $mux$ , the input rate of an aggregate traffic of class

- $j$  must be lower than the minimum guaranteed service rate, denoted  $R_j^{mux}$ ;
- 2) the **aggregate rate constraint**, stating that the load of an output port multiplexer is lower than the output link capacity  $C$ ;
  - 3) the **deadline constraint**, stating that the end-to-end delay bound of a flow  $f$  in class  $j$  ( $EED_{j,f}$ ) must be lower than its deadline  $Dl_f$ .

Consider  $F_j^{mux}$  the set of flows of a class  $j$  in an output port multiplexer  $mux$ , the optimisation problem can be formulated as follows:

$$\begin{aligned} & \forall f \in RC, \forall mux \in path_f, \\ & \underset{L_M^{mux}, L_R^{mux}, BW^{mux}}{\text{minimize}} EED_{RC,f}(L_M^{mux}, L_R^{mux}, BW^{mux}) \\ & \text{s.t. } \forall f \text{ in } j \in \{SCT, RC\}, \forall mux \in path_f : \\ & R_j^{mux} \geq \sum_{f \in F_j^{mux}} r_f \\ & \sum_{g \in F_{SCT}^{mux}} r_g + \sum_{f \in F_{RC}^{mux}} r_f \leq C \\ & Dl_f \geq EED_{j,f}(L_M^{mux}, L_R^{mux}, BW^{mux}) \end{aligned}$$

If we consider testing  $N$  values for each BLS parameter  $(L_M^{mux}, L_R^{mux}, BW^{mux})$  within  $m$  output ports for  $l$  flows, then we have a complexity of  $O(l^m \cdot N^{3 \cdot m})$  for the whole network. In order to drastically reduce such a complexity, we will minimize the delay bound for the aggregate traffic in RC class within each output port, instead of conducting one minimisation per-path per-flow; thus reducing the complexity down to  $O(m \cdot N^3)$ .

Hence, we define a local deadline (resp. local delay bound) for class  $j$  in each output port multiplexer  $mux$ , denoted  $Dl_j^{mux}$  (resp.  $delay_j^{mux}$ ), that has to be fulfilled by the aggregate traffic class  $j \in \{SCT, RC\}$  in the output port  $mux$ :

$$Dl_j^{mux} \geq delay_j^{mux}(L_M^{mux}, L_R^{mux}, BW^{mux})$$

The relaxed optimisation problem is then as follows:

$$\begin{aligned} & \forall mux, \\ & \underset{L_M^{mux}, L_R^{mux}, BW^{mux}}{\text{minimize}} delay_{RC}^{mux}(L_M^{mux}, L_R^{mux}, BW^{mux}) \\ & \text{s.t. } \forall mux, j \in \{SCT, RC\} : \\ & R_j^{mux} \geq \sum_{f \in F_j^{mux}} r_f \\ & \sum_{g \in F_{SCT}^{mux}} r_g + \sum_{f \in F_{RC}^{mux}} r_f \leq C \\ & Dl_j^{mux} \geq delay_j^{mux}(L_M^{mux}, L_R^{mux}, BW^{mux}) \end{aligned} \quad (2)$$

Based on the guaranteed service curves for RC and SCT classes within  $mux$  defined in [4] and the basic Network Calculus theorem to compute the delay bound in each  $mux$ ,

i.e., the delay bound is the maximum horizontal distance between the arrival and service curves, we can easily find out that the relaxed optimisation problem in (2) is a non-linear problem, with complex functions defining the delay bounds. There are many ways of solving such a problem numerically, such as brute force method, random search or heuristics. In our case, we will solve this problem based on heuristics taking advantages from conducted sensitivity analysis of our analytical model, which is not detailed in this paper due to the lack of space.

### B. Solving the problem

#### Computing $L_R^{mux}$

First, based on the minimum service curve guaranteed to SCT in Theorem 3 in [4], we have selected the value of  $L_R^{mux}$  maximizing the minimum service rate of SCT, while limiting the impact on RC traffic:

$$L_R^{mux} = MFS_{RC} \cdot BW^{mux} \quad (3)$$

#### Computing $L_M^{mux}$

Second, we have noticed during the conducted sensitivity analysis that when  $L_M^{mux}$  increases, the RC delay bound starts by decreasing, then increasing. So, our aim is to find the expression of  $L_M^{mux}$  at that inflection point to guarantee the minimum delay bound. Based on [4], the delay bound of RC class within  $mux$  is as follows:

$$\begin{aligned} & delay_{RC}^{mux}(L_M^{mux}, L_R^{mux}, BW^{mux}) \\ & = \frac{A}{(1 - BW^{mux}) \cdot C} \left( 1 + \frac{BW^{mux} \cdot (1 - BW^{mux}) \cdot MFS_{SCT}}{L_M^{mux} - L_R^{mux}} \right) \\ & + \frac{L_M}{(1 - BW^{mux}) \cdot C} + \frac{MFS_{SCT}}{C} - \frac{b_{RC}}{n_{RC}^{links} \cdot C - r_{RC}^{mux}} \end{aligned} \quad (4)$$

where  $A = b_{RC} + r_{RC}^{mux} \cdot \frac{b_{RC}}{n_{RC}^{links} \cdot C - r_{RC}^{mux}} + \max_{k \in \{SCT \cup RC \cup BE\}} MFS_k$  and  $n_{RC}^{links}$  the number of input links sending RC flows to  $mux$ .

To find the inflection point, we derive the delay function in Eq. (4) to find the null point of the derived function; thus:

$$L_M^{mux} = MFS_{RC} \cdot BW^{mux} + \sqrt{A \cdot (1 - BW^{mux}) \cdot BW^{mux} \cdot MFS_{SCT}} \quad (5)$$

Therefore, giving Eq.(3) and Eq.(5), we have reduced the number of unknown BLS parameters within  $mux$  to only one, i.e.,  $BW^{mux}$ , to solve the optimisation problem in (2). To compute  $BW^{mux}$ , we propose Algorithm 1, which takes into account as inputs  $Dl_{SCT}^{mux}$  and  $Dl_{RC}^{mux}$ . We use a loop to compute the possible values for  $BW^{mux}$  in Line 2. Inside the loop, we compute the corresponding values of  $L_R^{mux}$ , i.e.,  $lr$ , and  $L_M^{mux}$ , i.e.,  $lm$ , in Lines 3 and 4. Then, we compute the SCT and RC delay bounds in Lines 5 and 6. Next, in Line 7, we verify the local deadlines conditions. If they are fulfilled, we store the delays and  $bw$  in Outputs, in Line 8. Finally, after testing all the  $bw$  in the loop, we select the  $BW^{mux}$  leading to the minimum RC delay bounds, in Line 12. If no  $BW^{mux}$  fulfills the condition, we return  $+\infty$  for each delay bound. As

**Algorithm 1** BLS Bandwidth Reservation algorithm in a multiplexer  $mux$  knowing the local deadlines: BLSparams()

- 13: **else**
- 14:      $[-, +\infty, +\infty]$  %no admissible parameters
- 15: **end if**

---

we can notice, we need to define both local deadlines of SCT and RC within  $mux$  to enable Algorithm 1.

Hence, we have defined two methods to compute these local deadlines: Heuristic Deadline (HD) and Dichotomous Deadline (DD) methods.

### Heuristic Deadline Method

We propose to set the local deadline of class  $j$  in the output port multiplexer  $mux_i$  as the product of the sum of the multiplexer deadlines, denoted  $\sum Dl_k^{mux}$ , and the weight of class  $j$  rate going through multiplexer  $mux_i$ , relatively to the global class  $j$  rate in all the multiplexers  $mux$  in the network:

$$Dl_j^{mux_i} = \frac{\sum_{flw \in F_j^{mux_i}} r_{flw}}{\sum_{mux} \sum_{flw \in F_j^{mux}} r_{flw}} \cdot \sum Dl_j^{mux}$$

Using Eq.(1), we have  $\sum_{sw \in path_f} d_{j,f}^{sw} \leq Dl_{j,f} - d_j^{es} - d_{prop}$ ,

with  $d_{j,f}^{sw} = \frac{MFS_f}{C} + 1\mu s + delay_{j,f}^{mux}$ :

$$\begin{aligned} & \sum_{mux \in path_f} delay_{j,f}^{mux} \\ & \leq Dl_{j,f} - \sum_{mux \in path_f} \left( \frac{MFS_f}{C} + 1\mu s \right) - d_j^{es} - d_{prop} \\ & \leq \sum Dl_j^{mux} \\ & \Rightarrow \sum Dl_j^{mux} = \min_{f \in F_j^{mux}, mux \in path_f} \left\{ Dl_{j,f} \right. \\ & \quad \left. - \sum_{mux \in path_f} \left( \frac{MFS_f}{C} + 1\mu s \right) - d_j^{es} - d_{prop} \right\} \quad (6) \end{aligned}$$

We use the minimum to reduce the complexity, even though this strengthens the constraint. This method has the benefice of being simple to use. However, it has the potential flaw of imposing a local deadline to class  $j$  in a multiplexer,

without checking that the delay bounds in the other switches are able or not to reach their own deadlines. To cope with these limitations, we propose the second computation method, DD method described, in Algorithm 2.

### Dichotomous Deadline Method

To compute the delay bound of class  $SCT$  along the path of a flow  $f$ , we will use two deadline values: one leading to delay bounds equal or lower to the deadline, and one leading to delay bounds equal or higher than the deadline.

The first deadline is computed with the Heuristic Deadline method, and may lead to a lower SCT delay bound.

$$Dl_{SCT}^{under, mux} = \frac{\sum_{flw \in F_{SCT}^{mux}} r_{flw}}{\sum_m \sum_{flw \in F_{SCT}^m} r_{flw}} \cdot \sum_m Dl_{SCT}^m$$

To obtain a higher SCT delay bound, we consider the following SCT deadline:

$$Dl_{SCT}^{over, mux} = \sum_m Dl_{SCT}^m$$

The Dichotomous Deadline (DD) method is detailed in Algorithm 2.

From Line 2 to Line 10, we initialise the dichotomous search. In Lines 3, 4 and 5, we compute the initial Deadlines, i.e.,  $Dl_{RC}^{mux}$ ,  $Dl_{SCT}^{over, mux}$  and  $Dl_{SCT}^{under, mux}$  for each  $mux$ . This leads in Lines 6 and 7 to the computation of the corresponding SCT delay bounds  $delay_{SCT}^{over, mux}$  and  $delay_{SCT}^{under, mux}$  using Algorithm 1. After all the  $mux$  have been considered, we compute in Lines 9 and 10 the two dichotomous variables:  $\sum Dl_{SCT}^{under, mux}$  and  $\sum Dl_{SCT}^{over, mux}$ .

Then in Line 11, we check whether the value  $\sum_{mux \in path_f} delay_{SCT}^{over, mux}$  is actually lower than  $\sum Dl_{SCT}^{mux}$ . If not, we return  $Dl_{SCT}^{over, mux}$  since a dichotomous search is not possible. Else, we start the dichotomous search, where  $\sum Dl_{SCT}^{mux}$  is bounded by  $\sum_{mux \in path_f} delay_{SCT}^{over, mux}$  and  $\sum_{mux \in path_f} delay_{SCT}^{under, mux}$ .

In Line 14, we set the stop condition using an  $\epsilon \ll 0$  such as:  $\sum Dl_{SCT}^{mux} - \sum_{mux \in path_f} delay_{SCT}^{under, mux} \geq \epsilon$ .

The objective is to find a solution as close as possible to the  $\sum Dl_{SCT}^{mux}$  and respecting the deadline constraint.

Then, we start the next iteration in Line 15, by computing the current  $\sum Dl_{SCT}^{cur, mux}$ . We use it to compute the local deadlines in each  $mux$  and the resulting SCT delay bounds in Lines 17 and 18.

The final steps consist in determining whether  $\sum_{mux \in path_f} delay_{SCT}^{cur, mux}$  (the sum of the current delay bounds) is lower or higher than  $\sum Dl_{SCT}^{mux}$  in Line 20. Then, we redefine the values of the current loop, either  $\sum Dl_{SCT}^{over, mux}$  in Line 21, or  $\sum Dl_{SCT}^{under, mux}$  and  $Dl_{SCT}^{under, mux}$  in Lines 23 and 24.

## IV. PERFORMANCE EVALUATION

In this section, we first describe our case study. Afterwards, we assess the efficiency of the introduced bandwidth reservation methods to enhance the extended AFDX performance, in comparison to an intuitive method.

**Algorithm 2** Local deadline computation algorithm with dichotomous method, along the path of flow  $f$ : Dichotomous-Deadline()

**Require:**  $\forall \text{mux} \in \text{path}_f, \forall g \in F_k^{\text{mux},k} \in \{SCT, RC\}, MFS_g, r_g, b_g, \sum D_l^{\text{mux}}$   
**Ensure:**  $\forall \text{mux}, D_l^{\text{mux}}_{SCT}, D_l^{\text{mux}}_{RC}$

- 1:  $\text{Data} = [\forall \text{mux} \in \text{path}_f, D_l^{\text{mux}}_{RC}; \forall g \in F_k^{\text{mux},k} \in \{SCT, RC\}, MFS_g, r_g, b_g]$

### A. Case study

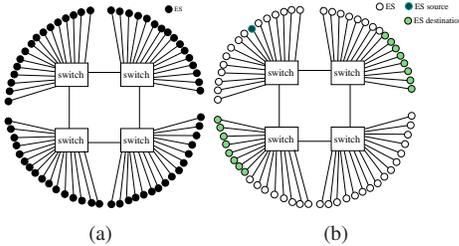

Fig. 3: Representative AFDX network: (a) Architecture; (b) Traffic communication patterns

Our case study is a representative avionics communication architecture of the A380, based on a 1-Gigabit AFDX backbone network, which consists of 4 switches and 64 end-systems as shown in Fig. 3 (a). Each circulating traffic flow on

the backbone network is a multicast flow with 16 destinations, and crosses two successive switches before reaching its final destinations. The first switch in the path receives traffic from 16 end-systems to forward it in a multicast way to its two neighboring switches. Afterwards, the second switch in the path, which receives traffic from the two predecessor switches, forwards the traffic in its turn to the final end-systems. Each end-system receives data from 16 end-systems. Figure 3 (b) shows the traffic communication patterns between the source and the final destinations of a given flow.

In this multi-hop network, each end-system  $es$  generates  $n_i^{es}$  flows of traffic type  $i \in \{SCT, RC, BE\}$ . We consider that all end-systems are identical and each generates the same number of flows  $n_i^{es}$ .

As a consequence, the utilisation rate in both the first and second switches is the bottleneck utilisation rate for each type of traffic  $i \in \{SCT, RC, BE\}$ ,  $UR_i^{bn} = 16 \cdot n_i^{es} \cdot \frac{MFS_i}{BAG_i} \cdot \frac{1}{C}$ .

We consider the traffics SCT, RC and BE defined in Table I and the scenarios detailed in Table II.

Concerning the intuitive method, we consider the following parameters:  $BW = UR_{SCT}^{bn}$ ,  $LR = MFS_{RC} \cdot BW$  and  $L_M = 80 \cdot MFS_{SCT} \cdot (1 - BW)$ , to enable the transmission of a maximum SCT burst of 80 frames within the BLS, i.e., a generated burst of 5 SCT flows per end-system.

Priority	Traffic type	MFS (Bytes)	BAG (ms)	deadline (ms)	jitter (ms)
0/2	SCT	64	2	2	0
1	RC	320	2	2	0
3	BE	1024	8	none	0.5

TABLE I: Avionics flow Characteristics

Scenarios	$Scenario_{SCT}$	$Scenario_{RC}$
$(UR_{SCT}; UR_{RC})$ (%)	$([0.1..80]; 20)$	$(20; [0.5..80])$
$(n_{SCT}^{es}; n_{RC}^{es})$	$([1 : 1 : 192]; 10)$	$(49; [1 : 1 : 39])$

### B. Numerical Results

In this section, we study the impact of optimized BLS bandwidth compared to the intuitive one on a multi-hop network. Hence, we compare the delay bounds of SCT and RC based on the extension of the timing analysis in [4] to the multi-hop case, under HD and DD methods in reference to the intuitive method. The results for the two scenarios are illustrated in Figures 4 and 5. It is worth noting that we only present the admissible results, i.e., when all the deadlines are fulfilled.

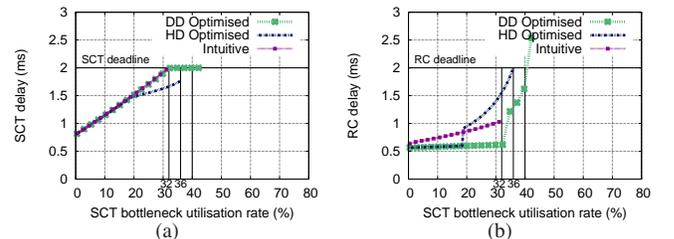

Fig. 4: Intuitive vs Optimisations for  $sc_{SCT}$ : (a) SCT delay bound; (b) RC delay bound

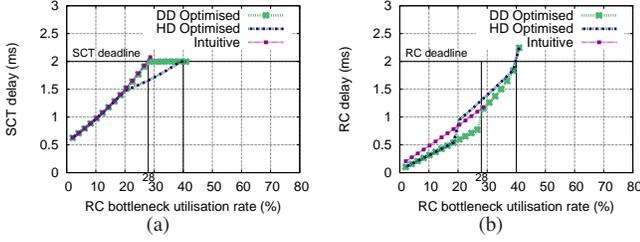

Fig. 5: Intuitive vs Optimisations for  $sc_{RC}$ : (a) SCT delay bound; (b) RC delay bound

First, concerning the maximum bottleneck utilisation rates: (i) in Figure 4, we note that the maximum bottleneck SCT utilisation rate is 32% with the intuitive method, 36% with HD method, and 40% with DD method; (ii) in Figure 5, the maximum bottleneck RC utilisation rate is 28% with the intuitive method, and 40% with both HD and DD methods.

These results show an improvement of the SCT (resp. RC) schedulability up to 25% (resp. 42%) under the optimized bandwidth reservation methods, in comparison to the intuitive one.

Secondly, in Figure 4(b), the RC delay bounds with HD method are lower than the delay bounds with the intuitive one until  $UR_{SCT} = 18\%$ . However, for  $UR_{SCT}$  between 18% and 32%, the intuitive method is better than HD one. The same issue is visible in Figure 5(b) for  $UR_{RC}$  between 20% and 28%.

To understand the reasons of this issue, in Figure 6, we present separately the SCT delay bound in the first and in the second switch output ports, denoted  $delay_{SCT}^{mux1}$  and  $delay_{SCT}^{mux2}$ . In Figure 6(a), we can separate the SCT delay bounds under HD method in 4 areas, with  $UR_{SCT}$ :

(i) between 0% and 20%,  $delay_{SCT}^{mux1} < D_{SCT}^{mux1}$  and  $delay_{SCT}^{mux2} < D_{SCT}^{mux2} \Rightarrow EED_{SCT} < D_{SCT}$ . The multiplexer deadline is reached in neither switches;

(ii) between 20% and 45%,  $delay_{SCT}^{mux1} = D_{SCT}^{mux1}$ ,  $delay_{SCT}^{mux2} < D_{SCT}^{mux2} \Rightarrow EED_{SCT} = D_{SCT}$ . The switch output port 1 deadline (about 1ms, see Figure 6(a)) is reached and the SCT delay bound remains at this deadline  $D_{SCT}^{mux1}$  until  $UR_{SCT} = 50\%$  (see Figure 6(a)). However, in the second switch output port, the SCT delay remains firmly below its deadline;

(iii) between 45% and 50%,  $delay_{SCT}^{mux1} = D_{SCT}^{mux1}$ ,  $delay_{SCT}^{mux2} = D_{SCT}^{mux2} \Rightarrow EED_{SCT} = D_{SCT}$ . The SCT end-to-end delay bound is equal to the end-to-end deadline, as the delays in both output ports are equal to their respective deadlines (see Figure 6);

(iv) between 50% and 80%,  $delay_{SCT}^{mux1} > D_{SCT}^{mux1}$  and  $delay_{SCT}^{mux2} = D_{SCT}^{mux2} \Rightarrow EED_{SCT} > D_{SCT}$ . The end-to-end delay bound is higher than the end-to-end deadline as the delay in the switch output port 1 is higher than its deadline (see Figure 6).

Hence, this highlights the fact that limiting the local deadline in an output port without taking into account the state of other ones in the path decreases the performance of the RC delay bounds.

Contrary to the HD method, the DD method takes into

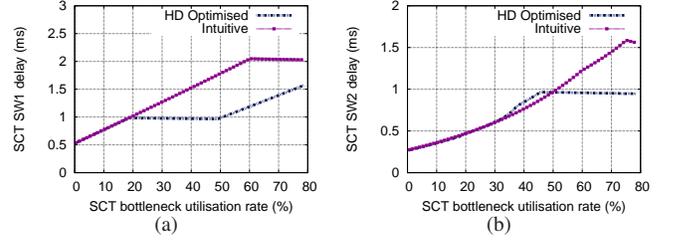

Fig. 6: Intuitive vs Heuristic Deadline Optimisation for  $sc_{SCT}$ : (a) Switch 1 (b) Switch 2

account the output ports along the flow path. In Figures 4 and 5, the RC delay bounds with DD method are better than the ones with both intuitive and HD methods. For instance at  $UR_{SCT} = 32\%$ , the RC delay bound is improved by 49% with reference to the intuitive one, and by 74% compared to HD method.

*We can conclude from these results that Dichotomous Deadline method leads to a great improvement over both the intuitive and Heuristic Deadline methods. The schedulability of SCT is actually increased by up to 31% and the RC delay bound is decreased by up to 75%. Nevertheless, the Dichotomous Deadline method needs much higher computation times, in comparison to Heuristic Deadline method, e.g., up to 10 times.*

## V. CONCLUSIONS

In this paper, we have proposed two optimized bandwidth reservation methods for TSN/BLS shapers in an extended AFDX, denoted Heuristic Deadline and Dichotomous Deadline methods, to enhance the network performance, in terms of schedulability and delay bounds. The conducted performance evaluation on a realistic avionics case study highlights the benefit of using such methods, and particularly the Dichotomous Deadline method. The latter leads to a great improvement over both the intuitive and Heuristic Deadline methods, in terms of schedulability (up to 31% for SCT) and delay bounds (up to 75% for RC), but at the expense of higher computation times, e.g., up to 10 times.

As a next step, we will generalize such analyses to an extended AFDX with multiple BLS classes to offer higher configuration flexibility.
