HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

An image based high throughput screen to identify regulators of Imp containing RNP granules

I. Context

In vivo, RNAs and proteins are frequently packaged into diverse dynamic macromolecular structures named mRNP granules. These assemblies form upon phase separation of individual RNA and protein components, a process involving the establishment of multivalent weak interactions and their regulations via post-translational modifications. Defects in their properties have been associated with several human pathologies. However, our knowledge of these dynamic structures relies essentially on the study of P bodies and stress granules.

We are interested in the highly conserved RNA binding protein Imp whose mammalian counterpart's overexpression correlates with poor prognosis in several cancers. In vivo, Imp is present in cytoplasmic RNP granules, distinct from P-bodies and visible both in neuronal cell bodies and axons. They are also detected in Drosophila S2R⁺ cultured cells.

Taking advantage of this cellular model, we have undertaken a genome-wide RNAi-based visual screen to identify factors that regulate the properties of Imp-containing granules. This implies combining high throughput microscopy with the development of a computational pipeline for automatic image analysis. This pipeline first segments and discriminates healthy from dead nuclei, storing this information in an interactive SQLite database that enables experimental quality control. Then, GFP-Imp granules are detected using the SPADE algorithm in the cytoplasm of healthy cells. Data from the pilot screen we have performed to validate the experimental design and develop our pipeline for data mining are presented.

In vivo, Imp is present in RNP granules, both in neuronal cell bodies (A) and axons (B). Shown here, the mushroom body neurons. (courtesy of Kavya Pushpalatha)

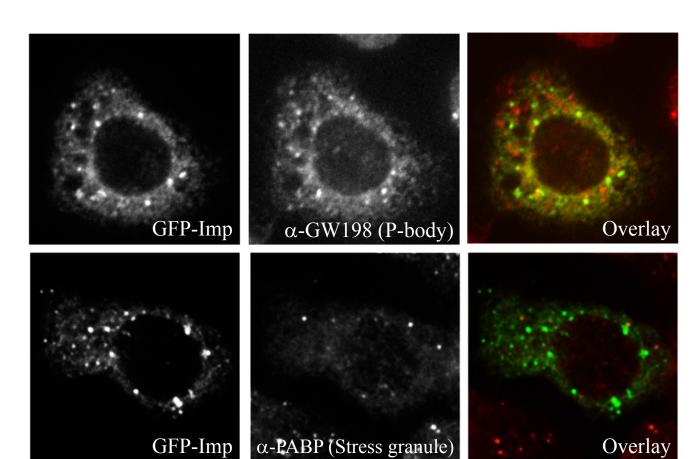

CellProfiler Analyst

Classifier training:

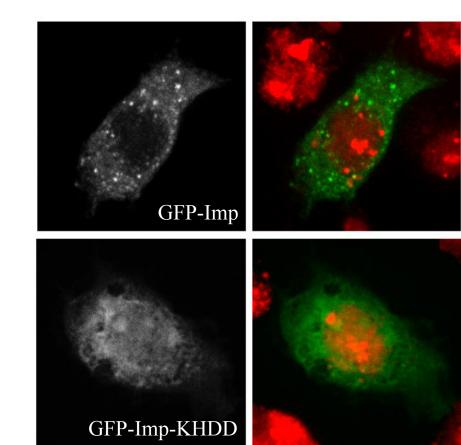

- 2 sets of 2585 objects

- 4 classes

- 25 rules

In S2R+ cells Imp granules are different from P bodies and stress granules

RNA binding activity is required for the assembly of Imp granules in vitro and in vivo (not shown)

CellProfiler

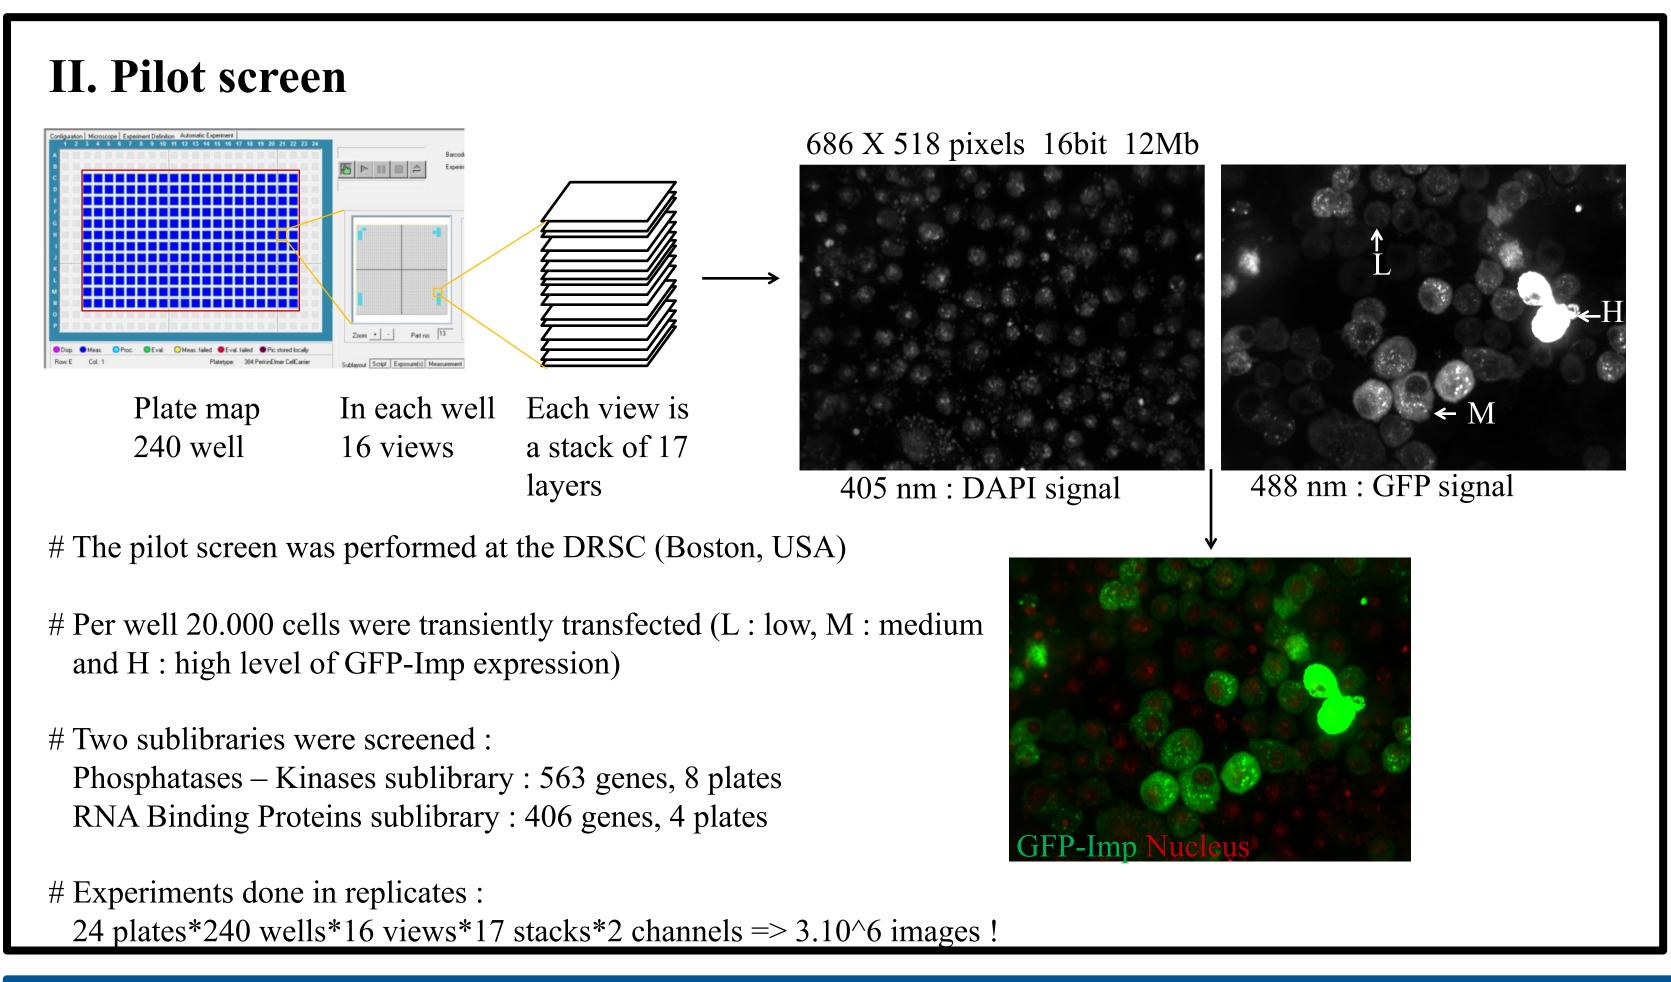

Database:

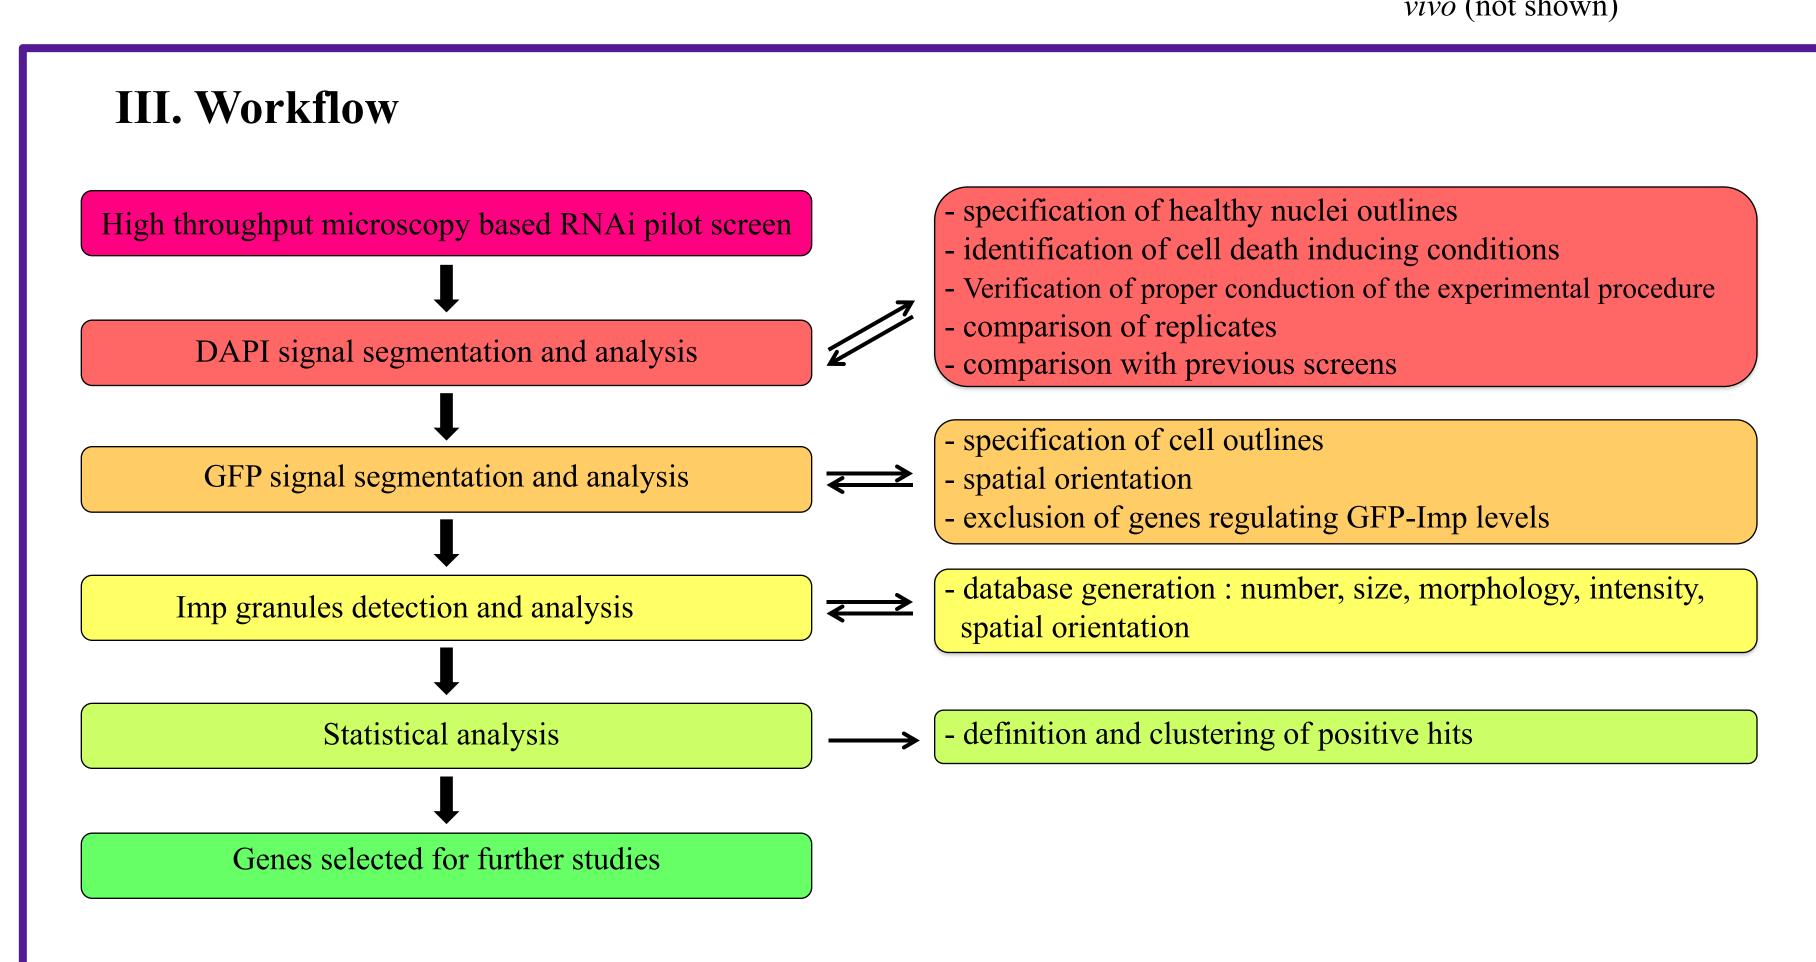

- 3 415 473 healthy nuclei

- 1 742 439 dead nuclei

- 1 156 646 vesicles

- 2 774 456 debris

IV. Experimental procedure quality check and selection of healthy cells CellProfiler 99,32 % of the images are For each view Object segmentation and correctly segmented Feature extraction → DAPI signal MIP Per image: 0,11 % blurred images, underestimation - nb of objects 0,07 % air bubble, no segmentation → 93 084 MIP - object size 0,5 % presence of spot, underestimation - object intensity - object granularity **RNA Binding Proteins** Kinases / Phosphatases Cell survival CkIIalpha (DRSC40838) 3,15 cpsf100 (DRSC14146) 5,15 proliferation 33 65 65 67 129 129 161 193 225 225 225 225 417 449 481 513 577 609 673 705 ago2 (DRSC40785) -5,54 greatwall (DRSC36639) -3,79 Cell death ago2 (DRSC31769) -6,38 Distribution of the robust z-scores from the pilot screen using living cells as readout (we used median normalisation per plate (excluding controls)). In this pilot screen, 812 different RNA strands were used to reduce the expression of one of the 406 genes encoding a RNA binding protein (A). 1696 different RNA strands were used to reduce the expression of one of the 563 genes encoding a kinase or protein phosphatase (B). Similarly to Mohr et al. we found that ago2 and cpsf100 rnai downregulation favor cell death and cell survival respectively. These results

Visual inspection of raw data indicates:

- (1) The cell population inside each well is heterogeneous.
- (2) In transfected cells, expression levels of the GFP-Imp molecule are variable: low, medium or high. Only cell expressing GFP-Imp at a low level are interesting.
- (3) Depending on the cells, the RNP-Imp granules may be more or less numerous, larger or smaller, they may accumulate locally or be distributed homogeneously throughout the cytoplasm.
- (4) Inactivation of most of the genes tested does not induce a detectable phenotype by eye
- (5) Hits with more granules were detected (about 1%)

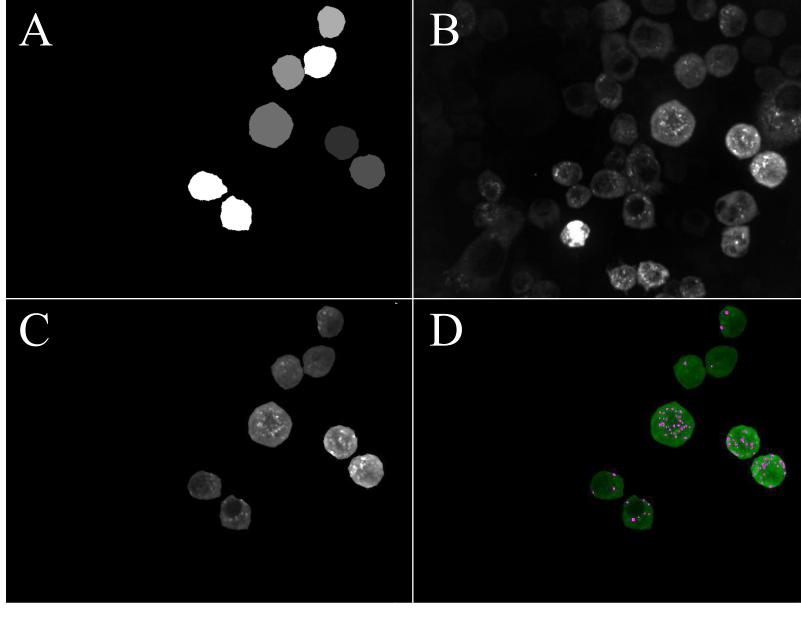

V. Semi-Automatic Cell Segmentation: from GFP MIP images to cell masks

validate the reproducibility of the experimental procedure and our statistical approach.

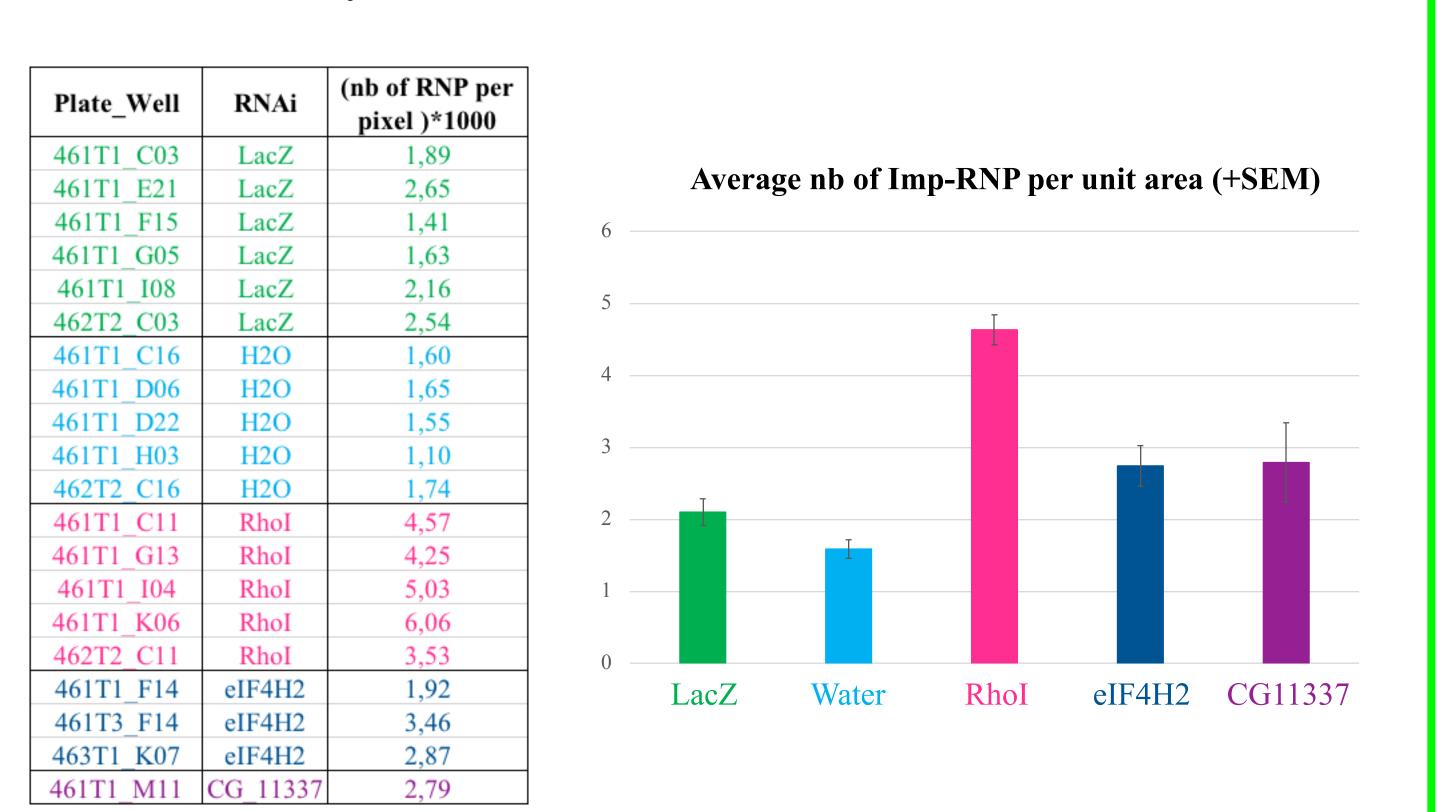

GFP MIP images (A) are first locally-normalized to reduce the effect on a nonuniform illumination. Then, a watershed-based segmentation produces the corresponding oversegmented (superpixels) image (B). Finally, the interface allows to manually select the superpixels to segment the cells of interest by creating masks (B). In the future, an automatic process for superpixels merging will be developed.

VI. SPADE: an algorithm for small particle detection

The mask generated by the supervised segmentation algorithm (A) is used to extract from the original MIP image pretreated for enhanced contrast normalization (B), the GFP positive cytoplasm of healthy cells whose intensity ranges from 100 to 1000 (C). This latter is analyzed by SPADE that combines the point process concept of minimizing an energy function with the use of a predefined dictionary of shapes, allowing the detection of small objects, ranging from 4 to 25 pixels in a heterogeneous context (D). 1. http://spade.gforge.inria.fr/ 2. https://pypi.python.org/

VII. Preliminary data:

Images from different control wells (LacZ and water) of one or two independent plates as well as images from 3 possible hits were analysed as described before (IV to VI). Results show robustness of the controls. As for quality control, we will use median normalisation per plate (excluding controls). Hits will be identified on the basis of their average number of IMP containing RNP per unit area as well as other criteria to be tested.

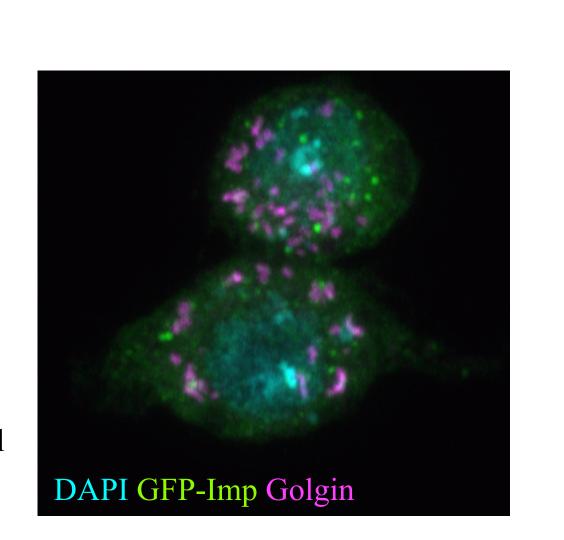

VIII. Perspectives

Automate the merging process for image treatment

Develop the statistical framework to detect hits

In vivo functional analysis of hits

Improve the experimental readout using additional markers (phalloïdin, organelle markers)
