Abstract

In silico optimisation, synthesis and binding evaluation of $\alpha_v\beta_3$ integrin's affinity for precursors of a new RGD peptidomimetics family are presented. The 2-pyrrolidinone building block was obtained by condensation of L-lysine with dimethoxydihydrofuran followed by reduction. The ring was functionalized with a carboxylic acid and a guanidinium appendage. On the pyrrolidinone heterocycle, the effects on affinity of position, length and relative geometry of the two acid or basic functionalized side chains introduced on the pyrrolidinone ring have been previously evaluated by docking studies. Peptidomimetics have finally been evaluated by competition binding assays for $\alpha_v\beta_3$ integrin's affinity using radio-ligands.

Keywords: peptidomimetics, RGD, Integrin, docking, synthesis, binding.

1. Introduction

Integrins are heterodimeric transmembrane receptors which regulate cell attachment and response to the extracellular matrix. They are involved in many physiopathological processes: blood coagulation, tumor-induced angiogenesis, osteoporosis, restenosis, acute renal failure, ocular diseases, metastasis formation and sickle cell anaemia, and represent interesting targets for therapeutic and diagnosis purposes.[1-4]

Among the 24 known integrins, $\alpha_v\beta_3$ integrin is of particular interest since it plays a key role in angiogenesis, a process considered for cancer therapy by inhibiting vascularisation of tumors.[5, 6] It is also overexpressed in solid tumors such as glioblastoma, melanomas, and ovarian, breast and prostate cancers where it takes part in metastases formation.

The tripeptide Arg-Gly-Asp (RGD) is the motif of recognition for $\alpha_v\beta_3$ and seven other integrins on several matrix proteins (vitronectin (VN), fibronectin (FN))... The specificity of each integrin depends on the conformation of this peptidic triad induced by the other residues.

Many studies have reported the development of linear and cyclic peptides, peptidomimetics or small molecules with affinity for RGD based integrins. Among them, a cyclic pentapeptide (c(-RGDf[*N*Me]V-) Cilengitide EMD 121974) presents a subnanomolar affinity for the $\alpha_v\beta_3$ integrin.[7] A Phase III study of Cilengitide is presently ongoing for glioblastoma, a very aggressive type of brain tumor.[8] However, recent studies showed that Cilengitide seemed unable to alter the pattern of glioblastoma progression. [9] Cilengitide also entered into Phase II trials for the treatment of several other types of cancers, such as prostate cancer, due to its capability to antagonize $\alpha_v\beta_3$, $\alpha_v\beta_5$ and $\alpha_5\beta_1$ integrins.[8]

Research efforts have been focused on changing the scaffold rigidity and the nature of the basic moiety. Peptidomimetics allow those modifications and also offer the possibility to incorporate unnatural amino acids and other building blocks to achieve a proper insertion of the molecule into the binding pocket.

A lot of studies describing access to peptidomimetics have recently been published.[10-16]

Few years ago, we described RGD mimics **1** based on indolizin-3-one skeleton.[17] Two of these mimics have shown moderate biological activity (Figure 1). The aim of this work is to develop new flexible structures having a single ring and of an additional amine function providing an anchor point for a drug or a carrier. *in silico* In order to increase the affinity for the integrin receptor (figure1). The synthesized peptidomimetics will be evaluated by competition binding assays to validate the docking studies

Figure 1: RGD peptidomimetics

2. Results and discussion

2.1 *In silico* studies

In order to evaluate and compare peptidomimetics's affinities for integrin before embarking on chemical experimental synthesis, molecular docking studies have been performed starting from the crystal structure of the human integrin alpha V beta 3 extracellular segment in complex with a cyclic pentapeptide ligand Arg-Gly-Asp-{d-Phe}-{*N*-methyl-Val-}, so-called cyclo(RGDF=N{Me}V) (PDB Accession code 1L5G)[18].

The binding mode of cyclo(RGDF=N{Me}V), taken into account for docking calculations, is best described as a three-points pharmacophore [19, 20] and is depicted using LigX [21] on Figure 2.

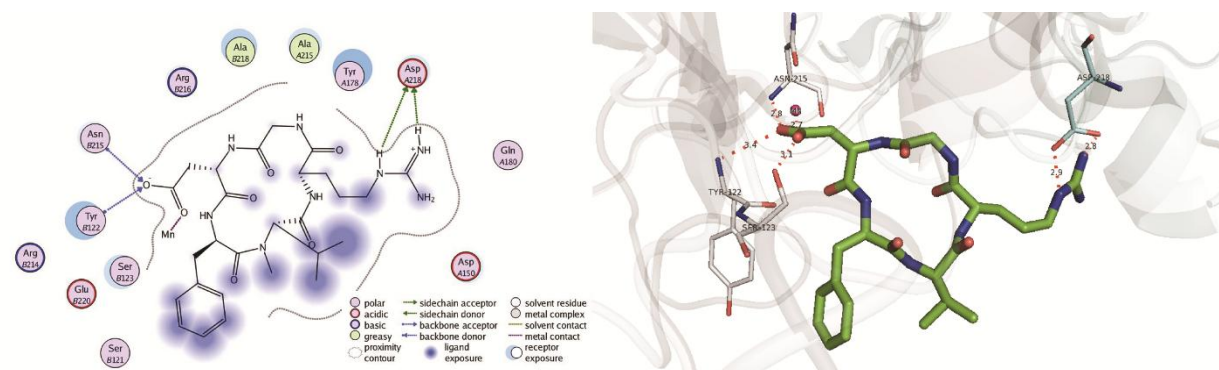

Figure 2 : LigX 2D-depiction (left side) and 3D-representation focused on Arg and Asp side chains (right side) of the binding mode of cyclo(RGDF=N{Me}V) to integrin alpha V beta 3 in PDB 1L5G

The Arg and Asp side chains of the ligand, mimic the corresponding residues of the adhesive RGD sequence and point in opposite directions, respectively contacting A and B chains. Those two groups are determinants for receptor recognition, whereas the dPhe group, performing intra-ligand and extra-ligand hydrophobic contacts with Tyr122 (chain B), has been introduced to enhance pharmacological potency [22, 23]. The arginine guanidinium group is held in place by a bidentate salt bridge with Asp218 and by an additional salt bridge with Asp150. One of the Asp carboxylate oxygen atom is in contact with a Mn²⁺ ion while the second Asp carboxyl oxygen forms hydrogen bonds with the backbone amides of Tyr122 and Asn215 and also contacts the aliphatic portion of the Arg214 side chain. The glycine residue, which completes the prototype RGD ligand sequence, lies at the interface between the A and B subunits and is involved in several hydrophobic interactions. The remaining two residues of the pentapeptide face away from the AB interface.

Peptidomimetics have been designed on the basis of cyclo(RGDF=N{Me}V) mainly with modulations including chains' length, stereochemistry and some basic feature as mapped on Figure 3. For this first

study, we did not consider the aromatic part of the three point pharmacophore. Further optimizations based upon aromatic insertion are ongoing.

Figure 3 : Structural basis of *in silico* optimization of peptidomimetics

Docking calculations were performed with the minimized conformations using the GOLD suite version 5.1[24, 25] into the active site initially containing the cyclo(RGDF=N{Me}V).

The best docking solutions were selected, first of all, on the basis of their attained fitness values and finally, after verification of the binding mode's preservation.

Best poses were obtained for derivatives of compounds **2** and **4** with guanidinium as basic features and specific stereochemistries : (2S,3S) configuration in compound **2** and (3S,5R) configuration in compound **4**. Docking results analysis showed that the acidic chains' length in compounds **3** did not allow to correctly reach the proximity of Mn^{2+} ion and to form hydrogen bonds with Tyr122 and Asn215.

Table 1 sums up the most significant results. Overlay representations of cyclo(RGDF=NMeV) with the best docking poses for compounds **2**, **3** and **4** with guanidinium feature are given as supplementary material (Figures S1,S2,S3).

Table 1 : Sum up of docking results. Compound references **1** to **4** are related to Figure 1 but calculations were done without any amine function to bind to a drug or a carrier.

2.2 Synthesis

2.2.1 Synthesis of the pyrrolidinone building block

The first step of the synthesis was the condensation of dimethoxydihydrofuran⁸ with L-CbzN^εLys-OMe **5** in acidic medium (Scheme 1). The resulting lactame **6** was directly hydrogenated. Using specific conditions (5% Pd/C as a catalyst in ethyl acetate) [26, 27] the carbobenzoxy protection was preserved and only 10 % of deprotected compound was observed. The saturated methyl ester was reduced with NaBH₄ to afford alcohol **7** in 38% yield over 3 steps. As direct allylation of **7** failed the alcohol group was protected as a *tert*butyldimethylsilyl ester (90 %) using TBDMSCl. Then the side chain on the pyrrolidinone skeleton had to be introduced with an appropriate relative configuration. An allyl group in position alpha with respect to the lactam carbonyl was chosen as it can be easily converted into various functions: alcohol, guanidine, carboxylic acid. This allylation was performed by treatment with allyl bromide after deprotonation using LDA in THF (scheme 2). The mixture of diastereoisomers obtained in 83/17 ratio was separated by chromatography on silica gel to give pure compounds **8a** (62%) and **8b** (13%). In order to modify the diastereoselectivity we turned towards less hindered protecting groups (allyl, MOM). The protected intermediates were obtained in moderate yield (62%, 64%). When allyl ether was used a single diastereomer was obtained in 74% yield but unfortunately it couldn't be deprotected afterwards and only degradation products were observed certainly due to the presence of two double bonds. Using MOM ether the diastereoisomers were obtained in 40% and 11% yields, after deprotection with TFA, the major one being the same as with the TBDMS protecting group. Therefore the synthesis was carried on using the TBDMS protected compound. After cleavage of the silyl ether with tetrabutylammonium fluoride, the alcohol was oxidized by using Jones reagent to give acids **9a** (72%, from major diastereoisomer) and **9b** (62%, from minor diastereoisomer). Tags **a** (major) or **b** (minor) will be applied from now on to point out each diastereomer.

Scheme 1: synthesis of the key product **9**

The absolute configuration of the C3 carbon atom bearing the allyl group on the diastereomers **9** could not be clearly inferred from spectroscopic data and only X-ray analysis of the major diastereoisomer **9a** allowed us to unequivocally confirm its *S* configuration. The ORTEP view reporting crystal structure of **9a** is shown in Figure S4.

The acid compound **9** was the key intermediate for introduction of the critical acid and basic functions. The synthesis was performed successively on the two diastereoisomers,

2.2.2 Introduction of acidic and basic functions

Coupling reactions (EDC, NMM, HOBT) of carboxylic acids **9a** and **9b** with β -Alanine *ter*-butylester led to compounds **10a** (90%) and **10b** (86%) and coupling reaction with glycine *ter*-butylester gave **11** (89%). Hydroboration of the double bond was conducted with borabicyclo-nonane followed by oxidation with H_2O_2 leading to the primary alcohol (70% yield). Then substitution of the hydroxyl group by a guanidine through a Mitsunobu reaction with DIAD/ PPh_3 and diBoc-guanidine afforded **12a** (78%), **12b** (85%) and **13a** (84%) in good yields. Deprotection by trifluoroacetic acid gave three mimics **15a** (80%), **16a** and **16b** (quantitative yield). The carbobenzyloxy protecting group mimics the drug or the carrier which could be link to RGD peptidomimetics. Palladium/carbon treatment of **12a** and **12b** followed by trifluoroacetic acid hydrolysis also gave two analogues **14a** and **14b**(Scheme 2)..

Scheme 2: introduction of acid and basic moiety

In a second sequence, we reversed the position of the carboxylic and guanidine groups (Scheme 3). The carboxylic acid **9a** was coupled (EDC, NMM, HOBT) with *N*-Fmoc1,2-diaminoethane to give **17** (91%). After an hydroboration step (61%) oxydation of the alcohol **18** with Jones reagent gave access to acid **19** (64%). After cleavage of the Fmoc group with piperidine the amino acid **20** was isolated in quantitative yield. The basic moiety (guanidine) was introduced via a substitution reaction with *N,N'*-diBoc-1*H*-pyrazole-1-carboxamide in a moderate yield (54%). Deprotection with trifluoroacetic acid gave quantitatively the new mimic **22**.

2.3 Competition Binding Assay for $\alpha_v\beta_3$ integrins affinity

Compounds **14a** and **14b** were previously tested by cell adhesion assay on S180 cells. The inhibition of adherence was quite the same as compounds **1**. To increase accuracy about their potential activity, we decided to test the new compounds by competition binding assay.

To accurately determine the affinity and specificity of our peptidomimetics for $\alpha_v\beta_3$ integrins, we used radioactive ^{125}I -labeled echistatin solid phase binding assay [28, 29]. Purified $\alpha_v\beta_3$ receptor was coated onto Microlite-2+ plates at a concentration of 50 ng/well as described in experimental section. ^{125}I -Echistatin was added into the wells to a final concentration L^* of 0.05 nM in binding buffer (50 μl /well) in the presence of competing ligand. cRGDfK or peptidomimetics dissolved in binding buffer at the concentrations indicated were added before the addition of radio-ligand.

After a 3h incubation at room temperature, the wells were washed and radioactivity was determined with a gamma counter (wizard 1470, Perkin Elmer). All measurements were done in triplicate with standard deviations of less than 10%. The results are presented in Table 2.

mimics	IC ₅₀ (μM)
c(RGDfK)	0.093
14a	#
14b	50
15a	#
16a	#
16b	100
20	#
22	>100 (30 on $\alpha_v\beta_5$)

Table 2: IC₅₀ towards $\alpha_v\beta_3$, obtained by competition binding assay

Measured affinities for $\alpha_v\beta_3$ and $\alpha_v\beta_5$ integrins are quite low compared to c(RGDfK) affinity. Compounds **14b** and **16b** differ only from the presence of NH₂ appendage protective moiety and both present a measurable affinity for integrin $\alpha_v\beta_3$, that indicates that activity must be induced by the right pharmacophoric acidic and basic functions. It is noticeable that inversed compound **22** presents more

affinity for $\alpha_v\beta_5$ than for $\alpha_v\beta_3$. Compounds **14b**, **16b** and **22** present low but measurable affinities for integrins $\alpha_v\beta_3$ and $\alpha_v\beta_5$ and correspond to the best docking scores. These compounds turned out to be promising compounds for further optimizations including insertion of an aromatic pharmacophoric function.

3. Conclusion

New series of peptidomimetics starting from *in silico* studies up to their binding evaluation after complete synthesis and characterization were designed. It turned out that these molecules had low activities compare to the cyclopentapeptide. Nevertheless active mimics matched best docking scores with the right scaffold length, the right stereochemistry and guanidinium function as basic feature. We can lean on them for the design of more successful structures. As previously described [30] and *in silico* predicted, compounds with an amine function as basic feature have less affinity for $\alpha_v\beta_3$ integrins. The introduction of a hydrophobic groups on the basis of a three-point pharmacophore should be improve the affinity of these ligands. *In silico* studies are in progress

We aim to link peptidomimetics to nanoparticles for diagnosis application in order to improve their affinity as it has been already demonstrated for c(RGDfK).[31]

4. Experimental section

4.1 General experimental methods

All commercially available reagents were used without further purification unless otherwise noted. Tetrahydrofuran was freshly distilled from benzophenone ketyl radical under argon prior to use. Column chromatography was performed with silica gel (35-70 mesh).

NMR spectra were recorded on 300 and 400 MHz Bruker Avance spectrometers. Chemical shifts are reported in ppm. Coupling constants (*J* values) are reported in Hertz. ^{13}C and ^1H peak assignments were made based on DEPT, HMQC, HSQC, HSBC data and IR spectra were recorded on a FT-IR spectrometer Perkin Elmer 1600. MS experiments were performed on a Z-Q- Micromass spectrometer. HRMS were performed on a LCT premier Waters. Specific rotations were measured at 20°C with a Perkin Elmer 341 polarimeter at 589 nm.

4.1.1 (2S)-6-Benzyloxycarbonylamino-2-(2-oxo-2,5-dihydro-pyrrol-1-yl)-hexanoic acid methyl ester **6**

To a solution of N^e-Z-L-lysine methyl ester hydrochloride (20g, 60 mmol) in 220 mL of water at 50 °C was added 11.52 g of citric acid and 7.26 mL (60 mmol) of dimethoxydihydrofuran. The reaction was stirred 10 min, then put in an ice bath and 32 g of sodium acetate were added by portion. The solution was stirred for 1 hour and extracted by CH_2Cl_2 (3 times) the organic layers was dried (MgSO_4) and concentrated under vacuum. A red-brown oil was obtained and filtered over vegetal charcoal (7 spoons) in CH_2Cl_2 . After filtration and evaporation of the solvent 14.35 g (66%) of red-brown oil was obtained. The crude product was used without further purification.

^1H NMR (300MHz, CDCl_3): δ_{H} 1.15 (m, 2H, H_4); 1.42 (m, 2H, H_5); 1.61-1.69 (m, 1H, H_3); 1.82-1.91 (m, 1H, H_3); 3.02 (dd, 2H, $J = 12.8, 6.7\text{Hz}$, H_6); 3.56 (s, 3H, COOMe); 3.81 (d, 1H, $J = 9\text{ Hz}$, H_5); 4.10 (d, 1H, $J = 9\text{ Hz}$, H_5); 4.73 (dd, 1H, $J = 10.6, 4.8\text{ Hz}$, H_2); 4.96 (s, 2H, PhCH_2); 5.51 (t, 1H, $J = 5.4\text{ Hz}$, NH); 6.02 (d, 1H, $J = 5.9\text{ Hz}$, H_4); 6.99 (d, 1H, $J = 5.9\text{ Hz}$, H_3); 7.18 (m, 5H, Ar). ^{13}C NMR (75 MHz, CDCl_3) δ_{C} 23.0 (C_4); 29.0 (C_5); 29.5 (C_3); 40.4 (C_6); 49.7 (C_5); 52.2 (COOMe); 53.0 (C_2); 66.2 (PhCH_2); 126.84 (C_4); 127.9 (C_{Ar}); 136.7 (C_{Arquat}); 144.3 (C_3); 156.6 (CO); 171.8-172.0 (2 CO).

4.1.2 (2S)-6-Benzyloxycarbonylamino-2-(2-oxo-pyrrolidin-1-yl)-hexanoic acid methyl ester

Ester (13.4 g, 37 mmol) was dissolved in 150 mL of ethyl acetate, 1.3 g of Pd/C 5% was added. The mixture was hydrogenated at atmospheric pressure for 16 hours. After filtration of the catalyst, washing with ethyl acetate, the solvent was removed under vacuum to yield 11.4 g (85%) of a brown oil. The crude product was used without further purification.

NMR ^1H (300 MHz, CDCl_3): δ_{H} 1.32 (m, 2H, H_4); 1.48-1.56 (m, 2H, H_5); 1.70-1.71 (m, 1H, H_3); 1.92-2.05 (m, 3H, H_3 , H_4); 2.39 (t, 2H, $J = 9\text{ Hz}$, H_3); 3.17 (dd, 2H, $J = 6.5, 13\text{ Hz}$, H_6); 3.29 (dd, 1H, $J = 8.5, 14\text{ Hz}$, H_5); 3.47 (dd, 1H, $J = 9, 15\text{ Hz}$, H_5); 3.69 (s, 3H, COOMe); 4.76 (dd, 1H, $J = 10.9; J = 4.8\text{ Hz}$, H_2); 5.08 (s, 2H, PhCH_2); 5.2 (bs, 1H, NH); 7.31 (m, 5H, Ar). 4.1.3 (5S)-6-Hydroxy-5-(2-oxo-pyrrolidin-1-yl)-hexyl]-carbamic acid benzyl ester 7

To the methyl ester (15 g, 41.4 mmol) dissolved in 500 mL of absolute alcohol, sodium borohydride (16.1 g, 414 mmol, 10 equiv) was added. The mixture was refluxed for 3 hours. After cooling, the solution was reduced under vacuum, borane precipitates were filtrated and washed with CH₂Cl₂. The filtrate was concentrated under reduced pressure and the residue was diluted with CH₂Cl₂ and HCl 1M, extracted twice by CH₂Cl₂. The organic phase was dried with MgSO₄ and evaporated to dryness, thereafter the residue was purified by flash chromatography on silica gel (EtOAc/MeOH, 95/5) to afford 9.3 g of **7** as light yellow oil (67%).

R_f = 0.24 (AcOEt/MeOH: 95/5) NMR ¹H (300MHz, CDCl₃): δ_H (ppm): 1.31 (m, 2H, H₃); 1.46-1.58 (m, 4H, H₄, H₂); 2.02 (m, 2H, H₄); 2.42 (t, 2H, J = 7.6 Hz, H₃); 3.07 (bs, 1H, OH); 3.19 (m, 2H, 2H₁); 3.30 (dd, 1H, J = 8.1, 13.4 Hz, H₅); 3.41 (dd, 1H, J = 7.8, 14.9 Hz, H₅); 3.57 (dd, 1H, J = 11.5, 20 Hz, H₆); 3.66 (dd, 1H, J = 4, 11.6 Hz, H₆); 4.05 (m, 1H, H₅); 5.11 (s, 2H, PhCH₂); 5.21 (m, 1H, NH); 7.34 (m, 5H, H_{Ar}). 4.1.4 (5S)-[6-(tert-Butyl-dimethyl-silyloxy)-5-(2-oxo-pyrrolidin-1-yl)-hexyl]-carbamic acid benzyl ester

Alcohol **7** (740 mg; 2.2 mmol) was dissolved in CH₂Cl₂ (10 mL) and *tert*-butyldimethylsilyl chloride (400 mg, 2.6 mmol; 1.2 equiv.) was added under argon. The solution was stirred for 14 hours and an aqueous saturated NH₄Cl solution was added. The aqueous layer was extracted with CH₂Cl₂. The organic phase was dried with MgSO₄ and the solvent removed under vacuum. The residue was purified by flash-chromatography on silica gel (ethyl acetate/cyclohexane, 60/40). Silyl ether was obtained as a pale beige oil in 90% yield (890 mg).

R_f = 0.4 (AcOEt/cyclohexane: 65/35). NMR ¹H (300MHz, CDCl₃): δ_H 0.06 (s, 2H, 2SiMe); 0.90 (s, 3H, Si^{*t*}Bu); 1.28 (m, 2H, 2H₃); 1.50-1.58 (m, 4H, H₄, H₂); 1.97 (m, 2H, H₄); 2.38 (t, 2H, J = 8 Hz, 2H₃); 3.20 (m, 2H, H₁); 3.32 (m, 1H, H₅); 3.42 (m, 1H, H₅); 3.64 (m, 2H, H₆); 4.12-4.13 (m, 1H, H₅); 5.08 (bs, 1H, NH); 5.11 (s, 2H, PhCH₂); 7.32-7.38 (m, 5H, H_{Ar}). NMR ¹³C (75 MHz, CDCl₃): δ_C -5.6 (SiMe); -5.5 (SiMe); 18.1 (C₄); 18.5 (SiC_{quat}); 23.1 (C₃); 25.8 (Si^{*t*}Bu); 27.5-29.5 (C₄/C₂); 31.4 (C₃); 40.8 (C₁); 43.8 (C₅); 52.5 (C₅); 63.9 (C₆); 66.5 (PhCH₂); 128.0-128.1-128.5 (C_{Ar}); 136.7 (C_{Arquat}); 156.5 (CO); 175.5 (CO). [α]_D²⁰: -18.0 (c = 0.8; CH₂Cl₂). IR (neat): ν_{max} 3320, 2928, 1667, 1248, 1112, 834 cm⁻¹. HRMS (ES⁺. [M + H]⁺): Calcd for C₂₄H₄₁N₂O₄Si 449.2830 Found 449.2830.

4.1.5 (3S, 5S)-[5-(3-Allyl-2-oxo-pyrrolidin-1-yl)-6-(tert-butyl-dimethyl-silyloxy)-hexyl]-carbamic acid benzyl ester 8a

A 30 mL LDA solution in THF was prepared from diisopropylamine (25.6 mmol; 3.6 mL; 2. éq.) and n-BuLi 1.6 M in hexane (25.6 mmol; 16 mL) cooled to -78 °C and was cannulated to amide **7** (12.7 mmol; 5.7 g) in THF (90 mL) maintained at -78 °C under argon. The solution was stirred at the same temperature for 20 min and allyl bromide (25.4 mmol; 2.2 mL; 2 equiv.) was slowly added. The mixture was stirred at -78 °C for 2h and then treated with an aqueous saturated NH₄Cl solution (60 mL). The aqueous phase was extracted several times with CH₂Cl₂. The organic phase was then dried with MgSO₄ and the solvent removed in vacuum. The residue was purified by flash chromatography on silica gel (AcOEt/cyclohexane: 80/20) to give the two diastereoisomers **8a** and **8b** in a 83/17 ratio and a 75% global yield. (3.9 g of pure **8a** as a pale yellow oil, 0.78 g of pure **8b** as a pale yellow oil.

4.2 Docking analysis

The crystal structure of the extracellular segment of human integrin alpha V beta 3 in complex with a cyclic pentapeptide ligand Arg-Gly-Asp-{d-Phe}-{*N*-methyl-Val-}, called cyclo(RGDF=N{Me}V) (PDB Accession code 1L5G) was retrieved from protein data bank and used for docking analysis. [18]

Ligands were built with Marvin software considering a pH value of 7.4 and minimized using calculator plugins[32]. To avoid wrong way calculations and emphasize the right binding mode, ligands were constructed with a simplified linker, but also without any. Herein, results are considered for molecules without any linker.

The protein file has been corrected before use : hydrogen atoms have been added, bond order were adjusted, initial complexed ligand has been deleted. Correct protonation states have been assigned to the residues.

Then, docking calculations using genetic algorithm search were performed with the minimized conformations using the GOLD suite version 5.1[24, 25] into the active site initially containing the ligand cyclo(RGDF=N{Me}V).

The cavity was detected with an active site radius of 10Å from the ligand. The chemPLP fitness function was chosen to evaluate the quality of the results. In the same run, the redocking of the ligand cyclo(RGDF=N{Me}V) gave us a reference chemPLP fitness score of 79.5 with a RMSD superposition of 0.96Å on heavy atoms of complexed initial ligand. Constraints based upon hydrogen-bonds involving two of the three point pharmacophoric functions described by Marinelli[19] and Moitessier[20] were used to favor a similar binding mode. The 10 resulting poses for each compound were clustered by RMSD up to 1.5Å.

The best clusters of poses docking solutions were selected, first of all, on the basis of the averaged attained fitness score values of poses within the clusters and finally, after verification of the binding mode's preservation. Pymol software was used for overlays graphical representations.

4.3 X-ray data collection and refinement

Small single crystal of **9** suitable for X-ray diffraction studies was obtained by using acetonitrile solvent. Single crystal XRD data collection was performed at ambient temperature on a Rigaku RAPID II RAXIS large area curved imaging plate detector diffractometer with graphite monochromated Cu K α radiation (λ = 1.54184 Å). Cell refinement, data reduction, and scaling were performed using the CrystalClear SM Expert 2.0 r4 package.[33]

The crystal structure was solved with direct methods using SHELXS-97 and final refinement, based on F², was carried out by full matrix least squares with SHELXL-97 software [34-36]. Refinement was performed anisotropically for all non-hydrogen atoms. Mainly, in the final stages of least-squares refinement, hydrogen atoms were assigned to idealized positions and were allowed to ride with thermal parameters fixed at 1.2 Ueq of the parent atom. The residual electron densities were of no chemical significance.

Relevant crystallographic datas are given in Table S1. Preparation of the material for publication was done

with the PLATON package with the help of the WinGX gui. [33, 37]
CCDC-1015520 record contains the supplementary crystallographic data for this paper. These data can be obtained free of charge from the Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.

4.4 $\alpha_v\beta_3$ Targeting Efficiency by Solid Phase Receptor Binding Assay

The receptor binding assays were performed as previously described.[28, 29] $\alpha_v\beta_3$ was diluted at 500 ng/mL in coating Buffer (20 mM tris, pH 7.4, 150 mM NaCl, 2mM CaCl₂, 1 mM MgCl₂, 1 mM MnCl₂) and an aliquot of 100 μ L/well was added to a 96-well microtiter plate (Microlite 2+) and incubated overnight at 4°C. The plate was washed once with blocking/binding buffer (20 mM tris, pH 7.4, 150 mM NaCl, 2mM CaCl₂, 1 mM MgCl₂, 1 mM MnCl₂, 1% Bovine Serum Albumine) and incubated an additional 2h at room temperature. The plate was rinsed twice with the same buffer and incubated with the radiolabeled ligand at the indicated concentrations for 3h at room temperature. For co-incubations, unlabeled competitor was included at the concentrations described. After an additional three washes with blocking/binding buffer, counts were solubilized with boiling 2N NaOH and subjected to γ -counting. Non specific binding of ligand to the receptor was determined with molar excess (200-fold) of the unlabeled ligand. Each data point is a result of the average of triplicate wells.

Acknowledgements

This work was supported by ANR 2010-BLAN-1007-1 funding. We are grateful to Dr Pascal Retailleau from ICSN, Gif sur Yvette for X-Ray data collection. The authors thank Dr Erwann Guenin from CSPBAT, Bobigny and Dr Serge Perard for rereading and advices.
