

ZEROS OF THE WIGNER DISTRIBUTION AND THE SHORT-TIME FOURIER TRANSFORM

KARLHEINZ GRÖCHENIG, PHILIPPE JAMING, AND EUGENIA MALINNIKOVA

ABSTRACT. We study the question under which conditions the zero set of a (cross-) Wigner distribution $W(f, g)$ or a short-time Fourier transform is empty. This is the case when both f and g are generalized Gaussians, but we will construct less obvious examples consisting of exponential functions and their convolutions. The results require elements from the theory of totally positive functions, Bessel functions, and Hurwitz polynomials. The question of zero-free Wigner distributions is also related to Hudson's theorem for the positivity of the Wigner distribution and to Hardy's uncertainty principle. We then construct a class of step functions S so that the Wigner distribution $W(f, \mathbf{1}_{(0,1)})$ always possesses a zero $f \in S \cap L^p$ for $p < \infty$, but may be zero-free for $f \in S \cap L^\infty$. The examples show that the question of zeros of the Wigner distribution may be quite subtle and relate to several branches of analysis.

1. INTRODUCTION

The aim of this paper is to investigate the zero set of the Wigner distribution of two functions $f, g \in L^2(\mathbb{R})$,

$$(1) \quad W(f, g)(z) = \int_{\mathbb{R}^d} f\left(x + \frac{t}{2}\right) \bar{g}\left(x - \frac{t}{2}\right) e^{-2\pi i \langle \xi, t \rangle} dt, \quad z = (x, \xi) \in \mathbb{R}^{2d}.$$

More precisely, we are investigating whether this zero set can be empty. Results here directly extend to other phase-space representations to which the Wigner transform is closely related. These include the ambiguity function and the short-time Fourier transform $V_g f(z) = \langle f, \pi(z)g \rangle_{L^2(\mathbb{R}^d)}$, $\pi(z)g(t) = e^{2i\pi\xi t} g(t-x)$ (see (2)).

The zero set of the short-time Fourier transform is important in the study of the generalized Berezin quantization and the injectivity of a general Berezin transform. The thesis of D. Bayer [5], partially published in [6], contains the following result (under a mild condition on $f, g \in L^2(\mathbb{R}^d)$): *If $V_g f(z) \neq 0$ for all $z \in \mathbb{R}^{2d}$, then the mapping $T \rightarrow \mathcal{B}T, \mathcal{B}(z) = \langle T\pi(z)g, \pi(z)f \rangle$ is one-to-one on the space of bounded operators on $L^2(\mathbb{R}^d)$.* The function $(z, w) \mapsto \langle T\pi(z)g, \pi(w)f \rangle$ may be interpreted as a special integral kernel associated to the operator T . Bayer's statement asserts that T is uniquely determined by the *diagonal* of this kernel. The assertion is relevant, because theorems of this type were known only in the context of complex analysis, see, e.g. [10, Cor. 1.70]. Zero-free Wigner distributions occur prominently in [26, 28] in a similar context. It is therefore natural to ask for examples that satisfy Bayer's assumptions:

Question. *Determine (all) pairs (f, g) such that $W(f, g)$ does not vanish.*

Clearly, if $f(t) = g(t) = e^{-\pi t^2}$ is a Gaussian, then $W(f, g)(x, \xi) = 2^d e^{-2\pi(x^2 + \xi^2)} \neq 0$ everywhere. More generally, if q, \tilde{q} are quadratic polynomials such that $f = e^{-q}, g =$

Key words and phrases. Wigner distribution, short-time Fourier transform, Hudson's theorem, poly-analytic function, convexity, Hurwitz polynomial, totally positive function.

$e^{-\tilde{q}} \in L^2(\mathbb{R}^d)$ (generalized Gaussian), then the Wigner distribution $W(f, g)$ is also zero-free. For a while, we have been unable to produce other pairs (f, g) for which $W(f, g)$ is zero-free which lead us to believe that such pairs might not exist. The aim of this paper is to show that our belief was false by providing several examples of Wigner distributions without zeros. In doing so, we explore several connections with other areas of analysis. Although we cannot offer a coherent theory of zero-free Wigner distributions, we feel that the above question is of interest in itself and warrants a deeper analysis. Part of the appeal of this problem comes from the connection to different branches of analysis. In our quest for zero-free Wigner distributions we touched the following topics in analysis.

(i) *Total positivity.* Most of our examples of zero-free Wigner distributions (or ambiguity functions) are obtained from the basic example of the one-sided exponential function $e^{-at}\mathbf{1}_{(0,\infty)}(t)$ by convolution. These happen to be totally positive functions, as follows from the fundamental classification of totally positive functions by Schoenberg [30]. However, not all totally positive functions possess a zero-free ambiguity functions, as can be seen from the symmetric exponential function $e^{-a|x|}$.

(ii) *Bessel functions and Hurwitz polynomials.* The Wigner distribution of the functions $f_n(t) = t^n e^{-t}\mathbf{1}_{(0,\infty)}(t)$ contains certain Bessel functions as a factor. Moreover, to verify that the ambiguity function of f_n is zero-free, one needs to know that certain polynomials have all their zeros in the left half-plane, i.e., whether they are Hurwitz polynomials. We answer this question by recourse to the classical properties of Bessel functions.

(iii) *Hudson's theorem.* The non-vanishing of a Wigner distribution seems inherently related to Hudson's theorem which asserts that a Wigner distribution is non-negative, if and only if both f and g are generalized Gaussians [16]. Indeed, variations of the proof of Hudson's theorem yield the following statement: *If $\operatorname{Re} W(f, g)$ does not have any zeros, then f and g must be generalized Gaussians.* Similar statement holds for the imaginary part of $W(f, g)$. For all other functions, the real and imaginary parts of the Wigner distribution must change sign, so the zero sets contain some hypersurfaces and the question is when these hypersurfaces do not intersect.

(iv) *Poly-analytic functions.* We also consider the case when both functions f and g are finite linear combinations of Hermite functions. We are lead to investigate the zeros of certain poly-analytic functions. Results of Balk [4] yield some hints about the zero set in this case. However, this direction does not seem to lead to new examples of zero-free Wigner distributions. We conjecture that no such examples exist in the class of finite linear combinations of Hermite functions.

(v) *Convexity and almost periodicity.* As a last class of functions we consider pairs f, g where one of the functions, say g , is a characteristic function of an interval. We conjecture that for any choice of $f \in L^2(\mathbb{R})$ the Wigner distribution $W(f, g)$ has zeros. To support our conjecture we study the following particular case. Let $g = \mathbf{1}_{(0,1)}$ and choose f to be a step function with discontinuities on $\mathbb{Z} \cup \alpha\mathbb{Z}$ for irrational α . If $f \in L^p$ for $p < \infty$, the Wigner distribution $W(f, \mathbf{1}_{(0,1)})$ must always have a zero. However, we will construct a delicate example of a step function f in L^∞ for which the corresponding Wigner distribution $W(f, \mathbf{1}_{(0,1)})$ does not have any zeros. This example shows that the non-existence of zeros of the Wigner distribution may be quite subtle and may depend sensitively on integrability or smoothness properties of the function classes considered. In this part we use convexity and almost periodicity as tools.

The article is organized as follows: in Section 2 we list some of the properties of the Wigner distribution and the ambiguity function. We list examples we found for which the

Wigner distribution is zero-free in Sections 3 and 4. In Section 5 we study the connection of zero-free Wigner distributions to Hudson's theorem. Open questions and interesting connections of the problem to other areas of analysis are discussed in Sections 4-7. In Section 6 we consider f and g to be finite linear combinations of Hermite functions and relate the corresponding Wigner distribution to the theory of poly-analytic functions. Section 7 is devoted to the case when g is the characteristic function of an interval.

2. SOME PROPERTIES OF THE WIGNER TRANSFORM

The Wigner transform is closely related to two other transforms in time-frequency analysis. The first one is the short-time Fourier transform

$$(2) \quad V_g f(x, \xi) = \int_{\mathbb{R}^d} f(t) \overline{g(t-x)} e^{-2\pi i \langle \xi, t \rangle} dt.$$

A simple computation shows that

$$(3) \quad W(f, g)(x, \xi) = e^{4\pi i x \cdot \xi} V_{I_g} f(2x, 2\xi),$$

with $I_g(t) = g(-t)$. The second transform is the ambiguity function which is a slightly more symmetric version of the short-time Fourier transform

$$A(f, g) = \int_{\mathbb{R}^d} f\left(t + \frac{x}{2}\right) \overline{g\left(t - \frac{x}{2}\right)} e^{-2i\pi \langle \xi, t \rangle} dt.$$

These transforms are related by the formulas

$$A(f, g) = e^{i\pi \xi x} V(f, g) \quad \text{and} \quad A(f, g)(x, \xi) = \frac{1}{2} W(f, I_g)(x/2, \xi/2).$$

Thus a pair (f, g) for which $A(f, g)$ does not vanish also provides a pair (f, g) for which the short-time Fourier transform and a pair (f, I_g) for which the Wigner-transform do not vanish.

Let us now list the invariance properties of the ambiguity function. To do so, we recall that, for $z = (x, \xi) \in \mathbb{R}^{2d}$, the phase-space shift of $f \in L^2(\mathbb{R}^d)$ along z is defined by $\pi(z)f(t) = e^{2\pi i \xi \cdot t} f(t - x)$. To every symplectic matrix $\mathcal{A} \in \text{Sp}(d, \mathbb{R})$ one can then associate a unitary operator $\mu(\mathcal{A})$ acting on $L^2(\mathbb{R}^d)$ such that

$$(4) \quad \pi(\mathcal{A}z) = \mu(\mathcal{A})\pi(z)\mu(\mathcal{A})^* \quad \forall z \in \mathbb{R}^{2d}.$$

Here $\mu(\mathcal{A})$ is determined only up to a phase factor and is called a metaplectic operator. The existence of metaplectic operators follows already from the Stone-von Neumann theorem [10, Thm. 1.50] and is all we need here. For the much deeper aspects of these operators and the subtle construction of the metaplectic representation we refer to [10] and the recent book [9]. For Theorem 5.4 we need the following formulas about the interaction between the Wigner distribution and the metaplectic operators.

Lemma 2.1. *Let $f, g \in L^2(\mathbb{R}^d)$, $w = (a, b), w' = (a', b') \in \mathbb{R}^{2d}$, and $\mathcal{A} \in \text{Sp}(d, \mathbb{R})$. Then for all $z \in \mathbb{R}^{2d}$*

$$(5) \quad W(\pi(w)f, \pi(w')g)(z) = e^{2i\pi \langle w-w', z \rangle + i\pi \langle b+b', a-a' \rangle} W(f, g)\left(z - \frac{w+w'}{2}\right)$$

$$(6) \quad W(\mu(\mathcal{A})f, \mu(\mathcal{A})g)(z) = W(f, g)(\mathcal{A}^*z).$$

See Prop. (1.92) for (5) (with slightly different normalizations), and Prop. (4.28) for (6), or the general references [9, 11].

As a consequence, if $W(f, g)$ does not vanish, so does $W(\pi(w)f, \pi(w')g)$ and $W(\mu(\mathcal{A})f, \mu(\mathcal{A})g)$. Note that when $\mathcal{A} = J = \begin{pmatrix} 0 & -I \\ I & 0 \end{pmatrix}$, $\mu(\mathcal{A})f$ is the Fourier transform of f . Thus every example of a zero-free Wigner distribution yields a whole class of related examples.

We will use a further property of the ambiguity function. For $\xi \in \mathbb{R}$, let us write $M_\omega f(t) = \pi(0, \omega)f(t) = e^{-2i\pi\omega t}f(t)$. Then

$$A(f, g)(x, \xi) = (M_{-\xi/2}f) * (M_{\xi/2}g^*)(x)$$

where $g^*(t) = \overline{g(-t)}$. As a consequence

$$(7) \quad \begin{aligned} A(f_1 * f_2, g_1 * g_2)(x, \xi) &= (A(f_1, g_1)(\cdot, \xi) *_1 A(f_2, g_2)(\cdot, \xi))(x) \\ &:= \int_{\mathbb{R}} A(f_1, g_1)(t, \xi) A(f_2, g_2)(x - t, \xi) dt. \end{aligned}$$

Finally we cite the version of Hardy's uncertainty principle for the Wigner distribution taken from [13].

Lemma 2.2. (i) If $|W(f, f)(z)| \leq Ce^{-2\pi|z|^2} = C'W(h_0, h_0)(z)$ for all $z \in \mathbb{R}^{2d}$, then $f = ch_0$.

(ii) Let $\gamma \in L^2(\mathbb{R}^d)$ be a generalized Gaussian and $\psi \in L^2(\mathbb{R}^d)$. If $W(\psi, \psi)(z) \leq W(\gamma, \gamma)(z)$ for all $z \in \mathbb{R}^{2d}$, then $\psi = c\gamma$.

Proof. (i) is Hardy's uncertainty principle for the Wigner distribution as proved in [13] (Lemma 3.3 and Remark 3.4).

(ii) follows from (i). We recall that every generalized Gaussian $\gamma = e^{Q(x)} \in L^2(\mathbb{R}^d)$ with a quadratic polynomial Q can be written in the form $\gamma = \pi(w)\mu(\mathcal{A})h_0$, where $h_0(x) = 2^{d/4}e^{\pi x \cdot x}$ is the normalized Gaussian, see e.g., [10], Prop. (4.73). Let $\psi_0 \in L^2(\mathbb{R}^d)$ such that $\psi = \pi(w)\mu(\mathcal{A})\psi_0$. Using (5) and (6), we obtain

$$\begin{aligned} |W(\psi_0, \psi_0)(\mathcal{A}^*(z - w))| &= |W(\psi, \psi)(z)| \\ &\leq CW(\gamma, \gamma)(z) = C'W(h_0, h_0)(\mathcal{A}^*(z - w)) \quad z \in \mathbb{R}^{2d}. \end{aligned}$$

By (i) this implies that $\psi_0 = ch_0$ and consequently $\psi = c\gamma$. ■

3. EXAMPLES

In this section we give several examples of pairs of functions for which the ambiguity function do not vanish.

Example 1. The first example is the Gaussian function. Write $\gamma_a(t) = e^{-\pi t^2}$ with $\operatorname{Re}(a) > 0$. Then a direct, well known computation shows that, if $\operatorname{Re}(a), \operatorname{Re}(b) > 0$,

$$(8) \quad A(\gamma_a, \gamma_b) = (a + b)^{-1/2} \exp\left(-\pi \frac{abx^2 + \xi^2}{a + b} + i \frac{a - b}{a + b} x\xi\right)$$

so that $A(\gamma_a, \gamma_b)$ does not vanish.

Using tensorisation and invariance properties of the Wigner distribution, it follows that, if $f, g \in L^2(\mathbb{R}^d)$ are generalized Gaussians $f = e^Q$ (for some quadratic polynomial), then $A(f, g)$ does not vanish.

A second family of examples is given by the one-sided exponential.

Example 2. For $a > 0$, let $\eta_a(t) = e^{-at} \mathbf{1}_{(0,+\infty)}(t)$. Then, for $a, b > 0$

$$(9) \quad A(\eta_a, \eta_b)(x, \xi) = \exp\left(-\frac{a-b}{2}x - \frac{a+b}{2}|x|\right) \frac{e^{-i\pi\xi|x|}}{a+b+2i\pi\xi} = \eta_{a,b}(x) \frac{e^{-i\pi\xi|x|}}{a+b+2i\pi\xi}$$

where $\eta_{a,b}(x) = (b-a)^{-1} \eta_a * I\eta_b(x) = \begin{cases} e^{-ax} & \text{when } x \geq 0 \\ e^{bx} & \text{when } x < 0 \end{cases}$. See also [21]. In particular,

$$A(\eta_a, \eta_a)(x, \xi) = \frac{e^{-(a+i\pi\xi)|x|}}{2(a+i\pi\xi)}$$

does not have any zeros. Since $A(I f, I g)(x, \xi) = A(f, g)(-x, -\xi)$, the ambiguity function of the one-sided exponential $I\eta_b, b > 0$, is

$$(10) \quad A(I\eta_b, I\eta_b)(x, \xi) = \frac{e^{-(b-i\pi\xi)|x|}}{2(b-i\pi\xi)},$$

and is also zero-free.

However, the ambiguity function $A(\eta_a, I\eta_b)(x, \xi) = 0$ for $x > 0$, because in this case $t \mapsto \eta_a(t+x/2)$ and $t \mapsto I\eta_b(t-x/2)$ have disjoint supports.

Example 3. Next we compute the ambiguity function of convolutions of exponentials of the form $f = \eta_a * \eta_b$ or $f = \eta_a * I\eta_b$ for $a, b > 0$. For a compact formula we write $\eta_{-a} = I\eta_a$.

Lemma 3.1. *Let $a, b > 0, a \neq b$. Then*

$$(11) \quad A(\eta_a * \eta_{\pm b}, \eta_a * \eta_{\pm b})(x, \xi) = \frac{1}{2(b^2 - a^2) + 4\pi i(\pm b - a)\xi} \left(\frac{e^{-(a+\pi i\xi|x|)}}{a + \pi i\xi} - \frac{e^{-(b\pm\pi i\xi)|x|}}{b \pm \pi i\xi} \right).$$

Furthermore, $A(\eta_a * \eta_{\pm b}, \eta_a * \eta_{\pm b})$ has no zeros.

Proof. To facilitate calculations, we set $\psi_u(x) = e^{-u|x|}$ for $u \in \mathbb{C}$. Given $a, b > 0$ set $u = a + \pi i\xi, v = b + \pi i\xi$. In this notation, (9) with $a = b$ becomes

$$A(\eta_a, \eta_a)(x, \xi) = \frac{1}{2u} \psi_u(x) \quad \text{and} \quad A(\eta_{-b}, \eta_{-b})(x, \xi) = \frac{1}{2\bar{v}} \psi_{\bar{v}}(x).$$

To find the ambiguity function of $f = \eta_a * \eta_b$, we use (7) and find that

$$(12) \quad A(f, f)(x, \xi) = \frac{\psi_u * \psi_v(x)}{4uv}.$$

Then for $x \geq 0$ we obtain

$$\begin{aligned} \psi_u * \psi_v(x) &= \int_{-\infty}^0 e^{ut-v(x-t)} dt + \int_0^x e^{-ut-v(x-t)} dt + \int_x^{+\infty} e^{-ut+v(x-t)} dt \\ &= \frac{e^{-vx}}{u+v} + \frac{e^{-ux} - e^{-vx}}{v-u} + \frac{e^{-ux}}{u+v} \\ &= e^{-ux} \left(\frac{1}{v+u} + \frac{1}{v-u} \right) + e^{-vx} \left(\frac{1}{v+u} - \frac{1}{v-u} \right) \\ &= \frac{2}{v^2 - u^2} (ve^{-ux} - ue^{-vx}). \end{aligned}$$

Since ψ_u is even, so is $\psi_u * \psi_v$, and then (12) yields

$$(13) \quad A(f, f)(x, \xi) = \frac{1}{2(v^2 - u^2)} \left(\frac{e^{-u|x|}}{u} - \frac{e^{-v|x|}}{v} \right),$$

from which (11) follows by substituting the values for u and v .

For the case $f = \eta_a * \eta_{-b}$, according to (10) we only have to replace v by \bar{v} in the above derivation, whence (11) follows for f .

Now assume that $A(\eta_a * \eta_b, \eta_a * \eta_b)(x, \xi) = 0$. Since $a \neq b$, the denominator $v^2 - u^2 \neq 0$ and (13) implies that

$$(14) \quad \frac{e^{-u|x|}}{u} = \frac{e^{-v|x|}}{v},$$

or

$$e^{(b-a)|x|} = e^{(v-u)|x|} = \frac{u}{v} = \frac{a + \pi i \xi}{b + \pi i \xi}.$$

For $b > a$, then left-hand side is greater than 1, whereas the modulus of the right-hand side is less than 1, which is impossible. Thus $A(\eta_a * \eta_b, \eta_a * \eta_b)$ does not have any zeros. Likewise for the case $b < a$.

Similarly, if $A(\eta_a * \eta_{-b}, \eta_a * \eta_{-b})(x, \xi) = 0$, then

$$(15) \quad \frac{e^{-u|x|}}{u} = \frac{e^{-\bar{v}|x|}}{\bar{v}},$$

or

$$(16) \quad e^{(b-a-2\pi i \xi)|x|} = e^{(\bar{v}-u)|x|} = \frac{u}{\bar{v}} = \frac{a + \pi i \xi}{b - \pi i \xi}.$$

Again for $b > a$, the modulus of the left-hand side is greater than 1, whereas the modulus of the right-hand side is less than 1, which is not possible. Thus $A(\eta_a * \eta_{-b}, \eta_a * \eta_{-b})$ does not have any zeros. \blacksquare

The case $a = b$ and $\eta_a * \eta_a = te^{-at} \mathbf{1}_{(0, \infty)}$ is treated below. The case of $\eta_a * \eta_{-a} = e^{-a|x|}$ is particularly interesting, as its Fourier transform is the Poisson kernel. In this case (11) holds for $\xi \neq 0$ and requires some easy modification for $\xi = 0$. If $\xi \neq 0$, then (16) turns into

$$e^{-2\pi i \xi |x|} = e^{(\bar{v}-u)|x|} = \frac{u}{\bar{v}} = \frac{a + \pi i \xi}{a - \pi i \xi}.$$

This equation is solvable, and therefore the ambiguity function of $e^{-a|x|}$ must have zeros. In Theorem 5.2 we will give a different explanation for this fact.

It is also possible to derive a formula for the ambiguity function of higher convolutions of the form $\eta_{a_1} * \eta_{a_2} * \dots * \eta_{a_n}$ for distinct values of $a_j > 0$. These expressions are much more complicated, and the analysis of their zeros requires a separate investigation.

Example 4. Let $a > 0$ and $f(t) = \eta_a * \eta_a(t) = t\eta_a(t)$. A direct computation shows that

$$A(f, \eta_a)(x, \xi) = \frac{x \mathbf{1}_{(0, +\infty)}(x) e^{-a(1+i\pi\xi)x}}{2(a+i\pi\xi)} + \frac{e^{-a(1+i\pi\xi)|x|}}{4(a+i\pi\xi)^2}.$$

Obviously, $A(f, \eta_a)(x, \xi)$ can not vanish if $x \leq 0$, while if $x \geq 0$, it is enough to notice that $2x(a+i\pi\xi) + 1$ can not vanish.

Example 5. Let $\gamma_{a,b}(t) = \exp(at - bt^2)$, where $a, b > 0$, then $\gamma_{a,b} \in L^2(\mathbb{R})$ and we claim that $A(\gamma_{a,b}, \gamma_{a,b})$ does not vanish. A straightforward computation (with the substitution

$s = 2b \cosh \frac{x}{2} e^t$) shows that

$$A(\gamma_{a,b}, \gamma_{a,b})(x, \xi) = \left(2b \cosh \frac{x}{2}\right)^{-2a+2\pi i\xi} \int_0^\infty s^{2a-1-2\pi i\xi} e^{-s} ds = \left(2b \cosh \frac{x}{2}\right)^{-2a+2\pi i\xi} \Gamma(2a - 2\pi i\xi).$$

The gamma function is well defined in the right half-plane and does not have zeros, so $A(\gamma_{a,b}, \gamma_{a,b})$ never vanishes. A similar computation shows that

$$A(\gamma_{a,b}, \gamma_{c,d}) = e^{(a-c)x/2} (be^{x/2} + de^{-x/2})^{-(a+c)+2\pi i\xi} \Gamma(a+c-2\pi i\xi)$$

and it has no zeros either.

One can now use the invariance properties of the ambiguity function to obtain more examples. For instance, using the Fourier transform, one obtains the following examples.

Example 6. Let us now write, for $a \neq 0$, $c_a(t) = \frac{1}{a+2i\pi t}$ and note that c_a is the Fourier transform of η_a when $a > 0$. It follows that $A(c_a, c_b)$ does not vanish for $a, b > 0$. Furthermore, except for the Poisson kernel $\frac{1}{a^2+4\pi^2 t^2}$ all rational functions of the form $c_a(t)c_b(\pm t) = \frac{1}{a+2i\pi t} \frac{1}{b\pm 2i\pi t}$ possess a non-vanishing ambiguity function, because they are the Fourier transform of $\eta_a * \eta_b$ or of $\eta_a * I\eta_b$.

Outlook and context. All functions in Examples 2-4 are special cases of *totally positive* functions. A function $g : \mathbb{R} \rightarrow \mathbb{R}$ is called totally positive (or a Polya frequency function), if for every choice of real numbers $x_1 < x_2 < \dots < x_n$ and $y_1 < y_2 < \dots < y_n$ with $n \in \mathbb{N}$ the inequality

$$\det (g(x_j - y_k))_{j,k=1,\dots,n} \geq 0.$$

According to a fundamental characterization of Schoenberg [30] the Fourier transform of a totally positive function in $L^1(\mathbb{R})$ can be factored as follows:

$$(17) \quad \hat{g}(\xi) = e^{-\gamma\pi\xi^2} e^{2\pi i\delta\xi} \prod_{j=1}^{\infty} (1 + 2\pi i\delta_j\xi)^{-1} e^{2\pi i\delta_j\xi},$$

with $\delta, \delta_j \in \mathbb{R}$, $0 \leq \gamma$, and $\sum_{j=1}^{\infty} \delta_j^2 < \infty$ and $\delta \in \mathbb{R}$. In this section we have analyzed the ambiguity function of the simplest totally positive functions, corresponding to the factorization $\hat{g}(\xi) = \prod_{j=1}^L (1 + 2\pi i\delta_j\xi)^{-1}$ for $L = 1$ and $L = 2$. These are just the functions $\eta_a, \eta_a * \eta_b, \eta_a * I\eta_b$.

At this time the role of totally positive functions in the classification of zero-free ambiguity functions remains unclear. Among all explicit examples considered, only the symmetric exponential $e^{-a|x|}$ has an ambiguity function with zeros. More generally, the ambiguity function of every *even* totally positive function has a zero. See also Theorem 5.2 below.

4. TOTALLY POSITIVE FUNCTIONS AND HURWITZ POLYNOMIALS

In this section we study a different class of totally positive functions and its relation to Bessel functions and Hurwitz polynomials. Let

$$f_n(t) = t^n e^{-t} \mathbf{1}_{(0,\infty)}(t) = t^n \eta_1(t).$$

This is a totally positive function with Fourier transform $\hat{f}(\xi) = (1 + 2\pi i\xi)^{-n}$ [30] and can also be written as $n! \eta_1 * \dots * \eta_1$ (n times). Its ambiguity function can be explicitly calculated as follows. Let A_n be the polynomial of degree n defined as follows:

$$(18) \quad A_n(z) = \sum_{k=0}^n \binom{n}{k} (n+k)! z^{n-k}$$

Lemma 4.1. *The ambiguity function of $f_n(t) = t^n e^{-t} \mathbf{1}_{(0,\infty)}(t)$ is given as*

$$(19) \quad A(f_n, f_n)(x, \xi) = e^{-|x|(1+i\pi\xi)} \frac{1}{(2+2\pi i\xi)^{2n+1}} A_n(|x|(2+2\pi i\xi)).$$

Proof. We rewrite the ambiguity function as follows:

$$\begin{aligned} A(f_n, f_n)(x, \xi) &= \int_{\mathbb{R}} \left(t + \frac{x}{2}\right)^n e^{-(t+x/2)} \mathbf{1}_{\mathbb{R}^+}(t + \frac{x}{2}) \left(t - \frac{x}{2}\right)^n e^{-(t-x/2)} \mathbf{1}_{\mathbb{R}^+}(t - \frac{x}{2}) e^{-2\pi i\xi t} dt \\ &= \int_{|x|/2}^{\infty} \left(t + \frac{x}{2}\right)^n \left(t - \frac{x}{2}\right)^n e^{-(2+2\pi i\xi)t} dt, \end{aligned}$$

since we need both $t > x/2$ and $t > -x/2$. For $x \neq 0$, we use the change of variables

$$u = \frac{t}{|x|} - \frac{1}{2}$$

(so that $t = |x|u + |x|/2$) to rewrite the integral as

$$\begin{aligned} A(f_n, f_n)(x, \xi) &= |x|^{2n+1} \int_0^{\infty} u^n (u+1)^n e^{-(|x|u+|x|/2)(2+2\pi i\xi)} du \\ &= e^{-|x|(1+i\pi\xi)} |x|^{2n+1} \int_0^{\infty} u^n (u+1)^n e^{-u|x|(2+2\pi i\xi)} du. \end{aligned}$$

The integral is just the Laplace transform of the polynomial

$$u^n (u+1)^n = \sum_{k=0}^n \binom{n}{k} u^{n+k}$$

at $\zeta = |x|(2+2\pi i\xi)$. Since $\mathcal{L}\{u^k\}(z) = \int_0^{\infty} u^k e^{-uz} du = k! z^{-k-1}$, we obtain

$$\int_0^{\infty} u^n (u+1)^n e^{-uz} du = \sum_{k=0}^n \binom{n}{k} (n+k)! z^{-n-k-1} = z^{-2n-1} A_n(z).$$

For $x = 0$, the ambiguity function is

$$A(f_n, f_n)(0, \xi) = \int_0^{\infty} t^{2n} e^{-t(2+2\pi i\xi)} dt = \mathcal{L}\{u^{2k}\}(2+2\pi i\xi) = (2n)! (2+2\pi i\xi)^{-2n-1}.$$

With $\zeta = |x|(2+2\pi i\xi)$ and $|x|^{2n+1} \zeta^{-2n-1} = (2+2\pi i\xi)^{-2n-1}$, the final formula for the ambiguity function on \mathbb{R}^2 is

$$A(f_n, f_n)(x, \xi) = e^{-|x|(1+i\pi\xi)} \frac{1}{(2+2\pi i\xi)^{2n+1}} A_n(|x|(2+2\pi i\xi)).$$

■

To show that the ambiguity function of f does not vanish, we need to know that A_n has no zeros on the right half-plane. A polynomial whose roots all have negative real part, is called a Hurwitz polynomial or a stable polynomial. For small n one can check the stability of A_n directly. For larger n , one could check the stability of A_n in principle

with the Routh-Hurwitz criterion [17, pages 225-230]. For this purpose, we associate to a polynomial $p(t) = a_0 t^n + a_1 t^{n-1} + \dots + a_n$, $a_0 > 0$ the $n \times n$ Hurwitz matrix

$$\mathcal{H} = (a_{2j-i})_{1 \leq i, j \leq n} = \begin{pmatrix} a_1 & a_3 & a_5 & a_7 & \cdots & 0 \\ a_0 & a_2 & a_4 & a_6 & \cdots & 0 \\ 0 & a_1 & a_3 & a_5 & \cdots & 0 \\ 0 & a_0 & a_2 & a_4 & \cdots & 0 \\ \vdots & \vdots & \vdots & \vdots & & \vdots \\ 0 & 0 & 0 & 0 & \cdots & a_n \end{pmatrix}$$

(with the convention $a_j = 0$ if $j < 0$ or $j > n$). Then p is a Hurwitz polynomial if and only if all principal minors of \mathcal{H} are positive [17, pages 225-230]. This criterion implies that the condition $a_j a_{j+1} - a_{j-1} a_{j+2} > 0$ is necessary for the stability of p . On the other hand, there exists an optimal value $\gamma > 0$, $\gamma \approx 2.1479$, such that $a_j a_{j+1} > \gamma a_{j-1} a_{j+2}$ is sufficient for p to be stable [22]. One can check that the polynomials A_n satisfy the necessary condition, but fail to satisfy the sufficient condition. The decisive hint comes from experimenting with Mathematica. It turns out that

$$(20) \quad A_n(z) = \pi^{-1/2} n! e^{z/2} z^{n+1/2} K_{n+1/2}\left(\frac{z}{2}\right),$$

where K_ν , $\nu \in \mathbb{R}$ is the Macdonald function or the modified Bessel function of the second kind [23, 24, 33]. For $\nu = n + 1/2$ it is the Laurent polynomial

$$K_{n+1/2}(z) = \left(\frac{\pi}{2z}\right)^{1/2} e^{-z} \sum_{k=0}^n \frac{(n+k)!}{k!(n-k)!} (2z)^{-k},$$

whence (20) follows immediately. One can also perform the change of variables $s = 2t/|x|$ in the first computation of $A(f_n, f_n)$ and directly obtain that

$$\begin{aligned} A(f_n, f_n)(x, \xi) &= \int_{|x|/2}^{\infty} \left(t + \frac{x}{2}\right)^n \left(t - \frac{x}{2}\right)^n e^{-(2+2\pi i \xi)t} dt \\ &= \left(\frac{|x|}{2}\right)^{2n+1} \int_1^{\infty} (s^2 - 1)^n e^{-(1+\pi i \xi)|x|s} ds \\ &= \frac{n!}{\sqrt{\pi}} \left(\frac{|x|}{1 + \pi i \xi}\right)^{n+1/2} K_{n+1/2}(|x|(1 + \pi i \xi)) \end{aligned}$$

Furthermore, for arbitrary $\nu \geq 0$, K_ν has roots only when $\operatorname{Re} z < 0$. In view of (20) A_n is therefore a Hurwitz polynomial [33].

By combining the accumulated knowledge about Bessel functions, we have therefore proved the following result.

Theorem 4.2. *The polynomial A_n is a Hurwitz polynomial. Thus the ambiguity function of $f_n(t) = t^n e^{-t} \mathbf{1}_{(0, \infty)}(t)$ does not have any zeros.*

Using the invariance of the problem under metaplectic operators, we see that the function $c_a^n(t) = \frac{1}{(a+2i\pi t)^n}$ has a zero-free ambiguity function. This follows because the Fourier transform of $x^n e^{-ax} \mathbf{1}_{(0, \infty)}(x) = \eta_a * \dots * \eta_a$.

Remark 1. Martin Ehler proposed a different proof that A_n is a Hurwitz polynomial. He observed that A_n can be interpreted as the hypergeometric function ${}_1F_1(n, 2n; z)$, whose zeros are known to lie in the left halfplane.

5. CONNECTION TO HUDSON'S THEOREM

We next discuss the connection of non-vanishing Wigner distributions to Hudson's theorem [16]. This theorem characterizes all non-negative Wigner distributions as follows:

Theorem 5.1 (Hudson-Lieb). *Let $f, g \in L^2(\mathbb{R}^d)$. Then $W(f, g) \geq 0$, if and only if $f = cg$ for $c \geq 0$ and g is a generalized Gaussian. In this case $W(f, g)(x, \xi) > 0$ for all $x, \xi \in \mathbb{R}$.*

As the connection to Hudson's theorem is not accidental, it is instructive to review its proof. For full details, we refer to [11, 16, 19], the cited bilinear version is due to Lieb [27].

One first uses the convolution relation $W(f, f) * W(g, g) = |V_g f|^2$ for the Wigner distribution. Using the Gaussian window $h_0(t) = 2^{d/4} e^{-\pi t \cdot t}$ with Wigner distribution $W(h_0, h_0)(z) = 2^d e^{-2\pi|z|^2}$, we may translate the statement about the zeros of the Wigner distribution into a statement about entire functions in the Bargmann-Fock space. The Bargmann transform of f is defined to be

$$(21) \quad Bf(z) = 2^{d/4} e^{-\pi z^2/2} \int_{\mathbb{R}^d} f(t) e^{-\pi t \cdot t} e^{2\pi t \cdot z} dt \quad z \in \mathbb{C}^d,$$

and it is connected to the short-time Fourier transform with respect to the Gaussian h_0 via

$$(22) \quad V_{h_0} f(\bar{z}) = e^{\pi i x \cdot \xi} Bf(z) e^{-\pi|z|^2/2}.$$

Here we identify the point $(x, \xi) \in \mathbb{R}^{2d}$ with $z = x + i\xi \in \mathbb{C}^d$. If $W(f, f) \geq 0$, then $W(f, f) * W(h_0, h_0)(z) > 0$ for all $z \in \mathbb{R}^{2d}$ and therefore

$$|V_{h_0} f(\bar{z})|^2 = |Bf(z)|^2 e^{-\pi|z|^2} \neq 0 \quad \text{for all } z \in \mathbb{C}^d.$$

If $V_{h_0} f(z) \neq 0$ for all $z \in \mathbb{R}^{2d}$, then the entire function Bf does not have zeros in \mathbb{C}^d and thus is of the form $Bf(z) = e^{h(z)}$ for some entire function h . However, since $V_{h_0} f$ is bounded, it follows that $|Bf(z)| = e^{\operatorname{Re} h(z)} \leq C e^{\pi|z|^2/2}$. Thus $\operatorname{Re} h(z) \leq C' + \pi|z|^2/2$. By Carathéodory's inequality h is then a quadratic polynomial. Inversion of the Bargmann transform yields the conclusion that f must be a generalized Gaussian.

The connection between zero-free Wigner distributions and Hudson's theorem now becomes apparent.

Theorem 5.2. *If $f \in L^2(\mathbb{R}^d)$ and $W(f, f)(x, \xi) \neq 0$ for all $x, \xi \in \mathbb{R}$, then f is a generalized Gaussian. Likewise, if $V_{I_f} f(x, \xi) \neq 0$ for all $x, \xi \in \mathbb{R}$, then f is a generalized Gaussian.*

Proof. Assume that $W(f, f) \neq 0$ everywhere. Since $W(f, f)$ is real-valued, this means that either $W(f, f)(z) > 0$ for all $z \in \mathbb{R}^2$ or $W(f, f)(z) < 0$ for all z , in which case $W(-f, f) > 0$ everywhere. By Theorem 5.1 f must be a generalized Gaussian. ■

Next we fix one of the functions and assume that $g(t) = h_0(t) = 2^{d/4} e^{-\pi t^2}$ is the normalized Gaussian in \mathbb{R}^d .

Proposition 5.3. *If $V_{h_0} f$ does not have any zero, then f is a generalized Gaussian.*

Proof. Since $|V_{h_0} f(\bar{z})| = |Bf(z)| e^{-\pi|z|^2/2}$ by (21), the entire function Bf does not have zeros in \mathbb{C}^d . The last part of the proof of Hudson's theorem sketched above now implies that f is a generalized Gaussian. ■

The standard polarization identity for the Wigner distribution now yields the following result on zeros of the real and imaginary parts of the Wigner distribution.

Theorem 5.4. *Let $f, g \in L^2(\mathbb{R}^d)$ and assume that the real part of $W(f, g)$ is never zero, $\operatorname{Re} W(f, g)(z) \neq 0$ for all $z \in \mathbb{R}^{2d}$. Then $f = a\gamma$ and $g = b\gamma$ for a generalized Gaussian γ and $a, b \in \mathbb{C}$. Similarly, if $\operatorname{Im} W(f, g)(z) \neq 0$ for all $z \in \mathbb{R}^{2d}$, then both f and g are generalized Gaussians.*

Proof. The polarization identity states that

$$W(f + g, f + g) - W(f - g, f - g) = 4\operatorname{Re} W(f, g).$$

Thus, if $\operatorname{Re} W(f, g)$ does not have any zeros, then we must have either

$$(23) \quad \begin{aligned} &W(f + g, f + g)(z) > W(f - g, f - g)(z) \\ \text{or} \quad &W(f + g, f + g)(z) < W(f - g, f - g)(z) \quad \forall z \in \mathbb{R}^{2d}. \end{aligned}$$

We only treat (23), the second case is obtained by replacing g by $-g$.

Proceeding as in the proof of Hudson's theorem, we convolve $W(f \pm g, f \pm g)$ with $W(h_0, h_0)(z) = 2^d e^{-2\pi|z|^2}$. Since convolution with a positive function preserves positivity, (23) implies the *strict* pointwise inequality

$$|V_{h_0}(f+g)|^2 = W(f+g, f+g) * W(h_0, h_0) > W(f-g, f-g) * W(h_0, h_0) = |V_{h_0}(f-g)|^2 \geq 0.$$

By Proposition 5.3 $f + g$ must be a generalized Gaussian $f + g = \gamma$.

Now, since $W(f - g, f - g) \leq W(\gamma, \gamma)$, Lemma 2.2 (ii) implies that $f - g = c\gamma$ for some $c \in \mathbb{C}$. Solving for f and g we obtain that $f = \frac{1+c}{2}\gamma$ and $g = \frac{1-c}{2}\gamma$, and therefore both f and g are multiples of the same generalized Gaussian. ■

6. POLYANALYTIC FUNCTIONS

To find examples of zero-free Wigner distributions, one might fix a window function g different from a Gaussian and see if every short-time Fourier transform $V_g f$ possesses at least one zero. We pursue this idea in dimension $d = 1$ for windows that are finite linear combinations of Hermite functions. This line of thought connects with the theory of poly-analytic functions and raises some new questions.

Let $g = ph_0$ where p is a polynomial and $h_0(t) = 2^{1/4} e^{-\pi t^2}$ is the normalized Gaussian on \mathbb{R} . We can then write g as a finite linear combination of Hermite functions,

$$(24) \quad g = \sum_{j=0}^N c_j h_j,$$

where $h_j(t) = c_j e^{\pi t^2} \frac{d^j}{dt^j} (e^{-2\pi t^2})$ is the j -th Hermite function with normalization c_j , such that $\|h_j\|_2 = 1$. It is well known that the short-time Fourier transform with respect to such a window is poly-analytic. To prepare the corresponding formulas, fix n and first consider $V_{h_n} f$. This short-time Fourier transform can be expressed with the help of the Bargmann transform of f as follows:

$$(25) \quad V_{h_n} f(x, -\xi) = \frac{1}{\sqrt{\pi^n n!}} e^{\pi i x \xi} e^{-\pi |z|^2 / 2} \sum_{k=0}^n \binom{n}{k} (-\pi \bar{z})^{n-k} B f^{(k)}(z).$$

See [8, 12] for some early references of this formula. Now assume that the window is of the form $g = \sum_{n=0}^N \sqrt{\pi^n n!} c_n h_n$ and denote the associated polynomial by $P(z) = \sum_{n=0}^N c_n z^n$.

Then

$$\begin{aligned}
V_g f(\bar{z}) &= e^{\pi i x \xi} e^{-\pi |z|^2/2} \sum_{n=0}^N c_n \sum_{k=0}^n \binom{n}{k} (-\pi \bar{z})^{n-k} B f^{(k)}(z) \\
&= e^{\pi i x \xi} e^{-\pi |z|^2/2} \sum_{k=0}^N \frac{1}{k!} \left(\sum_{n=k}^N c_n \frac{n!}{(n-k)!} (-\pi \bar{z})^{n-k} \right) B f^{(k)}(z) \\
(26) \quad &= e^{\pi i x \xi} e^{-\pi |z|^2/2} \sum_{k=0}^N \frac{1}{k!} B f^{(k)}(z) \overline{P^{(k)}(-\pi z)}.
\end{aligned}$$

From this explicit formula we see that the function $F(z) = e^{-\pi i x \xi} e^{\pi |z|^2/2} V_g f(\bar{z})$ satisfies the differential equation

$$(27) \quad \frac{\partial^{N+1}}{\partial \bar{z}^{N+1}} F = 0.$$

In the established terminology, F is poly-analytic of order $N+1$ and F is a version of the poly-analytic Bargmann transform of f [1, 4, 32]. Precisely given $g = \sum_{n=0}^N \sqrt{\pi^n n!} c_n h_n$ with associated polynomial $P(z) = \sum c_n z^n$, we define the poly-analytic Bargmann transform of f with respect to g to be

$$(28) \quad B_g f(z) = \sum_{k=0}^N \frac{1}{k!} B f^{(k)}(z) \overline{P^{(k)}(-\pi z)}.$$

Since $\frac{d^2}{dzd\bar{z}} = \frac{1}{4}\Delta$ is the standard Laplacian, (28) can also be written as

$$B_g f(z) = \sum_{k=0}^N \frac{1}{k!} 4^{-k} \Delta^k (B f(z) \overline{P(-\pi z)}).$$

The zero sets of poly-analytic functions are not well understood; in general they are not discrete and are algebraic curves in $\mathbb{C} \simeq \mathbb{R}^2$. The zero count is difficult even for such simple equations as $\bar{z} = P(z)$ for some polynomial P [4, 25].

We will use two known, non-trivial results about zeros of poly-analytic functions.

Theorem 6.1 (Balk). *If F is poly-analytic and entire, such that its zero set is contained in a bounded set, then $F(z) = e^{h(z)} Q(z, \bar{z})$ for some entire function h and some poly-analytic polynomial $Q(z, \bar{z})$.*

See [2] and [29] for a proof. From this result we obtain the following reduction.

Proposition 6.2. *Fix $g = ph_0$ for some polynomial p . If $V_g f$ does not have any zeros in \mathbb{C} , then $f(x) = q(x) e^{-(a'x^2 + b'x + c')}$ for some polynomial q and $a', b', c' \in \mathbb{C}$, $\operatorname{Re} a' > 0$.*

Proof. If the zero set of $V_g f$ is empty, then the zero set of the poly-analytic Bargmann transform $B_g f$ is also empty (and thus bounded). By Balk's theorem $B_g f$ factors into an entire function without zeros and a poly-analytic polynomial $Q(z, \bar{z})$, i.e., $B_g f(z) = e^{h(z)} Q(z, \bar{z})$ for h entire. Consequently, by (26) we see that

$$(29) \quad B_g f(z) = \sum_{k=0}^n \frac{1}{k!} B f^{(k)}(z) \overline{P^{(k)}(-\pi z)} = e^{h(z)} Q(z, \bar{z}).$$

Assume that $P(z) = z^n + \mathcal{O}(z^{n-1})$ and $Q(z, \bar{z}) = \sum_{j=0}^m p_j(z) \bar{z}^j$. Comparing the highest term in \bar{z} in (29), we conclude that $n = m$ and that

$$(-\pi)^n Bf(z) = e^{h(z)} p_n(z).$$

Since a function Bf in Fock space grows at most like $e^{\pi|z|^2/2}$, we conclude that $\operatorname{Re} h(z) \leq c + \pi|z|^2/2$ and therefore $h(z)$ must be a quadratic polynomial $h(z) = -(az^2 + bz + c)$ by Caratheodory's theorem. On the one hand, we have $Bf(z) = e^{-(az^2+bz+c)} p_n(z)$, and on the other hand,

$$\begin{aligned} Bf(iy)e^{-\pi y^2/2} &= V_{h_0} f(0, -y) = \int_{\mathbb{R}} f(t) e^{-\pi t^2} e^{2\pi i t y} dt \\ (30) \qquad \qquad \qquad &= \widehat{(f h_0)}(-y) = e^{-ay^2 - iby - c} p_n(iy). \end{aligned}$$

Now observe that the inverse Fourier transform of the generalized Gaussian $e^{-ay^2 - iby - c}$ is again a generalized Gaussian $e^{r(x)}$, and the polynomial $p_n(iy)$ turns into the differential operator $p_n(\frac{1}{2\pi} \frac{d}{dx})$. Consequently, $f h_0 = p_n(\frac{1}{2\pi} \frac{d}{dx}) e^{r(x)}$ and

$$f(x) = q(x) e^{-(a'x^2 + b'x + c')}$$

for some polynomial q . ■

In general we cannot say more about the form of f . If however, $f = qh_0$ with the standard Gaussian h_0 , then we can reduce the problem of zero-free Wigner distributions to a problem of polynomials of two variables by means of the *fundamental theorem of algebra for poly-analytic polynomials* [3, 4].

Theorem 6.3 (Balk). *Let $P(z, w)$ be a polynomial in two complex variables. If the exact degree of the poly-analytic polynomial $P(z, \bar{z})$ as a polynomial of two variables exceeds the exact degree of P in one of these variables by a factor more than two, the P has at least one zero.*

In other words, let $n_z = \deg_z p$, $n_{\bar{z}} = \deg_{\bar{z}} p$, and $s = \deg p$. If $s > 2 \min(n_z, n_{\bar{z}})$, then P has at least one zero. See [3, 4] for the proof.

From this we deduce the following consequence.

Proposition 6.4. *Assume that $g = ph_0$ and $f = qh_0$ for some polynomials p, q . If $V_g f$ does not have any zeros, then $\deg p = \deg q$.*

In other words, if f and g are finite linear combinations of Hermite functions, whose highest degrees differ, then the short-time Fourier transform $V_g f$ must have a zero.

Proof. Under the assumptions stated, Bf is a polynomial Q and the poly-analytic Bargmann transform is then (for N large enough)

$$(31) \qquad B_g f(z) = \sum_{k=0}^N \frac{1}{k!} Q^{(k)}(z) \overline{P^{(k)}(-\pi z)}$$

is a poly-analytic polynomial. Here $\deg_z B_g f = \deg Q$, $\deg_{\bar{z}} B_g f = \deg P$, and $\deg B_g f = \deg P + \deg Q$. If $\deg P \neq \deg Q$, then $\deg B_g f > 2 \min(\deg P, \deg Q)$, and by the fundamental theorem of algebra $B_g f$ must have a zero. ■

If the degree condition in the fundamental theorem is not satisfied, then a poly-analytic polynomial may not have any zeros, for instance, the polynomial $p(z, \bar{z}) = 1 + z\bar{z}$ does

not have any zeros. Note, however, that the poly-analytic polynomials arising in Proposition 6.4 have a very special structure.

Let us consider the simple example of degree 1 polynomials. It is enough to consider $P(z) = -z + \pi b$ and $Q(z) = z + a$ with $a, b \in \mathbb{C}$. Then we are looking for a root of the polynomial

$$Q(z)\overline{P(-\pi z)} + Q'(z)\overline{P'(-\pi z)} = \pi(z+a)(\bar{z} + \bar{b}) - 1.$$

Write $\zeta = \sqrt{\pi}(z+a)$ and $c = \sqrt{\pi}(b-\bar{a})$, the equation becomes $\zeta(\bar{\zeta} + c) = 1$. Writing c in polar coordinates $c = \rho e^{i\theta}$ and a further change of variable $\zeta = \xi e^{-i\theta}$ yields the equation $\xi(\bar{\xi} + \rho) = 1$. This equation has at least two real roots, namely $\frac{-\rho \pm \sqrt{\rho^2 + 4}}{2}$. This proves the following

Proposition 6.5. *If f or g is a linear combination of h_0, h_1 then $W(f, g)$ has a zero, unless f, g are both multiples of h_0 .*

In general, $B_g f$ may be written as a linear combination of various Laguerre polynomials or complex Hermite polynomials, see [10] or [18]. Thus $B_g f$ has a very special structure. One may therefore hope to prove the existence of a zero for the special poly-analytic polynomials of the form $B_g f$. An other simple example is constructed as follows: if $f = p h_0$ for some polynomial p of degree at least 1 and $g = I f$ (i.e., $g(x) = f(-x) = p(-x)h_0(x)$), then $|V_{I f} f(2z)| = W(f, f)$. The corresponding poly-analytic polynomial $B_{I f} f$ then has a zero by Hudson's theorem, although Balk's fundamental theorem of algebra does not apply.

7. AN EXAMPLE FOR BOUNDED FUNCTIONS: THE SHORT -TIME FOURIER TRANSFORM WITH A RECTANGULAR WINDOW

We next study a class of examples in which the decay properties are critical for the existence or non-existence of zeros of the short-time Fourier transform. For this purpose, we investigate the short-time Fourier transform of carefully constructed step functions. We consider the window $g = \mathbf{1}_{(0,1)}$ and step functions with discontinuities on the union $\mathbb{Z} \cup \alpha\mathbb{Z}$. We will need a simple lemma first.

Lemma 7.1. *Let $0 = a_1 < a_2 < \dots < a_n < a_{n+1} = 1$ and either $c_1 > c_2 > \dots > c_n > 0$ or $c_1 < c_2 < \dots < c_n$. Define f on $(0, 1)$ by*

$$f(x) = \sum_{k=1}^n c_k \mathbf{1}_{(a_k, a_{k+1})}.$$

Then there exists $\xi \in \mathbb{R}$ such that

$$\int_0^1 f(x) e^{-2\pi i x \xi} dx = 0$$

if and only if $a_2, \dots, a_n \in \mathbb{Q}$.

Proof. We first consider the case when c_j is strictly decreasing. For $\xi = 0$ we obtain

$$\int_0^1 f(x) e^{-2\pi i x \xi} dx = \int_0^1 f(x) dx = \sum_{k=1}^n c_k (a_{k+1} - a_k) > 0.$$

For $\xi \neq 0$ we set $I(\xi) = 2\pi i \xi \int_0^1 f(x) e^{2\pi i x \xi} dx = 2\pi i \xi \hat{f}(-\xi)$. Then

$$\begin{aligned} I(\xi) &= 2\pi i \xi \int_0^1 f(x) e^{2\pi i x \xi} dx = \sum_{k=1}^n c_k (e^{2\pi i a_{k+1} \xi} - e^{2\pi i a_k \xi}) \\ &= -c_1 + \sum_{k=2}^n (c_{k-1} - c_k) e^{2\pi i a_k \xi} + c_n e^{2\pi i \xi} \\ &= c_1 \left(\sum_{k=2}^n \frac{c_{k-1} - c_k}{c_1} e^{2\pi i a_k \xi} + \frac{c_n}{c_1} e^{2\pi i \xi} - 1 \right). \end{aligned}$$

Thus $\hat{f}(-\xi) = (2\pi i)^{-1} I(\xi) = 0$, if and only if

$$(32) \quad \sum_{k=2}^n \frac{c_{k-1} - c_k}{c_1} e^{2\pi i a_k \xi} + \frac{c_n}{c_1} e^{2\pi i \xi} = 1.$$

Since $|e^{2\pi i a_k \xi}| = 1$ and

$$\sum_{k=2}^n \frac{c_{k-1} - c_k}{c_1} + \frac{c_n}{c_1} = 1$$

with positive terms, (32) is a convex linear combination of points in the unit disc of \mathbb{C} .

As 1 is an extreme point of the unit disc, (32) holds if and only if it is a convex combination of 1's. Therefore, $I(\xi) = 0$ if and only if $e^{2\pi i a_k \xi} = 1$, $k = 2, \dots, n$, and $e^{2\pi i \xi} = 1$. This implies that $\xi \in \mathbb{Z} \setminus \{0\}$ and $a_k \xi \in \mathbb{Z} \setminus \{0\}$, $k = 2, \dots, n$. Thus, if one of the a_k 's is irrational, then $\hat{f}(\xi) \neq 0$ for all $\xi \neq 0$. Conversely, if all $a_k \in \mathbb{Q}$, write $a_k = p_k/q_k$, $p_k, q_k \in \mathbb{Z}$ and take $\xi = q_1 q_2 \cdots q_n$ then $I(\xi) = 0$. Note that this is true whatever the c_k 's are.

If $0 < c_1 < c_2 < \cdots < c_n$, we write

$$I(\xi) = c_n \left(-\frac{c_1}{c_n} \cdot 1 + \sum_{k=2}^n \frac{c_{k-1} - c_k}{c_n} e^{2\pi i a_k \xi} + e^{2\pi i \xi} \right),$$

and $I(\xi) = 0$ holds, if and only if

$$\frac{c_1}{c_n} + \sum_{k=2}^n \frac{c_k - c_{k-1}}{c_n} e^{2\pi i a_k \xi} = -e^{2\pi i \xi} = e^{2\pi i (\xi+1/2)}.$$

Again $\frac{c_1}{c_n} + \sum_{k=2}^n \frac{c_k - c_{k-1}}{c_n} = 1$ with positive terms, and the same convexity argument implies that $I(\xi) \neq 0$ whenever one of the a_k 's is irrational. \blacksquare

The case $c_{k+1} = c_k$ does not need to be considered, as this amounts to remove a_{k+1} . However, the proof of Lemma 7.1 no longer works when the sequence c_k is not monotonic. Instead we prove the following.

Lemma 7.2. *Let $\alpha \in (0, 1) \setminus \mathbb{Q}$, $0 < a < 1 - \alpha$, $0 < b, c < d$ and define*

$$f_a(t) = b \mathbf{1}_{(0,a)} + d \mathbf{1}_{(a,a+\alpha)} + c \mathbf{1}_{(a+\alpha,1)}.$$

Then there exists $a \in (0, 1 - \alpha)$ and $\xi \in \mathbb{R}$, such that $\hat{f}_a(\xi) = 0$.

Proof. We may assume without loss of generality that $d = 1$ and $0 < b, c < 1$. Since $f_a(t) > 0$ on $(0, 1)$, clearly $\hat{f}(0) = \int_0^1 f(t) dt > 0$. For $\xi \neq 0$ we use again $I(\xi) = 2\pi i \xi \hat{f}(-\xi)$. The computation shows that

$$\begin{aligned} I(\xi) &= b(e^{2\pi i a \xi} - 1) + (e^{2\pi i(a+\alpha)\xi} - e^{2\pi i a \xi}) + c(e^{2\pi i \xi} - e^{2\pi i(a+\alpha)\xi}) \\ &= e^{2\pi i a \xi}((1-c)e^{2\pi i \alpha \xi} - (1-b)) + ce^{2\pi i \xi} - b. \end{aligned}$$

If $I(\xi) = 0$, then

$$(33) \quad |(1-c)e^{-2\pi i \alpha \xi} - (1-b)|^2 = |ce^{-2\pi i \xi} - b|^2$$

or $(1-c)^2 + (1-b)^2 - 2(1-c)(1-b)\cos 2\pi \alpha \xi = c^2 + b^2 - 2bc\cos 2\pi \xi$. We obtain that $I(\xi) = 0$ implies the identity

$$(34) \quad 1 - b - c = (1 - b - c + bc)\cos 2\pi \alpha \xi - bc\cos 2\pi \xi.$$

Let $M = (1-b)(1-c) + bc = 1 - b - c + 2bc$. Since $M \pm (1-b-c) = \{2(1-b)(1-c), 2bc\}$, we have $|1-b-c| < M$. Consider the function $\psi(\xi) = (1-b-c+bc)\cos 2\pi \alpha \xi - bc\cos 2\pi \xi$. Clearly, $|\psi(\xi)| \leq M$, and more importantly, since $\alpha \notin \mathbb{Q}$, ψ is almost periodic and thus takes every value in $(-M, M)$ infinitely often. More precisely, for each $t \in (-M, M)$ there exists a uniformly discrete set Λ_t such that, for every $\xi \in \Lambda_t$, $(1-b-c+bc)\cos 2\pi \alpha \xi - bc\cos 2\pi \xi = t$. See, e.g., [7]. Let $\Lambda := \Lambda_{1-b-c} = \{\xi \in \mathbb{R} : (1-b-c+bc)\cos 2\pi \alpha \xi - bc\cos 2\pi \xi = 1-b-c\}$.

Exploiting (33) further, we see that $I(\xi) = 0, \xi \neq 0$, implies that either

- (i) $\frac{b-ce^{2\pi i \xi}}{(1-c)e^{2\pi i \alpha \xi} - (1-b)} = e^{i\theta}$ for some $\theta \in \mathbb{R}$, or
- (ii) $(1-c)e^{2\pi i \alpha \xi} - (1-b) = b - ce^{2\pi i \xi} = 0$. This identity is clearly impossible when $b \neq c$. If $b = c$, then $e^{2\pi i \alpha \xi} - 1 = e^{2\pi i \xi} - 1 = 0$, which again cannot happen because $\alpha \notin \mathbb{Q}$.

The remaining alternative (i) shows that $I(\xi) = 0$ for $\xi \neq 0$, if and only if

$$\frac{b - ce^{2\pi i \xi}}{(1-c)e^{2\pi i \alpha \xi} - (1-b)} = e^{i\theta} = e^{2\pi i a \xi}.$$

Given $\theta \in (0, 2\pi)$ we choose $\xi \in \Lambda$ so large that $a = \theta/\xi \in (0, 1 - \alpha)$. Thus we have shown that there exist $a \in (0, 1 - \alpha)$ and $\xi \in \mathbb{R}$ such that $\hat{f}_a(\xi) = 0$. ■

The following result shows that construction of a zero-free Wigner distributions with $g = \mathbf{1}_{(0,1)}$ might be rather delicate. We assume that f is a step function with jumps on $\mathbb{Z} \cup \alpha\mathbb{Z}$, then every short-time Fourier transform $V_g f$ with $f \in L^2(\mathbb{R})$ possesses a zero. However, if we “slightly” enlarge the function space and also consider bounded step functions, then we can produce a zero-free short-time Fourier transform $V_g f$.

Theorem 7.3. *Let $(c_k)_{k \in \mathbb{Z}} \subset \mathbb{R}$ be a bounded positive sequence. Let $\alpha \in (0, 1) \setminus \mathbb{Q}$ and define the sequence (a_k) by $a_{2k} = k$, $a_{2k+1} = k + \alpha$. Let $\chi = \mathbf{1}_{(0,1)}$ and*

$$(35) \quad \varphi = \sum_{k \in \mathbb{Z}} c_k \mathbf{1}_{(a_k, a_{k+1})}.$$

(i) *If $(c_k)_{k \in \mathbb{Z}}$ is monotonic, then $\varphi \in L^\infty(\mathbb{R})$ and $V_\chi f$ never vanishes.*

(ii) *If $\varphi \in L^p(\mathbb{R})$ for $1 \leq p < \infty$, then there exists $(x, \xi) \in \mathbb{R}^2$ such that $V_\chi f(x, \xi) = 0$.*

Proof. Clearly, for $1 \leq p \leq \infty$, $\varphi \in L^p(\mathbb{R})$, if and only if $(c_k) \in \ell^p(\mathbb{Z})$. We write

$$\varphi = \sum_{k \in \mathbb{Z}} (c_{2k} \mathbf{1}_{(k, k+\alpha)} + c_{2k+1} \mathbf{1}_{(k+\alpha, k+1)}).$$

Then the function $\varphi(t)\chi(t-x)$ is a step function consisting of three terms. To describe the correct terms, we write $x = j + u$ with $j \in \mathbb{Z}$ and $u \in [0, 1)$ and distinguish two cases.

Case 1. If $u \in [0, \alpha)$, then

$$\begin{aligned} (36) \quad & V_\chi \varphi(x, \xi) \\ &= \int_{\mathbb{R}} \left(c_{2j} \mathbf{1}_{(j+u, j+\alpha)}(t) + c_{2j+1} \mathbf{1}_{(j+\alpha, j+1)}(t) + c_{2j+2} \mathbf{1}_{(j+1, j+1+u)}(t) \right) e^{-2\pi i t \xi} dt \\ &= e^{-2\pi i (j+u) \xi} \int_0^1 \left(c_{2j} \mathbf{1}_{(0, \alpha-u)}(t) + c_{2j+1} \mathbf{1}_{(\alpha-u, 1-u)}(t) + c_{2j+2} \mathbf{1}_{(1-u, 1)}(t) \right) e^{-2\pi i t \xi} dt. \end{aligned}$$

We observe right away that at least one of the endpoints $\alpha - u$ or $1 - u$ must be irrational, since $\alpha \notin \mathbb{Q}$.

Case 2. If $u \in [\alpha, 1)$, then

$$\begin{aligned} (37) \quad & V_\chi \varphi(x, \xi) \\ &= \int_{\mathbb{R}} \left(c_{2j+1} \mathbf{1}_{(j+u, j+1)}(t) + c_{2j+2} \mathbf{1}_{(j+1, j+1+\alpha)}(t) + c_{2j+2} \mathbf{1}_{(j+1+\alpha, j+1+u)}(t) \right) e^{-2\pi i t \xi} dt \\ &= e^{-2\pi i \xi (j+u)} \int_0^1 \left(c_{2j+1} \mathbf{1}_{(0, 1-u)}(t) + c_{2j+2} \mathbf{1}_{(1-u, 1-u+\alpha)}(t) + c_{2j+3} \mathbf{1}_{(1-u+\alpha, 1)}(t) \right) e^{-2\pi i t \xi} dt. \end{aligned}$$

Again, at least one of the endpoints $1 - u$ and $1 - u + \alpha$ must be irrational, because $\alpha \notin \mathbb{Q}$.

Proof of (i): If the coefficient sequence (c_j) is monotonic, then Lemma 7.1 is applicable, and we conclude that $V_\chi \varphi(x, \xi) \neq 0$ for all $\xi \in \mathbb{R}$ and all $x \in \mathbb{R}$.

Proof of (ii): Assume now that $\varphi \in L^p(\mathbb{R})$ for $p < \infty$, then $(c_j) \in \ell^p$ cannot be monotonic. Thus there exists j_0 such that either $c_{2j_0}, c_{2j_0+2} < c_{2j_0+1}$ or $c_{2j_0+1}, c_{2j_0+3} < c_{2j_0+2}$. In the former case we choose $x = j_0 + u$ for $u \in (0, \alpha)$ (to be determined in a moment) and we work with (36). In the latter case we choose $x = j_0 + u$ for $u \in (\alpha, 1)$ and work with (37). In both cases the length of the middle interval $(\alpha - u, 1 - u)$ and $(1 - u, 1 - u + \alpha)$ is irrational. According to Lemma 7.2, there exists suitable u and $\xi \in \mathbb{R}$ such that $V_\chi \varphi(j_0 + u, \xi) = 0$. ■

Acknowledgement. The authors would like to thank the Erwin Schrödinger Institute for its hospitality and great conditions during the work on this paper. Special thanks go to Martin Ehler for his help with Mathematica and his helpful discussions. We are also grateful to Andrii Bondarenko, who showed Example 5 to us.

P.J. acknowledges that this study has been carried out with financial support from the French State, managed by the French National Research Agency (ANR) in the frame of the ‘‘Investments for the future’’ Programme IdEx Bordeaux - CPU (ANR-10-IDEX-03-02).
