Abstract: The material of *Hispanomys bijugatus* (Rodentia, Cricetodontinae) from La Grive-Saint Alban (Carrière Lechartier, fissure L3) is described for the first time and compared with all species of the genus known to date. As common in the Upper Aragonian populations of *Hispanomys*, this taxon evidences a low variability. *Hispanomys bijugatus* shows some progressive characters with respect to the remaining Aragonian congeneric species, such as the absence of labial and lingual cingula surrounding the upper and lower molar valleys respectively, the increase in the number of roots on the second lower molar, and the loss of mesoloph. This suggests that *H. bijugatus*, in spite of being one of the oldest species of the genus, is relatively derived with regard to the coeval congeneric species. Because *H. bijugatus* and *H. decedens* are believed to be closely related species within the same lineage, the fact that the former shows a more progressive dental morphology than the latter suggests that the unnamed fissure-filling from La Grive and La Grive M (with *H. decedens* only) are older than La Grive L3 (with *H. bijugatus* only). The coexistence of both species at locality L5 suggests an intermediate age.

#### Abstract

The material of *Hispanomys bijugatus* (Rodentia, ~~Cricetidae~~Cricetodontinae) from La Grive-Saint Alban (Carrière Lechartier, fissure L3) is described for the first time and compared with all species of the genus known to date. As common in the Upper

Aragonian populations of *Hispanomys*, this taxon evidences a low variability.

*Hispanomys bijugatus* shows some progressive characters with respect to the remaining Aragonian congeneric species, such as the absence of labial and lingual cingula surrounding the upper and lower molar valleys respectively, the increase in the number of roots on the second lower molar, and the lost of mesolophs. This suggests that *H.*

*bijugatus*, in spite of being one of the oldest species of the genus, is a relatively derived with regard to the coeval congeneric species. Because *H. bijugatus* and *H. decedens* are believed to be closely related species within the same lineage, the fact that the former shows a more progressive dental morphology than the latter suggests that the unnamed fissure-filling from La Grive and La Grive M (with *H. decedens* only) are older than La Grive L3 (with *H. bijugatus* only). The comparison of *H. bijugatus* with *H. decedens* (both recorded at various sites of La Grive Saint Alban) suggests that the most recent localities may be those in which *H. bijugatus* is recorded (L5 and L3). The oldest ones may be L7 and M, in which only the species *H. decedens* has been recovered. The coexistence of *H. bijugatus* and *H. decedens* both species at locality L3-L5 suggests for this locality an intermediate age between L5 on one side and L7 and M on the other.

## Résumé

Le matériel d'*Hispanomys bijugatus* (Rodentia, Cricetidae) de La Grive-Saint Alban (Carrière Lechartier, fissure L3) est décrit pour la première fois et comparé avec toutes les autres espèces du genre connues actuellement. Comme il a déjà été observé chez d'autres populations d'*Hispanomys* de l'Aragonien supérieur, ce taxon présente une faible variabilité. *Hispanomys bijugatus* montre des caractères dérivés par rapport au reste des espèces congénériques aragoniennes, tels que: l'absence de cingulum

labiaux et linguaux sur les molaires supérieures et inférieures, respectivement ;  
l'augmentation du nombre de racines de la deuxième molaire inférieure ; la perte des  
mésolophes. *H. bijugatus*, tout en étant une des plus anciennes espèces du genre, serait

donc plus évolué que les espèces d'*Hispanomys* contemporaines. Etant donné qu'*H.*  
*bijugatus* et *H. decedens* sont considérées comme des espèces proches au sein de la  
même lignée, le fait que la première montre une morphologie dentaire plus dérivée que  
la seconde suggère. La comparaison d'*H. bijugatus* avec *H. decedens* (tous deux présents  
dans plusieurs sites de La Grive Saint Alban) suggère que les gisements les plus récents  
sont ceux dans lesquels *H. bijugatus* a été recueilli (L5 et L3). Les plus anciens seraient  
ceux de la fissure non nommée de La Grive et La Grive M<sub>7</sub> (où seul *H. decedens* a été  
collecté) sont plus anciens que La Grive L3 (avec *H. bijugatus* seul). La coexistence de  
*H. bijugatus* et *H. decedens* espèces à La Grive L3-L5 suggère un âge intermédiaire  
entre celui de L5 d'un côté et celui de L7 et de M de l'autre.

## 1. Introduction

La Grive-Saint-Alban is the common name used to refer to various pits located on  
the territory of the municipality of Saint-Alban-de-Roche. These pits are constituted by

limestones whose fissures are filled by fossiliferous siderolitic clays. The name La Grive-Saint-Alban was given by Jourdan in 1861 in his first work dealing with the fauna of this area (specifically from the Peyre et Beau quarry). Jourdan was the first to carry out field works in the Peyre et Beau pit between 1845 and 1861. During the XIXth and XXth centuries, other pits such as the Milliat or the Lechartier ones were excavated. The pits were named after their owners and, therefore, they could be re-baptized when the owner changed. Nowadays, they are known with the following names: “Chemin départemental 24” (CD24), “carrière Lechartier” (L), “carrière Milliat” (M), “carrière Peyre et Beau” (P. B.), and “carrière nouvelle” (F), which is the most recently discovered one (Fig. 1). ~~One of us (Since 1962 one of us (P. M.)~~ has been interested in La Grive-Saint-Alban. He excavated at the found the first micromammal in La Grive-Saint-Alban (Lechartier and Milliat pits), and also found some micromammal remains at the Peyre et Beau pit. P. M. was the first person to ~~latter-evidencede~~ that the different fissure fillings are asynchronous (Mein, 1976).

All pits ~~, but P.B.,~~ have yielded micromammals, but remains of *Hispanomys* have only been ~~only~~-recovered in La Grive L, ~~and M and P.B. (where a unique m1 has been found by P. M.)~~ P.B. (where a sole m1 was found by P. M.) as well as in an unnamed fissure-filling. L (pit Lechartier) have eight fissure-fillings numbered from L1 to L8, but the only productive ones (from a palaeontological viewpoint) are L3, L5, L6, and L7. *H. bijugatus* has been recorded from fissures L3 and L5, whereas *H. decedens* has been found ~~from in an unnamed fissure-filling as well as in~~ fissures L3, L5, L7, ~~as well as, and from in~~ La Grive M (Mein and Ginsburg, 2002). Interestingly enough, almost all material of *H. decedens* from La Grive comes from this unnamed fissure. ~~Interesting (comes quite all material of *H. decedens* of La Grive. Interesting~~

**Formatted:** Justified, Indent: First line: 0.5", Tab stops: 2.95", Centered

**Formatted:** Not Highlight

**Formatted:** Highlight

We agree with Mein and Ginsburg (2002) who did not mention the presence of *H. decedens* in L7 because they considered that the low percentage of this taxon in the sample was possibly the result of “contamination”. The species *Hispanomys bijugatus* was originally erected as *Cricetodon (Hispanomys) bijugatus* by Mein and Freudenthal (1971), on the basis of isolated cheek teeth recorded from the locality L3 of La Grive-Saint Alban (Mein and Ginsburg, 2002). As Mein and Freudenthal’s (1971) work dealt with a whole revision and a new classification of the European tertiary cricetid record, a complete description of the wealth of material of *Cricetodon (Hispanomys) bijugatus* available could not be supplied and only a brief diagnosis was provided. Additional material of this taxon has been recovered at locality L5 (Mein and Freudenthal, 1971, Mein and Ginsburg, 2002; Maridet, 2002) as well as at ~~the localities of~~ Lo Fournas 5, Pyrénées-Orientales, France (Aguilar et al., 1999) and Jujurieux, Ain, France (Mein, 1999), which are both MN9 localities (Montuire et al., 2006; Mein, 1999).

Formatted: Not Highlight

The aim of the present work is to offer a detailed description of *Hispanomys bijugatus* as well as comparisons with all the other species of the genus known to date. The degree of evolution of the teeth of the two species of *Hispanomys* recovered at La Grive is used to elucidate the relative infill chronology of the different localities, which is controversial.

## 2. Material and methods

The systematic study presented below is based on the examination of original specimens of the MNCN, RUU, IPS, and FSL collections (see below), and data from the literature. We examined the following: original teeth of *Hispanomys bijugatus* and

*H. decedens* from La Grive Saint-Alban (Isère, France), *H. mediterraneus* from the localities of Montredon (Hérault, France), Soblay (Ain, France), and Dionay (Isère), *H. aguirrei* from Escobosa (Soria, Spain), *H. daamsi* from Can Missert (Barcelona, Spain), *H. dispectus* from Hostalets de Pierola and Castell de Barbera (Barcelona), *H. lavocati* from Hostalets de Pierola (~~Barcelona~~), *H. aragonensis* from Pedregueras 2A (Saragossa, Spain), *H. nombrevillae* from Molina de Aragón (Guadalajara, Spain), *H. peralensis* from Peralejos 4, Peralejos C, Peralejos D, Masía del Barbo 2A and Masía del Barbo 2B (Teruel, Spain), *H. thaleri* from Can Llobateres (Barcelona), *H. freudenthali* from Puente Minero (Teruel), and *H. adroveri* from Casa del Acero (Murcia, Spain).

The material of *Hispanomys bijugatus* from the iserois sites of La Grive-Saint Alban (Carrière Lechartier, fissure L3 and L5) is described for the first time and compared with the equivalent teeth of all the species of *Hispanomys* known to date. The occlusal measurements (maximum length and maximum width) were taken following Van de Weerd (1976) for all dental elements but upper second molars where the maximum length has been taken parallel to the labial side of the tooth. Measurements have been obtained using a Microscope Leitz Ortholux with a platinum ultrapack (Tab. 1, Fig. 2).

First, second, and third lower molars are designed as m1, m2, and m3 respectively, whereas first, second, and third upper molars as M1, M2, and M3. The terminology used in the tooth descriptions follows that of Freudenthal et al. (1994). We use the local subzones of Van Dam et al. (2001) when relevant.

SPECIES *Hispanomys bijugatus* Mein et Freudenthal, 1971

(Figs. 3, 4)

**Holotype:** FSL n° 65478: left isolated m1 (Mein and Freudenthal, 1971, p. 37, Pl. 2, Fig. 4)

**Paratypes:** FSL 66256-66524

**Type locality:** La Grive-Saint Alban (Carrière Lechartier, fissure L3)

**Age:** MN 8

**Other localities:** La Grive-Saint Alban (Carrière Lechartier, fissure L5 ~~and L7~~), Isère, France (Mein and Freudenthal, 1971); Lo Fournas 5, Pyrénées-orientales, France (Aguilar et al., 1999); Jujurieux, Ain, France (Mein, 1999)

**Extended diagnosis:** *Hispanomys* species of medium size, with weak or absent grooved upper incisors and low hypsodonty; having low values of the mean LM1/mean

LM3 and mean Lm1/mean Lm3 ratios (unreduced third lower and upper molars ~~not reduced~~); lower molars lacking cingula on the lingual valleys and having well-developed labial anterolophid; m1 having a double metalophid and lacking mesolophid, m2 and m3 with short, but distinct, mesolophid; three rooted m2; upper molars lacking mesoloph, enamel coated valley, and labial cingula, and having incomplete lingual cingula and partial anterior ectoloph; M1 with four roots, with spur of the anterolophule and prominent protostyle; upper molars with vestigial entomesoloph.

**Differential diagnosis:** Differing from *Hispanomys daamsi*, *H. thaleri*, *H. freudenthali*, and *H. adroveri*, in being smaller; differing from *H. castelnovi*, *H. aguirrei*, *H. daamsi*, *H. dispectus*, *H. thaleri*, *H. lavocati*, *H. nombrevillae*, *H. aragonensis*, *H. peralensis*, *H. baixasi*, *H. freudenthali*, and *H. adroveri* in having an entomesoloph on some upper molars; differing from ~~*H. castelnovi*~~, *H. decedens*, *H. aguirrei*, *H. daamsi*, *H. dispectus*, *H. lavocati*, *H. nombrevillae*, and *H. aragonensis* in lacking labial cingula surrounding the valleys on the upper molars; differing from *H. mediterraneus*, *H. peralensis*, *H. freudenthali*, and *H. adroveri* in having four rooted M1; differing from *H. daamsi*, *H. dispectus*, *H. thaleri*, *H. mediterraneus*, *H. peralensis*, *H. freudenthali*, and *H. adroveri* in having incomplete ectolophs on the M1 and M2; differing from *H. decedens*, *H. dispectus*, *H. thaleri*, and *H. aragonensis* in lacking enamel coated valley on the M1-M2; differing from *H. decedens*, *H. aguirrei*, *H. daamsi*, *H. dispectus*, *H. lavocati*, *H. thaleri*, and *H. aragonensis* in lacking mesoloph on the M1; differing from *Hispanomys castelnovi*, *H. dispectus*, *H. nombrevillae*, *H. thaleri*, *H. mediterraneus*, *H. peralensis*, *H. freudenthali*, and *H. adroveri* in having the M3 much less reduced; differing from *Hispanomys peralensis*, *H. freudenthali*, and *H. adroveri* in having labial anterolophid in all m1; differing from all species of

*Hispanomys* in having double metalophid on the m1 (some of them like *H. decedens*, *H. aguirrei*, *H. lavocati*, *H. nombrevillae*, *H. mediterraneus*, and *H. baixasi* have it in a major or minor part of the specimens, whereas in the remaining species it is absent) differing from *H. adroveri* in having very short or absent mesolophid on the m1; differing from *H. aragonensis*, *H. thaleri*, *H. nombrevillae*, and *H. aguirrei* in having the m2 three rooted; differing from *H. nombrevillae*, *H. aguirrei*, *Hispanomys peralensis*, *H. freudenthali*, and *H. adroveri* in having the m3 much more reduced.

### 3. 1. Description

**M1:** These teeth show a pronounced groove between the two lobes of the anterocone. The anterolophule connects the lingual lobe of the anterocone with the protocone. There is a labial spur of the anterolophule in some specimens. The protosinus is partially closed by a large protostyle that can be connected to the anteroloph by a ridge. The anterior ectoloph is well-developed; it is as high as the anterocone, and reaches or nearly reaches the anterior wall of the paracone closing the anterosinus. The forward paracone spur is usually absent. The protolophule is anterolabially directed and it is oblique. The long and strong backward paracone spur connects to a more labially located branch (posterior ectoloph), which arises from the anterior wall of the metacone, closing the mesosinus. The backward paracone spur emerges from the midpoint of the protolophule and is generally posterolabially oriented. All specimens lack the mesoloph, but some of them have the beginning of the anterior arm of the hypocone somewhat inflated. They have no cingula surrounding the labial valleys. The nearly transverse sinus is almost closed by a ridge, which emerges from the

hypocone. Some specimens show entostyle and a vestigial entomesoloph. These teeth have short labial and lingual posteroloph. They have four roots.

**M2:** The occlusal outline of these teeth is sub-rectangular, longer than wide, with its posterior part somewhat rounded and narrower than the anterior one. They have a well-~~develo~~developed lingual anteroloph and a distinct protosinus in the anterior margin of the teeth. The labial anteroloph is absent. The anterior ectoloph and the forward paracone spur are usually absent, but on occasion they are ~~on occasion~~ very low and tiny. Therefore, the anterosinus is generally open except in much worn specimens, in which it is closed. The paracone spur is long and strong, reaching a small anterior ridge of the metacone (posterior ectoloph) to entirely close the mesosinus. All teeth have the mesosinus larger than the anterosinus and they have no labial cingula surrounding the valleys. A true mesoloph is lacking, but some specimens have the beginning of the anterior arm of the hypocone slightly inflated. The backward paracone spur is generally posterolabially oriented; it emerges from the midpoint of the protolophule from which it rises to reach the labial side of the tooth. Some specimens show a short lingual spur emerging from the backward paracone spur. The protolophule is oblique and anterolingually directed. The sinus is usually closed by the junction of a ridge that emerges from the anterior side of the hypocone with another that descend from the posterior margin of the protocone (vestigial entomesoloph) (e.g., FSL 66482, FSL 66276; Fig.4.8). These teeth show short labial and lingual posterolophs; the latter one is more ~~develo~~developed than the former. These teeth have four roots.

**M3:** The occlusal outline of these teeth is rounded, longer than wide, with its posterior part narrower than the anterior one. The labial anteroloph is long and the lingual one is less ~~develo~~developed, but distinct. The anterosinus is somewhat

smaller than the mesosinus. The anterior ectoloph is lacking and the forward paracone spur is small or even absent. The backward paracone spur is long; in some specimens it emerges from the midpoint of the protolophule from which it rises to reach the labial side of the tooth. It usually connects to the posterior ectoloph, closing the mesosinus, but in some specimens it is free because of the absence of the posterior ectoloph (e.g., FSL 66501). The nearly transverse ~~protoloph~~protolophule connects to the junction between the posterior arm of the protocone and the anterior arm of the hypocone at about the centre of the tooth. These teeth usually have a long and distinct posteroloph but occasionally the metacone may be fused with the posteroloph making the latter indistinct. ~~The backward paracone spur is long, in some specimens it emerges from the midpoint of the protolophule from which it rises to reach the labial side of the tooth. It usually connects to the posterior ectoloph closing the mesosinus, but in some specimens it is free because of the absence of the posterior ectoloph (e.g., FSL 66501).~~ The posterior side of the protocone generally has a strong ledge, which is directed towards the hypocone. This ledge comes into the sinus closing it partially. The sinus is very anterolabially directed. These teeth have three or four roots and they are not reduced. Actually, the value of the ratio mean LM1/mean LM3 of the teeth is very low, one of the lowest ones obtained for any *Hispanomys* species known to date (Tab. 2).

**m1:** The occlusal outline of these teeth is sub-rectangular, longer than wide, with its anterior part somewhat rounded and narrower than the posterior one. The labial anterolophid is long and prominent. It reaches the anterior side of the protoconid, closing thereby the protosinusid. Specimen 66284 has a protostylid that is joined with the anteroconid by a labial spur of the anterolophulid. The lingual anterolophid is weak (e.g., 66288, 66286) or absent. The metalophulid is double. The mesolophid is usually

absent with some specimens showing a slight inflation at the end of the posterior arm of the protoconid, but it can be short (e.g., 66292). These teeth have usually no lingual cingula surrounding the valleys, but some of them (e.g., 66290, 66292, 66306, 66305) have it. Most of the teeth lack ectomesolophid, but in some of them (e.g., 66284) it is present. The sinusid is anterolingually directed. It is generally closed by the junction of two ridges; the first one emerging from the posterior wall of the protoconid and the second one from the anterior wall of the hypoconid. This ridge can bear an ectostylid. The posterosinusid is very small, but distinct. The posterolophid is long, but does not reach the posterior wall of the entoconid. These teeth are two-rooted.

**m2:** These teeth are rectangular in shape, though they are anteriorly and posteriorly rounded. They show a prominent labial anterolophid that reaches the anterolabial side of the protoconid, closing the protosinusid. The metalophid and the hypolophid are anterolabially directed. These teeth have not lingual cingula surrounding the valleys. The mesolophid is short or of medium size and free and it can join with the posterior side of the metaconid. The nearly transverse sinusid is partially closed by two ridges; the first one emerging from the posterior wall of the protoconid and the second one from the anterior wall of the hypoconid. The posterolophid is long, but does not reach the posterior side of the entoconid. These teeth are three rooted.

**m3:** The occlusal outline of these teeth is rectangular, longer than wide, with its posterior part rounded and somewhat narrower than the anterior one. They show a long and strong labial anterolophid that connects to the anterior wall of the protoconid, closing the protosinusid. The lingual anterolophid is absent. The mesolophid is short or of medium size and it can be free or connected to the posterior wall of the metaconid. The posterosinusid and mesosinusid are open; there are no lingual cingula surrounding

the valleys. The nearly transverse sinusid is partially closed by two ridges: the strongest emerges from the posterior wall of the protoconid, whereas the other comes out from the anterior wall of the hypoconid. An ectostylid can be present (e.g., FSL 66372). The posterolophid is long, but it does not join with the posterior wall of the entoconid, and a labial posterosinusid is very weak or lacking. These teeth are three-rooted.

### 3. 2. Comparisons

3. 2.1. ~~Comparison with~~ *Hispanomys castelnovi* Aguilar, Calvet et Michaux, 1994

#### 3.2.1.1. Historical background

This species was erected on the basis of several lower and upper isolated molars from the MN6 locality of Castelnou 6 (Pyrénées-orientales, France). The holotype (CTN 6 nr. 54), a single m1, is housed at the USTL (Aguilar et al., 1994). According to these authors this locality is Middle Miocene in age. However, the degree of evolution of the teeth of *Hispanomys castelnovi*, ~~which incidentally comes from a fissure filling,~~ may suggests a younger age.

#### 3.2.1.2. Comparison with *H. bijugatus*

The cheek teeth of *H. bijugatus* are larger than those of *H. castelnovi*. In addition, the ~~M1 and M2~~ upper molars of this species lack the entomesoloph, ~~and the M3 has no old entoloph~~ whereas ~~these structures~~ a vestigial entomesoloph ~~are is~~ present in some specimens of *Hispanomys bijugatus*. Furthermore, ~~some a few~~ upper molars of *H. castelnovi* have a low labial cingulum (Aguilar, pers. comm. 2009), whereas none of those of *H. bijugatus* has it. One of the most remarkable differences between these taxa is the absence of a double metalophulid on the m1 of *H. castelnovi*. This structure is always present on the m1 of *H. bijugatus*.

Formatted: Not Highlight

Formatted: Font: Italic

Formatted: Font: Not Italic

### 3. 2.2. ~~Comparison with~~ *Hispanomys decedens* (Schaub, 1925)

#### 3.2.2.1. Historical background

This species was ~~initially~~ erected by Schaub (1925: p. 13) as *Cricetodon sansaniense*

Lartet, 1851 var. *decedens*. Later on, this author raised this variety to the species level (Schaub, 1944: p. 454). Mein and Freudenthal (1971: p. 19) introduced the subgenus *Hispanomys* for a handful of supposedly derived *Cricetodon*. This subgenus was elevated to the genus level by Van de Weerd (1976: p. 106 *et seq.*).

—The holotype of this species (Lgr130), a left maxillary fragment with M1 and M2, comes from ~~the a~~ MN7/8 ~~unnamed & fissure-filling locality M~~ of La Grive-Saint Alban (Isère, France). It is housed in the MSNL. Alba et al. (2006) and Casanovas-Vilar (2007) mentioned the existence of additional material of *Hispanomys decedens* from various MN7/8 sites of the Can Mata series (Barcelona).

~~Alba et al. (2006) and Casanovas-Vilar (2007) mentioned the existence of additional material of *Hispanomys decedens* from the MN7/8 locality of Hostalets de Pierola (Barcelona, Spain).~~  
3.2.2.2. Comparison with *H. bijugatus*

The M1 and M2 of *H. decedens* show low labial cingula surrounding the valleys (absent in *H. bijugatus*). The upper molars of *H. decedens* have usually a mesoloph, which is absent on those of *H. bijugatus*, and the ectolophs are less developed than in the latter species. With regard to the lower molars, the percentage of m1 with a double metalophid in *H. decedens* is lower than in *H. bijugatus*. In contrast, there are more m1 with ectomesolophid in *H. decedens* than in *H. bijugatus*. The lingual anterolophid is usually more ~~developped~~developed on the m1 of *H. decedens* than in those of *H.*

Formatted: Font: Not Italic

Formatted: Font: Italic

Formatted: Font: Italic

Formatted: Indent: First line: 0.2"

Formatted: Font: Not Italic

*bijugatus*. Some m3 of *H. decedens* have the mesolophid long, ~~on the m3~~ whereas it is short or of medium size in *H. bijugatus*.

3.2.3. ~~Comparison with~~ *Hispanomys aguirrei* (Sesé in López-Martinez, Sesé ~~et &~~ Sanz-García, 1977)

#### 3.2.3.1. Historical background

This taxon was initially named *Cricetodon aguirrei* by Sesé in López-Martinez et al. (1977) and posteriorly reallocated by Agustí (1977a: p. 31) to the genus *Hispanomys*. The holotype (ES-221/224) is a left maxillary fragment with M1-M2 (kept in the collections of the MNCN) from the Middle Miocene (MN 7/8) locality of Escobosa I, Escobosa de Catalañazor (~~Soria, Spain~~). Additional material of this species has been found at the coeval localities Escobosa-M and Escobosa G-2 (Sesé in López-Martinez, Sesé & Sanz-García, 1977) and recently at the Upper Aragonian locality of Nombrevilla 2- (Saragossa, Spain) (López Guerrero et al., 2008).

#### 3.2.3.2. Comparison with *H. bijugatus*

About a quarter of the m1 of *Hispanomys aguirrei* shows a double metalophulid, whereas all m1 of *H. bijugatus* have it. Most of the m2 of *H. aguirrei* have two double roots, whereas those of *H. bijugatus* already are three rooted. The m3 of *H. aguirrei* from Escobosa are smaller than those of *H. bijugatus*. With regard to the upper molars, most of the M1 and M2 of *H. aguirrei* have well-~~develloped~~developed low cingula closing the labial valleys, some of them have mesoloph and lack entomesoloph. In contrast, both the labial cingula and the mesoloph are always missing on the M1 and M2 of *H. bijugatus*, and some of them have an entomesoloph. Even if the M3 of *H. aguirrei* are not much reduced, the value of the ratio *mean LM1/mean LM3* is higher in

Formatted: Font: Italic

Formatted: Indent: First line: 0.2"

Formatted: Font: Not Italic

Formatted: Font: Not Italic

Formatted: Font: Not Italic

this species than in *H. bijugatus*, which shows that a degree of reduction in the former taxon (Tab. 2). In addition, ~~some all the~~ M3 of *H. aguirrei* ~~lack the old entoloph and some of them~~ have a mesoloph, whereas ~~some of the~~ the mesoloph is missing on all M3 of *H. bijugatus* ~~have old entoloph and the mesoloph is missing on all of them~~.

### 3.2.4. ~~Comparison with~~ *Hispanomys daamsi* Agustí, Casanovas-Vilar et Furió, 2005

#### 3.2.4.1. Historical background

The holotype of this species (IPS 16444), a left mandible with m1-m3, is housed at the IPS. ~~The~~ This species was erected on the basis of several teeth recovered from the late Aragonian (MN 8) locality of Can Missert (~~Vallès Penedès Basin, Barcelona, Spain~~) (Agustí et al., 2005). Further material of this taxon has been recently reported from MN7/8 levels at Hostalets de Pierola, Barcelona, España (Alba et al., 2006; Casanovas-Vilar, 2007).

#### 3.2.4.2. Comparison with *H. bijugatus*

The cheek teeth of *H. daamsi* are larger than those of *H. bijugatus*. The M1 and M2 of *H. daamsi* show small cingula at the base of the labial valleys and lack the entomesoloph, whereas the labial cingula are missing in the M1 and M2 of *H. bijugatus* and some of them have the entomesoloph. Even if the M3 are not much reduced in *H. daamsi*, this taxon has a mean LM1/mean LM3 ratio higher than *H. bijugatus* (Tab. 2). In addition, all the M3 of *H. daamsi* lack ~~the old~~ vestigial entomesoloph, ~~entoloph~~ whereas it is present on some M3 of *H. bijugatus*. With respect to the lower molars, the m1 of *H. bijugatus* have a double metalophid, which is single on those of *H. daamsi*. ~~The m3 of *H. daamsi* usually show a better developed mesolophid than those of *H. bijugatus*.~~

Formatted: Font: Italic

Formatted: Indent: First line: 0.2"

Formatted: Indent: First line: 0.2"

3.2.5. ~~Comparison with~~ *Hispanomys dispectus* Agustí, 1980<sup>a</sup>

Formatted: Font: Not Italic

3.2.5.1. Historical background

Formatted: Font: Italic

This species was first cited by Agustí and Gibert (1979: pp. 17-18), but in a way that does not fulfil the requirements for the name to be considered as available (International Commission on Zoological Nomenclature, 1999, article 13.1). In particular, the short description does not provide characters purported to differentiate the taxon. The valid description of this taxon is provided by Agustí (1980<sup>a</sup>) as explicitly mentioned by Agustí and Gibert (1979: p. 17).

Formatted: Indent: First line: 0.2"

According to Agustí (1980<sup>a</sup>: p. 56), the material from Hostalets de Pierola described by Schaub (1944, 1947) and listed by Crusafont and Casanovas (1973) as *Cricetodon decedens* would pertain to *Hispanomys dispectus*. In addition, in the same work, this author stated that *H. cf. thaleri* from Castell de Barbera (Aguilar et al., 1979) and from La Bisbal I and La Bisbal II, Gerona, Spain (Gibert et al., 1980) pertains actually to *H. dispectus*.

The holotype of *Hispanomys dispectus* (IPS VP 610) is a complete left maxilla from a lower level (MN 8) of the Hostalets de Pierola locality (~~Vallès Penedès~~). Additional material of this species has been also recovered from the Vallès Penedès at the sites of Hostalets de Pierola (upper levels, MN 9), Can Feliu (MN 7/8), Castell de Barbera (MN 8), and Creu Conill 22 and 20 (MN 9) as well as from Ampurdá (Gerona) at the MN 9 locality of La Bisbal II (Agustí, 1980<sup>a</sup>, 1981; Gibert et al., 1980; Casanovas–Vilar et al., 2006).

3.2.5.2. Comparison with *H. bijugatus*

This species differs from *H. bijugatus* in having labial valleys surrounded by low cingula on the upper molars; and, ~~usually in some specimens,~~ quite well-developed mesoloph, which are absent on the upper molars of *H. bijugatus*. The value of the mean LM1/mean LM3 ratio of the teeth of *H. dispectus* is higher than that calculated for *H. bijugatus*, which has therefore the m3 less reduced (Tab. 2). With regard to the lower molars, the m1 *Hispanomys dispectus* lack the double metalophid, which is present in all m1 of *H. bijugatus*.

Formatted: Indent: First line: 0.2"

### 3.2.6. ~~Comparison with~~ *Hispanomys lavocati* (Freudenthal, 1966)

#### 3.2.6.1. Historical background

Formatted: Font: Italic

This taxon was erected by Freudenthal (1966) as a species of *Cricetodon*. Subsequent authors (Agustí, 1977a: p. 31 *et seq.*) reallocated it to the genus *Hispanomys*, an act with which we agree. The holotype of this species (VP 536), a complete left maxilla from the lower levels (MN 8) of the Hostalets de Pierola locality (~~Vallès Penedès~~), is housed in the IPS. Additional material of this taxon has been also recovered in the coeval locality of Sant Quirze, Barcelona, Spain (Agustí, 1977b) and Nombrevilla 2, ~~Saragossa, Spain~~ (López-Guerrero et al., 2008). The material from Viladecavalls described by Schaub (1947: p. 62) as *C. decedens* and reallocated to *H. lavocati* by Freudenthal (1966: p. 313), actually belongs to *H. thaleri* (Agustí, 1980: p. 59).

Formatted: Indent: First line: 0.2"

Formatted: Font: Not Italic

#### 3.2.6.2. Comparison with *H. bijugatus*

—*Hispanomys lavocati* is larger than *H. bijugatus*. With regard to the upper molars, the M1 and M2 of *H. lavocati* have labial cingula surrounding the valleys and, on occasions, a short mesoloph, both of which are absent on the upper molars of *H. bijugatus*. In addition, ~~some the~~ M3 of *H. lavocati* have a moderately long mesoloph,

which is lacking in *H. bijugatus*. With regard to the lower molars, those of *H. lavocati* have the mesolophids well-developed, whereas *H. bijugatus* have them short or even absent. Furthermore, the m1 of *H. lavocati* have a single metalophid, whereas it is double in those of *H. bijugatus*. ~~Most The~~ m2 of *H. lavocati* have two double roots, whereas those of *H. bijugatus* are three-rooted.

### 3.2.7. ~~Comparison with~~ *Hispanomys nombrevillae* (Freudenthal, 1966)

#### 3.2.7.1. Historical background

Freudenthal (1966) created the subspecies *Cricetodon decedens nombrevillae*. Later on, in their classification of the Cricetidae, Mein and Freudenthal (1971) reallocated it in the subgenus *Hispanomys*. According to them, most of the Can Llobateres material assigned to *Ruscinomys thaleri* by Hartenberger (1965) would pertain to that taxon (see discussion below). The holotype of *H. nombrevillae* (NO 258) is a single M1 from the lower Vallesian site (MN9, H) of Nombrevilla (~~Saragossa~~). It is housed in the IPS. Additional material of this species has been recovered from a ~~lower Vallesian~~ (MN 9) locality near Molina de Aragón, ~~Guadalajara, Spain~~ (Lacomba, 1988).

#### 3.2.7.2. Comparison with *H. bijugatus*

The size of the cheek teeth of *Hispanomys nombrevillae* is smaller than in *H. bijugatus*. In addition, the M1 and M2 of *H. nombrevillae* have low labial cingula surrounding the valleys; these cingula are absent on the upper molars of *H. bijugatus*. The M3 of *H. nombrevillae* are much reduced, being the values of the ratio mean LM1/mean LM3 of its teeth very high, whereas it is very low in *H. bijugatus*, which has not the third upper molars reduced (Tab. 2). With regard to the lower molars, none of the m1 of *H. nombrevillae* has a double metalophid, whereas it is present in all m1 of

Formatted: Font: Italic

Formatted: Indent: First line: 0.2"

Formatted: Indent: First line: 0.2"

*H. bijugatus*. The m2 of *H. nombrevillae* have two double roots, whereas those of *H. bijugatus* are three-rooted.

### 3.2.8. Comparison with *Hispanomys thaleri* (Hartenberger, 1965)

#### 3.2.8.1. Historical background

Hartenberger (1965) erected the new species *Ruscinomys thaleri* on the basis of cheek teeth from the MN 9b locality of Can Llobateres (~~Barcelona, Spain~~). Later on, Mein and Freudenthal (1971) discussed the status of *R. thaleri*. According to them, the holotype of this species would be a true *Ruscinomys*, but most of its paratypes would correspond to *Cricetodon Hispanomys* cf. *nombrevillae*. The comparison of the Vallesian material of Can Ponsic with that of Can Llobateres by Agustí (1984) led him to consider *H. thaleri* a homogeneous population, to which an emended diagnosis was given. This species has been also recovered from the MN 9 localities of Rubí- Terrassa-6E, Can Ponsic, and Riu Ripoll (Barcelona, Spain), and the MN 10 localities of Can Casablanques, Camí de Can Tarumbot-2, Rubí- Terrassa-7, Viladecavalls, Torrent de Febulines, Trinxera Sur Autopista II, Trinxera Nord Autopista II, and Can Jofresa, Barcelona, Spain (Agustí, 1981; Agustí and Gibert, 1982; Agustí et al., 1997). The holotype of *H. thaleri* (CL3630) is a single M1 housed at the IPS (Hartenberger, 1965).

#### 3.2.8.2. Comparison with *H. bijugatus*

One of the differences between the two taxa is the presence of the enamel-coated valley. Even if only few upper molars of *H. thaleri* have it, none of *H. bijugatus* show this structure. In addition, the M3 of *H. thaleri* are noticeably less reduced than those of *H. bijugatus* (~~Table-Tab. 2~~). None of the m1 of *H. thaleri* has a double metalophulid, whereas it is present in all m1 of *H. bijugatus*. The m2 of *H. thaleri* have two roots,

Formatted: Font: Italic

Formatted: Indent: First line: 0.2"

Formatted: Indent: First line: 0.2"

whereas those of *H. bijugatus* are three-rooted. Finally, the m3 of *H. thaleri* are less reduced than those of *H. bijugatus*.

### 3.2.9. ~~Comparison with~~ *Hispanomys aragonensis* (Freudenthal, 1966)

#### 3.2.9.1. Historical background

This species was originally erected as *Cricetodon decedens aragonensis* by Freudenthal (1966). Subsequently, Mein and Freudenthal (1971) reallocated it in the subgenus *Hispanomys*.

—The holotype of this species (PEC 1164), an isolated M1 from the lower Vallesien (MN9<sub>a</sub>(I)) locality of Pedregueras IIC (~~Saragossa, Spain~~), is housed in the IPS.

Additional material has been recovered from the MN 9<sub>b</sub>(I) localities of Pedregueras 1A and 2A (Freudenthal, 1966). Two teeth of this species have been also reported from the MN9<sub>a</sub>(H) locality of Los Valles de Fuentidueña, Segovia, Spain (Agustí, 1978: p. 139).

#### 3.2.9.2. Comparison with *H. bijugatus*

The upper molars of *Hispanomys aragonensis* have labial cingula surrounding the valleys, which are lacking on the upper molars of *H. bijugatus*. Some of the M1 and M2 of *Hispanomys aragonensis* have a small enamel-coated valley in the occlusal surface of

the paracone, whereas it is absent in all M1 and M2 of *H. bijugatus*. The M3 of

*Hispanomys aragonensis* are less reduced than those of *H. bijugatus* (Tab. 2). With

regard to the lower molars, some of those of *Hispanomys aragonensis* have a lingual

cingulum surrounding the valley, whereas it is lacking on those of *H. bijugatus*. With

regard to the lower molars, some m1 of *H. aragonensis* show two short mesolophids

The m1 of *Hispanomys aragonensis* have a single anterolophid, whereas there is only one

or none on the m1 of *H. bijugatus*. The metalophid is single in *H. aragonensis*.

Formatted: Font: Italic

Formatted: Indent: First line: 0.2"

Formatted: Indent: First line: 0.2"

Formatted: Font: Italic

Formatted: Font: Italic

~~whereas it is~~ ~~whereas it is~~ double on ~~the~~ all m1 of *H. bijugatus*. In addition, some m1 of *H. aragonensis* have a lingual anterolophid, which is lacking on the m1 of *H. bijugatus*. Finally, the m2 of *H. aragonensis* have two roots (with the posterior one being splitted). ~~whereas~~ those of *H. bijugatus* are three-rooted.

### 3.2.10. ~~Comparison with~~ *Hispanomys mediterraneus* Aguilar, 1982

#### 3.2.10.1. Historical background

Aguilar (1982) created this species on the basis of isolated cheek teeth from the Late Miocene (MN 10) site of Montredon, ~~Hérault, France~~. He gave a list of chresonyms, in which he states that (at least) a part of the material studied by Hartenberger (1965) and attributed to the species *Ruscinomys thaleri* and, ~~therefore thereby~~ (see discussion on *H. thaleri* above) *Hispanomys* cf. *nombrevillae* (incorrectly mentioned in the text as *H.* cf. *aragonensis*) discussed by Mein and Freudenthal (1971), pertained in fact to *H. mediterraneus*. However, the comparison of the Vallesian material of *H. thaleri* from Can Ponsic with that from Can Llobateres carried out by Agustí (1984) led him to consider *H. thaleri* a homogeneous population and invalidate this supposition. In addition, in the same list of chresonyms, Aguilar (1982) stated that the material from Montredon described by Thaler (1966, p. 151, Fig. 21E) as *Cricetodon* (*Cricetodon*) cf. *decedens* (and later on listed by Guérin and Mein (1971: p. 149) and figured by Enguesser (1972: pp. 288, 292)) as well as that described and figured as *Cricetodon* sp. 1 by Hartenberger and Thaler (1963: pp. 3333-3335) would also belong to *H. mediterraneus*.

The holotype of this species (MTN nr. 1509) is a single left M1 housed at the USTL. Additional material of this species has been recovered from the Upper Vallesian ~~and~~

Formatted: Font: Italic

Formatted: Indent: First line: 0.2"

~~lower Turolian~~ localities of Lo Fournas 7 (Aguilar, Escarguel & Michaux, 1999). The Turolien material of *H. mediterraneus* from Lo Fournas 6, as well as, that of *H. cf. mediterraneus* from Castelnou 1 and Castelnou 3 has been recently attributed to *H. baixasi* (Aguilar et al., 2007), and Lo Fournas 6, Pyrénées-orientales, France (Aguilar et al., 1999). Besides, *Hispanomys cf. mediterraneus* has been reported from the Turolien localities of Castelnou 1 and Castelnou 3, Pyrénées-orientales, France (Aguilar et al., 1999). Mein (1999) mentioned the presence of *H. mediterraneus* at the MN 10 French localities of Soblay (Ain) and Dionay (Isère) as well as *H. cf. mediterraneus*, at the coeval localities of Ambérieu 1 and 2 (Ain).

#### 3.2.10.2. Comparison with *H. bijugatus*

—The M1 and M2 of *Hispanomys mediterraneus* have the ectolophs more ~~devellopped~~ developed than those of *H. bijugatus*. In addition all M1 of the former species lack a labial spur of the anterolophule, which is present on some specimens of *H. bijugatus*. The M2 of *Hispanomys mediterraneus* have a much less ~~devellopped~~ developed lingual cingulum than those of *H. bijugatus*. With respect to the M3, those of *H. mediterraneus* are much reduced, whereas those of *H. bijugatus* are not that lessened (Tab. 2). With regard to the lower molars, none of the m1 of *Hispanomys mediterraneus*, but one, has double metalophulid, whereas all m1 of *H. bijugatus* have it. The m2 and m3 of *H. mediterraneus* usually have the mesolophid less ~~devellopped~~ developed than those of *H. bijugatus*.

### 3.2.11. *Comparison with* *Hispanomys peralensis* Van de Weerd, 1976

#### 3.2.11.1. Historical background

Formatted: Indent: First line: 0.2"

Formatted: Font: Italic

Van de Weerd (1976) erected the species *Hispanomys peralensis* based on material from the MN 10 locality of Peralejos C and assigned to this species material from other MN 10-11 localities of the Teruel-Alfambra region, ~~Spain~~ (Masia del Barbo 2A, Masía del Barbo 2B, Peralejos B, Peralejos D and Peralejos 4)(~~Peralejos D, Peralejos B, Peralejos 4, Masia del Barbo 2B, and Masía del Barbo 2A~~). The holotype (PERC 351) is an isolated M1 from the locality Peralejos C (Van de Weerd, 1976), which is correlated to the local subzone J3 (MN 10) of Van Dam et al. (2001). It is stored in the collection of the RUU. According to Van de Weerd (1976), the two species of *Cricetodon* from Masia del Barbo 2A and 2B described by Freudenthal (1966: pp. 308-310), but not named, also pertain to *H. peralensis*. Antunes and Mein (1979: p. 916) mentioned the presence of *H. peralensis* from the lower MN 10 site of Freiria de Rio Maior, Portugal. Freudenthal, Lacomba and Martín-Suárez (1991: p. 11) pointed out that the material from the MN 11 locality of Tortajada A (Teruel-Alfambra region), described as *H. freudenthali* by Van de Weerd (1976), as well as that from the MN 11 localities of Crevillente 1, 3 and 4 (Alicante, Spain) designed by De Bruijn et al. (1975: p. 297) as *H. sp. A*, also correspond to *H. peralensis*. More material of *H. peralensis* from this zone has been recovered at the localities Crevillente 2 and Crevillente 4B (Freudenthal et al., 1991). Alcalá et al. (2005, p. 201, Fig. 3) reported *H. peralensis* at the MN10-J3 localities MR604-A and B and *H. cf. peralensis* at MR604-B, Masía de la Roma, Teruel, Spain. Furthermore, van Dam et al. (2001) listed *H. peralensis* at various MN9 (I) and MN 10 localities of the Teruel-Alfambra region (Peralejos 5, Masía de la Roma 3, Masía de la Roma 4B, Masía de la Roma 4C, Masía de la Roma 6, Masía de la Roma 7, Masía del Barbo A, Masía de la Roma 9, Peralejos 4, Masía del Barbo B, Puente Minero 8, Puente Minero 10, Masada Rueda, and Peralejos C). In addition, they

Formatted: Indent: First line: 0.2"

Formatted: Font: Not Italic

Formatted: Font: Not Italic

Formatted: Font: Not Italic

mentioned the co-occurrence of this species and *H. aff. peralensis* at some of them (Peralejos 5, Masía de la Roma 3, Masía de la Roma 4C, Masía de la Roma 7, Masía del Barbo A, Peralejos 4, and Masía del Barbo B). Finally, van Dam et al. (2001) mentioned other localities where either *H. peralensis* or *H. aff. peralensis* is present (Masía de la Roma 4B, Masía de la Roma 6, Masía de la Roma 8, Masía de la Roma 9 La Salle, Masía de la Roma 11, and Los Aguanaces 5A). Furthermore, Van Dam et al. (2001) listed *H. peralensis* at various MN 10 localities of the Teruel Alfambra region (Masía de la Roma 4C, 6, and 7, Puente Minero 8, 10, and Masada Ruca 2A). They also mentioned *H. cf. peralensis* at Masía de la Roma 5, 8, 9, 11, La Salle, Peralejos A, La Gloria 14A/B, and Los Aguanaces 4, 5A, 5B. Besides, two m1 identified as *H. cf. peralensis* have been recovered from two MN10 localities (CRS2A and CR S2B) of the Cortasogas site, Calatayud Basin, Spain (Van Dam and Sanz Rubio, 2003). On the basis of very poor material (two isolated teeth and three fragments), Calvo et al. (1978) recognized *H. cf. peralensis* at the MN10 locality of Hajar-1, Albacete, Spain. *H. cf. peralensis* has been also cited from the MN11 site of Lobrieu, Vaucluse, France (Mein, 1999).

### 3.2.11.2. Comparison with *H. bijugatus*

The M1 of *Hispanomys peralensis* are four or five rooted, whereas those of *H. bijugatus* are four rooted. In addition, none of the M1 of *H. peralensis* has either labial spur on the anterolophule or entomesoloph, and all of them have a distinct forward paracone spur and a weak lingual cingulum. In contrast, some of the M1 of *H. bijugatus* have a labial spur on the anterolophule and an entomesoloph, they usually lack the forward paracone spur and have a strong lingual cingulum. Furthermore, the M2 of *H. peralensis* have the lingual cingulum less ~~developped~~developed than those of *H.*

Formatted: Font: Not Italic

Formatted: Spanish (International Sort)

Formatted: Font: Not Italic, Spanish (International Sort)

Formatted: Spanish (International Sort)

Formatted: Font: Not Italic

Formatted: Indent: First line: 0.2"

*bijugatus* and none of them have entomesoloph, whereas some of the M2 of *H. bijugatus* show a vestigial entomesoloph. The M3 of *H. peralensis* are much more reduced than those of *H. bijugatus* (Tab. 2) and they lack the posterior cingulum. This posterior cingulum is well developed and almost always present on the M3 of *H. bijugatus*, in which it emerges from the protocone reaching the posterior wall of the metacone. With regard to the lower molars, none of the m1 of *H. peralensis* has the double metalophulid, which is always present on the m1 of *H. bijugatus*. Finally, the m2 and m3 of *H. peralensis* have the mesolophid usually less ~~developped~~developed than those of *H. bijugatus*.

### 3.2.12. *Comparison with* *Hispanomys baixasi* Aguilar, Michaux et Lazzari, 2007

#### 3.2.12.1. Historical background

This species has been erected on the basis of mandibles, maxillae, and numerous isolated cheek teeth from the Turolian locality of Lo Fournas 16-M, Pyrénées-Orientales, France. Its holotype (Fou 16-M nr. 193) is a left M1. Further material of this species has been recovered at the coeval localities of Lo Fournas 6, Castelnou 1, and Castelnou 3, Pyrénées-Orientales, France (Aguilar et al., 2007).

#### 3.2.12.2. Comparison with *H. bijugatus*

Only few m1 of *H. baixasi* show a double metalophulid, whereas it is always present on the m1 of *H. bijugatus*. The m2 of *H. baixasi* show less developed mesolophid than in *H. bijugatus*. In addition, the m3 of *H. baixasi* are more reduced than those of *H. bijugatus*. With regard to the upper molars, those of *H. baixasi* have the ectoloph usually more developed than those of *H. bijugatus* and they lack the entomesoloph, which is present on some M1-M2 of *H. bijugatus*. The M3 of *H. baixasi* are much more

Formatted: Font: Italic

Formatted: Font: Italic, English (U.K.)

Formatted: Indent: First line: 0.2"

reduced than those of *H. bijugatus* and they lack the posteroloph, which is well ~~devellopped~~developed on the M3 of *H. bijugatus*.

### 3.2.13. ~~Comparisons with~~ *Hispanomys freudenthali* Van de Weerd, 1976

#### 3.2.13.1. Historical background

The validity of the species *Hispanomys freudenthali* from the MN12 locality of Masada del Valle 2, Teruel Alfambra region, Spain, was discussed by Freudenthal, Lacomba and Martín-Suárez (1991). According to these authors, the holotype of this species (MDV2-1241), one M1 housed in the RUU, can be distinguished neither by the morphology nor by the size from a M1 of *Pseudoruscinomys schaubi*. Consequently, according to Freudenthal et al. (1991), the nominal taxon *H. freudenthali* should be considered a junior synonym of *P. schaubi*. Freudenthal et al. (1991) pointed out that the specimen MDV2-1212, one m2, should be also attributed to *P. schaubi*.

Incidentally, *Pseudoruscinomys* is considered a synonym of *Ruscinomys* by Agustí (1980), who judges that *H. freudenthali* should be accommodated into the genus *Ruscinomys*. According to Freudenthal et al. (1991), the specimen (MDV2-1217), one m2, together with some m3 from the same locality would pertain in fact to *H. adroveri*.

The remaining material considered as *H. freudenthali* by Van de Weerd (1976) should be allocated to a new species, to which would also belong ~~s~~ the material from the ~~MN 10~~ MN 11 ~~locality-localities~~ of Los Aguanaces and ~~the MN 11 one of~~ Vivero del Pinos described as *H. freudenthali* by Adrover (1986). The presence of this taxon has been

mentioned by Alcalá et al. (1991) at the early Turolian (MN 11) locality of Puente Minero (Teruel, Spain). Furthermore, Van Dam et al. (2001) listed *H. freudenthali* at various MN12 (Masada Rueda 4, Masada Rueda 3, Masada del Valle 2, Los Mansuetos 2,

Formatted: Spanish (International Sort)

Tortajada B), MN11 (Valdecebro 4, Vivero de Pinos, Tortajada A, Los Aguanaces 3, Los Aguanaces, Regajo 2, Puente Minero 3, La Gloria 10, Masada Rueda 2, Puente Minero, Peralejos D) and MN10 (J3) (Los Aguanaces 6) localities from this area.

### 3.2.13.2. Comparison with *H. bijugatus*

The teeth of *H. freudenthali* are larger and more hypsodont than those of *H. bijugatus*. The M1 of the former species have usually five roots, whereas those of *H. bijugatus* always are four-rooted. In addition, the lingual cingulum is much less stronger on the M1 of *H. freudenthali* than in those of *H. bijugatus* and they lack the entomesoloph, which is present on some M1 and M2 of *H. bijugatus*. The M3 of *H. freudenthali* are much reduced, being the mean LM1/mean LM3 ratios very high, whereas they are very low in *H. bijugatus*, which has not the third upper molars reduced at all (Tab. 2). Therefore, on the M3 of *H. freudenthali* the anteroloph, anterior ectoloph, and forward paracone spur are totally fused with the protocone and the paracone, the sinus is usually very small or absent, and the posteroloph is lacking. In contrast, the M3 of *H. bijugatus* have a long anteroloph not connecting with the paracone, a quite large sinus, and a well-developed posteroloph. With regard to the lower molars, the m1 of *H. freudenthali* have a single metalophid, which is double in *H. bijugatus*; about half the individuals lack the anterolophid on the lower molars, which is always present in *H. bijugatus*.

### 3.2.14. ~~Comparison with~~ *Hispanomys adroveri* Agusti, 1986

#### 3.2.14.1. Historical background

Formatted: Font: Italic

The holotype of this species (F-CA 180) is an isolated M1 from the Middle Turolian (MN 12) locality of Casa del Acero, Fortuna Basin, Murcia, Spain. It is housed in the IPS. This species has been also recorded from the coeval locality of Crevillente 15; ~~Alicante, Spain~~ (Freudenthal et al., 1991). Additional material of this taxon has been recovered from the Late Turolian (MN 13) Librilla section (BS-141), ~~Fortuna Basin, Cuenca de Fortuna, Murcia, Spain~~ (Agustí et al., 1999, 2006). In addition, material attributed to *Hispanomys* aff. *adroveri* has been recovered from other Late Miocene localities of Crevillente (5, 8, 14, 17) (Freudenthal et al., 1991) and from the coeval locality of Canteras de Jun, Granada, Spain (García-Alix et al., 2008). According to Freudenthal et al. (1991), this taxon would be also represented in the MN 12 locality of Masada del Valle 2, Teruel-Alfambra region, Spain (see § on “*H. freudenthali*”).

#### 3.2.14.2. Comparison with *H. bijugatus*

This species is much larger and hypsodont than *H. bijugatus*. The M1 of *Hispanomys adroveri* are five rooted, whereas they are four rooted in *H. bijugatus*. Other differences between the two taxa include the more marked development of the ectolophs on the upper molars of *H. adroveri*, particularly on the M2, in which both labial valleys are closed (on the M2 of *H. bijugatus*, the anterosinus remains usually open due to the absence of the forward paracone spur). The M3 of *H. adroveri* are much reduced; they lack the posteroloph, have the sinus connected to the anterosinus and mesosinus and about half the specimens lack the ~~protoloph~~protolophule (the paracone being isolated). In contrast, the M3 of *H. bijugatus* are not reduced, the posteroloph is well-developed, the three sinuses are unconnected, and the ~~protoloph~~protolophule is well-developed. With regard to the lower molars, those of *H. adroveri* lack double metalophid and they show a well-developed mesolophid that normally joins with the metaconid, whereas in

Formatted: Indent: First line: 0.2"

Formatted: Font: Not Italic

Formatted: Indent: First line: 0.2"

*H. bijugatus* the metalophid is always double and the mesolophid usually absent. In addition, the m2 of *H. adroveri* lack the protosinusid, whereas it is present on the m1 of *H. bijugatus*.

### 3.2.15. ~~Comparison with~~ *Hispanomys lusitanicus* (Schaub, 1925)

This species was originally attributed to the genus *Cricetodon* by Schaub (1925) and reallocated to the subgenus *Hispanomys* by Mein and Freudenthal (1971). This taxon is based on one incomplete mandible with m1-m2 (unnumbered, MGISTL), which is supposed to come from the late Miocene (MN 10) of Carvalhal Novo (Azambujeira, Portugal). According to Antunes (1984), the holotype is damaged, not characteristic enough, and the taxon is badly-defined so that its validity is questionable. Pending a revision, this taxon is not considered in the present study.

## 3. Discussion

~~From the Upper Aragonian six~~ Seven taxa belonging to the genus *Hispanomys* are known ~~from Upper Aragonian strata: *H. castelnovi*, *H. decedens*, *H. bijugatus*, *H. aguirrei*, *H. daamsi*, *H. dispectus*, and *H. lavocati*.~~ During the ~~Upper-Late~~ Aragonian and ~~Lower~~ Early Vallesian, the main source of morphological variability are the different development of the ectolophs, the presence or absence of mesolophs and mesolophids, the existence of cingular structures in the upper and lower molars, and the increase in the number of roots in second molars (Agustí, 1981, 1982). Despite these morphological differences, the general pattern of the cheek teeth is rather homogeneous within each population. The most primitive morphologies are characterized by having

Formatted: Not Highlight

lower molars with well-developed labial anterolophids, with lingual anterolophids, with lingual cingula surrounding the valleys, with vestigial ectomesolophid on the m1, two rooted m2, and unreduced m3. On the other hand, the most primitive upper molars are characterized by having mesolophs, labial cingula surrounding the valleys, quite incomplete ectolophs, vestigial entomesoloph, ~~and old-entoloph~~, four rooted M1, and unreduced M3.

From La Grive-Saint Alban two species of *Hispanomys* have been recovered, *H. bijugatus* and *H. decedens*. The first taxon has been found in La Grive-Saint Alban at localities L3 and L5, whereas *H. decedens* has been recovered at localities ~~L3 and L7L5, as well as from La Grive-Saint Alban-M, and at the unnamed fissure-filling.~~

The age of the different fissure-fillings of La Grive-Saint Alban is controversial. According to Mein and Ginsburg (2002), the oldest localities would be La Grive M and L7, which were correlated to the MN7, whereas the youngest ones would be La Grive L3 and L5, which they correlated with MN8. On the contrary, Maridet (2003: p. 197) pointed out that La Grive L3 and L5 would be actually the oldest of La Grive localities, being followed by L7 and finally by M, which would be the youngest one.

If we compare the degree of evolution of the teeth in *Hispanomys bijugatus* and in *H. decedens*, it appears that the former shows a more progressive dental morphology. *H. bijugatus* has indeed the following derived characters, which are lacking in *H. decedens*: 1-) absence of labial and lingual cingula surrounding the upper and lower molar valleys respectively, 2-) absence of mesoloph on the upper molars, 3-) ectolophs more ~~developped~~ developed, 4-) lower percentage of m1 showing vestigial ectomesolophid, 5-) less important development of the lingual anterolophid on the m1, and 6-) less marked development of the mesolophid on the m3.

All these differences suggest that *Hispanomys bijugatus* is more derived than *H. decedens*. Because these species are believed to be closely related species within the same lineage ~~Therefore~~ (Mein & Freudenthal, 1971: fig. 1; Chaline & Mein, 1979: fig. 33; Agustí, 1980: fig. 4; Aguilar, 1982: fig. 6), La Grive M ~~and L7~~ (both with *H. decedens* only) may be older than La Grive L3 and L5 (with *H. bijugatus*), as suggested by Mein and Ginsburg (2002). The same is true for the unnamed fissure-filling. The coexistence of the two species at La Grive ~~L3-L5~~ may indicate an older age for this locality than for ~~L5L3~~, ~~at~~ from which only *H. bijugatus* has been recovered. As mentioned above, Mein and Ginsburg (2002) did not take into account the two M3 of *H. decedens* found in L7. Interestingly enough, should the presence of *H. decedens* in L7 not be due to “contamination”, this locality (as La Grive M) may be older than La Grive L3 and L5 as also suggested by Mein and Ginsburg (2002).

Formatted: Font: 12 pt

#### 4. Conclusion

The species *Hispanomys bijugatus* from La Grive-Saint Alban shows a low variability as common in the populations of *Hispanomys* from the Upper Aragonian. Even if *Hispanomys bijugatus* have some of the typically primitive dental characters of the Aragonian species of *Hispanomys*, such as the not reduced M3, it shows a lot of progressive characters. These are: the absence of labial and lingual cingula surrounding the upper and lower molar valleys respectively, the increase of the number of roots on the second lower molar, and the lost of mesolophs on the upper molars. This suggests that *H. bijugatus* is a relatively derived with respect to the coeval congeneric species.

For that reason a younger age is inferred for the localities La Grive L3 and L5, where this taxon has been recovered, than for La Grive L7 and M and for the unnamed fissure-filling, in which *H. decedens* has been found.

## Acknowledgements

J. van Dam and W. Wessels (Rijksuniversiteit Utrecht, Utrecht) kindly lent material of *Hispanomys* kept in their institution. Various aspects of this paper were improved thanks to the critical reading of J.-P. Aguilar (Université Montpellier 2, Montpellier) and M. A. Álvarez-Sierra (Universidad Complutense, Madrid). L. Celià Gelabert and J. Galindo Torres (Instituto Catalán de Paleontología, Sabadell) allowed the examination of material under their care. This study has been partly funded by research project CGL2008-05813-CO2-01 conducted by J. Morales. R.L.A. holds a Ramón y Cajal contract.

## TABLES

**Table 1.** Length and width measurements (mm) of the lower and upper molars of *Hispanomys bijugatus* from La Grive-Saint Alban (Carrière Lechartier, fissure L3), Isère, France.

Locality	Tooth type	LENGTH					WIDTH			
		min	mean	max	sd	N	min	mean	max	sd
La Grive-St Alban L3	m1	2,44	2,60	2,80	0.09	50	1,54	1,63	1,81	0.07
La Grive-St Alban L3	M1	2,97	3,23	3,50	0.11	49	1,92	2,05	2,18	0.06
La Grive-St Alban L3	m2	2,40	2,54	2,74	0.08	43	1,65	1,83	1,93	0.06
La Grive-St Alban L3	M2	2,30	2,47	2,61	0.08	42	1,80	1,92	2,07	0.07
La Grive-St Alban L3	m3	2,32	2,47	2,72	0.07	39	1,58	1,68	1,80	0.06
La Grive-St Alban L3	M3	1,80	1,97	2,18	0.08	41	1,57	1,70	1,93	0.07

**Table 2.** M1/M3 (mm) length ratio for all species of *Hispanomys* known to date from various localities. Calculated from data in Aguilar (1982), Aguilar et al. (1994, 2007), Agustí (1977, 1980, 1981, 1986), Agustí et al. (2005), Casanovas-Vilar (2007), Casanovas-Vilar et al. (2006), Freudenthal et al. (1991), Lacomba (1988), López Martínez et al. (1977), Mein and Freudenthal (1971), van Dam (personal data, 2007), and van de Weerd (1976).

Madrid, le 30 mars 2009

Cher Collègue,

Veillez trouver téléchargée la version corrigée de notre manuscrit intitulé «First detailed description of *Hispanomys bijugatus* Mein et Freudenthal, 1971 (Rodentia, Cricetodontinae) from the Upper Aragonian of La Grive-Saint Alban (France): biostratigraphical implications».

Les modifications sont indiquées grâce à l'outil « suivi des modification » de MS WORD. Nous avons pris en compte l'ensemble des suggestions des deux réviseurs, ce qui a amélioré notre étude.

Nous espérons que vous trouverez ce travail prêt à être publié dans Geobios et restons à votre disposition pour toute information supplémentaire.

Bien cordialement,

Raquel López-Antoñanzas
